DRUGDEX® Evaluations

METHYLPHENIDATE

0.0 Overview

1) Class

a) This drug is a member of the following class(es):
Amphetamine Related
Central Nervous System Agent
CNS Stimulant

2) Dosing Information

a) Methylphenidate

1) Pediatric

a) safety and effectiveness not established in pediatric patients under 6 years of age (Prod Info DAYTRANA

1) Attention deficit hyperactivity disorder

a) apply TOPICALLY 2 hours before needed effect and remove 9 hours after application; week-1, 1 (2)); week-3, 20 mg (25 cm(2)); week-4, 30 mg (37.5 cm(2)); titrate dose to effect (Prod Info DAYTR

b) Methylphenidate Hydrochloride

1) Adult

a) individualize dosage according to need and response of patient (Prod Info CONCERTA(R) extended-relea

1) Attention deficit hyperactivity disorder

a) immediate-release (IR), 10 to 60 mg/day ORALLY divided 2 to 3 times daily, preferably 30 to 45

b) extended-release (Concerta(R)), (age up to 65 yr), no prior methylphenidate therapy, initial, 18 o adjust dosage at weekly intervals in 18 mg increments; MAX 72 mg/day (Prod Info CONCERTA(R)

c) extended-release (Concerta(R)), (age up to 65 yr) conversion from prior methylphenidate therapy to 15 mg/day), 18 mg ORALLY in morning; (prior therapy of 20 to 30 mg/day); 36 mg in morning; (pr morning; (prior therapy of 40 to 60 mg/day), 72 mg in morning (Prod Info CONCERTA(R) extended-

d) extended-release (Metadate(R) CD), 20 mg ORALLY once daily in the morning; may adjust dosa MAX 60 mg/day

e) extended-release (Ritalin LA(R), no prior methylphenidate therapy), 20 mg ORALLY once daily i intervals in 10 mg increments; MAX 60 mg/day

f) extended-release (Ritalin LA(R), prior methylphenidate therapy), once daily (taken in the morning total daily oral dose of prior methylphenidate therapy; may adjust dosage at weekly intervals in 10 m

2) Fatigue

a) immediate release, 7.5 mg ORALLY twice daily, titrate up to MAX 60 mg/day

3) Narcolepsy

a) immediate release, 10- to 60 mg/day ORALLY divided 2 to 3 times daily, preferably 30 to 45 min

2) Pediatric

a) safety and effectiveness not established in pediatric patients under 6 years of age (Prod Info CONCERTA

b) individualize dosage according to need and response of patient (Prod Info CONCERTA(R) extended-relea

1) Attention deficit hyperactivity disorder

a) immediate-release, (age 6 yr and older) 5 mg ORALLY twice daily (before breakfast and lunch); intervals; MAX 60 mg/day

b) extended-release (Concerta(R)), (age 6 to 12 yr) no prior methylphenidate therapy, initial, 18 mg dosage at weekly intervals in 18 mg increments; MAX 54 mg/day (Prod Info CONCERTA(R) extend

c) extended-release (Concerta(R)), (age 13 to 17 yr) no prior methylphenidate therapy, initial, 18 m dosage at weekly intervals in 18 mg increments; MAX 72 mg/day or 2 mg/kg/day (Prod Info CONCE

d) extended-release (Concerta(R)), (age 6 to 17 yr) conversion from prior methylphenidate therapy 15 mg/day), 18 mg ORALLY in morning; (prior therapy of 20 to 30 mg/day), 36 mg in morning; (prior (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

e) extended-release (Concerta(R)), (age 13 to 17 yr) conversion from prior methylphenidate therapy 60 mg/day), 72 mg ORALLY in the morning (Prod Info CONCERTA(R) extended-release oral tablets

f) extended-release (Metadate(R) CD), (age 6 y and older) 20 mg ORALLY once daily in the mornir mg increments; MAX 60 mg/day

g) extended-release (Ritalin LA(R), (no prior methylphenidate therapy), 20 mg ORALLY once daily intervals in 10 mg increments; MAX 60 mg/day

h) extended-release (Ritalin LA(R), (prior methylphenidate therapy), once daily (taken in the mornin total daily oral dose of prior methylphenidate therapy; may adjust dosage at weekly intervals in 10 m

2) Narcolepsy

a) (age 6 y and older) immediate-release, 5 mg ORALLY twice daily (before breakfast and lunch); d intervals; MAX 60 mg/day

3) Contraindications

a) Methylphenidate

1) marked agitation, anxiety, and tension; may aggravate symptoms (Prod Info DAYTRANA(TM) transdermal sys

2) glaucoma (Prod Info DAYTRANA(TM) transdermal system, 2006)

3) hypersensitivity to methylphenidate or other components of the product (Prod Info DAYTRANA(TM) transderm
4) monoamine oxidase inhibitors, such as isocarboxazid, phenelzine, selegiline, tranylcypromine, within 14 days (Prod Info DAYTRANA(TM) transdermal system, 2006)
5) tics, motor (Prod Info DAYTRANA(TM) transdermal system, 2006)
6) Tourette's syndrome, family history or diagnosis (Prod Info DAYTRANA(TM) transdermal system, 2006)

b) Methylphenidate Hydrochloride
1) angina pectoris; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) extended release (TM) extended release oral capsules, 2008)
2) cardiac arrhythmias; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) extended relea CD(TM) extended release oral capsules, 2008)
3) fructose intolerance, glucose-galactose malabsorption, or sucrase-isomaltase insufficiency; contains sucrose ((TM) extended release oral capsules, 2008)
4) glaucoma (Prod Info METADATE CD(TM) extended release oral capsules, 2008; Prod Info RITALIN(R) oral ta tablets, 2006)
5) halogenated anesthetics; risk of sudden blood pressure increase during surgery, do not take on day of surgery (TM) extended release oral capsules, 2008)
6) heart failure; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) extended release oral
7) hypersensitivity to methylphenidate or other components of the product (Prod Info METADATE CD(TM) extend RITALIN(R) oral tablets, RITALIN-SR(R) sustained-release oral tablets, 2006)
8) hypertension, severe; may increase blood pressure (Prod Info METADATE CD(TM) extended release oral cap extended release oral capsules, 2008)
9) hyperthyroidism or thyrotoxicosis; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) e METADATE CD(TM) extended release oral capsules, 2008)
10) marked agitation, anxiety, and tension; may aggravate symptoms (Prod Info METADATE CD(TM) extended r (R) oral tablets, RITALIN-SR(R) sustained-release oral tablets, 2006)
11) monoamine oxidase inhibitors, such as isocarboxazid, phenelzine, selegiline, tranylcypromine, within 14 days crisis (Prod Info METADATE CD(TM) extended release oral capsules, 2008; Prod Info RITALIN(R) oral tablets, R 2006)
12) myocardial infarction, recent; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) exte METADATE CD(TM) extended release oral capsules, 2008)
13) tics, motor (Prod Info METADATE CD(TM) extended release oral capsules, 2008; Prod Info RITALIN(R) oral tablets, 2006)
14) Tourette's syndrome, family history or diagnosis (Prod Info METADATE CD(TM) extended release oral capsu RITALIN-SR(R) sustained-release oral tablets, 2006)

4) Serious Adverse Effects
a) Methylphenidate
1) Contact dermatitis
2) Decreased body growth
3) Drug dependence
4) Lowered convulsive threshold
5) Mania
6) Psychotic disorder
7) Tic

b) Methylphenidate Hydrochloride
1) Aggressive behavior
2) Cerebrovascular accident
3) Dead - sudden death
4) Decreased body growth
5) Drug dependence
6) Gastrointestinal obstruction
7) Mania
8) Myocardial infarction
9) Psychotic disorder
10) Seizure
11) Visual disturbance

5) Clinical Applications
a) Methylphenidate
1) FDA Approved Indications
a) Attention deficit hyperactivity disorder

b) Methylphenidate Hydrochloride
1) FDA Approved Indications
a) Attention deficit hyperactivity disorder
b) Narcolepsy

2) Non-FDA Approved Indications
a) Fatigue

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms

Methylphenidate
Methylphenidate HCl
Methylphenidate Hydrochloride
Methylphenidylacetate

C) Physicochemical Properties

1) Molecular Weight

a) 269.77 (Fleeger, 1994)

1.2 Storage and Stability

A) Methylphenidate

1) Preparation

a) Topical application route

1) APPLICATION

a) Apply the patch to a clean, dry area of the hip area 2 hours before an effect is needed. Avoid wa
When applying the patch the next morning, place on the opposite hip at a new site if possible (Prod
2006).

b) Apply patch immediately after opening the pouch and removing the protective liner. Do not use if
press firmly in place with palm of the hand for approximately 30 seconds. Make sure there is good c
around the edges. Once the patch has been properly placed, bathing, swimming, or showering will r
that a patch should fall off, a new patch may be applied at a different site, but the total recommende
Do not expose the patch application site to direct external heat sources, such as heating pads, elect
wearing the patch. Temperature-dependent increases in methylphenidate exposure of greater than
DAYTRANA(TM) transdermal system, 2006).

2) DISPOSAL OF PATCH

a) After patch removal, fold patch so the patch adheres to itself. The folded patch may be flushed d
lidded container. If the patient discontinues the prescription, each unused patch should be removed
liner, folded onto itself, and flushed down the toilet or disposed of in an appropriate lidded container
system, 2006).

B) Methylphenidate Hydrochloride

1) Preparation

a) Oral route

1) For extended-release tablets, the dose should be given once daily in the morning, with or without foo
liquids and must not be chewed, divided, or crushed (Prod Info CONCERTA(R) extended-release oral ta

2) For extended-release capsules, the dose should be given once daily in the morning. Capsules may b
over a spoonful of applesauce; the applesauce should not be warm, and the drug/applesauce mixture sh
(Prod Info RITALIN LA(R) oral extended-release capsule, 2004). Capsule contents of Ritalin(R) LA shou
RITALIN LA(R) oral extended-release capsule, 2004).

C) Transdermal route

1) Patch, Extended Release

a) Store at 25 degrees Celsius (77 degrees Fahrenheit); excursions permitted between 15 and 30 degrees C
store patches unpouched. Use within 2 months after opening tray (Prod Info DAYTRANA(TM) transdermal sy

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Other Disease States

1.3.1 Normal Dosage

1.3.1.A Methylphenidate Hydrochloride

1.3.1.A.1 Oral route

Attention deficit hyperactivity disorder

Cancer; Adjunct

Dementia

Depression, Monotherapy

Narcolepsy

Shivering, Postanesthesia; Treatment and Prophylaxis

Syncope

Traumatic brain injury

1.3.1.A.1.a Attention deficit hyperactivity disorder

1) Extended-Release

a) The recommended starting dose of Concerta(R) extended-release tablet for new patients is morning. Dosage may be adjusted weekly in 18 mg increments to a maximum of 72 mg per day methylphenidate regimens may follow the dosage conversion recommendation below (Prod Info 2008):

Previous Methylphenidate Daily Dose	Recommended Concerta Dose
5 mg twice or 3 times daily	18 mg in the mor
10 mg twice or 3 times daily	36 mg in the mor
15 mg twice or 3 times daily	54 mg in the mor
20 mg twice or 3 times daily	72 mg in the mor

b) Pharmacologic treatment of attention deficit hyperactivity disorder may be needed for extend indicate how long the patient should be treated. The physician should periodically reevaluate th off medication to assess the patient's functioning without pharmacotherapy. Improvement may b temporarily or permanently discontinued. The dosage should be reduced or discontinued if para adverse events occur. If improvement is not observed after appropriate dosage adjustments ov drug should occur (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

c) For methylphenidate extended release capsules (Metadate(R) CD), the starting dose is 20 n breakfast. Doses may be increased by 20 mg at weekly intervals to a MAXIMUM dose of 60 mg dosages above 60 mg are not recommended (Prod Info Metadate(R) CD, 2002).

2) Immediate-Release

a) Recommended dosage is from 10 to 60 milligrams daily. Average dose is 20 to 30 milligram times daily preferably 30 to 45 minutes before meals (Prod Info RITALIN(R) oral tablet, RITALIN

b) Methylphenidate in doses of 10 to 90 milligrams orally daily was reported more effective tha disorder, residual type, in adults in a double-blind crossover trial (Wender et al, 1985).

1.3.1.A.1.b Cancer; Adjunct

1) The combination of oral methylphenidate 15 milligrams (mg) daily (10 mg at breakfast and 5 mg to enhance the analgesic efficacy of the narcotic agents and decrease sedation in patients with chro et al, 1987a).

1.3.1.A.1.c Dementia

1) Some of the negative symptoms associated with vascular dementia and dementia of Alzheimer's milligrams/day in an open-label, non-blinded preliminary study. Results were similar among the 12 A (Galynker et al, 1997a).

1.3.1.A.1.d Depression, Monotherapy

1) Methylphenidate 5 to 40 milligrams per day appears to be safe and effective for the treatment of lacking contraindications for use (Frye, 1997a; Emptage & Semla, 1996a).
2) Methylphenidate 10 to 20 milligrams per day produced a positive response in 7 of 8 post-liver tra symptoms (Plutchik et al, 1998a).
3) Acute stroke patients (n=21) receiving methylphenidate 30 milligrams per day demonstrated grea activities of daily living, and motor function than patients receiving placebo in a prospective, random (Grade et al, 1998a).
4) A report of the efficacy of methylphenidate in the treatment of depression in cancer patients has Methylphenidate was given in doses of 10 milligrams orally three times daily initially, with subsequer period of 2 to 3 days; increases to a maximum of 80 milligrams daily were permitted by week 2 of tre marked improvement, with 13 showing moderate improvement; maximum improvement was genera

1.3.1.A.1.e Narcolepsy
1) Recommended dosage is from 10 to 60 milligrams daily. Average dose is 20 to 30 milligrams dai SR(R) oral tablet, 2004).
2) Doses should be administered 2 to 3 times daily preferably 30 to 45 minutes before meals (Prod tablet, 2004).

1.3.1.A.1.f Shivering, Postanesthesia; Treatment and Prophylaxis
1) Methylphenidate 20 mg suppressed postoperative shivering in 17 of 42 post-anesthetic patients received halothane anesthesia (Imray & White, 1968).

1.3.1.A.1.g Syncope
1) Six of 7 patients with recurrent NEUROCARDIOGENIC SYNCOPE became clinically asymptoma milligrams 3 times daily for 7 months. The patients were previously unresponsive to or poorly tolerar

1.3.1.A.1.h Traumatic brain injury
1) Methylphenidate 0.25 milligrams/kilogram twice daily improved speed of mental processing in pa injury, but orienting to distractions, sustained attention, and motor speed were unaffected (Whyte et

1.3.2 Dosage in Renal Failure
A) Methylphenidate Hydrochloride
1) Due to minimal excretion as unchanged drug (Faraj et al, 1974a; Prod Info RITALIN LA(R) oral extended- methylphenidate are unlikely to be altered significantly in renal impairment, suggesting no need for dose adju

1.3.3 Dosage in Hepatic Insufficiency
A) Methylphenidate Hydrochloride
1) As methylphenidate is metabolized primarily to ritalinic acid (essentially inactive) via non-microsomal este are unlikely to be altered significantly in liver disease (Prod Info RITALIN LA(R) oral extended-release capsul adjustment. However, adequate studies in this setting are lacking.

1.3.6 Dosage in Other Disease States
A) Methylphenidate Hydrochloride
1) GLAUCOMA
a) Use of methylphenidate in patients with glaucoma is contraindicated (Prod Info RITALIN(R) oral table has been suggested that when used cautiously in conjunction with glaucoma medications and regular op pressure measurements, methylphenidate may be safe in patients with well-controlled, open-angle glauc

1.4 Pediatric Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Other Disease States

1.4.1 Normal Dosage

Methylphenidate

Methylphenidate Hydrochloride

1.4.1.A Methylphenidate

1.4.1.A.1 Transdermal route

1.4.1.A.1.a Attention deficit hyperactivity disorder

1) The recommended dose titration schedule for children 6 to 12 years of age for the treatment of a the table below (Prod Info DAYTRANA(TM) transdermal system, 2006):

	Upward Titration, if Response is Not Maximiz	
	Week 1	Week 2
Patch size	12.5 cm(2)	18.75 cm(2)
Nominal Delivered Dose *	10 mg/9 hrs	15 mg/9 hrs
Delivery rate *	1.1 mg/hr	1.6 mg/hr
Key: * = nominal in vivo delivery rate in pediatric subjects aged 6 to 12 when applied to the hip, centimeters squared mg = milligrams, hrs = hours		

Individualize titration, final dosage, and wear time for each patient according to the needs and r before desired effect and remove patch 9 hours after application. The patch may be removed e is preferred or late day side effects occur. The dose titration schedule applies to methylphenida children (Prod Info DAYTRANA(TM) transdermal system, 2006).

2) Although the design of a double-blind, placebo-controlled, randomized trial did not allow for evalu not appear to be improved efficacy with a dose increase from 20 mg over 9 hours to 30 mg over 9 h system, 2006).

2) Safety and effectiveness not established in pediatric patients under 6 years of age (Prod Info DAYTRANA

1.4.1.B Methylphenidate Hydrochloride

1.4.1.B.1 Oral route

1.4.1.B.1.a Attention deficit hyperactivity disorder

1) Extended Release

a) For Ritalin(R) LA extended-release capsules, the starting dose recommended by the manufa gradual upward titration based on efficacy and tolerability; weekly 10-mg increments to a maxim RITALIN LA(R) oral extended-release capsule, 2004). When a lower initial dose is desired, low may given; following titration to 10 mg twice daily of the immediate-release formulation, patients Ritalin(R) LA dose guidelines are for these latter patients, and those currently receiving immedi methylphenidate who are to be switched to Ritalin(R) LA (Prod Info RITALIN LA(R) oral extende

1) Patients currently receiving methylphenidate 10 mg twice daily or 20-mg methylphenida daily

2) Patients currently receiving methylphenidate 15 mg twice daily should be given Ritalin(R

3) Patients currently receiving methylphenidate 20 mg twice daily or 40-mg methylphenida daily

4) Patients currently receiving methylphenidate 30 mg twice daily or 60-mg methylphenida daily

The recommended starting dose of Concerta(R) extended-release tablet for new patients a day in the morning. Dosage may be adjusted weekly in 18 mg increments to a maximum of and to a maximum of 72 mg per day (not to exceed 2 mg/kg/day) in adolescents 13 to 17 y thrice daily regimens of methylphenidate may follow the dosage conversion recommendati release oral tablets, 2008):

Previous Methylphenidate Daily Dose	Recommended Concerta(R) Starting Dose
5 mg twice or 3 times daily	18 mg in the morning
10 mg twice or 3 times daily	36 mg in the morning
15 mg twice or 3 times daily	54 mg in the morning
20 mg twice or 3 times daily	72 mg in the morning (age 13 to 17 years only)

Initial conversion dosage should not exceed 54 milligrams (mg) daily in children 6 to 12 yea 17 years of age. Following conversion, doses may be adjusted if needed up to the maximu generally occur at weekly intervals (Prod Info CONCERTA(R) extended-release oral tablets Pharmacologic treatment of attention deficit hyperactivity disorder may be needed for exter that indicate how long the patient should be treated. The physician should periodically reev with trials off medication to assess the patient's functioning without pharmacotherapy. Impr either temporarily or permanently discontinued. The dosage should be reduced or discontir other adverse events occur. If improvement is not observed after appropriate dosage adjus of the drug should occur (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

b) CHILDREN 6 YEARS & OLDER: For methylphenidate extended release capsules (Metadate once daily in the morning before breakfast. Doses may be increased by 20 mg at weekly interva

once daily in the morning. Daily dosages above 60 mg are not recommended. Metadate CD ext whole or the content of the capsule may be sprinkled onto a tablespoonful of applesauce and ta capsule or its content (Prod Info Metadate(R) CD, 2002).
c) Average total daily dose was 34.3 mg/day for EXTENDED-RELEASE METHYLPHENIDATE mg/day for IMMEDIATE-RELEASE METHYLPHENIDATE (n=94) among children 6 to 12 years comparing the efficacy of the 2 formulations of the drug. Immediate-release (given 3 times daily methylphenidate had comparable efficacy, and both were significantly superior to placebo (p les

2) Immediate Release
a) In children over 6 years of age, usual dose is 5 milligrams twice daily increased at weekly int to administer 5 milligrams before breakfast and lunch (Prod Info RITALIN(R) oral tablet, RITALI
b) The maximum recommended dose is 60 milligrams. Drug should be discontinued if there is (Prod Info RITALIN(R) oral tablet, RITALIN-SR(R) oral tablet, 2004).
c) According to the results of one triple-blind, placebo controlled, crossover study involving 25 (ADHD), three times a day dosing produces the most reliable improvements in the treatment of on weight, ranged from 5 to 20 milligrams (mean dose = 8.8 milligrams; 0.30 milligram/kilogram dosing schedule was associated with a greater improvement in behavioral measures compared were no significant differences between the two dosing schedules in the incidence of adverse e
d) In 11 hyperkinetic children aged 7 to 12, 0.3 milligram/kilogram/day markedly improved impu milligram/kilogram/day produced results similar to placebo in a double blind study (Brown & Sle to be no more efficacious and more toxic than lower (0.3 milligram/kilogram/day) doses (Holliste
e) Isolated studies have raised the possibility that a small group of children may develop some al, 1980; Eichlseder, 1985; Winsberg et al, 1974). Other non-controlled studies have observed medications in children with attention deficit disorders (Riddle & Rapoport, 1976; Charles et al, determined whether some hyperactive children who initially respond to methylphenidate develo is probably a rare occurrence. In patients who become less responsive to methylphenidate ther dosing or noncompliance should also be considered.
f) Methylphenidate 0.3 milligram/kilogram twice daily at 8 am and 12 noon for 14 days improve children (n=14) with acquired attention disorder secondary to brain injury in a double-blind, plac 1998).

1.4.2 Dosage in Renal Failure

A) Methylphenidate
1) Transdermal methylphenidate has not been studied in patients with renal insufficiency (Prod Info DAYTRA

B) Methylphenidate Hydrochloride
1) Due to minimal excretion as unchanged drug (Faraj et al, 1974a; Prod Info RITALIN LA(R) oral extended- methylphenidate are unlikely to be altered significantly in renal impairment, suggesting no need for dose adju

1.4.3 Dosage in Hepatic Insufficiency

A) Methylphenidate
1) Transdermal methylphenidate has not been studied in patients with hepatic insufficiency (Prod Info DAYT

B) Methylphenidate Hydrochloride
1) As methylphenidate is metabolized primarily to ritalinic acid (essentially inactive) via non-microsomal este are unlikely to be altered significantly in liver disease (Prod Info RITALIN LA(R) oral extended-release capsul adjustment. However, adequate studies in this setting are lacking.

1.4.5 Dosage in Other Disease States

A) Methylphenidate Hydrochloride
1) EPILEPSY
a) Use of methylphenidate (0.3 milligram/kilogram once daily) appears to be safe and effective to treat a children with epilepsy who are seizure free, while receiving antiepileptic drugs, before starting methylphe for those children still having seizures while receiving antiepileptic drugs (Gross-Tsur et al, 1997a).

2) TOURETTE'S SYNDROME
a) In a 2-year non-blinded, prospective, follow-up study of 32 children (aged 6.1 to 11.9 years) receiving from a previous trial (mean 16.5 milligrams (mg), range 5 to 40 mg), long-term methylphenidate therapy with attention deficit hyperactivity disorder (ADHD) and chronic multiple tic disorder or Tourette's syndror not worsen tics in patients with ADHD and Tourette's syndrome, the possibility of individual exacerbation 1999a).

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Initial Response

a) ATTENTION-DEFICIT/HYPERACTIVITY DISORDER, ORAL: within 2 weeks (Prod Info Ritalin(R) LA, 200

1) Represents time to significant improvement in symptoms scores in children treated with 10 to 40 mg

2.2 Drug Concentration Levels

A) Peak Concentration

1) TRANSDERMAL: 39 ng/mL (Prod Info DAYTRANA(TM) transdermal system, 2006).

a) The mean peak d-methylphenidate plasma concentration was 39 ng/mL (0 to 114 ng/mL) in pediatric child wear times of transdermal methylphenidate. These mean peak concentrations varied inversely by age rangin to 53 ng/mL (18 to 83 ng/mL) in 6 year olds (Prod Info DAYTRANA(TM) transdermal system, 2006).

b) The mean peak d-methylphenidate concentrations were 1.9 times higher for transdermal methylphenidate over a period of 7.5 to 10.5 hours, when Tmax usually occurs. These higher concentrations were consistent a and 4 days of multiple dosing the Cmaxs were higher with chronic dosing of transdermal methylphenidate. Si produced similar Cmaxs as single doses of the once daily oral methylphenidate (Prod Info DAYTRANA(TM) t

2) ORAL (Ritalin and Ritalin-SR at 0.3 mg/kg): Children-10.8 ng/mL(Gillis & editor, 2000); Adults-7.8 nanograms 3.7 ng/mL (Prod Info Concerta™, 2000a).

a) Ritalin and Ritalin-SR brands of methylphenidate- Following administration of 0.3 mg of methylphenidate p nanograms per mL(Gillis & editor, 2000); Adults-7.8 nanograms per mL(Gillis & editor, 2000)

b) Peak plasma concentrations showed marked variability between subjects (Gillis & editor, 2000).

c) Concerta brand of methylphenidate-Following administration of 18 mg of methylphenidate: 3.7 nanograms

d) Metadate(R) CD brand of methylphenidate-Following administration of 20 mg of Metadate(R) CD: an early ml due to the immediate release component, and a later maximum concentration of 10.9 nanograms per mL component (Prod Info Metadate CD(R), 2001).

e) The peak plasma concentration was increased by 30% when Metadate(R) CD 40 mg was administered fo

f) Dose-proportionality was demonstrated in peak plasma concentrations and area under the concentration-t methylphenidate.

B) Time to Peak Concentration

1) ORAL: 1 to 3 hours (Dayton et al, 1970); 6 to 8 hours (extended- release tablets or capsules) (Prod Info Conce

a) In 35 healthy adults, the PEAK PLASMA CONCENTRATION of methylphenidate after a single dose of OR immediate-release 5 mg every 4 hours, and a single dose of slow-release 20 mg was 3.75 ng/mL, 4.17 ng/ml PEAK PLASMA CONCENTRATION was 6.7 hours, 6.5 hours, and 3.7 hours, respectively (Modi et al, 2000).

b) The peak plasma concentration of a SINGLE and MULTIPLE doses of methylphenidate OROS(R) formula respectively and the time to peak concentration was 7.4 hours and 6.6 hours, respectively in 32 healthy adult

c) Following 20 to 100 milligrams (mg) doses of methylphenidate, plasma levels of 0.02 mg/liter (L) were rep levels reported to range from 1 to 3 hours after a single oral dose (Dayton et al, 1970).

d) Plasma levels varied from 7.7 to 22.5 nanograms/milliliter (ng/mL) in 4 children with attention deficit disorc orally twice daily (Hungund et al, 1979).

e) Following a single oral dose of methylphenidate extended-release capsules (Ritalin(R) LA) in children or a approximately 4 hours apart, with the second peak usually somewhat higher than the first. Compared to imm 4 hours apart, a lower second peak level, higher interpeak minimum level, and less peak/trough fluctuations a Ritalin(R) LA, 2002a).

f) With a 20-mg dose of Ritalin(R) LA in children, the first peak plasma level (mean) occurred in 2 hours (10 ng/mL) in an unpublished study; the mean interpeak minimum plasma level was 6 ng/mL (4.5 hours) (Prod In

2) TRANSDERMAL: average lag time was 3.1 hours (Prod Info DAYTRANA(TM) transdermal system, 2006)

a) The average lag time (time to any d-methylphenidate is detectable in the circulation) was 3.1 hours (range transdermal system, 2006).

C) Area Under the Curve

1) ORAL (20 mg, long acting): 45.8 ng x h/mL (Modi et al, 2000)

a) With a single 20-mg dose of Ritalin(R) LA, the mean AUC(0-infinity) in adult was 45.8 ng x h/mL and in ch LA, 2002a).

b) The AUC of methylphenidate is 2 times higher when heat is applied to transdermal methylphenidate after when the patch is applied to inflamed skin (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) In 35 healthy adults, the AUC of methylphenidate after a single dose of OROS(R) formulation 18 mg, 3 do and a single dose of slow-release 20 mg was 42 ng x h/mL, 38 ng x h/mL, and 47 ng x h/mL, respectively (M

d) The AUC of a single and multiple doses of methylphenidate OROS(R) formulation 18 mg was 32.9 ng x h healthy adults (Modi et al, 2000).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Bioavailability

1) ORAL: 10 to 52% (immediate-release, children) (Prod Info Ritalin(R) LA, 2002a).

B) Effects of Food

1) None (Prod Info DAYTRANA(TM) transdermal system, 2006; Prod Info Concerta(TM), 2001).

a) Food does not affect the pharmacokinetics or the pharmacodynamics of extended-release oral methy methylphenidate (Prod Info DAYTRANA(TM) transdermal system, 2006; Prod Info Concerta(TM), 2001).

b) Cmax and AUC of methylphenidate after a single dose in 26 healthy adults were unaffected by taking compared to taking the whole capsule (Prod Info Metadate(R) CD, 2002a).

C) DOSAGE FORM ABSORPTION

1) Extended-release Capsules

a) Ritalin(R) LA extended-release capsules have a bimodal release profile, using the SODAS(R) (Spher dose is in immediate-release beads, with the remainder in enteric-coated, delayed-release beads (enabli 2002b). Single daily doses of Ritalin(R) LA extended-release capsules 20, 30, and 40 milligrams (mg) pr twice-daily administration of immediate release Ritalin(R) tablets 10, 15, or 20 mg, respectively (Prod Inf

2) Extended-release Tablets

a) Concerta(R) extended-release tablet uses osmotic pressure to deliver methylphenidate at a constant tri-layer core surrounded by a semipermeable membrane with an immediate-release overcoat, which dis (such as the gastrointestinal tract) providing the initial dose. As water permeates through a laser-drilled o through the orifice by the osmotic pressure created by the polymer excipients in the core. The membrane rate at which water enters the tablet core. The tablet must be swallowed whole with the aid of liquids, an Info Concerta(TM), 2001).

3) Sustained-release Tablets

a) Ritalin SR(R) tablets are formulated with a wax matrix core in which the medication is placed into cha in half would disrupt the medication channels in the tablet core and thereby alter the sustained release c Ritalin SR(R) tablets in half is not recommended (Pers Comm, 1987).

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding

a) 10% to 33% (Prod Info RITALIN LA(R) oral extended-release capsule, 2004; Hungund et al, 1979).

B) Distribution Kinetics

1) Volume of Distribution

a) 1.1 to 6 liters/kilogram (L/kg) (Prod Info Ritalin(R) LA, 2002a; Hungund et al, 1979).

1) Vd in children (Hungund et al, 1979).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) TISSUES, extensive (Prod Info Ritalin(R) LA, 2002a; Faraj et al, 1974).

a) Methylphenidate is rapidly and extensively metabolized by nonmicrosomal hydrolytic esterases in live (Prod Info Ritalin(R) LA, 2002a).

B) Metabolites

1) Ritalinic acid (essentially inactive) (Prod Info DAYTRANA(TM) transdermal system, 2006)(Foraj et al, 197 LA, 2002a; Dayton et al, 1970).

a) Ritalinic acid (alpha-phenyl-piperidine acetic acid) possess minimal-to-no pharmacologic activity (Pro 2006; Prod Info Ritalin(R) LA, 2002a). Clinical efficacy is mainly due to the parent compound.

b) Compared to oral administration on a mg/kg basis, transdermal methylphenidate results in higher exp pass effect. Minimal to no l-methylphenidate is systemically available after oral administration. In contras high as d-methylphenidate after transdermal methylphenidate administration (Prod Info DAYTRANA(TM)

2) Hydroxymethylphenidate and hydroxyritalinic acid (only small amounts of each in plasma) (Prod Info Rital

a) 6-oxo-alpha-phenyl-2-piperidine acetic acid (Foraj et al, 1974)(Bartlett & Egger, 1972; Dayton et al, 1

2.3.4 Excretion

A) Kidney

1) Renal Excretion (%)

a) Immediate release: 78% to 97%, less than 1% unchanged (Prod Info RITALIN LA(R) oral extended-re Faraj et al, 1974; Dayton et al, 1970); sustained release, children: 67% (Prod Info RITALIN(R) oral tablet release, adults: 86% (Prod Info RITALIN(R) oral tablet, RITALIN-SR(R) oral tablet, 2004).

1) About 90% of radiolabeled methylphenidate was recovered in the urine after oral dosing. Ritalinic

dose (Prod Info Concerta(TM), 2001).

B) Feces

1) Immediate-release: 1% to 3% (Prod Info RITALIN LA(R) oral extended-release capsule, 2004)

C) Other

1) PLASMA CLEARANCE, 3.1 to 8.5 L/kg/hr in children (Shader et al, 1999; Hungund et al, 1979).

2.3.5 Elimination Half-life

A) Parent Compound

1) (Oral) 2 to 7 hours (average, 3 hours) (Shader et al, 1999; Faraj et al, 1974); (Intravenous) 1 to 2 hours (F

a) In children aged 6 to 12 years, the mean elimination half-life for transdermal methylphenidate applied removal of the patch and 1.4 to 2.9 hours for d-methylphenidate and l-methylphenidate, respectively (Pro 2006).

b) In 36 healthy adults, the plasma half-life of methylphenidate after a single dose of methylphenidate O immediate-release 5 mg every 4 hours, and a single dose of slow-release 20 mg was 3.5 hours, 3.0 hou

c) The elimination half-life of a single dose and multiple doses (once a day on day 3 through day 6) of m was 3.9 hours (Modi et al, 2000).

B) Metabolites

1) Ritalinic acid, 3 to 4 hours (Prod Info Ritalin(R) LA, 2002a).

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING

1) Methylphenidate

a) Transdermal (Patch, Extended Release)

1) Methylphenidate patch should be given cautiously to patients with a history of drug dependence or alcoho tolerance and psychological dependence with varying degrees of abnormal behavior. Frank psychotic episod Careful supervision is required during withdrawal from abusive use, since severe depression may occur. Wit unmask symptoms of the underlying disorder that may require follow-up (Prod Info DAYTRANA(TM) transde

2) Methylphenidate Hydrochloride

a) Oral (Tablet; Tablet, Extended Release; Tablet, Chewable; Capsule, Extended Release; Solution)

1) Methylphenidate hydrochloride should be given cautiously to emotionally unstable patients, such as those alcoholism, because such patients may increase dosage on their own initiative.

2) Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of a occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe overactivity can be unmasked. Long term follow-up may be required because of the patient's basic personalit tablet, RITALIN-SR(R) oral sustained-release tablet, 2004; Prod Info METHYLIN(R) oral solution, 2004; Prod Prod Info RITALIN LA(R) oral extended-release capsule, 2004).

3.1 Contraindications

A) Methylphenidate

1) marked agitation, anxiety, and tension; may aggravate symptoms (Prod Info DAYTRANA(TM) transdermal sys

2) glaucoma (Prod Info DAYTRANA(TM) transdermal system, 2006)

3) hypersensitivity to methylphenidate or other components of the product (Prod Info DAYTRANA(TM) transderm

4) monoamine oxidase inhibitors, such as isocarboxazid, phenelzine, selegiline, tranylcypromine, within 14 days (Prod Info DAYTRANA(TM) transdermal system, 2006)

5) tics, motor (Prod Info DAYTRANA(TM) transdermal system, 2006)

6) Tourette's syndrome, family history or diagnosis (Prod Info DAYTRANA(TM) transdermal system, 2006)

B) Methylphenidate Hydrochloride

1) angina pectoris; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) extended release (TM) extended release oral capsules, 2008)

2) cardiac arrhythmias; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) extended relea CD(TM) extended release oral capsules, 2008)

3) fructose intolerance, glucose-galactose malabsorption, or sucrase-isomaltase insufficiency; contains sucrose ((TM) extended release oral capsules, 2008)

4) glaucoma (Prod Info METADATE CD(TM) extended release oral capsules, 2008; Prod Info RITALIN(R) oral ta

tablets, 2006)
5) halogenated anesthetics; risk of sudden blood pressure increase during surgery, do not take on day of surgery
(TM) extended release oral capsules, 2008)
6) heart failure; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) extended release oral
7) hypersensitivity to methylphenidate or other components of the product (Prod Info METADATE CD(TM) extend
RITALIN(R) oral tablets, RITALIN-SR(R) sustained-release oral tablets, 2006)
8) hypertension, severe; may increase blood pressure (Prod Info METADATE CD(TM) extended release oral cap
extended release oral capsules, 2008)
9) hyperthyroidism or thyrotoxicosis; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) e
METADATE CD(TM) extended release oral capsules, 2008)
10) marked agitation, anxiety, and tension; may aggravate symptoms (Prod Info METADATE CD(TM) extended r
(R) oral tablets, RITALIN-SR(R) sustained-release oral tablets, 2006)
11) monoamine oxidase inhibitors, such as isocarboxazid, phenelzine, selegiline, tranylcypromine, within 14 days
crisis (Prod Info METADATE CD(TM) extended release oral capsules, 2008; Prod Info RITALIN(R) oral tablets, R
2006)
12) myocardial infarction, recent; may increase blood pressure or heart rate (Prod Info METADATE CD(TM) exte
METADATE CD(TM) extended release oral capsules, 2008)
13) tics, motor (Prod Info METADATE CD(TM) extended release oral capsules, 2008; Prod Info RITALIN(R) oral
tablets, 2006)
14) Tourette's syndrome, family history or diagnosis (Prod Info METADATE CD(TM) extended release oral capsu
RITALIN-SR(R) sustained-release oral tablets, 2006)

3.2 Precautions

A) Methylphenidate
1) history of drug dependence or alcoholism; abuse potential (Prod Info DAYTRANA(TM) transdermal system, 20
2) cardiac abnormalities, structural; sudden death has been reported with CNS stimulant treatment (Prod Info DA
3) contact sensitization; may lead to future systemic sensitization or other systemic reactions when methylphenid
DAYTRANA(TM) transdermal system, 2006)
4) depression, severe; should not be used to treat (Prod Info DAYTRANA(TM) transdermal system, 2006)
5) EEG abnormalities; may lower convulsive threshold (Prod Info DAYTRANA(TM) transdermal system, 2006)
6) external heat source exposure; increase release of drug from patch (Prod Info DAYTRANA(TM) transdermal s
7) fatigue states, normal; should not be used to prevent or treat (Prod Info DAYTRANA(TM) transdermal system,
8) psychosis; may exacerbate symptoms of behavior disturbance and thought disorder (Prod Info DAYTRANA(TI
9) seizures, history of; may lower convulsive threshold (Prod Info DAYTRANA(TM) transdermal system, 2006)
10) underlying medical conditions that may be compromised by increases in blood pressure or heart rate such as
myocardial infarction, or hyperthyroidism (Prod Info DAYTRANA(TM) transdermal system, 2006)
B) Methylphenidate Hydrochloride
1) history of drug dependence or alcoholism; abuse potential (Prod Info RITALIN(R) oral tablets, RITALIN-SR(R)
2) bipolar disorder; risk of induction of a mixed/manic episode (Prod Info METADATE CD(TM) extended release
3) cardiac abnormalities, structural or other heart problems; sudden death has been reported with CNS stimulant
RITALIN-SR(R) sustained-release oral tablets, 2006)
4) depression, severe; should not be used to treat (Prod Info RITALIN(R) oral tablets, RITALIN-SR(R) sustained-
5) EEG abnormalities; may lower convulsive threshold (Prod Info RITALIN(R) oral tablets, RITALIN-SR(R) sustai
6) fatigue states, normal; should not be used to prevent or treat (Prod Info RITALIN(R) oral tablets, RITALIN-SR(
7) psychosis; may exacerbate symptoms of behavior disturbance and thought disorder (Prod Info RITALIN(R) ora
tablets, 2006)
8) seizures, history of; may lower convulsive threshold (Prod Info RITALIN(R) oral tablets, RITALIN-SR(R) sustai
9) underlying medical conditions that may be compromised by increases in blood pressure or heart rate such as
myocardial infarction, or hyperthyroidism (Prod Info RITALIN(R) oral tablets, RITALIN-SR(R) sustained-release or

3.3.1 Cardiovascular Effects

Methylphenidate

Methylphenidate Hydrochloride

3.3.1.A Methylphenidate

Increased blood pressure

Increased heart rate

3.3.1.A.1 Increased blood pressure

a) Modest increases in systolic and diastolic blood pressure have been reported in studies. Use methylp underlying medical conditions (such as preexisting hypertension, heart failure, recent myocardial infarctic with increases in blood pressure (Prod Info DAYTRANA(TM) transdermal system, 2006).

3.3.1.A.2 Increased heart rate

a) Modest increases in heart rate have been reported in studies. Use methylphenidate cautiously in pati as preexisting hypertension, heart failure, recent myocardial infarction, or hyperthyroidism) may be comp DAYTRANA(TM) transdermal system, 2006).

3.3.1.B Methylphenidate Hydrochloride

Angina

Bradyarrhythmia

Cardiorespiratory arrest

Cerebral vasculitis

Dead - sudden death

Hypertension

Myocardial infarction

Premature beats

Raynaud's phenomenon

Supraventricular tachycardia

Tachyarrhythmia

Ventricular premature beats

3.3.1.B.1 Angina

a) Angina pectoris was reported during postmarketing experience with methylphenidate hydrochloride e extended-release oral tablets, 2008).

3.3.1.B.2 Bradyarrhythmia

a) Bradycardia was reported during postmarketing experience with methylphenidate hydrochloride exter extended-release oral tablets, 2008).

3.3.1.B.3 Cardiorespiratory arrest

a) Adults

1) A 19-year-old male suffered full cardiopulmonary arrest after inhaling crushed methylphenidate ta damage and subsequently developed fever, tachycardia, and elevated CK-MB concentrations. Echo hypokinesis with low ejection fraction, consistent with a congestive cardiomyopathy or global myoca revealed cardiac lesions that were similar to catecholamine cardiomyopathy without the contraction principal metabolite of methylphenidate) were 2 to 3 times the therapeutic concentrations upon adm methylphenidate may be fatal (Massello & Carpenter, 1999).

3.3.1.B.4 Cerebral vasculitis

a) Children

1) A case of cerebral vasculitis was reported in an 8-year-old boy who was taking methylphenidate behavioral problems. A year and a half after he started the methylphenidate treatment, he suddenly intensity over a 4-month period. At the third episode, the paresthesias resulted in ataxia, dysmetria i the left upper limb. Cerebral angiogram revealed bilateral complete occlusion of the posterior cerebr arteries, indicating localized vasculitis. After discontinuing the methylphenidate treatment, he was fre

3.3.1.B.5 Dead - sudden death

a) Incidence: rare

b) Adults

1) Sudden death, stroke, and myocardial infarction have occurred in adults taking usual doses of st cases is unknown, however, adults have a greater likelihood than children of having serious structur serious heart rhythm abnormalities, coronary artery disease, or other serious cardiac problems. Adu treated with stimulant drugs. Perform a thorough history to determine if there is a family history of su physical exam to assess the existence of cardiac disease prior to prescribing these drugs to patients oral tablets, 2008).

c) Children and Adolescents - With Preexisting Cardiac Risk

1) Taking usual doses of stimulant drugs may cause sudden death in children and adolescents with problems. Children or adolescents with known serious cardiac problems should not be treated with s determine if there is a family history of sudden death or ventricular arrhythmia and a physical exam t to prescribing these drugs to patients (Prod Info CONCERTA(R) extended-release oral tablets, 2008

d) Children and Adolescents - Healthy

1) A retrospective, case-controlled study examines the association between stimulant medication, in sudden death in healthy children and adolescents. In a collection of data from state vital statistics ar of sudden death in children and adolescents between the ages of 7 to 19 years were matched and c passengers in motor vehicle accidents. The study determined that 1.8% (n=10) of youths who exper stimulant medication compared with only 0.4% (n=2) of youths in the motor vehicle accident group (p=0.02). Limitations to this study included the time lag between the youths stimulant medication use of information regarding clinical diagnoses, inconsistent postmortem inquiry, and the exclusion of de stated that this finding should be considered when evaluating the overall risk and benefit of stimulan (Gould et al, 2009). Given the limitations of this study, the U.S. Food and Drug Administration is una associated with stimulant medication (US Food and Drug Administration, 2009).

3.3.1.B.6 Hypertension

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Hypertension occurred in less than 1% of patients on methylphenidate hydrochloride extended-releas trials (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

c) Modest increases in average blood pressure (about 2 to 4 mmHg) have been caused by the use of st changes in blood pressure. Medical conditions that place patients at risk when blood pressure increases

heart failure, recent myocardial infarction, or ventricular arrhythmia (Prod Info CONCERTA(R) extended-

d) Adults

1) During a placebo-controlled, 7-week dose-titration study (n=401), adults taking methylphenidate mg/day) had mean changes from baseline in standing blood pressure that ranged from 0.1 to 2.2 mı compared with 1.1 mmHg and -1.8 mmHg, respectively, for placebo treated patients. At the end of d controlled, 5-week fixed-dose study (n=226), adults taking methylphenidate hydrochloride extended- mean changes from baseline blood pressure of -1.2 mmHg systolic and 1.1 diastolic, compared with placebo treated patients (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

2) Since methylphenidate is not used as frequently in adults, there is little literature regarding the ca hypertensive adults. Methylphenidate has been shown to increase blood pressure in patients who a (Flemenbaum, 1972a).

e) Children

1) Compared to placebo, systolic and diastolic blood pressure increased approximately 1 to 4 mmH times a day methylphenidate. In a randomized, placebo-controlled trial of 177 adolescent subjects, r mmHg diastolic above baseline blood pressures for subjects taking methylphenidate hydrochloride (experienced compared to 0.7 mmHg systolic and 1.4 mmHg diastolic for patients receiving the place oral tablets, 2008).

3.3.1.B.7 Myocardial infarction

a) Adults

1) Myocardial infarction, sudden deaths, and stroke have occurred in adults taking usual doses of s cases is unknown, however, adults have a greater likelihood than children of having serious structur serious heart rhythm abnormalities, coronary artery disease, or other serious cardiac problems. Adu treated with stimulant drugs. Perform a thorough history to determine if there is a family history of su physical exam to assess the existence of cardiac disease prior to prescribing these drugs to patients oral tablets, 2008).

3.3.1.B.8 Premature beats

a) Extrasystoles were reported during postmarketing experience with methylphenidate hydrochloride ex extended-release oral tablets, 2008).

3.3.1.B.9 Raynaud's phenomenon

a) Raynaud's phenomenon was reported during postmarketing experience with methylphenidate hydroc CONCERTA(R) extended-release oral tablets, 2008).

3.3.1.B.10 Supraventricular tachycardia

a) Supraventricular tachycardia was reported during postmarketing experience with methylphenidate hy CONCERTA(R) extended-release oral tablets, 2008).

3.3.1.B.11 Tachyarrhythmia

a) Summary

1) Compared to placebo, resting pulses increased approximately 2 to 6 beats per minute (bpm) dur day methylphenidate. In a randomized, placebo-controlled trial of 177 adolescent subjects, mean inc rate for subjects taking methylphenidate hydrochloride extended-release (up to 72 mg/day (1.4 mg/k for patients receiving the placebo. During a placebo-controlled, 7-week dose-titration study (n=401), extended-release (36 to 108 mg/day) experienced dose-dependent mean increases of 3.9 to 9.8 bp with 2.7 bpm in the placebo group. In a second placebo-controlled, 5-week fixed-dose study (n=226 extended-release (18, 36, and 72 mg/day) experienced mean changes from baseline in resting puls bpm in the placebo group. Monitor patients for larger changes in heart rate. Medical conditions that include those with preexisting hypertension, heart failure, recent myocardial infarction, or ventricular extended-release oral tablets, 2008).

b) Incidence: 4.8% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

c) Adults

1) Tachycardia occurred in 4.8% of adult patients on methylphenidate hydrochloride extended-relea placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCERTA(R) exter

3.3.1.B.12 Ventricular premature beats

a) Ventricular extrasystoles were reported during postmarketing experience with methylphenidate hydro CONCERTA(R) extended-release oral tablets, 2008).

3.3.2 Dermatologic Effects

Methylphenidate

Methylphenidate Hydrochloride

3.3.2.A Methylphenidate

Contact dermatitis

Erythema

3.3.2.A.1 Contact dermatitis

a) Although, no cases of contact sensitization has occurred when transdermal methylphenidate is used
than 9 hours and alternating application sites on the hip); contact sensitization may occur. However, con
in clinical effectiveness studies. Contact sensitization is characterized by erythema with intense local rea
significantly improve within 2 days or spreads beyond the patch site. Diagnosis should be confirmed by a
not indicative of contact sensitization. Once a patient is sensitized to transdermal methylphenidate, admi
sensitization or other systemic reactions. Systemic reactions include flare-up of previous dermatitis or of
eruptions in previously unaffected skin; headache; fever; malaise; arthralgia; diarrhea; or vomiting. Patie
transdermal methylphenidate might not be able to take methylphenidate in any form (Prod Info DAYTRA

1) A study designed to provoke skin sensitization demonstrated transdermal methylphenidate to be
were exposed continuously for 3 weeks, followed by a 2 week rest period, and the challenge/rechall
irritating than both the placebo control and the saline control. At least 18 (13.5%) of subjects (n=133
methylphenidate based on the results of the challenge and/or rechallenge phases of the study (Proc
2006).

3.3.2.A.2 Erythema

a) Erythema of no or minimal discomfort is a common adverse effect with the use of transdermal methyl
efficacy studies, the majority of subjects experienced minimal to definite erythema. In general, the erythe
therapy or discontinuation from treatment. If erythema is accompanied by intense local reaction (edema,
improve within 2 days or spreads beyond the patch site, then contact sensitization should be suspected.
papules do not resolve or significantly reduce within 24 hours after patch removal (Prod Info DAYTRANA

3.3.2.B Methylphenidate Hydrochloride

Alopecia

Erythema

Erythroderma

Generalized hyperhidrosis

Rash

3.3.2.B.1 Alopecia

a) Alopecia has been reported in postmarketing experience with methylphenidate hydrochloride extende
release oral tablets, 2008).

3.3.2.B.2 Erythema

a) Erythema has been reported in postmarketing experience with methylphenidate hydrochloride extend
release oral tablets, 2008).

3.3.2.B.3 Erythroderma

a) A case of a 73-year-old white female treated with 10 milligrams (mg) twice daily of methylphenidate fo
has been reported (Weil, 1968). Two days after initiating therapy, the patient developed an itching RASH
fever. Discontinuation of the drug and treatment with antihistamines and prednisone resulted in resolutio
reinstitution of the methylphenidate, the dermatitis reappeared and was again abolished upon discontinu

3.3.2.B.4 Generalized hyperhidrosis

a) Incidence: 5.1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)
b) Adults

1) Hyperhidrosis has occurred in 5.1% of adult patients on methylphenidate hydrochloride extended
patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

3.3.2.B.5 Rash

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)
b) Rash and rash-macular have occurred in less than 1% of patients on methylphenidate hydrochloride (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.3 Endocrine/Metabolic Effects

Methylphenidate

Methylphenidate Hydrochloride

3.3.3.A Methylphenidate

Decreased body growth

Weight decreased

3.3.3.A.1 Decreased body growth

a) It is unknown if chronic use of stimulants, including methylphenidate, in children may cause suppress transdermal system, 2006). However, multiple studies identified growth suppression with oral methylphe 1980; Croche et al, 1979; Satterfield et al, 1979; Oettinger et al, 1977; McNutt et al, 1977; Gross, 1976; M Millichap, 1975; Safer et al, 1975; Safer & Allen, 1975; Safer et al, 1972; Eisenberg, 1972; Satterfield et

1) Long-term treatment with oral methylphenidate, especially with doses greater than 20 milligrams of growth in some hyperactive children; however, the growth retarding effects appear transient, and reduced with prolonged therapy in most children. The duration of growth suppression and the doses weight deficits after the first year of treatment may be offset by growth spurts in the second year of t pertaining to the effects of stimulants on growth is complicated since methods of measuring growth have had a follow-up period ranging from 1 to 16 years have generally failed to demonstrate a signif with CNS stimulants (Mattes & Gittelman, 1983; Hollister, 1980; Croche et al, 1979; Satterfield et al, Gross, 1976; McNutt et al, 1976; Gross, 1976; Millichap & Millichap, 1975; Safer et al, 1975; Safer & 1972). Investigators supporting the observation that methylphenidate can induce some growth supp result from some disorder in growth hormone secretion. However, data evaluating this hypothesis ha al, 1979; Barter & Kammer, 1978; Brown, 1977; Brown & Williams, 1976). It has also been suggeste stimulants, the temporary deficit in height gain that occurs is related to ADHD-associated delayed m is associated with dysregulation of several neurotransmitter systems that may alter neuroendocrine al, 1998).

2) In 1 study, use of methylphenidate was shown to slightly diminish the response to growth hormo deficiency (IGHD), but not those with idiopathic short stature (ISS). Methylphenidate therapy had a r magnitude of the effect was small and the magnitude of the difference in the change in height betwe methylphenidate and children with IGHD not treated with methylphenidate decreased with time (Rac

3) One study compared the growth of 63 hyperactive children, 29 received dextroamphetamine (me methylphenidate (median, 20 mg/day) and 14 received no medication. Height measurements were r years from student health records. Long-term administration of dextroamphetamine and methylphen inhibition of growth when compared to the control group; however, when the mean percentile loss w centimeters (cm), GROWTH SUPPRESSION was only minimal, 1.5 and 1 cm/year, respectively. Gr greater than 20 mg/day of methylphenidate (Safer & Allen, 1973). A follow-up study demonstrated th the CNS stimulant during the summer months (Safer et al, 1975).

4) One study involving 72 hyperactive children found a statistically significant decrease in height aft 1.03 centimeters (cm)), but the initial first year height deficits were made up the second year by a gr suggested the development of tolerance to growth suppression with prolonged treatment (Satterfield growth with continued treatment was eluded to by another study (Gross, 1976). In this study of 60 cl dose, 34 milligrams (mg)/day), no significant decrease in height was noticed during the first year and duration 5.1 years), the height was statistically greater than the predicted norms.

3.3.3.A.2 Weight decreased

a) Incidence: 9% (Prod Info DAYTRANA(TM) transdermal system, 2006)
b) A decreased weight occurred in 9% of patients on transdermal methylphenidate compared with 0% o (n=183) (Prod Info DAYTRANA(TM) transdermal system, 2006).

3.3.3.B Methylphenidate Hydrochloride

3.3.3.B.1 Decreased body growth

a) Children

1) Studies of children ages 7 to 10 years who were randomized to either methylphenidate or non-m

frame, and children ages 10 to 13 years in naturalistic subgroups of newly treated and non-medicati indicate that children who are treated 7 days per week throughout the year experience slowing grow growth in height and 2.7 kg less growth in weight over 3 years) without growth rebound during this d treatment with stimulants (Prod Info CONCERTA(R) extended-release oral tablets, 2008).
2) Long-term treatment with methylphenidate, especially with doses greater than 20 milligrams (mg growth in some hyperactive children; however, the growth retarding effects appear transient, and ov reduced with prolonged therapy in most children. The duration of growth suppression and the doses weight deficits after the first year of treatment may be offset by growth spurts in the second year of t pertaining to the effects of stimulants on growth is complicated since methods of measuring growth have had a follow-up period ranging from 1 to 16 years have generally failed to demonstrate a signif with CNS stimulants (Mattes & Gittelman, 1983; Hollister, 1980; Croche et al, 1979; Satterfield et al, Gross, 1976; McNutt et al, 1976; Gross, 1976; Millichap & Millichap, 1975; Safer et al, 1975; Safer & 1972). Investigators supporting the observation that methylphenidate can induce some growth supp result from some disorder in growth hormone secretion. However, data evaluating this hypothesis ha al, 1979; Barter & Kammer, 1978; Brown, 1977; Brown & Williams, 1976). It has also been suggeste stimulants, the temporary deficit in height gain that occurs is related to ADHD-associated delayed m is associated with dysregulation of several neurotransmitter systems that may alter neuroendocrine al, 1998).
3) In 1 study, use of methylphenidate was shown to slightly diminish the response to growth hormo deficiency (IGHD), but not those with idiopathic short stature (ISS). 4) One study compared the growth of 63 hyperactive children, 29 received dextroamphetamine (me methylphenidate (median, 20 mg/day) and 14 received no medication. Height measurements were r years from student health records. Long-term administration of dextroamphetamine and methylphen inhibition of growth when compared to the control group; however, when the mean percentile loss w centimeters (cm), GROWTH SUPPRESSION was only minimal, 1.5 and 1 cm/year, respectively. Gr greater than 20 mg/day of methylphenidate (Safer & Allen, 1973). A follow-up study demonstrated th the CNS stimulant during the summer months (Safer et al, 1975).
5) One study involving 72 hyperactive children found a statistically significant decrease in height aft 1.03 centimeters (cm)), but the initial first year height deficits were made up the second year by a gr suggested the development of tolerance to growth suppression with prolonged treatment (Satterfield growth with continued treatment was eluded to by another study (Gross, 1976). In this study of 60 cl dose, 34 milligrams (mg)/day), no significant decrease in height was noticed during the first year and duration 5.1 years), the height was statistically greater than the predicted norms.

3.3.4 Gastrointestinal Effects

Methylphenidate

Methylphenidate Hydrochloride

3.3.4.A Methylphenidate

Decrease in appetite

Loss of appetite

Nausea

Vomiting

3.3.4.A.1 Decrease in appetite

a) Incidence: 26% (Prod Info DAYTRANA(TM) transdermal system, 2006)
b) Decreased appetite occurred in 26% of patients on transdermal methylphenidate compared with 5% study (n=183) (Prod Info DAYTRANA(TM) transdermal system, 2006).

3.3.4.A.2 Loss of appetite

a) Incidence: 5% (Prod Info DAYTRANA(TM) transdermal system, 2006)
b) Anorexia occurred in 5% of patients on transdermal methylphenidate compared with 1% of placebo t (Prod Info DAYTRANA(TM) transdermal system, 2006). During an open-label study (n=191) of 40-month worn for 12 hours daily, anorexia occurred in 46% of subjects leading to a 4% discontinuation rate (Prod

2006).

3.3.4.A.3 Nausea

a) Incidence: 12% (Prod Info DAYTRANA(TM) transdermal system, 2006)

b) Nausea occurred in 12% of patients on transdermal methylphenidate compared with 2% of placebo t (Prod Info DAYTRANA(TM) transdermal system, 2006).

3.3.4.A.4 Vomiting

a) Incidence: 10% (Prod Info DAYTRANA(TM) transdermal system, 2006)

b) Vomiting occurred in 10% of patients on transdermal methylphenidate compared with 5% of placebo (Prod Info DAYTRANA(TM) transdermal system, 2006).

3.3.4.B Methylphenidate Hydrochloride

Constipation

Decrease in appetite

Gastrointestinal obstruction

Indigestion

Loss of appetite

Nausea

Stomach ache

Upper abdominal pain

Vomiting

Xerostomia

3.3.4.B.1 Constipation

a) Incidence: 1.4% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Constipation has been reported in 1.4% of adult patients on methylphenidate hydrochloride exter patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

3.3.4.B.2 Decrease in appetite

a) Incidence: 25.3% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Decreased appetite has been reported in 25.3% of adult patients on methylphenidate hydrochlor 6.6% of patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info C 2008).

c) In a direct, double-blind, crossover comparison of adverse effect profiles, both dextroamphetamine 0. methylphenidate 0.3 mg/kg twice daily were well-tolerated in 125 children with attention deficit disorder (reported more frequently during drug therapy than at baseline were appetite suppression (both drugs) ar mean severity of adverse effects was significantly higher in the dextroamphetamine group. However, onl discontinue therapy because of adverse effects (Efron et al, 1997).

3.3.4.B.3 Gastrointestinal obstruction

a) Rare cases of obstructive symptoms have been reported in patients with known gastrointestinal narro the ingestion of drugs in nondeformable controlled-release formulations. This drug should only be used i whole (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.4.B.4 Indigestion

a) Incidence: 2.2% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Indigestion has been reported in 2.2% of adult patients on methylphenidate hydrochloride extenc patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

3.3.4.B.5 Loss of appetite

a) Incidence: 1.7% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Anorexia has been reported in 1.7% of adult patients on methylphenidate hydrochloride extended-rel placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCERTA(R) extended-

3.3.4.B.6 Nausea

a) Incidence: 12.8% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Nausea has been reported in 12.8% of adult patients on methylphenidate hydrochloride extende patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

3.3.4.B.7 Stomach ache

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Stomach discomfort occurred in less than 1% of patients on methylphenidate hydrochloride extended clinical trials (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.4.B.8 Upper abdominal pain

a) Incidence: 5.9% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Children

1) Upper abdominal pain has been reported in 5.9% of children and adolescent patients on methylp (n=321) compared with 3.8% of patients on placebo (n=318), in 4 double-blind, placebo-controlled c release oral tablets, 2008).

3.3.4.B.9 Vomiting

a) Incidence: 1.7%, adults; 2.8%, children (Prod Info CONCERTA(R) extended-release oral tablets, 200

b) Adults

1) Vomiting has been reported in 1.7% of adult patients on methylphenidate hydrochloride extende patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

c) Children

1) Vomiting has been reported in 2.8% of children and adolescent patients on methylphenidate hyd with 1.6% of patients on placebo (n=318), in 4 double-blind, placebo-controlled clinical trials (Prod In tablets, 2008).

3.3.4.B.10 Xerostomia

a) Incidence: 14% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Dry mouth has been reported in 14% of adult patients on methylphenidate hydrochloride extende patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

3.3.5 Hematologic Effects

3.3.5.A Methylphenidate Hydrochloride

Eosinophil count raised

Leukopenia

Pancytopenia

Thrombocytopenia

Thrombocytopenic purpura

3.3.5.A.1 Eosinophil count raised

a) Methylphenidate abuse by the intravenous route can cause an eosinophilia (Hayashi et al, 1980). Abs 30,338.

3.3.5.A.2 Leukopenia

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Leukopenia occurred in less than 1% of patients on methylphenidate hydrochloride extended-release Leukopenia was also reported during open-label studies. Periodically monitor CBC, differential, and plate CONCERTA(R) extended-release oral tablets, 2008).

3.3.5.A.3 Pancytopenia

a) Pancytopenia was reported during postmarketing experience with methylphenidate hydrochloride ext extended-release oral tablets, 2008).

3.3.5.A.4 Thrombocytopenia

a) Thrombocytopenia was reported during postmarketing experience with methylphenidate hydrochlorid extended-release oral tablets, 2008).

1) Children

a) Thrombocytopenia was reported in a 10-year-old boy who received methylphenidate for atte had been treated with methylphenidate for 10 months when a routine blood count revealed thro within 2 weeks of drug discontinuation (Kuperman et al, 2003).

3.3.5.A.5 Thrombocytopenic purpura

a) Thrombocytopenic purpura was reported during postmarketing experience with methylphenidate hydr CONCERTA(R) extended-release oral tablets, 2008).

3.3.6 Hepatic Effects

3.3.6.A Methylphenidate Hydrochloride

Autoimmune hepatitis

Hepatotoxicity

3.3.6.A.1 Autoimmune hepatitis

a) Autoimmune hepatitis occurred in a 57-year-old, asymptomatic Caucasian male 1 month following ini a history of orthotopic liver transplantation secondary to chronic hepatitis C infection 4 years prior, was fo chemistries during a routine scheduled follow-up. Baseline liver chemistries had been stable in the montl AST, ALT, and total bilirubin were 572 units/L, 338 units/L, and 2.7 mg/dL, respectively. Medications take venlafaxine, omeprazole, hydrochlorothiazide, fosinopril, and a multivitamin. Long-acting methylphenidat presentation for impaired concentration and depressive symptoms. The patient denied alcohol abuse an and did not have any fever, chills, abdominal pain, or urine discoloration. Physical examination revealed hepatosplenomegaly evident. No change in mental status or asterixis was found on neurological examin anti-smooth muscle antibody (1:40) and antinuclear antibody (1:80), with a nucleolar pattern, and an elev normal at baseline. A liver biopsy showed severe lobular and periportal necroinflammatory infiltrate with eosinophils, but lacking endothelialitis and bile duct damage. Subsequently, methylphenidate therapy wa normalize. Besides methylphenidate, other prior medications were continued and prednisone 10 mg/day chemistries returned to patient's approximate baseline values over the next few months, and a liver biop improvement. Later, the patient was started on combination amphetamine/dextroamphetamine with no fu 2007).

3.3.6.A.2 Hepatotoxicity

a) Liver dysfunction is a rare side effect of methylphenidate. Intravenous abuse of methylphenidate was marked elevations in bilirubin, SGOT and SGPT in a 19-year-old black woman. Hepatic biopsy revealed cells and eosinophils. Focal collections of mononuclear cells with Kupffer cell hyperplasia was observed rechallenge with 20 milligrams (mg) intravenously (IV) methylphenidate (Ritalin(R)) twice daily for 2 days hepatotoxicity (Mehta et al, 1984). These data suggest the hepatotoxic potential of the drug when given

3.3.7 Immunologic Effects

3.3.7.A Methylphenidate Hydrochloride

Anaphylaxis

Angioedema

Auricular dilatation

Bullous eruption

Generalized exfoliative dermatitis

Generalized pruritus

Immune hypersensitivity reaction

Nasopharyngitis

3.3.7.A.1 Anaphylaxis

a) Hypersensitivity reactions such as anaphylactic reactions have been reported in postmarketing exper extended-release (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.7.A.2 Angioedema

a) Hypersensitivity reactions such as angioedema has been reported in postmarketing experience with r (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.7.A.3 Auricular dilatation

a) Hypersensitivity reactions such as auricular swelling has been reported in postmarketing experience release (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.7.A.4 Bullous eruption

a) Hypersensitivity reactions such as bullous conditions have been reported in postmarketing experienc release (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.7.A.5 Generalized exfoliative dermatitis

a) Hypersensitivity reactions such as exfoliative conditions have been reported in postmarketing experie extended-release (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.7.A.6 Generalized pruritus

a) Hypersensitivity reactions such as pruritus have been reported in postmarketing experience with metl (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.7.A.7 Immune hypersensitivity reaction

a) Hypersensitivity reactions to methylphenidate are rare in occurrence. However, 2 cases have been re and in the other case erythema multiforme was described (Rothschild, 1972); (Weil, 1968).

3.3.7.A.8 Nasopharyngitis

a) Incidence: 2.8% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Children

1) Nasopharyngitis has occurred in 2.8% of child and adolescent patients (n=321) on methylphenid compared with 2.2% of patients on placebo (n=318), in 4 double-blind, placebo-controlled clinical tri oral tablets, 2008).

3.3.8 Musculoskeletal Effects

Methylphenidate

Methylphenidate Hydrochloride

3.3.8.A Methylphenidate

3.3.8.A.1 Bone finding

a) Oral methylphenidate did not significantly affect BONE MINERAL DENSITY and BONE TURNOVER from 3 to 10 years), who were treated with a mean dose of methylphenidate 10 milligrams for an average disorder (ADHD), their bone mineral density (as measured by using dual photon absorptiometry), serum for BONE MINERALIZATION), urinary deoxypyridinoline excretion (an indicator of BONE RESORPTION significantly different from boys of the control group (n=9). All the children in the treatment group were wi period (Lahat et al, 2000).

b) In a retrospective cohort study of 42 male and female children (between 7 and 16 years old), dental r dose of 30 milligrams (mg) of oral methylphenidate (MH) for a mean duration of 54 months. Inclusion crit MH for a minimum of 2 years at the time of panoramic radiograph. The gender-and age-matched control had not ingested any long-term medication. An oral, written, and radiographic review of gender- and age outcome of the study was the dental age difference score, which was defined as dental age score for MH The mean dental age score for MH subjects was approximately 6 months behind matched control subjec compared, MH and control subjects were similar (p =0.27). Multiple regression demonstrated there were length of drug use were considered (Batterson et al, 2005).

3.3.8.B Methylphenidate Hydrochloride

Arthralgia

Bone finding

Muscle rigidity

Muscle twitch

Myalgia

3.3.8.B.1 Arthralgia

a) Arthralgia has been reported in postmarketing experience with methylphenidate extended-release (Pr tablets, 2008).

3.3.8.B.2 Bone finding

a) Children

1) Methylphenidate did not significantly affect bone mineral density and bone turnover in children. In years), who were treated with a mean dose of methylphenidate 10 milligrams for an average of 13 m (ADHD), their bone mineral density (as measured by using dual photon absorptiometry), serum bon bone mineralization), urinary deoxypyridinoline excretion (an indicator of bone resorption), and seru different from boys of the control group (n=9). All the children in the treatment group were within the (Lahat et al, 2000).

2) In a retrospective cohort study of 42 male and female children (between 7 and 16 years old), der average dose of 30 milligrams (mg) of methylphenidate (MH) for a mean duration of 54 months. Incl mg/day of MH for a minimum of 2 years at the time of panoramic radiograph. The gender-and age-m were healthy and had not ingested any long-term medication. An oral, written, and radiographic revi compared. The main outcome of the study was the dental age difference score, which was defined a score for control subjects. The mean dental age score for MH subjects was approximately 6 months when the median differences were compared, MH and control subjects were similar (p =0.27). Multip difference in scores when gender, age, or length of drug use were considered (Batterson et al, 2005

3.3.8.B.3 Muscle rigidity

a) Incidence: 1.9% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Muscle tightness has occurred in 1.9% of adult patients on methylphenidate hydrochloride exten patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

3.3.8.B.4 Muscle twitch

a) Muscle twitching has been reported in postmarketing experience with methylphenidate extended-rele oral tablets, 2008).

3.3.8.B.5 Myalgia

a) Myalgia has been reported in postmarketing experience with methylphenidate extended-release (Pro tablets, 2008).

3.3.9 Neurologic Effects

Methylphenidate

Methylphenidate Hydrochloride

3.3.9.A Methylphenidate

Headache

Insomnia

Lowered convulsive threshold

Tic

3.3.9.A.1 Headache

a) During an open-label study (n=191) of 40-month duration with transdermal methylphenidate worn for subjects(Prod Info DAYTRANA(TM) transdermal system, 2006)

3.3.9.A.2 Insomnia

a) Incidence: 13% (Prod Info DAYTRANA(TM) transdermal system, 2006)

b) Insomnia occurred in 13% of patients on transdermal methylphenidate compared with 5% of placebo (Prod Info DAYTRANA(TM) transdermal system, 2006). During an open-label study (n=191) of 40-month worn for 12 hours daily, insomnia occurred in 30% of subjects leading to a 4% discontinuation rate (Prod 2006).

3.3.9.A.3 Lowered convulsive threshold

a) There is some clinical evidence that methylphenidate may lower convulsive threshold in patients with prior electroencephalogram (EEG) abnormalities in the absence of a history of seizures, and, very rarely prior EEG evidence of seizures. Discontinue methylphenidate if seizures develop (Prod Info DAYTRANA

1) Children with attention deficit hyperactive disorder (ADHD) who have normal electroencephalogr they receive stimulant therapy for ADHD (methylphenidate, dextroamphetamine, or combination am (R)). However, children with epileptiform EEGs may have considerable risk for eventual seizure, alth be attributable to use of the stimulant. These conclusions were based on a study of 234 children wit ADHD. All had EEGs prior to parental choosing of stimulant treatment or foregoing stimulant treatme children (15.4%) demonstrated epileptiform abnormalities compared with 198 with normal EEGs. Of treatment for ADHD. Three of the 30 who received stimulant therapy experienced seizures (p less th year-old male, and a 6-year-old male. The girl was treated uneventfully with methylphenidate for 12 methylphenidate experienced a 4-minute generalized tonic-clonic seizure. Her EEG had revealed a boys, the first experienced a 2-minute generalized tonic clonic seizure with focal onset 3 years after an episode at 10 months after initiation of methylphenidate; he was heard to fall and was unrespons EEGs of both boys had shown rolandic spikes, a focal epileptiform abnormality. One child who had a beginning methylphenidate (Hemmer et al, 2001).

3.3.9.A.4 Tic

a) Incidence: 7% (Prod Info DAYTRANA(TM) transdermal system, 2006)

b) Tic occurred in 7% of patients on transdermal methylphenidate compared with 0% of placebo treated Transdermal methylphenidate is contraindicated in patients with motor tics or with a family history or diag DAYTRANA(TM) transdermal system, 2006).

1) The incidence of TICS emergence was 7.8% in children treated with stimulant medication (methy for attention deficit hyperactivity disorder, based on a retrospective chart review (n=555). These stim if they were free of tics and without a history of tics according to the practice of the settings in which 8.3% of subjects treated with methylphenidate, 6.3% treated with dextroamphetamine, and 7.7% tre to dose or duration of stimulant therapy. Mean age of subjects was 11 years. A significant correlatio development of tics. As the authors noted, these children may have developed tics, regardless of tre et al, 2001).

2) Although stimulant therapy was suspected to exacerbate tics, long-term methylphenidate treatme effective in children with attention-deficit hyperactivity disorder (ADHD) and chronic multiple tic disor blinded, prospective, follow-up study, 32 children (age ranging from 6.1 and 11.9 years) received mi previous trial (mean 16.5 milligrams (mg), range=5 to 40 mg). The children were evaluated in a simu their on-task, fidgeting, worksheet behaviors, and vocal and motor tic frequency. In almost every me than placebo (p ranging from less than 0.001 to 0.03). There was no difference in tic condition betwe behaviors were not significantly different between baseline and placebo, whereas children spent sig medication conditions than placebo (p less than 0.001). There was no significant difference betweer growth table values. Systolic blood pressure and heart rate were significantly increased (p=0.02 and clinically insignificant. Although this study showed methylphenidate did not worsen tics in patients w possibility of individual exacerbation of tic cannot be ruled out (Gadow et al, 1999). In another study syndrome, abrupt withdrawal of methylphenidate and dextroamphetamine in long-term therapy DID frequency (Nolan et al, 1999).

3) Tourette's syndrome may be exacerbated or precipitated by the use of stimulant medications for children. Early signs of Tourette's syndrome or tics are difficult to distinguish from hyperactive and a therefore mistakenly be treated with stimulant medications (dextroamphetamine, methylphenidate, p the severe motor and phonic tics requiring discontinuation of the stimulants and possible institution o having an attention deficit disorder, clinical evaluation for Tics and Tourette's Syndrome in the childr stimulant medication. In children with no symptoms of Tourette's syndrome but with a familial history use of stimulants is contraindicated in children with Tourette's Syndrome. If tics occur during stimula discontinued (Lowe et al, 1982).

4) Numerous case reports have demonstrated tics either starting or worsening after methylphenidat is no correlation between stimulant dosages (high or low) or duration of treatment, and tic developm

days, months, even years. Many of the patients who developed tics years later were within the age r
so it is unknown if disease onset was independent of stimulant use. The highest risk for tic exacerba
are treated with stimulant medication early in life and/or for a long duration. Investigators have noted
tics, discontinuing the stimulant decreased tic severity but did not necessarily completely resolve the

3.3.12.B.5 Crying associated with mood

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Tearfulness has occurred in less than 1% of patients on methylphenidate hydrochloride extended-rel trials (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.12.B.6 Depression

a) Incidence: 1.7% to 3.9% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Depression has occurred in 1.7% of adult patients on methylphenidate hydrochloride extended-re on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCERTA(R) ex

2) Depressed mood has occurred in 3.9% of adult patients on methylphenidate hydrochloride exten patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

3.3.12.B.7 Disorientated

a) Disorientation has been reported during postmarketing experience with methylphenidate hydrochlorid extended-release oral tablets, 2008).

3.3.12.B.8 Feeling angry

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Anger has occurred in less than 1% of patients on methylphenidate hydrochloride extended-release i (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.12.B.9 Feeling nervous

a) Incidence: 3.1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Nervousness has occurred in 8.2% of adult patients on methylphenidate hydrochloride extended on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCERTA(R) ex

3.3.12.B.10 Irritability

a) Incidence: 5.8% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Irritability has occurred in 5.8% of adult patients on methylphenidate hydrochloride extended-rele placebo (n=212), in 2 double-blind, placebo-controlled clinical trials .

3.3.12.B.11 Mania

a) In a review of 49 randomized, controlled pediatric ADHD clinical trials involving pscyhostimulant medi methylphenidate hydrochloride, modafinil and dextromethylphenidate hydrochloride), the rate of psychos active drug was 1.48 (95% CI, 0.74 to 2.65) per 100 person-years, with no comparable adverse events r the US Food and Drug Administration to manufacturers of marketed ADHD drugs for submission of postı events between 2000 and 2005, yielded a total of 865 reports (pediatrics and adults) in which signs and/ reported. The majority of reports involved pediatric subjects, with almost half of the reports in children 10 of cases involving no prior history of similar psychiatric conditions. Visual and/or tactile sensations of inse reported. Positive rechallenge was reported for each of the psychostimulant medications (methylphenida and mixed salts of a single entity amphetamine product) included in the analysis; and in many cases a st onset of psychiatric symptoms ranged from days to weeks, but in some cases it was months or years fro onset (Mosholder et al, 2009).

b) Stimulants may induce mixed/manic episodes in patients with comorbid bipolar disorders. Exercise ca (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

c) Stimulants may cause treatment-emergent psychotic or manic symptoms (eg, hallucinations, delusion of mania or psychotic illness. In a pooled analysis of multiple short-term, placebo-controlled studies, thes 0.1% of patients treated with stimulants (n=3482) compared with 0% in placebo treated patients (Prod In tablets, 2008).

d) Methylphenidate was associated with mania in a 10-year-old boy who was treated for severe hyperac received increasing doses up to 45 milligrams (mg) daily, which resulted in manic episodes during the th resulted in improvement over 2 days and lithium carbonate therapy was initiated. This patient had a posi

3.3.12.B.12 Mood swings

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Mood swings have occurred in less than 1% of patients on methylphenidate hydrochloride extended- clinical trials (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.12.B.13 O/E - hypervigilance

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Hypervigilance has occurred in less than 1% of patients on methylphenidate hydrochloride extended- clinical trials (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.12.B.14 Obsessive-compulsive disorder

a) High-dose methylphenidate was associated with obsessive-compulsive symptoms in a 10-year-old gi hyperactive disorder (ADHD), for which she was receiving methylphenidate (doses increased gradually t clonidine (0.025 mg nightly). For 2 years, the child was uncontrollably stealing from peers, teachers, neig was unable to control her urge to steal. The dose of methylphenidate was tapered to 30 mg/day. Her ste occasional basis. She was hospitalized so methylphenidate could be withdrawn under observation; sertr ADHD were observed after methylphenidate withdrawal; stealing episodes were further reduced. At 1-ye (Kotsopoulos & Spivak, 2001).

3.3.12.B.15 Psychotic disorder

a) In a review of 49 randomized, controlled pediatric ADHD clinical trials involving pscyhostimulant medi methylphenidate hydrochloride, modafinil and dextromethylphenidate hydrochloride), the rate of psychos active drug was 1.48 (95% CI, 0.74 to 2.65) per 100 person-years, with no comparable adverse events r the US Food and Drug Administration to manufacturers of marketed ADHD drugs for submission of postı events between 2000 and 2005, yielded a total of 865 reports (pediatrics and adults) in which signs and/ reported. The majority of reports involved pediatric subjects, with almost half of the reports in children 10 of cases involving no prior history of similar psychiatric conditions. Visual and/or tactile sensations of inse reported. Positive rechallenge was reported for each of the psychostimulant medications (methylphenida and mixed salts of a single entity amphetamine product) included in the analysis; and in many cases a st onset of psychiatric symptoms ranged from days to weeks, but in some cases it was months or years fro onset (Mosholder et al, 2009).

b) Hallucinations have been reported during postmarketing experience with methylphenidate hydrochlor extended-release oral tablets, 2008).

3.3.12.B.16 Reduced libido

a) Incidence: 1.7% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Decreased libido has occurred in 1.7% of adult patients on methylphenidate hydrochloride exten patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCER

3.3.12.B.17 Restlessness

a) Incidence: 3.1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults
1) Restlessness has occurred in 3.1% of adult patients on methylphenidate hydrochloride extended on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCERTA(R) ex

3.3.12.B.18 Stuttering
a) Stuttering has been temporally associated with the use of pemoline (9.375 milligrams(mg)/day) and n in a 3-year-old girl. The stuttering stopped with the discontinuation of each drug (Burd & Kerbeshian, 19

3.3.12.B.19 Tension
a) Incidence: 1.2% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)
b) Adults
1) Tension has occurred in 1.2% of adult patients on methylphenidate hydrochloride extended-relea placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info CONCERTA(R) exter

3.3.13 Renal Effects

3.3.13.A Methylphenidate Hydrochloride

3.3.13.A.1 Urogenital finding
a) Methylphenidate has been shown to increase urinary catecholamines.
b) Intravenous abuse of methylphenidate can result in the development of a foreign body granuloma in t cornstarch) contained in the tablets (Hahn, 1969).

3.3.14 Reproductive Effects

3.3.14.A Methylphenidate Hydrochloride

3.3.14.A.1 Erectile dysfunction
a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)
b) Erectile dysfunction has occurred in less than 1% of patients on methylphenidate hydrochloride in pla Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.15 Respiratory Effects

Methylphenidate

Methylphenidate Hydrochloride

3.3.15.A Methylphenidate

Nasal congestion

Nasopharyngitis

3.3.15.A.1 Nasal congestion
a) Incidence: 6% (Prod Info DAYTRANA(TM) transdermal system, 2006)
b) Nasal congestion occurred in 6% of patients on transdermal methylphenidate compared with 1% of p (n=183) (Prod Info DAYTRANA(TM) transdermal system, 2006).

3.3.15.A.2 Nasopharyngitis
a) Incidence: 5% (Prod Info DAYTRANA(TM) transdermal system, 2006)
b) Nasopharyngitis occurred in 5% of patients on transdermal methylphenidate compared with 2% of pla (n=183) (Prod Info DAYTRANA(TM) transdermal system, 2006).

3.3.15.B Methylphenidate Hydrochloride

Cough

Dyspnea

Respiratory finding

Upper respiratory infection

3.3.15.B.1 Cough

a) Incidence: 1.9% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Children

1) Cough has occurred in 1.9% of children and adolescent patients on methylphenidate hydrochlori 0.3% of patients on placebo (n=318), in 4 double-blind, placebo-controlled clinical trials (Prod Info C 2008).

3.3.15.B.2 Dyspnea

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Dyspnea has occurred in less than 1% of patients on methylphenidate hydrochloride extended-releas trials (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.15.B.3 Respiratory finding

a) Pulmonary dysfunction associated with methylphenidate use is related to inappropriate parenteral adı abusers dissolve methylphenidate tablets, which contain fillers such as talc, in water and then inject the ı potential to embolize in the lung and produce pulmonary dysfunction (Hahn et al, 1969). Also with intrave arterial hypertension and medial hypertrophy of muscular pulmonary arteries, including fibrous intimal pr (Arnett, 1976).

3.3.15.B.4 Upper respiratory infection

a) Incidence: 2.2% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Adults

1) Upper respiratory infections have occurred in 2.2% of adult patients on methylphenidate hydroch 0.9% of patients on placebo (n=212), in 2 double-blind, placebo-controlled clinical trials (Prod Info C 2008).

3.3.16 Other

Methylphenidate

Methylphenidate Hydrochloride

3.3.16.A Methylphenidate

Drug dependence

Viral disease

3.3.16.A.1 Drug dependence

a) Marked tolerance and psychological dependence with varying degrees of abnormal behavior have be abused methylphenidate. Frank psychotic episodes can occur, particularly with parenteral abuse. Risk fa alcoholism. Withdrawing methylphenidate in a patient who has abused it may lead to severe depression. may unmask symptoms of the underlying disorder that may require follow-up (Prod Info DAYTRANA(TM

1) Among children with attention deficit disorder treated with methylphenidate, no strong conclusive methylphenidate with the occurrence of adult drug abuse.

2) Ingestion of high doses (doses above those normally recommended) of methylphenidate for exte the euphoric effect and psychological dependence. Dependence on methylphenidate may be charac degrees of abnormal behavior. Intravenous administration of methylphenidate has been reported to of 30 to 100 milligrams (mg)/day for 14 days. Severe depression and amphetamine-like withdrawal s belligerence, anxiety, muscular aches, chills, tremors, sleep disturbances, lethargy, exhaustion, and methylphenidate withdrawal. Withdrawal therapy usually consists of adjunctive neuroleptic and/or ar gradual methylphenidate withdrawal. The gradual tapering of methylphenidate doses in dependent i duration of withdrawal symptoms. Further studies are needed to justify any advantage of gradual ov this drug may result in toxic psychosis. Multiple organ failure including hepatic, renal, pancreatic, an intravenous or intra-arterial injection of crushed methylphenidate tablets (Keeley & Licht, 1985; Stec Gunby, 1979; Extein, 1978; Spensley, 1972; Spensley & Rockwell, 1972; AtLee, 1972; Lindell et al, 1970).

3.3.16.A.2 Viral disease

a) During an open-label study (n=191) of 40 months duration with transdermal methylphenidate worn fo

of subjects (Prod Info DAYTRANA(TM) transdermal system, 2006).

3.3.16.B Methylphenidate Hydrochloride

Drug dependence

Drug tolerance - finding

Fatigue

Fever

3.3.16.B.1 Drug dependence

a) Methylphenidate hydrochloride should be given cautiously to patients with a history of drug depender to marked tolerance and psychological dependence, with varying degrees of abnormal behavior (Prod In tablets, 2008).

b) Among children with attention deficit disorder treated with methylphenidate, no strong conclusive evic methylphenidate with the occurrence of adult drug abuse.

c) Ingestion of high doses (doses above those normally recommended) of methylphenidate for extende euphoric effect and psychological dependence. Dependence on methylphenidate may be characterized abnormal behavior. Intravenous administration of methylphenidate has been reported to produce depend milligrams (mg)/day for 14 days. Severe depression and amphetamine-like withdrawal symptoms includi anxiety, muscular aches, chills, tremors, sleep disturbances, lethargy, exhaustion, and suicidal ideations Withdrawal therapy usually consists of adjunctive neuroleptic and/or antidepressant therapy along with a The gradual tapering of methylphenidate doses in dependent individuals may not altered the severity or studies are needed to justify any advantage of gradual over abrupt drug withdrawal. Chronic ingestion of organ failure including hepatic, renal, pancreatic, and pulmonary toxicity may occur following intravenous methylphenidate tablets (Keeley & Licht, 1985; Stecyk, 1985; Anon, 1985; Hodding et al, 1980; Gunby, 1 Rockwell, 1972; AtLee, 1972; Lindell et al, 1972; Sugar et al, 1971; Hopkins & Taylor, 1970).

3.3.16.B.2 Drug tolerance - finding

a) Two double-blind, randomized, crossover trials evaluating the effectiveness of various drug delivery p tolerance to methylphenidate may exist in the treatment of children with attention deficit hyperactivity dis methylphenidate delivery patterns (twice-daily, flat, and ascending) and placebo were compared. The tw methylphenidate was designed to produce typical school day peak and trough concentrations. The flat re followed by a uniform methylphenidate concentration throughout the day. The ascending regimen produc low-drug concentration early in the morning to a high-drug concentration by the end of the day. The flat c for measures of efficacy than the twice daily regimen in the afternoon, which suggests that acute tolerar may be emerging throughout the day. In Study II, 32 children were assigned three treatments profiles (th the timing of the middle bolus of the three-times daily regimen was either 9:30 am (tid-am) or 1:30 pm (ti increases in efficacy were measured in the tid-am regimen after the second dose compared with large in following the second dose. Following the administration of the third bolus dose in each regimen, a larger regimen compared with small increases in efficacy for the tid-pm regimen. The interpretation of these pa hypothesis. The results of Study I and Study II support the hypothesis that acute tolerance may contribut drug delivery compared with immediate-release drug delivery of methylphenidate (Swanson et al, 1999).

3.3.16.B.3 Fatigue

a) Incidence: less than 1% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Fatigue has occurred in less than 1% of patients on methylphenidate hydrochloride extended-release (Prod Info CONCERTA(R) extended-release oral tablets, 2008).

3.3.16.B.4 Fever

a) Incidence: 2.2% (Prod Info CONCERTA(R) extended-release oral tablets, 2008)

b) Children

1) Pyrexia has occurred in 2.2% of child and adolescent patients on methylphenidate hydrochloride of patients on placebo (n=318), in 4 double-blind, placebo-controlled clinical trials in placebo-control CONCERTA(R) extended-release oral tablets, 2008).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info Concerta(R), 2001) (All Trim

a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other) studies in women and animals are not available. Drugs should be given only if the potential benefit justifies th

2) Australian Drug Evaluation Committee's (ADEC) Category: B2 (Batagol, 1999)

a) Drugs which have been taken by only a limited number of pregnant women and women of childbearing ag malformation or other direct or indirect harmful effects on the human fetus having been observed. Studies in available data show no evidence of an increased occurrence of fetal damage.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

3) Crosses Placenta: Unknown

4) Clinical Management

a) Although a causal relationship between methylphenidate and teratogenic effects has not been found, the has yet to be confirmed. Until additional data are available, caution should be exercised with the use of methy

5) Literature Reports

a) No human studies of pregnancy outcomes after exposure to methylphenidate have been published and th inadvertent exposure during pregnancy. Adequate studies to establish safe use of methylphenidate during pr Concerta(R), 2001). One source describes a series of women (n=11) who used methylphenidate (dose unspe no birth defects or other abnormalities were reported in any of the infants and all 11 were considered normal al, 1993) discussed the outcomes of another 38 women who used methylphenidate during pregnancy. Althou be premature, growth retarded, and to show signs of neonatal withdrawal, no increase in congenital abnorma small that no pattern or estimate of risk can be determined at this time.

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk wh potential benefits of drug treatment against potential risks before prescribing this drug during breastfeeding.

2) Clinical Management

a) It is not known whether methylpheidate is excreted into human breast milk and the potential for adverse e drug are unknown. Given the drug's low molecular weight of approximately 270, transfer into milk would be e

3) Literature Reports

a) No reports describing the use of methylphenidate during human lactation or measuring the amount, if any

3.5.1.A Amitriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCA monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.B Amoxapine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. 6) Clinical Management: Clinicians should monitor patient response to methylphenidate therapy when carba
methylphenidate levels may also be helpful. Doses of methylphenidate may need to be increased to maintain
7) Probable Mechanism: induction by carbamazepine of cytochrome P450 3A4-mediated methylphenidate m
8) Literature Reports
a) A 7-year-old male with severe mental retardation and attention deficit disorder was failing to respond
thiothixene 10 mg daily. Other drug therapy included carbamazepine 1000 mg daily to control grand mal
medication compliance, plasma levels of methylphenidate were measured two hours after the morning d
their metabolites could be found. Doses were increased to methylphenidate 30 mg every four hours and
efficacy or side effects. Both agents were then discontinued (Behar et al, 1998).
b) Attention deficit/hyperactivity disorder (ADHD) was being treated with methylphenidate 20 mg three ti
mood lability and significant impulsivity, carbamazepine was introduced at 200 mg daily. The strict two-h
serum level was 5.3 ng/mL (normal range 5 to 20 ng/mL) at this time. ADHD symptoms began to worsen
800 mg daily. Six weeks after the start of combination therapy, the patient's methylphenidate and ritalinic
decreased to 4.2 ng/mL. A month later, the carbamazepine dose was increased to 1000 mg daily with a
an increase in her methylphenidate dose to 35 mg three times daily, her methylphenidate and ritalinic ac
ng/mL. After another two months, her carbamazepine dose was 1200 mg daily with a steady-state blood
increased to 60 mg three times daily to regain the benefit from the drug that she had experienced before
Behar, 1999).

3.5.1.E Citalopram

1) Interaction Effect: increased selective serotonin reuptake inhibitor plasma concentrations
2) Summary: Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metab
(SSRIs). Downward dose adjustments of the SSRI may be necessary when it is used concurrently with methy
discontinuing methylphenidate, the SSRI dose may need to be adjusted as needed (Prod Info METADATE C
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Use caution when prescribing methylphenidate to patients who take an selective se
use of methylphenidate and an SSRI may cause elevated SSRI plasma concentrations. Consider a decrease
coadministered. Additionally, consider adjusting the SSRI dose if necessary when initiating or discontinuing m
CD(R) extended-release oral capsules, 2007).

7) Probable Mechanism: inhibition of selective serotonin reuptake inhibitor metabolism by methylphenidate

3.5.1.F Clomipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.G Clorgyline

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)

2) Summary: Coadministration of methylphenidate and a monoamine oxidase inhibitor may result in hyperte such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with mor Info Concerta(TM), 2000). The concomitant administration of methylphenidate with monoamine oxidase inhib be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days (Prod Info DAY

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and methylphenidate is contra the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.

7) Probable Mechanism: unknown

3.5.1.H Clovoxamine

1) Interaction Effect: increased selective serotonin reuptake inhibitor plasma concentrations

2) Summary: Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metab (SSRIs). Downward dose adjustments of the SSRI may be necessary when it is used concurrently with meth discontinuing methylphenidate, the SSRI dose may need to be adjusted as needed (Prod Info METADATE C

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Use caution when prescribing methylphenidate to patients who take an selective se use of methylphenidate and an SSRI may cause elevated SSRI plasma concentrations. Consider a decrease coadministered. Additionally, consider adjusting the SSRI dose if necessary when initiating or discontinuing m CD(R) extended-release oral capsules, 2007).

7) Probable Mechanism: inhibition of selective serotonin reuptake inhibitor metabolism by methylphenidate

3.5.1.I Desipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte

from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with
Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m

1) Interaction Effect: increased selective serotonin reuptake inhibitor plasma concentrations
2) Summary: Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metab
(SSRIs). Downward dose adjustments of the SSRI may be necessary when it is used concurrently with meth
discontinuing methylphenidate, the SSRI dose may need to be adjusted as needed (Prod Info METADATE C
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Use caution when prescribing methylphenidate to patients who take an selective se
use of methylphenidate and an SSRI may cause elevated SSRI plasma concentrations. Consider a decrease
coadministered. Additionally, consider adjusting the SSRI dose if necessary when initiating or discontinuing n
CD(R) extended-release oral capsules, 2007).
7) Probable Mechanism: inhibition of selective serotonin reuptake inhibitor metabolism by methylphenidate

3.5.1.Z Nialamide

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Coadministration of methylphenidate and a monoamine oxidase inhibitor may result in hyperte
such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with mor
Info Concerta(TM), 2000). The concomitant administration of methylphenidate with monoamine oxidase inhib
be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days (Prod Info DAY
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and methylphenidate is contra
the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.AA Nortriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte
from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit
Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m
most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
& Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCA
monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf
capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if
closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen
amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet
VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab
2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o
imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i
effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb
methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th
pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g
fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical
doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc
1969). However, a systemic review of stimulants in the treatment of depression concluded that although
ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt
appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.AB Opipramol

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte
from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit

5) Substantiation: theoretical
6) Clinical Management: Use caution when prescribing methylphenidate to patients who take an selective se
use of methylphenidate and an SSRI may cause elevated SSRI plasma concentrations. Consider a decrease
coadministered. Additionally, consider adjusting the SSRI dose if necessary when initiating or discontinuing m
CD(R) extended-release oral capsules, 2007).
7) Probable Mechanism: inhibition of selective serotonin reuptake inhibitor metabolism by methylphenidate

3.5.1.AN Toloxatone

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Coadministration of methylphenidate and a monoamine oxidase inhibitor may result in hyperte
such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with mor
Info Concerta(TM), 2000). The concomitant administration of methylphenidate with monoamine oxidase inhib
be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days (Prod Info DAY
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and methylphenidate is contra
the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.AO Tranylcypromine

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)

2) Summary: Coadministration of methylphenidate and a monoamine oxidase inhibitor may result in hyperte such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with mor Info Concerta(TM), 2000). The concomitant administration of methylphenidate with monoamine oxidase inhib be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days (Prod Info DAY
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and methylphenidate is contra the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.AP Trimipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.AQ Tyrosine

1) Interaction Effect: increased adverse effects
2) Summary: Tyrosine prolonged the effect of methylphenidate in rats (Woods & Meyer, 1991a).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if tyrosine and methylphenidate are used together. Monitor the p methylphenidate.
7) Probable Mechanism: not specified
8) Literature Reports

a) Exogenous tyrosine supplementation prolonged the effect of methylphenidate (MPD) in rats. Simultar MPD into the nucleus accumbens of Sprague-Dawley rats resulted in potentiation and prolongation of th final 20 minutes of infusion when dopamine concentrations already declined during the MPD-alone expe maximum MPD effect was observed (Woods & Meyer, 1991).

3.5.1.AR Warfarin

1) Interaction Effect: increased warfarin plasma concentrations and an increased risk of bleeding
2) Summary: Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metab warfarin. Downward dose adjustments of warfarin may be necessary when it is used concurrently with methy should be closely monitored, when initiating or discontinuing methylphenidate, and should be reassessed per dose adjustments may be made as necessary in order to maintain the desired level of anticoagulation (Prod I

2006).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of methylphenidate and warfarin may increase warfarin levels due methylphenidate. Consider a decrease in warfarin dose when these agents are coadministered. Additionally, discontinuing methylphenidate and adjust warfarin dose if necessary.
7) Probable Mechanism: inhibition of warfarin metabolism by methylphenidate

3.5.1.AS Zimeldine
1) Interaction Effect: increased selective serotonin reuptake inhibitor plasma concentrations
2) Summary: Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metab (SSRIs). Downward dose adjustments of the SSRI may be necessary when it is used concurrently with methy discontinuing methylphenidate, the SSRI dose may need to be adjusted as needed (Prod Info METADATE C
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Use caution when prescribing methylphenidate to patients who take an selective se use of methylphenidate and an SSRI may cause elevated SSRI plasma concentrations. Consider a decrease coadministered. Additionally, consider adjusting the SSRI dose if necessary when initiating or discontinuing n CD(R) extended-release oral capsules, 2007).
7) Probable Mechanism: inhibition of selective serotonin reuptake inhibitor metabolism by methylphenidate

3.5.5 Intravenous Admixtures

Drugs

Solutions

3.5.5.1 Drugs

Amobarbital

Dextran

Methohexital

Pentobarbital

Phenobarbital

Procainamide

Procaine

Secobarbital

Thiopental

3.5.5.1.A Amobarbital
1) Incompatible
a) Methylphenidate (incompatible with amobarbital; conditions not specified) (Kramer et al, 1971)

3.5.5.1.B Dextran
1) Compatible
a) Dextran 70 6% in Dextrose 5% in water with methylphenidate 30 mg/L, physically compatible for al, 1961b; Smith, 1965)
b) Dextran 70 6% in Sodium chloride 0.9% with methylphenidate 30 mg/L, physically compatible fo al, 1961b; Smith, 1965)

3.5.5.1.C Methohexital
1) Incompatible
a) Methohexital (barbiturates physically incompatible with methylphenidate; drug concentrations an

3.5.5.1.D Pentobarbital
1) Incompatible
a) Pentobarbital (barbiturates physically incompatible with methylphenidate; drug concentrations an

3.5.5.1.E Phenobarbital
1) Incompatible
a) Methylphenidate 1 mL, reconstituted, with phenobarbital 1 mL, reconstituted, both added to Steri was reported within 2 hours; exact drug concentrations not specified (Misgen, 1965a)
b) Phenobarbital barbiturates physically incompatible with methylphenidate; drug concentrations an

3.5.5.1.F Procainamide
1) Compatible
a) Methylphenidate 1 mL, reconstituted, with procainamide 1 mL, reconstituted, both added to Steri for 2 hours (Misgen, 1965).

3.5.5.1.G Procaine
1) Compatible
a) Procaine (0.1% in Sodium chloride 0.9% with methylphenidate 30 mg/L physically compatible; cc
b) Methylphenidate (30 mg/L with procaine 1 g/L physically compatible in Sodium chloride 0.9%; cc

3.5.5.1.H Secobarbital
1) Incompatible
a) Secobarbital (barbiturates physically incompatible with methylphenidate; drug concentrations anc

3.5.5.1.I Thiopental
1) Incompatible
a) Thiopental (barbiturates physically incompatible with methylphenidate; drug concentrations and c
b) Methylphenidate (incompatible with barbiturates; conditions not specified) (Kramer et al, 1971a)

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters

A) Methylphenidate

1) Therapeutic

a) Physical Findings

1) Improvement in the mental and behavioral symptoms of attention deficit hyperactivity disorder (ADHD hyperactivity, and cognitive performance.

2) Periodic reassessment of the need for continued methylphenidate treatment (by temporarily withdraw behavioral symptoms and their severity; slow dose-tapering may be indicated to prevent withdrawal sym system, 2006).

2) Toxic

a) Laboratory Parameters

1) Monitor CBC, differential, and platelet counts periodically during prolonged therapy (Prod Info DAYTR

b) Physical Findings

1) The American Academy of Pediatrics (AAP) does not recommend the routine use of electrocardiogra evaluations (which were previously recommended by the American Heart Association (AHA) scientific st place the child at risk for sudden cardiac death) before initiating stimulant therapy to treat attention-defici The APA cited specific reasons for changing the recommendation including: lack of evidence establishin treat ADHD and sudden cardiac death (SCD), the frequency of sudden unexpected deaths among patier in the general population of children, and lack of cost-effective analysis to support ECG screening or spe al, 2008).

2) Based on the American Academy of Pediatrics (AAP) and the American Heart Association (AHA) con monitoring recommendations have been established to assist clinicians in the evaluation of children treat methylphenidate, for ADHD (Perrin et al, 2008; Vetter et al, 2008):

- Conduct a thorough examination prior to initiating methylphenidate therapy for a diagnosis of ADH symptoms indicative of a cardiac condition, including palpitations, near syncope, or syncope.
- Obtain a complete family and patient history for conditions associated with SCD, and determine cu counter medications.
- Conduct a complete physical evaluation of the patient for hypertension, cardiac murmurs, physical signs of irregular cardiac rhythms.
- Perform further evaluation if family history, patient history or physical exam is suggestive of cardiac and if indicated, consult pediatric cardiologist .
- Continue to assess the patient for cardiac symptoms and any changes in family history at follow up
- Blood pressure and heart rate should be evaluated at baseline, during routine follow-up within 1 to months. Increases in blood pressure and heart rate have been reported with stimulant use.

3) Assess growth determinations (body weight and height) periodically (Prod Info DAYTRANA(TM) trans

4.2 Patient Instructions

A) Methylphenidate (Absorbed through the skin)

Methylphenidate

Treats attention deficit hyperactivity disorder (ADHD). This medicine is a stimulant.

When This Medicine Should Not Be Used:
You should not apply this medicine if you or your child have had an allergic reaction to methylphenidate. You shou
or if you are anxious, tense, or agitated most of the time. You should not use this medicine if you have muscle tics
that causes you to have muscle twitches or to make sounds you are not able to control. Do not use this medicine
called an MAO inhibitor (MAOI), such as Eldepryl®, Marplan®, Nardil®, or Parnate®, in the past 14 days. This me
than 6 years of age unless your doctor tells you otherwise.

How to Use This Medicine:
Patch

Your doctor will tell you how many patches to use, where to apply them, and how often to apply them. Do not
than your doctor tells you to.
This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your d
Ask your pharmacist for the Medication Guide if you do not have one. Your doctor might ask you to sign some
information.
The Medication Guide will show the body areas where you or your child can wear the patch. When putting on
these areas. Do not put the new patch on the same place you or your child wore the last one. Be sure to rem
Wash your hands with soap and water before and after applying a patch. Make sure the skin area is clean (fr
powder, oil, or lotion before you apply the patch.
Leave the patch in its sealed wrapper until you are ready to put it on. Tear the wrapper open carefully. NEVE
Do not use any patch that has been cut by accident.
Apply the patch right away after removing it from the pouch or sealed wrapper.
Do not put the patch over burns, cuts, or irritated skin.
Put on a new patch if the old one has fallen off and cannot be reapplied. Remove the new patch 9 hours after

If a Dose is Missed:

If you forget to wear or change a patch, put one on as soon as you can. If it is almost time to put on your next
skip the one you missed. Do not apply extra patches to make up for a missed dose.

How to Store and Dispose of This Medicine:

Store the patches at room temperature in a closed container, away from heat, moisture, and direct light.
Throw any used patch away so that children or pets cannot get to it. There is still enough medicine in a used
throwing away a patch, fold it in half with the sticky sides together and flush it down the toilet, and then wash
When you stop treatment with this medicine, take all of the leftover patches out of the pouches and flush ther
the protective liners down the toilet. Put them in a trash can with a cover. You will also need to throw away ol
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a

Make sure your doctor knows if you or your child are also using cold or allergy medicines, clonidine (Catapres
(such as captopril, metoprolol, Capoten®, or Lopressor®), a blood thinner (such as warfarin or Coumadin®),
phenytoin, primidone, Dilantin®, or Mysoline®), or medicines to treat depression (such as clomipramine, desi
Anafranil®, Celexa®, Effexor®, Lexapro™, Norpramin®, Paxil®, Tofranil®, or Zoloft®).

Warnings While Using This Medicine:

Make sure your doctor knows if you or your child are pregnant, planning to become pregnant, or breastfeedin
of seizures, heart disease, high blood pressure, depression or mental illness, thyroid problems, skin problems
alcohol problems.
This medicine may be habit-forming. If you feel that the medicine is not working as well, do not use more than
instructions.
Tell your doctor right away if you or your family notices any unusual changes in behavior, such as an increas
suicidal thinking or behaviors. Also tell your doctor if you have hallucinations or any unusual thoughts, especi
This medicine may make you dizzy or drowsy. It may also cause blurred vision or other vision problems. If an

do anything else that could be dangerous if you are not alert or not able to see well.
This medicine may cause slow growth. If your child is using this medicine, the doctor will need to keep track c
that your child is growing properly.
This medicine may cause skin irritation. Tell your doctor about any skin rash that occurs where this medicine
Avoid putting this medicine near external sources of direct heat, such as hair dryers, heating pads, electric bl
Your doctor will need to check your blood at regular visits while you are using this medicine. Be sure to keep

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, c
Changes in vision.
Chest pain or shortness of breath.
Convulsions or tremors.
Fast, pounding, or irregular heartbeat.
Fever, chills, runny or stuffy nose, cough, sore throat, and body aches.
Lightheadedness, dizziness, or fainting.
Mood or mental changes, confusion, or unusual behavior.
Seeing, hearing, or feeling things that are not there.
Severe redness, swelling, itching, or blistering of the skin where the patch is worn.
Uncontrollable muscle movements or twitching.

If you notice these less serious side effects, talk with your doctor:
Decreased appetite.
Feeling restless or nervous.
Headache.
Nausea or vomiting.
Trouble sleeping.
Warmth or redness in your child's face, neck, arms, or upper chest.
Weight loss.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

B) Methylphenidate (By mouth)
Methylphenidate

Treats attention deficit hyperactivity disorder (ADHD) and narcolepsy (sudden attacks of uncontrollable sleepines

When This Medicine Should Not Be Used:
You should not use this medicine if you or your child have had an allergic reaction to methylphenidate. You shoul
if you are anxious, tense, or agitated most of the time. You should not use this medicine if you have muscle tics o
that causes you to have muscle twitches or to make sounds you are not able to control. Do not use this medicine
called an MAO inhibitor (MAOI), such as Eldepryl®, Marplan®, Nardil®, or Parnate®, in the past 14 days. This me
years of age unless your doctor tells you otherwise.

How to Use This Medicine:
Long Acting Capsule, Liquid, Tablet, Chewable Tablet, Long Acting Tablet
Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed
best for you. Do not use more medicine or use it more often than your doctor tells you to.
This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your d

Seeing, hearing, or feeling things that are not there.
Trouble seeing or blurred vision.
Uncontrollable muscle movements or twitching.
Vomiting, agitation, confusion, sweating, fever, or tremors.

If you notice these less serious side effects, talk with your doctor:
Feeling restless or nervous.
Headache.
Nausea, loss of appetite, or stomach pain.
Runny or stuffy nose, cough, or sore throat.
Trouble sleeping.
Weight loss.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Oral and transdermal methylphenidate are primarily used as an adjunct to the treatment of attention deficit disorde
6 years of age (oral) and 6 to 12 years (transdermal) (Prod Info DAYTRANA(TM) transdermal system, 2006; Prod Info
METHYLIN(R) chewable tablets, 2004; Prod Info RITALIN(R) oral tablet, RITALIN-SR(R) oral tablet, 2004; Prod Info M
2002). Children who exhibit ADHD-like symptoms that are secondary to environmental factors and/or other primary ps
be candidates for use of stimulants such as methylphenidate (Prod Info DAYTRANA(TM) transdermal system, 2006).
Advisory Committee recommends that transdermal methylphenidate be used after oral forms have been considered. T
risks of sensitization of the topical form (FDAAdvisoryCommittee.com, 2005). Patients who develop a contact sensitiza
be able to take methylphenidate in any form (Prod Info DAYTRANA(TM) transdermal system, 2006). Methylphenidate
narcolepsy.
B) Sustained-release methylphenidate (MSR) therapy for cognitive impairment in HIV-1-infected substance abusers r
neuropsychological test performance when compared to placebo treatment in a pilot study. However, when used as a
confirm superiority over placebo (van Dyck et al, 1997).
C) Other potential therapeutic uses of methylphenidate include treatment of depression, chronic pain, brain tumors, sy
cocaine abuse (Frye, 1997; Emptage & Semla, 1996; Plutchik et al, 1998; Grade et al, 1998; Meyers et al, 1998; Levin
1987; Grubb et al, 1996; Whyte et al, 1997).

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION
1) Methylphenidate is a mild central nervous system stimulant; the drug has similar pharmacological properties a
activity and minimal effects on the cardiovascular system. Although its exact mechanism of action is not known, m
brainstem arousal system, cortex, and subcortical structures including the thalamus to produce its stimulant effect
exerts its behavioral effects in children has not been determined (Prod Info DAYTRANA(TM) transdermal system,
B) REVIEW ARTICLES
1) A review of the efficacy and safety of methylphenidate treatment in children with attention deficit disorder acco
cancer, epilepsy, traumatic brain injury, encephalitis, and mental retardation has been provided (Weber & Lutschg

2) The OROS(R) extended-release formulation of methylphenidate is reviewed, including pharmacodynamics, ph
al, 2001).

4.5 Therapeutic Uses

Methylphenidate

Methylphenidate Hydrochloride

4.5.A Methylphenidate

4.5.A.1 Attention deficit hyperactivity disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, no; Pediatric, yes (6 to 12 years)
Efficacy: Pediatric, Effective
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Transdermal methylphenidate, in a 9-hour of delivery once daily dose, is an effective treatment of at
providing symptom reduction (McGough et al, 2006)
Transdermal methylphenidate is indicated for the treatment of attention deficit hyperactivity disorder
DAYTRANA(TM) transdermal system, 2006)
Transdermal methylphenidate improves behavior measures when compared to placebo (Pelham et
Long-term effects (greater than 7 weeks) in children have not been well established (Prod Info DAY

c) Pediatric:

1) In pediatric patients age 6 to 12 years with attention deficit hyperactivity disorder (ADHD), the use of
wear time of 9 hours resulted in optimal treatment results when compared with placebo (PTS), according
Patients with a mean age 9.1 years, 72% male, and a total score of 26 or higher on the ADHD rating sca
who were known to be responsive to stimulants, or naive to stimulants (37%) were included in the intent
optimization phase, patients were randomized to receive one of 4 optimized daily doses of MTS (n=41) c
optimized to the MTS patch delivering 16 or 20 mg dose over 9 hours. After one week of treatment, patie
following week. All patients attended 2 days of simulated classroom, which provided 12 to 14 hours of ob
performance data. Patients in the MTS group performed significantly better compared with the PTS grou
(Swanson, Kotkin, Agler, M-Flynn and Pellham Teacher Rating Scale). The least square (LS) mean of th
significantly lower (improved) (3.2 +/- 0.58) compared with the PTS group (8 +/- 0.58, p less than 0.0001
post-dose assessment at 2 hours, continuing through the final 12 hour postdose assessment. Comparing
number of math problems attempted was 113.8 versus 86.2 (difference of 27.5, 95% CI, 19.48 - 35.59, p
math problems correct was 109.4 versus 80.7 (difference of 28.7, 95% CI, 21.09 - 35.34, p less than 0.0
Global Impressions) the MTS group was more likely rated as improved compared with the PTS group (79
on the parent rated CGI-I scores of 71.1% versus 15.8% (p less than 0.0001). In the safety assessment
emergent adverse events in 24 patients recorded in the MTS group compared with 25 events in 18 patie
occurring 2% or more, comparing the MTS with the PTS group, the incidence of any adverse effect was
nausea (3% vs 0%) (McGough et al, 2006).

2) Transdermal methylphenidate (MTS) was effective for the treatment of attention deficit hyperactivity d
double-blind, placebo-controlled, randomized trial. All patients received MTS in an open-label phase to d
15 mg, 20 mg, and 30 mg for 5 weeks). Then patients were randomized to placebo or MTS patch (at the
for 9 hours every day, then removed. The primary efficacy outcome was the mean differences in change

double-blind, placebo-controlled, randomized trial. Children were randomized to placebo or MTS patch in
milligrams (mg), 15 mg, 20 mg, and 30 mg for 5 weeks. Then the patients were followed for 2 weeks dur
dose. The patch was worn for 9 hours every day, then removed. The primary efficacy outcome was the r
ADHD-Rating Scale-IV between MTS and placebo. ADHD-Rating Scale-IV improved statistically more w
the study did not allow for evaluation of a dose-response, in general, there did not appear to be improved
9 hours to 30 mg over 9 hours (Prod Info DAYTRANA(TM) transdermal system, 2006).

4) In a multicenter, double-blind, randomized, dose-ranging study of transdermal methylphenidate (MTS
MTS were superior to placebo in behavioral measures. Enrolled in the study were 33 boys and 3 girls, ag
the summer treatment program. Patients were randomized to receive placebo, MTS 6.25 centimeters sq
(2), worn for at least 12 hours daily. The time of application was also studied along with the dose and pat
patch either 60 or 120 minutes before the start of the summer treatment program day. Therefore, there w
administered one time to each patient. Patients were instructed to continue their usual medication regime

a placebo practice day. During the day patients participated in both academic and nonacademic activities system that assessed point systems, time outs, and daily report cards. After the 8 study days, the point s noncompliance, interruption, complaining, conduct problems, and negative verbalizations) were all signif placebo in pairwise comparisons (p less than 0.05). The classroom measures for following rules and the significantly improved at all MTS doses compared to placebo in pairwise comparisons (p less than 0.05). among the groups for the amount of classroom work completed correctly. The daily report cards also sho groups and the placebo group in pairwise comparisons (p less than 0.05). The most common side effects across doses) and trouble sleeping (47% of the children across doses), with incidence increasing with hi in 40% to 50% of the patients, more incidence on active MTS than placebo days (Pelham et al, 2005).
5) Transdermal methylphenidate (MTS) combined with behavioral modification produced significant imp hyperactivity disorder (ADHD) compared to either treatment alone. The study enrolled 25 boys and 2 girl in a summer treatment program. Patients were randomly assigned to receive placebo, MTS 12.5 centime cm(2) on Monday through Thursday for 24 days. The drug conditions were double-blind and varied on a drug condition once each week. All of the MTS doses were applied at 7 a.m. and removed at 3:30 p.m. E basis, so each patient had 2 days in each medication condition without behavioral treatment and 4 days treatment. The children spent 2 hours each day in an academic setting and the remainder of their day co behavior was assessed using a point system (following activity rules, rule violations, noncompliance, inte negative verbalizations), classroom measures (rule violations, completed work and accuracy of complete tests showed significant improvement at all three doses of MTS compared to placebo in point system crit daily report cards (all doses of MTS compared to placebo in pairwise tests, p less than 0.05). Exceptions not statistically significant at any dose of MTS regardless of behavior modification, interruption was not s modification and completion of classroom work was not significant at MTS 12.5 cm(2) with no behavior m adverse effect that increased as the dose increased was loss of appetite (Pelham et al, 2005).

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes (Concerta(R), age up to 65 yr); Pediatric, yes (age 6 yr and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

The efficacy of methylphenidate extended-release (ER) tablets (Concerta(R)) for the treatment of AI
double-blind, placebo-controlled, randomized trials involving a total of 627 patients aged 18 to 65 ye
oral tablets, 2008).
Extended-release methylphenidate maintained effectiveness in children aged 6 to 13 years with ADI
(n=407) (Wilens et al, 2005).
Extended-release methylphenidate has been well tolerated and clinically superior to placebo during
involving children with ADHD and who were 6 years of age and older (Greenhill et al, 2002; Pelham
Extended-release methylphenidate demonstrated equivalent efficacy to immediate-release methylph
controlled trials involving children aged 6 and older with a diagnosis of ADHD (Pelham et al, 2001; W
The racemic mixture of L- and D-amphetamine was equivalent to methylphenidate in the treatment o
placebo-controlled trial (n=25) and was still effective 4 to 5 hours post-administration (Pelham et al,
Oral methylphenidate appears to be safe and effective in children with epilepsy who are seizure free
starting methylphenidate therapy (Gross-Tsur et al, 1997a).
Both methylphenidate and clonidine are beneficial in ADHD with tics; however, the combination app
agent alone (Anon, 2002a).

c) Adult:

1) The efficacy of methylphenidate extended-release (ER) tablets (Concerta(R)) was demonstrated in tw
randomized trials involving a total of 627 patients aged 18 to 65 years who had been diagnosed with atte

2) Methylphenidate in doses of 10 to 90 milligrams (mg) orally daily was reported more effective than pla
disorder, residual type, in adults in a double-blind crossover trial (Wender et al, 1985). A moderate-to-ma
patients (57%), as compared to only 4 patients (11%) receiving placebo. Improvement was observed in a
lability and impulsivity.

d) Pediatric:

1) Monotherapy - Extended Release

a) In a multisite, open-label study once daily OROS methylphenidate (Concerta(R)) was found to m
deficit/hyperactivity disorder (ADHD) for up to 2 years. A total of 407 children between the ages of 6
229 children completed the 24-month trial. Patients were initially assigned to receive one of three do
milligrams (mg) once daily) which was based on their dose in a previous efficacy or pharmacokinetic
downward in 18 mg increments throughout the 24 month trial depending on clinical response and ad
medication reduced or stopped for weekends or non-school days and to take medication holidays. E
parents/caregivers, teachers and researchers by using the Global Assessment of Effectiveness ratir
all groups throughout the study period. Values for parent/caregiver global assessment ranged from 8
Investigator assessment for the second year of treatment ranged from 91% to 95%. Parent treatmer
pleased, very pleased, or extremely pleased with OROS methylphenidate at the time of their last ob
dose increased 26% from baseline (35.2 mg (baseline) to 44.2 mg (month 21/24)). The majority of r
the 407 children treated in the study, 363 (89.2%) reported at least one adverse event, and 282 (69.

investigators deemed to be possibly related to OROS methylphenidate (headache, insomnia, decrea were no significant differences found in patients expected height and weight for their age at the end slight changes in blood pressure and heart rate throughout the study with the only significant increas +/- 8.1 mmHg at baseline to 108.1 +/- 8.7 mmHg at end of study; p less than 0.0001). No clinically s liver function tests were found throughout the trial (Wilens et al, 2005).

b) In a 2-week, unpublished double-blind study involving 134 children with ADHD (6 to 12 years), m (Ritalin(R) LA) 10 to 40 milligrams (mg) daily were statistically superior to placebo in improving symp Scale for Teachers (CADS-T) during the second week (first-week data not provided). The dose rang a previous dose-titration phase (Prod Info RITALIN LA(R) oral extended-release capsule, 2004).

c) Compared with placebo, a 3-week course of once daily methylphenidate (Metadate CD(R)) (give significantly improved symptoms of attention-deficit hyperactivity disorder over the course of the mo double-blind, multi-center trial (n=321 children, 6 to 16 years of age). The form of methylphenidate u formulation (also called 'modified-release'), which released approximately 30% of its dose on an imn release. Subjects (n=158) randomized to methylphenidate (MPH) initiated therapy as 20 milligrams titrated to effect (maximum 60 mg/day), with the mean dose reaching 40.7 mg/day (1.28 mg/kilogran teacher-rated Conners' Global Index dropped from 12.7 to 4.9 in the MPH group after 3 weeks, whe placebo group (p less than 0.001, MPH versus control (least squares mean)). For MPH-treated chilc 4.8 and the mean afternoon score to 5.4, showing that MPH had a sustained effect throughout the s parents demonstrated a similar pattern to that of teachers (a drop of 6.2 versus 2.8 points for MPH a Clinical Global Impression ratings by investigators classified 64% of the MPH group as responders (with 27% of the placebo group. Most common adverse effects were headache, anorexia, abdominal occurring significantly more often in the MPH group than in controls (9.7% vs 2.5%; p=0.007). Two M adverse events. No serious side effects were reported in either group (Greenhill et al, 2002).

d) In a double-blind, cross-over study (n=68), 7-day courses of EXTENDED-RELEASE METHYLPH demonstrated equivalent efficacy to IMMEDIATE-RELEASE METHYLPHENIDATE given 3 times a were significantly superior to PLACEBO for treatment of attention- deficit/hyperactive disorder (ADH who met diagnostic criteria for ADHD (DSM-IV) and who had received a stable dose of MPH for at le the 3 established MPH dose levels. The dose levels were: (1) Concerta(R) 18 milligrams (mg) once Concerta(R) 36 mg once daily or IR MPH 10 mg 3 times a day; or (3) Concerta(R) 54 mg once daily dosing in the study was 35 mg of Concerta(R) and 29 mg of immediate release (IR) MPH. Teachers card which was sent home to the child's parents (who provided rewards for a positive report card). T Inattention/Overactivity (I/O) with Aggression (IOWA) Conners Rating Scale. Parents also completec Scales each week. Children attended 3 Saturday Laboratory Sessions, with ratings made on acader On all domain ratings by all reviewers in all settings, Concerta(R) and IR MPH provided significantly than 0.001). The only differences between the 2 MPH formulations was in 2 parent ratings (I/O and (R) significantly better than IR MPH ratings (p less than 0.05). In the laboratory sessions, rule violati observed disruptive behaviors were significantly different for MPH (both forms) compared with place withdrawals due to adverse events occurred. Most common adverse effects of MPH were headache of motor tics, all during IR MPH therapy. Poor sleep was reported in 16%, 7%, and 10% of recipients dosing, respectively. Usual appetite was reported for 77%, 66%, and 59% during the same 3 treatm diastolic blood pressure were significantly higher in both MPH groups (p less than 0.05), as was mea (Pelham et al, 2001).

e) In a multi-center, double-blind trial (n=277), a 4-week course of Concerta(R) (EXTENDED-RELE demonstrated to be significantly more effective than placebo (p less than 0.001), and to have similar (IR MPH) in children 6 to 12 years of age with attention-deficit/hyperactive disorder. Enrollees were OROS 18 milligrams (mg) once daily or IR MPH 5 mg 3 times a day; (2) OROS 36 mg once daily or mg once daily or IR MPH 15 mg 3 times a day. Children who had not received MPH previously parti determine their MPH dose; those who had previously used MPH were converted to one of the estab OROS, IR MPH, or placebo. Average total daily dose was 29.5 mg/day for those taking the immedia extended-release form-OROS (n=94). The primary efficacy measure was the IOWA Conners Rating and Oppositional/Defiance subscales completed by both teachers and parents. Ratings on the IOW efficacy for extended-release and immediate-release methylphenidate. Fifty- nine subjects discontin placebo group, 11 (16%) from the extended-release group, and 10 (14%) from the immediate-releas during the study. No significant difference between groups was observed in sleep quality; more chilc as eating less than usual compared with the control group. Five patients had tics reported as advers (Wolraich et al, 2001)

2) Monotherapy - Immediate Release

a) General Information

1) Controlled, blinded studies have shown methylphenidate to be effective in increasing attentic hyperkinetic children (Barkley & Cunningham, 1979)(Charles et al, 1979a; Klorman et al, 1979). occur in restrictive environments, and not in "free play" settings (Barkley & Cunningham, 1979). drug improves the behavioral style, not learning efficiency (Whalen et al, 1979) and has adverse Cunningham, 1979b) and judgmental behavior. Other studies have found that methylphenidate function, motor performance, social behavior, and right hemisphere functioning, but has little eff 1996; Famularo & Fenton, 1987; Werry et al, 1980). Tachyphylaxis may occur (Charles et al, 19 effective in children with epilepsy who are seizure free, while receiving antiepileptic drugs, befor et al, 1997a).

b) The racemic mixture of L and D-amphetamine (Adderall(R)) was as least as effective as methylp

attention deficit hyperactivity disorder (ADHD), and was more effective at 4 to 5 hours post-administ duration of action). In this within-subject, double-blind, placebo-controlled, crossover study, 25 childı methylphenidate 10 milligram (mg), 17.5 mg, Adderall(R) 7.5 mg, 12.5 mg, and placebo twice a day manner every day for 24 days. Teachers and counselors rated their behavior throughout the day an duration of action (noon and 5 p.m.). Parents rated them at the end of the day and in the evening fo placebo, Adderall(R) and methylphenidate significantly improved in-school behaviors (p less than 0. measures (p less than 0.0001), recess violations (p less than 0.0001), and after-school behaviors (p significantly affected by time (p less than 0.01). Adderall(R) consistently resulted in higher effect size consistently resulted in higher ES than lower doses. Adderall(R) was also significantly more effectiv day (p less than 0.05). The ES of both drugs dropped at midday and steadily increased in the aftern afternoon dose. Side effects were reported more frequently with Adderall(R) but did not preclude the eliminated from the study due to exacerbation of his motor tic condition. Further studies are needed Adderall(R), and to compare the efficacy of methylphenidate to D-amphetamine (Pelham et al, 1999

c) Two double-blind, randomized, cross-over trials evaluating the effectiveness of various drug deliv acute tolerance to methylphenidate may exist in the treatment of children with attention deficit hyper methylphenidate delivery patterns (twice-daily, flat, and ascending) and placebo were compared. Th methylphenidate was designed to produce typical school day peak and trough concentrations. The f peak followed by a uniform methylphenidate concentration throughout the day. The ascending regim level from a low drug concentration early in the morning to a high drug concentration by the end of t less efficacious for measures of efficacy than the twice daily regimen in the afternoon, which sugges methylphenidate concentrations may be emerging throughout the day. In Study II, 32 children were daily, ascending, and placebo) where the timing of the middle bolus of the three-times daily regimen after the 7:30 am dose. Only small increases in efficacy were measured in the tid-am regimen after in efficacy in the tid-pm regimen following the second dose. Following the administration of the third efficacy was observed in the tid-am regimen compared with small increases in efficacy for the tid-pm suggests a consistency with the tolerance hypothesis. The results of Study I and Study II support th to the reduced efficacy of sustained-release drug delivery compared with immediate-release drug de 1999a).

d) Methylphenidate 0.4 to 1.2 milligrams/kilogram (mg/kg)/day, in two divided doses, was reported children with attention deficit disorder without hyperactivity (ages, 7 to 12 years). During one acaden resulted in an improvement in school grades, when compared to a preceding grading period and the that methylphenidate may be useful in this type of attention deficit disorder and controlled studies ar

3) Use In Patients With Epilepsy

a) Use of methylphenidate (0.3 milligram/kilogram once daily) appears to be safe and effective to tr (ADHD) in children with EPILEPSY who are seizure free, while receiving antiepileptic drugs, before month study involving 30 children with epilepsy and ADHD, none of the 25 children who were seizur seizures while taking methylphenidate. Of the 5 children continuing to have seizures despite antiepil showed no change or a reduction in seizures while receiving methylphenidate. In this study methylp However, the authors advise that caution is warranted for those children still having seizures while r 1997a).

4) Use In Patients With Neurofibromatosis

a) Use of methylphenidate can improve cognitive, academic, and social behavior in children with at neurofibromatosis type 1 (NF1). This study involved children with ADHD and NF1 (n=20), those with normally developing children (n=14). Methylphenidate was given to each child in the ADHD-NF1 gro of methylphenidate (5 to 15 milligrams (mg) daily; average 7.5 mg) to children with ADHD and NF1 of Variables of Attention (TOVA) scores and the Child Behavior Checklist (CBCL) scores. In additior behavior improved and aggressive behavior declined in children with ADHD and NF1. Children in th significant improvement in measured variables (Mautner et al, 2002).

5) Use In Patients With Tourette's Syndrome Or Tics

a) In children with attention deficit hyperactive disorder (ADHD) and TICS (both by DSM-IV criteria) (MPH) alone, or combination CLONIDINE/MPH provided symptomatic improvement in ADHD withou CLONIDINE/MPH combination therapy provided the greatest benefit. This finding emanated from a years of age (n=136). Subjects were randomized to placebo (n=32), clonidine alone starting at 0.1 m 5 mg/day (n=37), or combination clonidine/MPH (n=33). Average daily doses were 0.25 mg for cloni MPH, 25.7 mg for MPH alone, and 26.1 mg for MPH given with clonidine. Based on the primary end Teacher), a significant treatment effect was observed for clonidine (compared to no clonidine; p=0.0 p=0.003), and either clonidine or MPH was more effective than placebo (both p=0.02). However, the was seen with combination clonidine/MPH (p less than 0.0001 compared to placebo). Worsening of 8 receiving MPH alone, 6 on combination clonidine/MPH, and 7 receiving placebo. Compared with p treatment groups according to the Yale Global Tic Severity Scale, the Global Tic Rating Scale, and were well tolerated except for sedation caused by clonidine; 48% of those receiving clonidine report clonidine seemed to be most helpful for impulsivity and hyperactivity, while MPH appeared most hel

b) Tourette's syndrome may be exacerbated or precipitated by the use of stimulant medications for children. Early signs of Tourette's Syndrome or TICS are difficult to distinguish from hyperactive and therefore mistakenly be treated with stimulant medications (dextroamphetamine, methylphenidate, p the severe motor and phonic tics requiring discontinuation of the stimulants and possible institution having an attention deficit disorder, clinical evaluation for Tics and Tourette's Syndrome in the childr stimulant medication. In children with no symptoms of Tourette's Syndrome but with a familial histor

The use of stimulants is contraindicated in children with Tourette's Syndrome. If tics occur during sti
discontinued (Lowe et al, 1982a).
c) Although stimulant therapy was suspected to exacerbate tics, LONG-TERM methylphenidate tre
effective in children with attention-deficit hyperactivity disorder (ADHD) AND CHRONIC MULTIPLE
In this 2-year non-blinded, prospective, follow-up study, 32 children (age ranging from 6.1 and 11.9
methylphenidate from a previous trial (mean 16.5 milligrams (mg), range=5 to 40 mg). The children
months for 2 years for their on-task, fidgeting, worksheet behaviors, and vocal and motor tic frequen
significantly worse at baseline than placebo (p ranging from less than 0.001 to 0.03). There was no
methylphenidate. ADHD behaviors were not significantly different between baseline and placebo, wl
task during the medication conditions than placebo (p less than 0.001). There was no significant diff
when compared to growth table values. Systolic blood pressure and heart rate were significantly inc
considered clinically insignificant. Although this study showed methylphenidate did not worsen tics ir
the possibility of individual exacerbation of tic cannot be ruled out (Gadow et al, 1999a). In another s
syndrome, abrupt withdrawal of methylphenidate and dextroamphetamine in long-term therapy DID
frequency (Nolan et al, 1999a).

4.5.B.2 Autistic disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Methylphenidate may be useful in the treatment of autism
Methylphenidate may improve concentration, hyperactivity, constructive behavior, and stereotyped r
sadness and exacerbate temper tantrums

c) Pediatric:

1) One group of investigators reported the efficacy of methylphenidate 10 to 50 milligrams daily (mean,
an open study involving 9 children (4 to 16 years of age). All children improved significantly during treatm
movements or significant toxicity. The authors suggest that a placebo-controlled, two month study of hyp
evaluate the efficacy of methylphenidate in this patient population (Birmaher et al, 1988).
2) Methylphenidate 10 milligrams orally twice daily was reported beneficial in a 6-year-old boy with autis
randomly administered methylphenidate or placebo daily, under double-blind conditions. Methylphenidat
and hyperactivity, as well as constructive behavior and stereotyped movements; negative effects were ol
exacerbation of temper tantrums); however, beneficial effects were considered to outweigh these negati
suggests that methylphenidate may not be contraindicated in autistic children. More studies are required
in autism.

b) Summary:

Efficacy in the treatment of senile dementia is questionable; available data are anecdotal
Some of the negative symptoms associated with vascular dementia or dementia of Alzheimer's type
Withdrawn, non-agitated patients with moderate dementia are most likely to respond to methylpheni

c) Adult:

1) Results of an open-label, non-blinded preliminary study indicate that the negative symptoms associat Alzheimer's type respond to methylphenidate (10 to 20 milligrams/day). Results were similar for Alzheim patients. Depressive symptoms in this population did not respond to methylphenidate. Some cognitive im dementia, but not in those with dementia of Alzheimer's type. It appears that withdrawn, non-agitated pat to respond to methylphenidate (Galynker et al, 1997a).

2) Methylphenidate has been used to treat senile dementia and is possibly effective; however, there are stems from clinical experience and anecdotes. Most references to the use of methylphenidate (or amphe (Rossman, 1979; Anon, 1978; Yesavage & Hollister, 1978; Borowitz, 1976; Steinberg, 1976).

4.5.B.10 Depression, Combination therapy

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

A 4-week, randomized, double-blind, placebo-controlled study of patients with treatment-resistant de demonstrated no statistically significant benefit with the addition of extended-release methylphenida antidepressant therapy (n=60) (Patkar et al, 2006)

The results of a small case series involving 5 patients appear to indicate that methylphenidate (10 to augmenting the therapeutic effects of serotonin selective reuptake inhibitors (SSRIs) (eg, fluoxetine, depression (Stoll et al, 1996)

The combination of MAO inhibitors (tranylcypromine, isocarboxazid, phenelzine) and stimulants (am as therapy of severe treatment-resistant depression (Feighner et al, 1985)

The combination of MAO inhibitors and stimulants plus tricyclic antidepressants (amitriptyline, protrip effective and safe in this type of intractable depression (Feighner et al, 1985)

c) Adult:

1) A 4-week, randomized, double-blind, placebo-controlled study of patients with treatment-resistant dep demonstrated no statistically significant benefit with the addition of extended-release methylphenidate hy antidepressant therapy. Patients (n=60; mean age, 48.5 years) with major depressive disorder who had therapy were randomized to either methylphenidate (n=30) or placebo (n=30), with methylphenidate dos

in 18-mg/day increments each week to a maximum dose of 54 mg/day. Subjects maintained their preexis
period. The primary efficacy measurement was the change in the 21-item Hamilton Depression Rating S
treatment), with a response defined as at least 50% reduction and remission defined as a score of 7 or le
were included changes in the Clinical Global Impression-Improvement and Severity (CGI-I and CGI-S, re
Depression Inventory-Second Edition (BDI-II) scores. There were no statistically significant differences b
primary or secondary efficacy measurements. Changes in the mean HAM-D-21 scores were -6.9 for the
group (p=0.22). Patients receiving methylphenidate achieved response and remission (40% and 13.3%,
receiving placebo (23.3% and 3.3%, respectively), but the differences were not statistically significant (p=
statistically significant differences for changes in CGI-I (p=0.34), changes in CGI-S (p=0.18), or BDI-II (p=
moderate in severity and the dropout rates were similar between groups (Patkar et al, 2006).
2) The results of a small case series involving 5 patients appear to indicate that methylphenidate (10 to
augmenting the therapeutic effects of serotonin selective reuptake inhibitors (SSRIs) (eg, fluoxetine, paro
depression. In this series, methylphenidate added to ineffective or only partially effective SSRI treatment
symptoms, without side effects, significant tolerance, or abuse of methylphenidate (Stoll et al, 1996).
3) The combination of MAO inhibitors (tranylcypromine, isocarboxazid, phenelzine) and stimulants (amp
as therapy of severe treatment-resistant depression. In addition, the combination of MAO inhibitors and s
(amitriptyline, protriptyline, amoxapine, nortriptyline) has also been effective and safe in this type of intra
suggested that the following regimen be utilized when combining these agents: (1) the individual drugs a
has had a prior partial response; (2) with combined MAO inhibitor and stimulant therapy, the MAO inhibit
dextroamphetamine or methylphenidate in 2.5 milligrams (mg) increments to stabilize blood pressure an
administering the combination of MAO inhibitors, stimulants, and antidepressants, the tricyclic antidepres
days, adding the MAO inhibitor during the daytime for 4 to 5 days, then adding low doses of the stimulan
response is positive. The most frequent complication of this therapy is orthostatic hypotension; other pati
and agitation. However, no serious side effects or life-threatening reactions were reported.

4.5.B.11 Depression, Monotherapy

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Improves selected types of depression (Ayd, 1985; Janowsky et al, 1973); (Rickels et al, 1970 & 197
Effective for depression in medically ill elderly patients (Frye, 1997a; Emptage & Semla, 1996a)
Effective for depression associated with cancer and cardiac surgery (Macleod, 1998; Fernandez et a
May be effective for depressive and/or cognitive symptoms in post liver transplant and post-stroke p
1998a)

c) Adult:

1) GENERAL INFORMATION

a) Studies have shown that methylphenidate (10 to 30 milligrams (mg)/day) can improve selected c
et al, 1973); (Rickels et al, 1970 & 1972). However, 1 study found methylphenidate ineffective for de
methylphenidate may exacerbate pre-existing agitation, anxiety, mania, psychosis, or depression. M
safe and effective for the treatment of depression in medically ill elderly patients lacking contraindica
action, usually within 2 to 5 days, is a potential advantage over other antidepressants in this patient
1996a). Methylphenidate has been effective in the treatment of depression associated with cancer a
et al, 1987); (Kaufmann et al, 1984). Methylphenidate may be useful for the treatment of depressive
transplant and post-stroke patients (Grade et al, 1998a; Plutchik et al, 1998a).

2) Results of a small, uncontrolled, preliminary study indicate that methylphenidate may be useful for the
symptoms in post liver transplant patients. In this study, a positive response was reported in 7 of 8 patier
milligrams/day. Methylphenidate was noted to improve cognition, mood, motivation, appetite, and alertne
3) Results of a prospective, randomized, double-blind, placebo- controlled study indicate that methylphe
stroke depression. In this study, acute stroke patients (n=21) receiving methylphenidate (30 milligrams/d

b) Summary:
Methylphenidate may reduce sedation and fatigue and improve cognition and quality of life in patients wi

c) Adult:
1) Methylphenidate appears to reduce sedation and fatigue and improve cognition and quality of life in p adversely affecting seizure activity. In this open-label, non-randomized, pilot study involving 8 epilepsy p years) on multiple antiepileptic drugs (AEDs), methylphenidate (dosage range 7.5 to 25 milligrams (mg)/ patients' current AED regimens for 3 months. Six of 8 patients were seizure free at baseline, 5 remained experienced an increase, 1 a decrease, and 1 no change in seizure activity. Overall, all quality of life indi scores, and emotional well-being scores showed significant improvement from baseline after methylpher analogue scale fatigue scores decreased 63.3% from baseline (p=0.015). Methylphenidate did not signif serum concentrations of AEDs changed less than 10% from baseline to the end of the study. No serious 2002).

4.5.B.13 Fatigue

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
May reduce fatigue in some HIV-positive patients
Methylphenidate may be effective for alleviating fatigue in patients with advanced cancer

c) Adult:
1) Methylphenidate may be effective for alleviating fatigue in patients with advanced cancer. In this preli with advanced cancer were given methylphenidate 5 to 30 milligrams daily for a mean evaluation period responders (at least 30% improvement). Mean visual analogue scale (VAS) scores for fatigue before and (p=0.01). According to log-rank test, there was a significant difference in survival time between responde respectively; p=0.01). Adverse effects were relatively mild and reversible (Sugawara et al, 2002).
2) A 6-week course of an oral psychostimulant medication, METHYLPHENIDATE or PEMOLINE, reduc quality of life also tended to improve with methylphenidate and pemoline therapy, and drug-induced side least 5 on a 10-point scale for persistent fatigue. Methylphenidate (n=53) was initiated at 7.5 milligrams (mg/day (mean end-of-study dose 51 mg/day); pemoline (n=45) was started at 18.75 mg twice daily with study dose 96 mg/day). At 6 weeks, total scores on the Piper Fatigue Scale (patient-rated) were significa pemoline-treated subjects compared with placebo (p=0.04). Also, on the patient-rated visual analog scal significantly higher for those receiving methylphenidate or pemoline (p=0.02). No significant differences comparing methylphenidate and pemoline. Significant correlations were found between improvement in f dropped out due to side effects (methylphenidate (2), pemoline (2), control (1)). Only jitteriness and hype often by those on methylphenidate or pemoline than those on placebo (Breitbart et al, 2001a).

4.5.B.14 Finding related to coordination / incoordination - Impaired cognition

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category B

Methylphenidate is effective for the treatment of narcolepsy in adults and children 6 years and over
Methylphenidate improves performance and ability to stay awake
Methylphenidate has been used for various diseases which exhibit hypersomnia as a prominent clin

c) Adult:

1) Methylphenidate (10 to 60 milligrams/day) is indicated for the treatment of narcolepsy in adults and cl
performance and ability to stay awake (Prod Info RITALIN(R) oral tablet, RITALIN-SR(R) oral tablet, 200
1987a; Mitler et al, 1986c; Honda et al, 1979a).

2) Methylphenidate has been shown to be effective in the treatment of post-traumatic narcolepsy. In 1 c
twice daily was successfully used to treat narcolepsy resulting from moderate brain injury. Following the
tetrad of narcolepsy: cataplexy, excessive daytime sleepiness, sleep paralysis, and hypnagogic hallucina
methylphenidate, the patient was completely asymptomatic (Francisco & Ivanhoe, 1996).

3) Methylphenidate has been used for various diseases such as Kleine-Levin syndrome, myotonic dystr
exhibit hypersomnia as a prominent clinical feature. The treatment of HYPERSOMNOLENCE follows the
that the response to CNS stimulants including pemoline, methylphenidate, and dextroamphetamine is les

hypersomnolence, pemoline is usually inadequate so methylphenidate, dextroamphetamine, phenmetraz prescribed (Culebrar, 1996; Guilleminault, 1994; Guilleminault, 1994a; Aoyama et al, 1994; Jozefowicz &

a) In hypersomnolence associated with myotonic dystrophy of a central origin rather than due to sle 40 milligrams/day) has resulted in sustained benefit in some patients for several years (2 to 6 years) al, 1986).

b) KLEINE-LEVIN SYNDROME, a periodic hypersomnia, is a rare primary condition featuring episo hyperphagia and hypersexuality. Episodes typically appear in adolescent males and last from sever remission. In 1 case report, Kleine-Levin syndrome was successfully treated with methylphenidate (1976). In another case report, methylphenidate therapy (40 mg/day) was only partially successful in 1978).

4.5.B.18 Paraphilia; Adjunct

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective adjunctive treatment for some cases of paraphilia

c) Adult:

1) An 8-week course of sustained release METHYLPHENIDATE added to selective serotonin reuptake i produced additional improvement in some patients with paraphilia (n=14) or paraphilia-related behavior (study (n=26). Indications for addition of methylphenidate to SSRI therapy included retrospective diagnos residual sexual target symptoms despite SSRI, residual depressive symptoms, relapse of sex/depressive effects such as fatigue. The mean dose of methylphenidate was 40 milligrams (mg)/day (range 20 to 100 outlets per week and minutes per day related to paraphilia decreased significantly during SSRI treatmen methylphenidate AND SSRI treatment, further reductions occurred in total sexual outlets per week (p=0.((p=0.04). With methylphenidate plus an SSRI, total sexual outlet measure decreased by 39% (p=0.003), behavior decreased by 44% (p=0.04). Side effects of methylphenidate therapy (usually managed by dos (1), increased sex drive (1), shallow sleep (2), distractibility (2), and mild anxiety (2) (Kafka & Hennen, 20

4.5.B.19 Schizophrenia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class III; Pediatric, Class III
Strength of Evidence: Adult, Category C; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Methylphenidate has had some success in the treatment of schizophrenia in adults and children
Methylphenidate may provoke schizophrenic symptoms with intensification of preexisting psychotic s

c) Adult:

1) Methylphenidate 40 milligrams intravenously (over 90 seconds) was reported effective in eliminating l schizophrenic patient who had been unresponsive to intravenous phenobarbital (Frost, 1989).

2) When administered intravenously in a dose of 0.5 milligram/kilogram methylphenidate has provoked s preexisting psychotic symptoms in actively ill patients. It was noted that symptom activation occurred wit minutes and persisted 2 to 6 hours. It was also noted that antipsychotic agents did not appear to effect p (Janowsky et al, 1973).

d) Pediatric:

1) Methylphenidate in doses of 10 milligrams (mg) twice daily in combination with chlorpromazine has b 11-year-old boy. Prior neuroleptic therapy was ineffective (Rogeness & Macedo, 1983).

Thioridazine

4.6.A Amphetamine

4.6.A.1 Attention deficit hyperactivity disorder

a) SUMMARY: In comparative studies, Adderall(R) (combination AMPHETAMINE/DEXTROAMPHETAMINE efficacy in the treatment of attention deficit hyperactive disorder in children. METHYLPHENIDATE requires tv daily doses.

b) The racemic mixture of L- and D-amphetamine (ADDERALL(R)) was at least as effective as methylphenic deficit hyperactivity disorder (ADHD), and was more effective at 4 to 5 hours post-administration (beyond me this within-subject, double-blind, placebo-controlled, crossover study, 25 children with ADHD (mean age 9.6 (mg), 17.5 mg, Adderall(R) 7.5 mg, 12.5 mg, and placebo twice a day (at 7:45 a.m. and 12:15 p.m.) in a rand and counselors rated their behavior throughout the day and at times beyond methylphenidate's expected dur them at the end of the day and in the evening for possible rebound effects. When compared to placebo, Adde improved in-school behaviors (p less than 0.0001 and 0.001, respectively), classroom measures (p less than and after-school behaviors (p less than 0.0001). Drug effects were significantly affected by time (p less than effect size (ES) than methylphenidate and higher doses consistently resulted in higher ES than lower doses. than methylphenidate at midday and end of day (p less than 0.05). The ES of both drugs dropped at midday implicating the possibility of reducing the afternoon dose. Side effects were reported more frequently with Ad medications. Only 1 patient was eliminated from the study due to exacerbation of his motor tic condition. Furt possibility of once daily dosing of Adderall(R), and to compare the efficacy of methylphenidate to D-amphetar

c) Once-daily Adderall(R) (combination AMPHETAMINE/DEXTROAMPHETAMINE) appeared to be as effec treatment of attention deficit hyperactive disorder in children aged 6 to 12 years, according to a double-blind, Also, a mid-afternoon dose of either Adderall or methylphenidate (MPH) produced better evening behavior th although either active treatment tended to induce loss of appetite and sleep difficulties. In a randomized mani received each day 1 of 7 treatment protocols: (1)MPH 0.3 milligram/kilogram (mg/kg) at 7:30, 11:30, and 15:3 MPH 0.15 mg/kg at 15:30; (3)MPH 0.3 mg/kg at 7:30; (4)Adderall 0.3 mg/kg at 7:30 and 15:30; (5)Adderall 0. 15:30; (6)Adderall 0.3 mg/kg at 7:30; or (7)placebo. While twice-daily MPH 0.3 mg/kg did not differ significant single morning-dose MPH 0.3 mg/kg produced less significant effects than either once-daily Adderall 0.3 mg/ MPH began to lose its effectiveness approximately 6.5 hours later. Evening behavior was rated better after M no evening differences were seen after mid-afternoon doses of either 0.3 or 0.15 mg/kg. Children showed dif responded more positively to MPH, 37% responded more positively to Adderall, and 38% responded equally responding more positively to MPH, one dose of MPH was sufficient to carry them all day and into the evenin positively to Adderall needed only once-daily dosing of the drug (Pelham et al, 1999aa).

4.6.B Clonidine

4.6.B.1 Attention deficit hyperactivity disorder

a) In children with attention deficit hyperactive disorder (ADHD) and TICS (both by DSM-IV criteria), CLONID or combination CLONIDINE/MPH provided symptomatic improvement in ADHD without causing worsening of therapy provided the greatest benefit. This finding emanated from a double-blind, multi-center trial in children randomized to placebo (n=32), clonidine alone starting at 0.1 milligram (mg)/day (n=34), MPH alone starting clonidine/MPH (n=33). Average daily doses were 0.25 mg for clonidine alone, 0.28 mg for clonidine given wit MPH given with clonidine. Based on the primary endpoint (Conners Abbreviated Questionnaire-Teacher), a s clonidine (compared to no clonidine; p=0.002), and for MPH (compared to no MPH; p=0.003), and either clon (both p=0.02). However, the greatest improvement on symptomatic ratings was seen with combination clonid placebo). Worsening of tics was reported in 9 receiving clonidine alone, 8 receiving MPH alone, 6 on combin Compared with placebo, severity of tics decreased in all active treatment groups according to the Yale Globa and the Tic Symptom Self-Report. Study medications were well tolerated except for sedation caused by cloni this side effect. The authors observed that clonidine seemed to be most helpful for impulsivity and hyperactiv inattentiveness (Anon, 2002).

b) An open pilot study compared oral and transdermal clonidine to methylphenidate in attention deficit disorc equivalent to methylphenidate (MPH). Both were more effective than placebo. In another study, MPH acted p deficit and moderate hyperactivity. In ADHD children with symptoms of hyperarousal, hyperactivity, and aggr

4.6.C Dexmethylphenidate

4.6.C.1 Attention deficit hyperactivity disorder

a) No comparisons with methylphenidate have been published, and data released by the manufacturer have this data is available. In a completed 4- week, placebo-controlled study described in the package insert (Prod to 20 milligrams (mg) daily was compared to methylphenidate 10 to 40 mg daily (each in two divided doses) i age). Patients included had all subtypes of ADHD (combined type, inattentive type, hyperactive-impulsive typ significantly greater improvement of symptom scores from baseline on the Swanson, Noland, and Pelham (S (mean change, -0.7 versus -0.2). Although methylphenidate was the comparator, no results for methylphenid

b) In manufacturer releases, apparently referring to the same package insert trial described above, the effica reported similar to methylphenidate (Anon, 2001)(Anon, 2001a). Earlier releases also did not indicate a signif drugs (Anon, 1999; Anon, 1999a), although they were carefully prepared to avoid this conclusion.
c) One manufacturer release suggested a longer duration of action of dexmethylphenidate in ADHD; in this s dexmethylphenidate was reportedly seen at all time points, but there was failure of methylphenidate to contro hours postdose) (Anon, 1999). However, the duration of action of methylphenidate was not given, precluding relative to dexmethylphenidate. The duration of dexmethylphenidate in this trial was similar to that of methylp suggesting this difference is small. No study has provided comparative improvements in symptom scores fror points.
d) Available studies have not indicated a more favorable adverse- effect profile for dexmethylphenidate com 2001).

4.6.D Dextroamphetamine

4.6.D.1 Attention deficit hyperactivity disorder

a) SUMMARY: In comparative studies, Adderall(R) (combination AMPHETAMINE/DEXTROAMPHETAMINE efficacy in the treatment of attention deficit hyperactive disorder in children. METHYLPHENIDATE requires tw daily doses.
b) The racemic mixture of L- and D-amphetamine (ADDERALL (R)) was at least as effective as methylpheni deficit hyperactivity disorder (ADHD), and was more effective at 4 to 5 hours post-administration (beyond met this within-subject, double-blind, placebo-controlled, crossover study, 25 children with ADHD (mean age 9.6 y (mg), 17.5 mg, Adderall (R) 7.5 mg, 12.5 mg, and placebo twice a day (at 7:45 a.m. and 12:15 p.m.) in a ranc Teachers and counselors rated their behavior throughout the day and at times beyond methylphenidate's exp Parents rated them at the end of the day and in the evening for possible rebound effects. When compared to significantly improved in-school behaviors (p less than 0.0001 and 0.001, respectively), classroom measures than 0.0001), and after-school behaviors (p less than 0.0001). Drug effects were significantly affected by time resulted in higher effect size (ES) than methylphenidate and higher doses consistently resulted in higher ES t significantly more effective than methylphenidate at midday and end of day (p less than 0.05). The ES of both increased in the afternoon, implicating the possibility of reducing the afternoon dose. Side effects were report preclude the use of both medications. Only 1 patient was eliminated from the study due to exacerbation of his to evaluate the possibility of once daily dosing of Adderall(R), and to compare the efficacy of methylphenidate
c) Once-daily Adderall(R) (combination AMPHETAMINE/DEXTROAMPHETAMINE) appeared to be as effec treatment of attention deficit hyperactive disorder in children aged 6 to 12 years, according to a double-blind, Also, a mid-afternoon dose of either Adderall or methylphenidate (MPH) produced better evening behavior th although either active treatment tended to induce loss of appetite and sleep difficulties. In a randomized mani received each day 1 of 7 treatment protocols: (1)MPH 0.3 milligram/kilogram (mg/kg) at 7:30, 11:30, and 15:3 MPH 0.15 mg/kg at 15:30; (3)MPH 0.3 mg/kg at 7:30; (4)Adderall 0.3 mg/kg at 7:30 and 15:30; (5)Adderall 0. 15:30; (6)Adderall 0.3 mg/kg at 7:30; or (7)placebo. While twice-daily MPH 0.3 mg/kg did not differ significant single morning-dose MPH 0.3 mg/kg produced less significant effects than either once-daily Adderall 0.3 mg/ MPH began to lose its effectiveness approximately 6.5 hours later. Evening behavior was rated better after M no evening differences were seen after mid-afternoon doses of either 0.3 or 0.15 mg/kg. Children showed dif responded more positively to MPH, 37% responded more positively to Adderall, and 38% responded equally responding more positively to MPH, one dose of MPH was sufficient to carry them all day and into the evenin positively to Adderall needed only once-daily dosing of the drug (Pelham et al, 1999a).
d) In a direct, double-blind, cross-over comparison of adverse effect profiles, both DEXTROAMPHETAMINE METHYLPHENIDATE 0.3 mg/kg twice daily were well-tolerated in 125 children with attention deficit disorder reported more frequently during drug therapy than at baseline were appetite suppression (both drugs) and ins severity of adverse effects was significantly higher in the dextroamphetamine group. However, only 1.6% of c because of adverse effects (Efron et al, 1997).

4.6.E Lithium

4.6.E.1 Attention deficit hyperactivity disorder

a) In a preliminary randomized, double-blind, crossover study, lithium and methylphenidate had comparable attention-deficit/hyperactivity disorder (ADHD). Adult patients (n=32) met the Diagnostic and Statistical Manu criteria for ADHD at age 7 years and at the time of the study. Patients were randomly assigned to receive eith 8 weeks of the study, and then switch to the other 8-week treatment arm after a 2-week washout period. For dose of 10 milligrams (mg) once daily for the first 2 weeks; the daily dose was increased by 10 mg every 2 we study arm. For the lithium arm, the initial oral dose was 300 mg once daily for 2 weeks; the daily dose was inc for the 8 week duration of the study arm. After the first 2 weeks of the study arm, lithium and MPH administra study arm, the average daily doses of MPH and lithium carbonate were 38.9 mg and 1173 mg, respectively. the study; 9 patients dropped out due to side effects (4 of 9), lack of perceived benefit (4 of 9), or relocation to improvement of ADHD, as assessed by a 30% or more reduction in the Conners' Adult ADHD Rating Scale s and Impulsivity, was 48% for the MPH arm and 37% for the lithium arm. When evaluating only the patients th improvement rate was 47% and 43% for the MPH and lithium arms, respectively. Side effects included heada orthostatic hypertension. A limitation of the study was the presence of a substantial arm effect, in which the ir maintained during the second arm. In addition, the study had small number of patients and lacked a placebo sequence by arm interaction, suggesting that MPH and lithium had comparable efficacy (Dorrego et al, 2002)

4.6.F Pemoline

Attention deficit hyperactivity disorder

Fatigue

Narcolepsy

4.6.F.1 Attention deficit hyperactivity disorder

a) In a retrospective chart review (n=485), METHYLPHENIDATE (MPD) and PEMOLINE (PEM) were both e hyperactive disorder (ADHD) and attention deficit disorder (ADD) (DSM- IV) in children 4 to 18 years of age; l treatment were shown by more PEM-treated than MPD-treated patients (PEM 225 of 245 (92%); MPD 168 of scale for treatment efficacy ranged from 1 to 4; 1-poor or no response; 2-initially good but not sustained; 3-go efficacy ratings for the MPD and PEM groups were 2.7 and 3.5, respectively. Most frequent adverse effects w and insomnia and irritability for the PEM group. The rates of drug discontinuation for lack of efficacy were 32% Discontinuations due to adverse effects were higher in the PEM group (22% compared with 5% for MPD). No either group. Standard doses were 1.44 milligrams/kilogram (mg/kg) for PEM given once daily and 0.4 mg/kg release form and in 2 or 3 divided doses daily for the immediate-release form. The sustained-release form of the immediate-release form (Andriola, 2000).

4.6.F.2 Fatigue

a) A 6-week course of an oral psychostimulant medication, METHYLPHENIDATE or PEMOLINE, reduced th quality of life also tended to improve with methylphenidate (MPH) and PEMOLINE (PEM) therapy, and drug-i score of at least 5 on a 10-point scale for persistent fatigue. MPH (n=53) was initiated at 7.5 milligrams (mg) t (mean end-of-study dose 51 mg/day); PEM (n=45) was started at 18.75 mg twice daily with maximum titration mg/day). At 6 weeks, total scores on the Piper Fatigue Scale (patient- rated) were significantly improved amo with placebo (p=0.04). Also, on the patient-rated visual analog scale for fatigue (VAS-F), the energy subscore MPH or PEM (p=0.02). No significant differences were found on any outcome measurement comparing MPH between improvement in fatigue and better quality of life. Five patients dropped out due to side effects (MPH hyperactivity were experienced significantly more often by those on MPH or PEM than those on placebo (Bre

4.6.F.3 Narcolepsy

a) One group of investigators studied the efficacy of methylphenidate, pemoline, and protriptyline in the treat data. Six subjects received methylphenidate at dosages of 10 milligrams (mg), 30 mg, and 60 mg/day (1 wee pemoline at dosages of 18.75 mg, 56.25 mg, and 112.5 mg/day (1 week at each dosage). Two subjects recei and 60 mg/day and two subjects received protriptyline dosages of 10 mg, 20 mg, and 40 mg/day (1 week at e randomized from patient to patient. Nine healthy subjects with no sleep disorder received placebos and serve methylphenidate significantly improves the ability of the narcoleptic to stay awake, pemoline seems to improv significantly alter the ability to stay awake or perform. More data are needed to confirm these findings, and fu

4.6.G Protriptyline

4.6.G.1 Narcolepsy

a) Protriptyline did not improve either the ability to stay awake or perform tasks in a double-blind, parallel (by 1986). Three dose levels of 3 drugs were compared in the treatment of narcolepsy in 17 patients. The drugs milligrams (mg)/day), methylphenidate (10, 30, or 60 mg/day) and protriptyline (10, 30, and 60 mg/day). Meth and perform tasks. Pemoline improved the ability to perform tasks, but not to stay awake.

4.6.H Thioridazine

1) Adverse Effects

a) One group of investigators reported a controlled study of methylphenidate and thioridazine in improving co subaverage children. Twenty-seven children with subaverage IQs participated in a double-blind, placebo-con methylphenidate (0.4 milligrams/kilogram/day and thioridazine (1.75 milligrams/kilogram/day. The children we attention, and performance on a series of electronically-controlled cognitive-motor tests. Methylphenidate imp omission errors on an attentional task, and reduced seat movements on two tasks. Thioridazine had no signif performance. It did not produce deleterious effects on IQ performance when subjects received reinforcers for did not adversely effect performance on any of the cognitive-motor performance tests (Aman et al, 1991).

DRUGDEX® Evaluations

DULOXETINE

0.0 Overview

1) Class
- **a)** This drug is a member of the following class(es):
  - Antidepressant
  - Central Nervous System Agent
  - Neuropathic Pain Agent
  - Serotonin/Norepinephrine Reuptake Inhibitor

2) Dosing Information
- **a)** Duloxetine Hydrochloride
  - **1)** Adult
    - **a)** Diabetic peripheral neuropathy - Pain
      - **1)** 60 mg ORALLY once daily (Prod Info CYMBALTA(R) delayed-rele
    - **b)** Fibromyalgia
      - **1)** initial, 30 mg ORALLY once daily for 1 week; increase to recomm CYMBALTA(R) delayed-release oral capsules, 2008)
    - **c)** Generalized anxiety disorder
      - **1)** 60 mg ORALLY once daily, may start at 30 mg ORALLY once dai depending on tolerability (Prod Info CYMBALTA(R) delayed-release
      - **2)** may increase by increments of 30 mg once daily to a MAX of 120 additional benefit in clinical trials (Prod Info CYMBALTA(R) delayed-r
    - **d)** Major depressive disorder
      - **1)** initial (acute), 20 mg ORALLY twice daily up to 60 mg/day (once d release oral capsules, 2008)
      - **2)** maintenance, 60 mg ORALLY once daily (Prod Info CYMBALTA(
    - **e)** Urinary incontinence
      - **1)** 40 mg ORALLY twice daily (clinical trial dosing) (Weinstein et al, 2
  - **2)** Pediatric
    - **a)** safety and efficacy in pediatric patients have not been established (Pro

3) Contraindications
- **a)** Duloxetine Hydrochloride
  - **1)** concomitant use of MAOIs (Prod Info Cymbalta(R) Delayed-release oral ca
  - **2)** narrow-angle glaucoma, uncontrolled; increased risk of mydriasis (Prod Inf

4) Serious Adverse Effects
- **a)** Duloxetine Hydrochloride
  - **1)** Bleeding, Abnormal
  - **2)** Depression, worsening
  - **3)** Hepatotoxicity
  - **4)** Serotonin syndrome
  - **5)** Suicidal thoughts
  - **6)** Withdrawal sign or symptom

5) Clinical Applications
- **a)** Duloxetine Hydrochloride
  - **1)** FDA Approved Indications
    - **a)** Diabetic peripheral neuropathy - Pain
    - **b)** Fibromyalgia
    - **c)** Generalized anxiety disorder
    - **d)** Major depressive disorder
  - **2)** Non-FDA Approved Indications
    - **a)** Urinary incontinence

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring

B) Synonyms

Duloxetine
Duloxetine HCl
Duloxetine Hydrochloride

C) Physicochemical Properties

1) Duloxetine Hydrochloride

a) Molecular Weight

1) 333.88 (Prod Info CYMBALTA(R) delayed-release oral capsules,

b) Solubility

1) Slightly soluble in water (Prod Info CYMBALTA(R) delayed-releas

1.2 Storage and Stability

A) Duloxetine Hydrochloride

1) Preparation

a) Oral route

1) Duloxetine hydrochloride (HCl) capsules should be swallowed wh
food or mixed with liquids. Duloxetine HCl may be given with food or
release oral capsules, 2008).

B) Duloxetine Hydrochloride

1) Oral route

a) Capsule, Delayed Release

1) Store at controlled room temperature, 25 degrees Celsius (77 deg
degrees Celsius (59 and 86 degrees Fahrenheit) (Prod Info CYMBAL

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Geriatric Patients

1.3.1 Normal Dosage

1.3.1.A Duloxetine Hydrochloride

1.3.1.A.1 Oral route

Diabetic peripheral neuropathy - Pain

Fibromyalgia

Generalized anxiety disorder

Major depressive disorder

Urinary incontinence

1.3.1.A.1.a Diabetic peripheral neuropathy - Pain

1) The recommended dose of duloxetine for the treatment of ne 60 milligrams (mg) once daily. There is no evidence that doses h lower starting dose may be considered for patients in whom tole oral capsules, 2008).

2) Therapy Withdrawal

a) Abrupt discontinuation of duloxetine has lead to sympton irritability, and nightmare. Gradual reduction of the dose, rat symptoms occur following a decrease in dose, resuming the smaller decreases (Prod Info CYMBALTA(R) delayed-releas

1.3.1.A.1.b Fibromyalgia

1) The recommended dose for the management of fibromyalgia mg once daily for 1 week and increase to 60 mg/day based on tc The duration of maintenance therapy should be based on clinica clinical trials (Prod Info CYMBALTA(R) delayed-release oral cap maintained at 6 months of therapy (Russell et al, 2008). Howeve in clinical trials, even among those who did not respond to the 6(adverse events (Prod Info CYMBALTA(R) delayed-release oral c

2) Therapy Withdrawal

a) Abrupt discontinuation of duloxetine has lead to sympton irritability, and nightmare. Gradual reduction of the dose, rat symptoms occur following a decrease in dose, resuming the smaller decreases (Prod Info CYMBALTA(R) delayed-releas

1.3.1.A.1.c Generalized anxiety disorder

1) The recommended dose of duloxetine for the treatment of ge without regard to meals. If tolerability is a concern, patients may mg once daily. There is no evidence that doses greater than 60 r my be increased by increments of 30 mg once daily to a maximu delayed-release oral capsules, 2008).

2) Therapy Withdrawal

a) Abrupt discontinuation of duloxetine has lead to sympton irritability, and nightmare. Gradual reduction of the dose, rat symptoms occur following a decrease in dose, resuming the smaller decreases (Prod Info CYMBALTA(R) delayed-releas

1.3.1.A.1.d Major depressive disorder

1) Initial (acute) Therapy

a) The recommended initial dose of duloxetine hydrochlorid milligrams (mg) orally twice daily. The dose may be increase tolerability is a concern, patients may be started at 30 mg or is no evidence that doses greater than 60 mg/day confer an oral capsules, 2008).

2) Maintenance Therapy

a) The recommended maintenance dose of duloxetine hydr is 60 milligrams orally once daily. Maintenance treatment wi Reassess the dose and the need for maintenance therapy ir release oral capsules, 2008).

3) Therapy Withdrawal

a) Abrupt discontinuation of duloxetine has lead to sympton irritability, and nightmare. Gradual reduction of the dose, rat symptoms occur following a decrease in dose, resuming the smaller decreases (Prod Info CYMBALTA(R) delayed-releas

1.3.1.A.1.e Urinary incontinence

1) In clinical trials, duloxetine 40 milligrams orally twice daily wa incontinence episodes in clinical trials among women with stress Dmochowski et al, 2003) and mixed urinary incontinence (Bent e

1.3.2 Dosage in Renal Failure

A) Duloxetine Hydrochloride

1) In renally impaired patients, duloxetine should be initiated at a lower d recommended for patients with end-stage renal disease (requiring dialysis

milliliters/minute) (Prod Info CYMBALTA(R) delayed-release oral capsules

1.3.3 Dosage in Hepatic Insufficiency

A) Duloxetine Hydrochloride

1) Duloxetine is not recommended for use in patients with any hepatic ins capsules, 2008).

1.3.4 Dosage in Geriatric Patients

A) Duloxetine Hydrochloride

1) No dosage adjustment is recommended for elderly patients. Caution is CYMBALTA(R) delayed-release oral capsules, 2008).

1.4 Pediatric Dosage

1.4.1 Normal Dosage

1.4.1.A Duloxetine Hydrochloride

1) The safety and efficacy in pediatric patients have not been established 2008).

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Duloxetine Hydrochloride

a) Initial Response

1) Depression, oral: within 2 weeks (Hirschfeld et al, 2005).

a) Patients treated with duloxetine experienced significant impro (HAMD-17) compared to placebo-treated patients by the second week trials, which compared duloxetine 60 mg orally once daily (depressive disorder, rapid improvements in the individual sympto and psychic anxiety were demonstrated by the end of the first we

b) Peak Response

1) Platelet serotonin uptake inhibition, oral: 4 to 6 hours (Kasahara e

a) Represents time to maximal or near-maximal inhibition in plat pharmacodynamic parameter may correlate with CNS activity (Is for clinical monitoring has not been determined.

B) Duration

1) Duloxetine Hydrochloride

a) Multiple Dose

1) Platelet serotonin uptake inhibition, oral: at least 7 days (Kasahara

a) Represents duration of inhibition after the last dose of a regim levels of duloxetine were no longer detectable.

2.2 Drug Concentration Levels

A) Duloxetine Hydrochloride

1) Therapeutic Drug Concentration

a) DEPRESSION, not established.

1) Studies attempting to define plasma levels that are associated wit

2) Significant inhibition of serotonin uptake in platelets from healthy s concentrations exceeding 5 ng/mL (Ishigooka, 1997). This pharmaco 1997; Kasahara et al, 1996), although its usefulness for clinical monit

2) Peak Concentration

a) Oral: 13 ng/mL (20-mg dose) (Johnson et al, 1995).

1) Following single oral doses of 20 mg, a mean peak duloxetine pla desmethyl metabolite (active) were less than 2 ng/mL (Johnson et al,

3) Time to Peak Concentration

a) Oral: 6 to 10 hours (Prod Info CYMBALTA(R) delayed-release oral cap

1) Maximal plasma concentrations (Cmax) of duloxetine occur 6 hou
presence of food (Prod Info CYMBALTA(R) delayed-release oral cap
2) Values represent times to peak levels over the range of 10 to 40 r
higher doses. Duloxetine exhibits linear pharmacokinetics (Sharma e
3) Steady-State: Steady-state has been reached in 3 to 5 days with 2
in healthy subjects; with the latter regimen, the mean peak plasma le
1995).
4) During oral administration of 20 and 30 mg twice daily in healthy s
approximately 15 ng/mL and 20 ng/mL, respectively, in one study (Sh

4) Area Under the Curve
a) After a single 60-milligram dose of duloxetine, patients with end stage
Cmax and AUC values approximately 100% greater than those of patients
glucuronide and 5-hydroxy, 6-methoxy duloxetine sulfate, the major circul
approximately 7- to 9-fold higher and would be expected to increase furth
release oral capsules, 2008).
b) After a single 20-milligram dose of duloxetine, 6 cirrhotic patients with
fold increase in AUC compared to non-cirrhotic patients (Prod Info CYMB

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Duloxetine Hydrochloride
1) Bioavailability
a) Oral: 30% to 80% (Bymaster et al, 2005).
1) The absolute oral bioavailability of a 60-mg dose averaged 5(
b) There is a median 2-hour lag until absorption begins (Prod Info C
c) With an evening dose, there is a 3-hour delay in absorption and a
dose (Prod Info CYMBALTA(R) delayed-release oral capsules, 2008)
2) Effects of Food
a) slows absorption
b) Food does not affect Cmax but delays time to peak concentration
(Prod Info CYMBALTA(R) delayed-release oral capsules, 2008).

2.3.2 Distribution

A) Distribution Sites
1) Duloxetine Hydrochloride
a) Protein Binding
1) greater than 90%, primarily to albumin and alpha-1-acid glyco
capsules, 2008).
b) Other Distribution Sites
1) Saliva, 0% (Johnson et al, 1995).
B) Distribution Kinetics
1) Duloxetine Hydrochloride
a) Volume of Distribution
1) 1640 L (Prod Info CYMBALTA(R) delayed-release oral capsu

2.3.3 Metabolism

A) Metabolism Sites and Kinetics
1) Duloxetine Hydrochloride
a) LIVER, extensive (Sharma et al, 2000; Artigas, 1995).
1) The major metabolic pathways involve oxidation of the naphtl
cytochrome P450 (CYP) isozymes, CYP1A2 and CYP2D6 (Prod
B) Metabolites
1) Duloxetine Hydrochloride

a) 4-hydroxy duloxetine glucuronide (inactive) (Prod Info CYMBALTA Lantz et al, 2003).
1) Approximately 47% of a given dose is conjugated to 4-hydrox since the inhibition constant (Ki) values for serotonin and norepir compound duloxetine (Bymaster et al, 2005).
b) 5-hydroxy-6-methoxy duloxetine sulfate (inactive) (Prod Info CYM 2005; Lantz et al, 2003).
1) Approximately 22% of a given dose is conjugated to 5-hydrox activity since the inhibition constant (Ki) values for serotonin and parent compound duloxetine (Bymaster et al, 2005).

2.3.4 Excretion

A) Kidney
1) Duloxetine Hydrochloride
a) Renal Excretion (%)
1) 70% (Prod Info CYMBALTA(R) delayed-release oral capsules
a) Excreted mainly as metabolites; only trace amounts (less CYMBALTA(R) delayed-release oral capsules, 2008).
B) Feces
1) Duloxetine Hydrochloride
a) 20% (Prod Info CYMBALTA(R) delayed-release oral capsules, 20
1) Approximately 20% of duloxetine is excreted in the feces (Pro is unclear from available data if this represents unabsorbed drug
C) Total Body Clearance
1) Duloxetine Hydrochloride
a) 114 L/hr (Sharma et al, 2000).
1) Value after oral doses in healthy subjects.
2) Cirrhotic (Child-Pugh Class B) patients (n=6) had a clearance a 20-milligram dose of duloxetine (Prod Info CYMBALTA(R) dela

2.3.5 Elimination Half-life

A) Parent Compound
1) Duloxetine Hydrochloride
a) Elimination Half-Life
1) 12 hours (range: 8 to 17 hours) (Prod Info CYMBALTA(R) del
a) Duloxetine pharmacokinetics are dose proportional over release oral capsules, 2008).
b) The elimination half-life of duloxetine in 6 cirrhotic patien a significantly longer half-life (47.8 hours vs 13.5 hours, p <

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING
1) Duloxetine Hydrochloride
a) Oral (Capsule, Delayed Release)
Suicidality and Antidepressant Drugs
Antidepressants increased the risk compared to placebo of suicidal th young adults in short-term studies of major depressive disorder (MDD of duloxetine hydrochloride or any other antidepressant in a child, ad need. Short-term studies did not show an increase in the risk of suici beyond age 24; there was a reduction in risk with antidepressants co certain other psychiatric disorders are themselves associated with inc started on antidepressant therapy should be monitored appropriately unusual changes in behavior. Families and caregivers should be adv the prescriber. Duloxetine hydrochloride is not approved for use in pe

capsules, 2009).

3.1 Contraindications

A) Duloxetine Hydrochloride

1) concomitant use of MAOIs (Prod Info Cymbalta(R) Delayed-release oral ca
2) narrow-angle glaucoma, uncontrolled; increased risk of mydriasis (Prod Inf

3.2 Precautions

A) Duloxetine Hydrochloride

1) suicidal ideation and behavior or worsening depression; increased risk, par
first few months of therapy or following changes in dosage (Prod Info Cymbalt
2) abnormal bleeding has been reported, including life-threatening hemorrhag
2009)
3) abrupt withdrawal; serious discontinuation symptoms have been reported (
4) alcohol, substantial use; increased risk of liver injury (Prod Info Cymbalta(F
5) bipolar disorder; increased risk of precipitation of a mixed/manic episode (F
6) concomitant use of thioridazine or serotonergic drugs (serotonin precursors
inhibitors); use is not recommended (Prod Info Cymbalta(R) Delayed-release c
7) concomitant use of potent CYP1A2 inhibitors (fluvoxamine, cimetidine, quin
be avoided (Prod Info Cymbalta(R) Delayed-release oral capsules, 2009)
8) concomitant use of CNS-acting drugs, 5-hydroxytryptamine receptor agonis
warfarin), tricyclic antidepressants (nortriptyline, amitriptyline, imipramine), phe
flecainide); use cautiously (Prod Info Cymbalta(R) Delayed-release oral capsu
9) conditions that slow gastric emptying, such as diabetes; may affect stability
capsules, 2009)
10) diabetes; may worsen glycemic control (Prod Info Cymbalta(R) Delayed-r
11) hepatic impairment; use is not recommended (Prod Info Cymbalta(R) Dela
12) hepatotoxicity, including hepatitis, jaundice, and elevated transaminase le
release oral capsules, 2009)
13) liver disease, chronic; may aggravate condition (Prod Info Cymbalta(R) D
14) mania, history; risk of activation of mania/hypomania (Prod Info Cymbalta
15) narrow-angle glaucoma, controlled; increased risk of mydriasis (Prod Info
16) renal impairment, severe and end stage renal disease (creatinine clearan
Cymbalta(R) Delayed-release oral capsules, 2009)
17) seizures, history (Prod Info CYMBALTA(R) delayed-release oral capsules
18) serotonin syndrome has been reported, including cases that are life-threa
monitoring recommended (Prod Info CYMBALTA(R) delayed-release oral caps
19) use of duloxetine within 14 days of MAOI discontinuation (Prod Info CYMB
20) use of an MAOI within 5 days after duloxetine discontinuation (Prod Info C
21) urinary retention requiring hospitalization and/or catheterization has been
capsules, 2008)
22) volume-depleted, elderly, or concurrent diuretic therapy; hyponatremia, sy
(SIADH) has occurred with duloxetine; discontinue if symptoms develop (Prod
23) report suspected adverse reaction to Eli Lilly and Company at 1-800-LillyR
(Prod Info CYMBALTA(R) delayed-release oral capsules, 2008)

3.3 Adverse Reactions

Cardiovascular Effects

Dermatologic Effects

Endocrine/Metabolic Effects

Gastrointestinal Effects

Hematologic Effects

Hepatic Effects

Musculoskeletal Effects

Neurologic Effects

3.3.1 Cardiovascular Effects

3.3.1.A Duloxetine Hydrochloride

3.3.1.A.1 Increased blood pressure

a) In clinical trials of all indications, duloxetine hydrochloride treatme
systolic and up to 2.3 mmHg in diastolic blood pressures compared w
therapy initiation and periodically during treatment (Prod Info CYMBA
b) Small increases in systolic/diastolic blood pressure and decrease
twice-daily dosing in recumbent healthy subjects; no significant effect
position (Sharma et al, 2000a).

3.3.1.A.2 Orthostatic hypotension

a) Orthostatic hypotension and syncope have been associated with t
first week of therapy, but can occur at any time and is especially seer
who are on concomitant medications that induce orthostatic hypotens
(fluvoxamine, cimetidine, quinolone antimicrobials (ciprofloxacin, eno
capsules, 2008).

3.3.1.A.3 Palpitations

a) Incidence: 1% to 2% (Prod Info CYMBALTA(R) delayed-release o
b) In pooled clinical trials of major depressive disorder and generaliz
of patients receiving duloxetine hydrochloride (n=2995) compared wit
also reported in 1% or greater of patients receiving duloxetine hydroc
indications of duloxetine (Prod Info CYMBALTA(R) delayed-release c
c) In placebo-controlled trials, palpitations were reported in 2% of fib
compared with 2% of patients receiving placebo (n=535) (Prod Info C

3.3.1.A.4 Syncope

a) Orthostatic hypotension and syncope have been associated with t
first week of therapy, but can occur at any time and is especially seer
who are on concomitant medications that induce orthostatic hypotens
(fluvoxamine, cimetidine, quinolone antimicrobials (ciprofloxacin, eno
capsules, 2008).

3.3.2 Dermatologic Effects

3.3.2.A Duloxetine Hydrochloride

Flushing

Pruritus

Rash

3.3.2.A.1 Diaphoresis

a) Incidence: 6% to 8% (Prod Info CYMBALTA(R) delayed-release o
b) In major depressive disorder and generalized anxiety disorder pla
patients receiving duloxetine hydrochloride compared with 2% of the
delayed-release oral capsules, 2008).
c) In diabetic peripheral neuropathy placebo-controlled trials, hyperh
receiving duloxetine hydrochloride at 60 mg twice daily, 6% of the 22
daily, compared 2% of the 223 subjects receiving placebo (Prod Info
d) In fibromyalgia placebo-controlled trials, hyperhidrosis was report
compared with 1% of patients receiving placebo (n=535) (Prod Info C
e) In clinical trials of all approved indications, hyperhidrosis was repo
with 2% of patients receiving placebo (n=3048), and was one of the r
CYMBALTA(R) delayed-release oral capsules, 2008).

3.3.2.A.2 Flushing

a) Incidence: 2% to 3% (Prod Info CYMBALTA(R) delayed-release o
b) In major depressive disorder and generalized anxiety disorder pla
patients receiving duloxetine hydrochloride compared with less than
CYMBALTA(R) delayed-release oral capsules, 2008).
c) In fibromyalgia placebo-controlled trials, hot flush was reported in
compared with 2% of patients receiving placebo (n=535) (Prod Info C

3.3.2.A.3 Pruritus

a) Incidence: 3% (Prod Info CYMBALTA(R) delayed-release oral cap
b) In fibromyalgia placebo-controlled trials, pruritus was reported in 3
compared with 2% of patients receiving placebo (n=535) (Prod Info C

3.3.2.A.4 Rash

a) Incidence: 4% (Prod Info CYMBALTA(R) delayed-release oral cap
b) In fibromyalgia placebo-controlled trials, rash was reported in 4%
compared with 2% of patients receiving placebo (n=535) (Prod Info C

3.3.3 Endocrine/Metabolic Effects

3.3.3.A Duloxetine Hydrochloride

Blood glucose abnormal

Hyponatremia

Syndrome of inappropriate antidiuretic hormone secretion

Weight loss

3.3.3.A.1 Blood glucose abnormal

a) Based on pooled data from three 12-week, double-blind, randomiz
week, open-label extension phase (n=867), duloxetine therapy was a
(FPG) among patients treated for diabetic peripheral neuropathy (DP
randomized to receive placebo (n=339) or duloxetine 60 mg once or
patients were then re-randomized in a 2:1 ratio during the extension p
investigator-driven routine care (n=287), such as gabapentin, venlafa
history of DPN, and more than 88% had type 2 diabetes mellitus. The
(mg/dL) (10.1 millimoles/liter (mmol/L)) and 7.8%, respectively. Dulox
with placebo during the acute phase (9 mg/dL (0.5 mmol/L) vs -2 mg/
routine care during the extension phase (12 mg/dL (0.67 mmol/L) vs
changes in HbA1C associated with duloxetine was significantly differ

vs 0.19%; p less than 0.001) (Hardy et al, 2007).

3.3.3.A.2 Hyponatremia

a) Summary

1) Hyponatremia has been associated with duloxetine therapy. S reported and were reversible upon duloxetine discontinuation. In syndrome of inappropriate antidiuretic hormone secretion (SIADI patients are at greater risk of hyponatremia. Discontinuation of d symptomatic hyponatremia (Prod Info CYMBALTA(R) delayed-re

b) Hyponatremia developed in 5 depressed patients after approxima duloxetine. The 5 patients (35 to 70 years old) had a history of recurr severe acute episode. Duloxetine was initiated at 30 mg/day followec was subsequently increased to 90 mg/day or 120 mg/day, after 3 to 4 medications were lorazepam and zopiclone. Serum osmolality, and s week after the dose increase, patients developed fatigue, lethargy, ar in all patients. Duloxetine was discontinued in 4 patients and the dose on water restriction (less than 1200 mL/day), and the intake of sodiur salt tablets in 2 patients. Symptoms of hyponatremia and serum sodi hyponatremia such as advanced age, thiazide diuretics, polypharmac insufficiency, hypothyroidism, tumors, respiratory disease, or acute c Lindstaedt, 2007).

c) In a case report, a 48-year-old woman developed syndrome of ina hyponatremia and seizures when administered duloxetine. The patier upon psychiatric evaluation was diagnosed with minor depression an days later, she developed 2 generalized seizures, was afebrile, coma analysis revealed serum sodium level of 103 mEq/L, and a BUN of 6 diagnosed with SIADH (urinary sodium 118 mEq/L, serum osmolality The patient was inadvertently rechallenged with duloxetine on days 3 levels 120 mEq/L on day 3, and 98 mEq/L on day 4) and she had 1 a 2 days the patient regained consciousness and was uneventfully disc

3.3.3.A.3 Syndrome of inappropriate antidiuretic hormone secretion

a) Hyponatremia has been associated with duloxetine therapy. Seru and were reversible upon duloxetine discontinuation. In many cases inappropriate antidiuretic hormone secretion (SIADH). The elderly, pa greater risk of hyponatremia. Discontinuation of duloxetine therapy sh hyponatremia (Prod Info CYMBALTA(R) delayed-release oral capsul

b) In a case report, a 48-year-old woman developed syndrome of ina hyponatremia and seizures when administered duloxetine. The patier upon psychiatric evaluation was diagnosed with minor depression an she developed 2 generalized seizures, was afebrile, comatose, and h revealed serum sodium level of 103 mEq/L, and a BUN of 6 mg/dL. D SIADH (urinary sodium 118 mEq/L, serum osmolality 215 mOsm/kg H inadvertently rechallenged with duloxetine on days 3 and 4, which rep on day 3, and 98 mEq/L on day 4) and she had 1 additional seizure. patient regained consciousness and was uneventfully discharged 7 d

3.3.3.A.4 Weight loss

a) Incidence: 2% (Prod Info CYMBALTA(R) delayed-release oral cap

b) In major depressive disorder and generalized anxiety disorder pla patients receiving duloxetine hydrochloride compared with less than with duloxetine hydrochloride for up to 10 weeks in clinical trials show placebo-treated patients showed a weight gain of approximately 0.2 k 2008).

c) In diabetic peripheral neuropathy placebo-controlled clinical trials, weeks experienced a mean weight loss of approximately 1.1 kg, com placebo-treated patients (Prod Info CYMBALTA(R) delayed-release c

d) In fibromyalgia placebo-controlled trials, patients receiving duloxe weight loss of approximately 0.4 kg compared with a mean weight ga Info CYMBALTA(R) delayed-release oral capsules, 2008).

3.3.4 Gastrointestinal Effects

3.3.4.A Duloxetine Hydrochloride

Constipation

Decrease in appetite

Diarrhea

Indigestion

Loose stool

Nausea

Taste sense altered

Vomiting

Xerostomia

3.3.4.A.1 Constipation

a) Incidence: 5% to 15% (Prod Info CYMBALTA(R) delayed-release
b) In major depressive disorder and generalized anxiety disorder pla
patients receiving duloxetine hydrochloride compared with 4% of the
delayed-release oral capsules, 2008).
c) In diabetic peripheral neuropathy placebo-controlled trials, constip
hydrochloride at 60 mg twice daily, 11% of the 228 patients at 60 mg
with 3% of the 223 subjects receiving placebo (Prod Info CYMBALTA
d) In fibromyalgia placebo-controlled trials, constipation was reporte
compared with 4% of patients receiving placebo (n=535) (Prod Info C
e) In clinical trials of all approved indications, constipation was repor
with 4% of patients receiving placebo (n=3048), and was one of the r
CYMBALTA(R) delayed-release oral capsules, 2008).

3.3.4.A.2 Decrease in appetite

a) In major depressive disorder and generalized anxiety disorder pla
occurred in 7% of the 2995 patients receiving duloxetine hydrochloric
(Prod Info CYMBALTA(R) delayed-release oral capsules, 2008).
b) In diabetic peripheral neuropathy placebo-controlled trials, decrea
patients receiving duloxetine hydrochloride at 60 mg twice daily, 7% c
20 mg daily, compared with less than 2% of the 223 subjects receivin
capsules, 2008).
c) In fibromyalgia placebo-controlled trials, decreased appetite (inclu
duloxetine hydrochloride (n=876) compared with 2% of patients recei
release oral capsules, 2008).
d) In clinical trials of all approved indications, decreased appetite (in
duloxetine (n=4843) compared with 2% of patients receiving placebo
adverse reactions (Prod Info CYMBALTA(R) delayed-release oral cap

3.3.4.A.3 Diarrhea

a) Incidence: 7% to 13% (Prod Info CYMBALTA(R) delayed-release
b) In major depressive disorder and generalized anxiety disorder pla
patients receiving duloxetine hydrochloride compared with 7% of the
delayed-release oral capsules, 2008).
c) In diabetic peripheral neuropathy placebo-controlled trials, diarrhe
hydrochloride at 60 mg twice daily, 11% of the 228 patients at 60 mg
with 6% of the 223 subjects receiving placebo (Prod Info CYMBALTA
d) In fibromyalgia placebo-controlled trials, diarrhea was reported in
compared with 8% of patients receiving placebo (n=535) (Prod Info C
e) In clinical trials of all approved indications, diarrhea was reported
7% of patients receiving placebo (n=3048) (Prod Info CYMBALTA(R)

3.3.4.A.4 Indigestion

a) Incidence: 4% to 5% (Prod Info CYMBALTA(R) delayed-release o
b) In diabetic peripheral neuropathy placebo-controlled trials, dyspep
hydrochloride at 60 mg twice daily, 4% of the 228 patients at 60 mg c
less than 3% of the 223 subjects receiving placebo (Prod Info CYMB

c) In fibromyalgia placebo-controlled trials, dyspepsia was reported i
compared with 3% of patients receiving placebo (n=535) (Prod Info C

3.3.4.A.5 Loose stool

a) Incidence: 2% to 3% (Prod Info CYMBALTA(R) delayed-release o
b) In diabetic peripheral neuropathy placebo-controlled trials, loose s
hydrochloride at 60 mg twice daily, 3% of the 228 patients at 60 mg c

hydrochloride at 60 mg twice daily, 8% of the 228 patients at 60 mg c
7% of the 223 subjects receiving placebo (Prod Info CYMBALTA(R) c
d) In fibromyalgia placebo-controlled trials, insomnia (including midd
reported in 16% of patients receiving duloxetine hydrochloride (n=876
(Prod Info CYMBALTA(R) delayed-release oral capsules, 2008).
e) In clinical trials of all approved indications, insomnia was reported
with 7% of patients receiving placebo (n=3048) (Prod Info CYMBALT

3.3.9.A.4 Restless legs syndrome

a) In a prospective, naturalistic study of patients (median age, 46 yea
271 (9%) subjects experienced new-onset restless leg syndrome (RL
treatment. Antidepressants included fluoxetine, paroxetine, citaloprar
and mirtazapine. Mirtazapine led to a marked decline of RLS in 28%
other antidepressants showed RLS symptoms (newly occurred or det
occurred early in treatment (median of 2.5 days, range 1 to 23 days)

3.3.9.A.5 Seizure

a) Incidence: 0.03% (Prod Info CYMBALTA(R) delayed-release oral
b) In placebo-controlled clinical trials, seizures occurred in 0.03% (3/
hydrochloride compared with 0.01% (1/6770) of patients receiving pla
surveillance reports (Prod Info CYMBALTA(R) delayed-release oral c
c) In a case report, a 48-year-old woman developed syndrome of ina
hyponatremia and seizures when administered duloxetine. The patier
upon psychiatric evaluation was diagnosed with minor depression an
she developed 2 generalized seizures, was afebrile, comatose, and h
revealed serum sodium level of 103 mEq/L, and a BUN of 6 mg/dL. D
SIADH (urinary sodium 118 mEq/L, serum osmolality 215 mOsm/kg h
inadvertently rechallenged with duloxetine on days 3 and 4, which rep
on day 3, and 98 mEq/L on day 4) and she had one additional seizur
patient regained consciousness and was uneventfully discharged 7 d

3.3.9.A.6 Somnolence

a) Incidence: 7% to 21% (Prod Info CYMBALTA(R) delayed-release
b) In major depressive disorder and generalized anxiety disorder pla
sedation) occurred in 10% of the 2995 patients receiving duloxetine h
placebo (Prod Info CYMBALTA(R) delayed-release oral capsules, 20
c) In diabetic peripheral neuropathy placebo-controlled trials, somno
hydrochloride at 60 mg twice daily, 15% of the 228 patients at 60 mg
with 5% of the 223 subjects receiving placebo. Somnolence led to dis
patients and none in the placebo-treated group (Prod Info CYMBALT
d) In fibromyalgia placebo-controlled trials, somnolence (including hy
receiving duloxetine hydrochloride (n=876) compared with 3% of pati
delayed-release oral capsules, 2008).
e) In clinical trials of all approved indications, somnolence (including
receiving duloxetine (n=4843) compared with 3% of patients receiving
reported adverse reactions (Prod Info CYMBALTA(R) delayed-releas

3.3.9.A.7 Tremor

a) Incidence: up to 5% (Prod Info CYMBALTA(R) delayed-release or
b) In major depressive disorder and generalized anxiety disorder pla
patients receiving duloxetine hydrochloride compared with less than
CYMBALTA(R) delayed-release oral capsules, 2008).
c) In diabetic peripheral neuropathy placebo-controlled trials, tremor
hydrochloride at 60 mg twice daily, 1% of the 228 patients at 60 mg c
0% of the 223 subjects receiving placebo (Prod Info CYMBALTA(R) c
d) In fibromyalgia placebo-controlled trials, tremor was reported in 4
compared with 1% of patients receiving placebo (n=535) (Prod Info C

3.3.9.A.8 Vertigo

a) Incidence: 1% or greater (Prod Info CYMBALTA(R) delayed-relea
b) Vertigo has been reported in 1% or greater of patients receiving d
indications (n=27,229) (Prod Info CYMBALTA(R) delayed-release ora

3.3.10 Ophthalmic Effects

3.3.10.A Duloxetine Hydrochloride

Blurred vision

Mydriasis

3.3.10.A.1 Blurred vision

a) Incidence: 1% or greater (Prod Info CYMBALTA(R) delayed-relea
b) In major depressive disorder and generalized anxiety disorder pla
patients receiving duloxetine hydrochloride compared with 2% of the
delayed-release oral capsules, 2008).
c) In placebo-controlled trials, blurred vision was reported in 2% of fi
compared with 1% of patients receiving placebo (n=535) (Prod Info C
d) Blurred vision has been reported in 1% or greater of patients (n=2
all indications (Prod Info CYMBALTA(R) delayed-release oral capsule

3.3.10.A.2 Mydriasis

a) In clinical trials, duloxetine hydrochloride has been associated witl uncontrolled narrow-angle glaucoma and should be used cautiously i delayed-release oral capsules, 2008).

3.3.12 Psychiatric Effects

3.3.12.A Duloxetine Hydrochloride

Agitation

Anxiety

Bipolar disorder, Rapid cycling induction

Depression, worsening

Dream disorder

Posttraumatic stress disorder, exacerbation of symptoms

Suicidal thoughts

3.3.12.A.1 Agitation

a) Incidence: 5% to 6% (Prod Info CYMBALTA(R) delayed-release o
b) In major depressive disorder and generalized anxiety disorder pla nervousness, restlessness, tension, and psychomotor agitation) occu hydrochloride compared with 3% of the 1955 subjects receiving place 2009).
c) In placebo-controlled trials, agitation (including feeling jittery, nerv was reported in 6% of fibromyalgia patients receiving duloxetine hydr placebo (n=535) (Prod Info CYMBALTA(R) delayed-release oral caps

3.3.12.A.2 Anxiety

a) Incidence: 3% (Prod Info CYMBALTA(R) delayed-release oral cap
b) In major depressive disorder and generalized anxiety disorder pla patients receiving duloxetine hydrochloride compared with 2% of the delayed-release oral capsules, 2009).

3.3.12.A.3 Bipolar disorder, Rapid cycling induction

a) A 17-year-old female (weight 45 kg) with bipolar disorder experier starting duloxetine. Significant medical history included a depressive medications were oral sodium valproate 400 mg/day and oral olanzap became depressed without reason, with signs of sadness, frequent c and would not do any work. She was started on oral duloxetine 20 m excessively, was euphoric, had assertions of high intelligence and ab aggressive and abusive behavior. It was subsequently noticed that ab euphoria and depression. Duloxetine was stopped, the dose of sodiu olanzapine was maintained at 10 mg/day. At week 4 follow-up, her m depressive symptoms (Desarkar et al, 2007).

3.3.12.A.4 Depression, worsening

a) Clinical worsening of depression has been reported in patients rec months of treatment and during dose adjustments. It may persist unti antidepressants for any indication should be monitored for signs of cl capsules, 2009).

3.3.12.A.5 Dream disorder

a) Incidence: 2% to 3% (Prod Info CYMBALTA(R) delayed-release o
b) In major depressive disorder and generalized anxiety disorder pla occurred in 2% of the 2995 patients receiving duloxetine hydrochloric (Prod Info CYMBALTA(R) delayed-release oral capsules, 2009).
c) In placebo-controlled trials, abnormal dreams (including nightmare duloxetine hydrochloride (n=876) compared with 1% of patients recei

release oral capsules, 2009).

3.3.12.A.6 Posttraumatic stress disorder, exacerbation of symptom

a) In a case report, a 53-year-old Vietnam veteran with post- traumat depression experienced severe exacerbation of PTSD symptoms. Th propranolol, and risperidone. Within 1 week of beginning duloxetine 6 Vietnam, nightmares, emotional numbing, increased startle response Decreasing his duloxetine dose to 30 mg per day lessened the PTSD did the symptoms return to baseline (Deneys & Ahearn, 2006).

3.3.12.A.7 Suicidal thoughts

a) Adult and pediatric patients being treated with antidepressants for anxiety, agitation, panic attacks, insomnia, irritability, hostility (aggres hypomania, or mania may be at risk of suicidal ideation and behavior with other psychiatric and nonpsychiatric disorders. If these symptom necessary to discontinue medications when symptoms are severe, su symptoms. Patients and their caregivers should be provided with the patients especially during the initial few months of therapy or at times oral capsules, 2009).

b) A causal role for antidepressants in inducing suicidality has been antidepressants in a child or adolescent must balance this risk with th controlled trials of nine antidepressants (citalopram, fluoxetine, fluvox nefazodone, and venlafaxine extended-release) including over 4400 obsessive compulsive disorder (OCD), or other psychiatric disorders, few months of therapy was demonstrated in patients receiving antide suicidality was most consistently observed in the trials that included p trials in other psychiatric indications, such as obsessive compulsive d

1) In a pooled analyses of placebo-controlled trials in adults with trials (median duration of 2 months) of 11 antidepressant drugs i among the drugs studied. However, for almost all drugs studied, patients. The risk difference (drug versus placebo in the number additional cases in patients less than 18 years of age, 5 addition to 64 years, and 6 fewer cases in patients 65 years and older. No the adult trials; however, the number of suicides was insufficient use (ie, beyond several months) in pediatric patients is not know maintenance trials in adults with depression to substantiate a del (Prod Info LEXAPRO(R) Oral solution, Oral tablets, 2009; Anon,

3.3.13 Renal Effects

3.3.13.A Duloxetine Hydrochloride

Delay when starting to pass urine

Increased frequency of urination

Urinary retention

3.3.13.A.1 Delay when starting to pass urine

a) Urinary hesitation has been associated with the use of selective s Info CYMBALTA(R) delayed-release oral capsules, 2008).

3.3.13.A.2 Increased frequency of urination

a) Incidence: 1% to 5% (Prod Info CYMBALTA(R) delayed-release o

b) In diabetic peripheral neuropathy placebo-controlled trials, pollaki hydrochloride at 60 mg twice daily, 1% of the 228 patients at 60 mg d of the 223 subjects receiving placebo (Prod Info CYMBALTA(R) dela

3.3.13.A.3 Urinary retention

a) Urethral retention has been associated with the use of selective s During postmarketing surveillance of duloxetine, cases of urinary rete reported (Prod Info CYMBALTA(R) delayed-release oral capsules, 20

3.3.14 Reproductive Effects

3.3.14.A Duloxetine Hydrochloride

Abnormal ejaculation

Erectile dysfunction

Late ejaculation

Orgasm disorder

Reduced libido

3.3.14.A.1 Abnormal ejaculation

a) Incidence: 2% to 4% (Prod Info CYMBALTA(R) delayed-release o
b) In major depressive disorder and generalized anxiety disorder pla
failure and ejaculation dysfunction) occurred in 2% of the male patien
1% of the male patients receiving placebo (Prod Info CYMBALTA(R)

a) Incidence: 7% (Prod Info CYMBALTA(R) delayed-release oral cap
b) In fibromyalgia placebo-controlled trials, upper respiratory tract inf
hydrochloride (n=876) compared with 6% of patients receiving placeb
capsules, 2008).

3.3.16 Other

3.3.16.A Duloxetine Hydrochloride

Fatigue

Fever

Serotonin syndrome

Withdrawal sign or symptom

3.3.16.A.1 Fatigue

a) Incidence: 2% to 15% (Prod Info CYMBALTA(R) delayed-release
b) In major depressive disorder and generalized anxiety disorder pla
10% of the 2995 patients receiving duloxetine hydrochloride compare
CYMBALTA(R) delayed-release oral capsules, 2008).
c) In diabetic peripheral neuropathy placebo-controlled trials, fatigue
hydrochloride at 60 mg twice daily, 10% of the 228 patients at 60 mg
with 5% of the 223 subjects receiving placebo. Fatigue led to disconti
none in the placebo-treated group (Prod Info CYMBALTA(R) delayed
d) In fibromyalgia placebo-controlled trials, fatigue (including astheni
hydrochloride (n=876) compared with 8% of patients receiving placeb
capsules, 2008).
e) In clinical trials of all approved indications, fatigue was reported in
6% of patients receiving placebo (n=3048) (Prod Info CYMBALTA(R)

3.3.16.A.2 Fever

a) Incidence: 1% to 3% (Prod Info CYMBALTA(R) delayed-release o

b) In diabetic peripheral neuropathy placebo-controlled trials, pyrexia hydrochloride at 60 mg twice daily, 1% of the 228 patients at 60 mg c 1% of the 223 subjects receiving placebo (Prod Info CYMBALTA(R) c

3.3.16.A.3 Serotonin syndrome

a) Serotonin syndrome, including life-threatening cases, or neurolept reported with the use of duloxetine alone. Signs and symptoms of ser hallucination, coma), autonomic instability (eg, tachycardia, labile blo hyperreflexia, incoordination) and/or gastrointestinal symptoms (eg, r resemble NMS with symptoms including hyperthermia, muscle rigidity signs, and mental status changes. Serotonin syndrome occurs most c including triptans, with drugs that impair metabolism of serotonin, incl antagonists (Prod Info Cymbalta(R) Delayed-release oral capsules, 2

3.3.16.A.4 Withdrawal sign or symptom

a) Incidence: 1% or greater (Prod Info CYMBALTA(R) delayed-relea

b) In clinical trials, abrupt discontinuation of duloxetine resulted in 1% dizziness, nausea, headache, fatigue, paresthesia, vomiting, irritabilit vertigo compared with patients discontinuing placebo. During marketi (SNRIs), reports of dysphoric mood, irritability, agitation, dizziness, se headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, limiting, however some have been severe. All patients should be mor should be gradually tapered. If intolerable symptoms occur, treatmen instituting a more gradual decrease in dose (Prod Info CYMBALTA(R

c) In a pooled analysis of 9 clinical trials divided into three categories duloxetine n=490, placebo n=380), 2 long-term placebo-controlled (3 open-label study (52 weeks; duloxetine n=553), discontinuation-emer therapy was abruptly stopped. Patients experiencing at least one DE 22.9% placebo), 9.1% (versus 2% placebo) and 50% (open-label), re common DEAE was dizziness reported in 12.4% (vs. 0.8% placebo), respectively, followed by nausea (5.9% (vs 0.3% placebo), 0.8% (vs 0.8% placebo), 0.8% (vs 0% placebo), and 7.2% (open-label)). Patier moderate in severity, and incidence and severity was not affected by DEAEs resolved by study end with 68.2%, 47.1% and 63.7% resolvin placebo-controlled, and long-term open-label studies, respectively. Th less than 2 weeks prior to discontinuation of duloxetine therapy (Pera

d) Small increases in heart rate and sleep disturbances (insomnia, a discontinuation of multiple-dose administration in healthy subjects (SI relatively high (20 to 40 mg twice daily). Withdrawal data following on patients are unavailable.

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Pro (All Trimesters)

a) Either studies in animals have revealed adverse effects on the fetus (te studies in women or studies in women and animals are not available. Dru potential risk to the fetus.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

2) Crosses Placenta: Unknown

3) Clinical Management

a) Due to the lack of adequate, well-controlled studies in pregnant women only if the potential benefit outweighs the potential risk to the fetus. Becau SSRI- and SNRI-exposed neonates late in the third trimester, the potentia should be taken into account. Tapering duloxetine may be considered in p CYMBALTA(R) delayed-release oral capsules, 2008).

4) Literature Reports

a) Neonates exposed to serotonin and norepinephrine reuptake inhibitors complications necessitating extended hospitalization, respiratory support, upon delivery. Respiratory distress, cyanosis, apnea, seizures, temperatu hypotonia, hyperreflexia, tremor, jitteriness, irritability, and constant crying of a toxic effect of the drug or a drug discontinuation syndrome. In some c syndrome (Prod Info CYMBALTA(R) delayed-release oral capsules, 2008

b) There are no adequate and well-controlled studies with duloxetine in p studies of rats and rabbits treated with oral duloxetine up to 45 mg/kg/day recommended human dose [MRHD; 60 mg/day] on a mg/m(2) basis for ra decreased. When pregnant rats were treated with duloxetine 30 mg/kg/da

weights decreased, and the incidence of stillborn pups and pup mortality i
mg/kg/day (2 times the MRHD). Maternal exposure to 30 mg/kg/day also
and decreased habituation of locomotor activity) (Prod Info CYMBALTA(F

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inade
breastfeeding. Weigh the potential benefits of drug treatment against pote

2) Clinical Management

a) Duloxetine is excreted in human breast milk at approximately 0.14% o
adverse effects in the nursing infant from exposure to the drug are unkno
(Prod Info CYMBALTA(R) delayed-release oral capsules, 2008; Lobo et a
outweigh the potential risk to the infant and duloxetine is administered to
closely for adverse effects (Lobo et al, 2008)

3) Literature Reports

a) Duloxetine was found in human breast milk during a study of 6 lactatin
weeks postpartum), who received duloxetine 40 mg twice daily for 3.5 da
mcg/day (range, 4 to 15 mcg/day). The estimated daily infant dose was 2
approximately 0.14% (maximum 0.25%) of the maternal dose. The mean
0.25 (95% CI, 0.18 to 0.35). Excretion of duloxetine metabolites into brea

cause elevated plasma concentrations of the antiarrhythmic (Prod Info CY
class IC antiarrhythmic serum concentrations and ECG for signs of potent
hypotension); adjust dose accordingly. Alternatively, consider selecting ar
pharmacokinetics of class IC antiarrhythmic agents.
7) Probable Mechanism: inhibition of CYP2D6-mediated metabolism of c

3.5.1.EJ Reviparin

1) Interaction Effect: increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for mainta that the combined use of selective serotonin and norepinephrine reuptake associated with an increased risk of bleeding. Bleeding events reported h life-threatening hemorrhages. A population-based, case-controlled study with concomitant selective serotonin reuptake inhibitors (SSRIs) resulted bleeding (Schalekamp et al, 2008). Altered anticoagulant effects (includin coadministration of serotonin and norepinephrine reuptake inhibitors with release oral capsules, 2008). Conversely, one case report described a pe dose in a patient maintained on acenocoumarol (Monastero et al, 2007).

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: When duloxetine and an anticoagulant are giver Patients who are taking warfarin should be monitored closely for altered a duloxetine therapy is initiated or discontinued (Prod Info CYMBALTA(R) d

7) Probable Mechanism: unknown

8) Literature Reports

a) A population-based, case-controlled study of new coumarin users selective serotonin reuptake inhibitors (SSRIs) resulted in an increas Using national pharmacy and hospitalization records, Netherlands re abnormal bleeding and compared them with 5818 control subjects al was 220 days (range, 1 to 4690 days). Patients on SSRIs showed gr (adjusted odds ratio (OR) 1.7, 95% confidence interval (CI), 1.1 to 2.5 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et

b) A case report describes a 44-year-old female patient maintained after 55 days of concomitant duloxetine treatment. Warfarin was initia medication regimen included atorvastatin 10 mg, warfarin 7.5 mg to 1 mg, and albuterol extended-release 4 mg twice a day. Duloxetine 30 day 58, only the warfarin was discontinued, and by day 85 the patien mcg/mL (therapeutic range 2 to 8 mcg/mL). Intravenous vitamin K 10 the INR was again elevated at 6.4, vitamin K-dependent clotting facto normal. Duloxetine was then discontinued, and 4 days later the INR r to 54%. INR was 0.9 by day 105, and warfarin was restarted on day maintained on 7.5 to 10 mg/day. According to the Naranjo algorithm, probable. The authors suggest that duloxetine may have an effect on warfarin from its protein-binding sites, or may have unique metabolic

c) A 63-year-old woman successfully maintained on acenocoumarol mechanical, prosthetic mitral-valve substitution experienced a persist mg/day. Ten hours after taking duloxetine, the patient was taken to th blood pressure had increased to 190/110 mmHg and her INR had dra administered intravenously for the headache and hypertension, dulox titrated to 12 mg/wk. Twenty-one days later, the INR returned to base Follow-up examinations on days 28, 56, 84, 168, and 252 revealed st family interviews discounted the possibility of acenocoumarol self-into measured and the patient was not genotyped for CYP2D6 or CYP1A duloxetine was deemed as probable based on the Naranjo Adverse D

3.5.1.EK Rizatriptan

1) Interaction Effect: increased risk of serotonin syndrome

2) Summary: A life-threatening condition known as serotonin syndrome m combination with a serotonin and norepinephrine reuptake inhibitor (SNRI include restlessness, hallucinations, loss of coordination, fast heart beat, overreactive reflexes, nausea, vomiting, and diarrhea. Clinicians should b that either the triptan or the SNRI may be prescribed by a different physici are prescribed this combination and monitor them closely for symptoms o dose increases (Prod Info CYMBALTA(R) delayed-release oral capsules,

3) Severity: major

4) Onset: unspecified

Possible Side Effects While Using This Medicine:

Call your doctor right away if you notice any of these side effects:

Allergic reaction: Itching or hives, swelling in your face or hands, swelling
breathing.
Aggression, anxiety, anger, or hostility.
Dark-colored urine or pale stools.
Extreme sleepiness or drowsiness.
Fast or uneven heartbeat, or dizziness.
Feeling confused, nervous, restless, or clumsy.
Lightheadedness or fainting.
Muscle spasms, twitching, or stiffness.
Nausea, vomiting, loss of appetite, or pain in your stomach.
Panic attacks, tremors, or feeling irritable.
Severe nausea or diarrhea.
Unexplained fever, sweating, or shivering.
Unusual behavior, or thoughts about hurting yourself.
Unusual bleeding or bruising.
Unusual tiredness or weakness.
Yellowing of your skin or the whites of your eyes.

If you notice these less serious side effects, talk with your doctor:

Blurred vision.
Cough, sore throat, or runny or stuffy nose.
Dry mouth, constipation, upset stomach, or mild nausea or diarrhea.
Feeling tired, or having trouble sleeping.
Headache.
Increased sweating.
Problems with sex, or loss of interest in sex.
Problems with urination.
Skin rash.
Weight loss.

If you notice other side effects that you think are caused by this medicine, tell

4.3 Place In Therapy

A) Duloxetine Hydrochloride

1) Depression

a) Duloxetine hydrochloride is indicated for the acute and maintenance tr
and venlafaxine, duloxetine is a serotonin/norepinephrine reuptake inhibit
capsules, 2008). These agents are claimed to be at least as effective as t

selective serotonin reuptake inhibitors (SSRIs). The primary role of SNRIs who have responded poorly to other agents (eg, tricyclics or SSRIs).

b) At present, duloxetine is not recommended over other available SNRIs

2) Diabetic Peripheral Neuropathic Pain

a) Duloxetine is indicated for the treatment of neuropathic pain associate release oral capsules, 2008). At doses of either 60 milligrams (mg) once c neuropathic pain compared to placebo in randomized, double-blind, phas between the once-daily and twice-daily dose, the once-daily dose was bet al, 2005; Raskin et al, 2005).

3) Generalized Anxiety Disorder

a) Duloxetine is effective for the treatment of generalized anxiety disorde Info CYMBALTA(R) delayed-release oral capsules, 2008). If duloxetine tre should periodically monitor their patients for long-term effectiveness (Proc multicenter, randomized, double-blind trial (n=487), monotherapy with dul comparable efficacy to extended-release venlafaxine 77 to 225 mg/day ar generalized anxiety disorder (Hartford et al, 2007).

4) Fibromyalgia

a) Duloxetine is indicated for the management of fibromyalgia (Prod Info was established in several randomized, placebo-controlled, double-blind t or women alone. In a 12-week, randomized, double-blind, placebo-contro was effective and safe in the treatment of fibromyalgia in female patients 2005). In another randomized, double- blind trial (n=207) trial, a 12-week fibromyalgia compared with placebo, and women were affected to signific reduction in pain severity seen at 3 months following treatment with oral d another multicenter, randomized, double-blind, placebo-controlled trial (n=

4.4 Mechanism of Action / Pharmacology

A) Duloxetine Hydrochloride

1) Mechanism of Action

a) Duloxetine is a dual-selective serotonin (5HT) and norepinephrine reup unrelated, the mechanism and pharmacodynamic characteristics of duloxe (Artigas, 1995; Pinder, 1997; Sharma et al, 2000). Duloxetine is the (+)-is structural similarity to fluoxetine and tomoxetine.

b) Duloxetine is a secondary amine, whereas venlafaxine and milnacipra to inhibit norepinephrine and 5HT uptake in preclinical studies; both dulox norepinephrine reuptake, whereas milnacipran was a more potent inhibito Duloxetine has exhibited higher potency at both reuptake sites than milna Goodnick, 1999). In vitro, duloxetine has not shown significant affinity for 5HT-1A, 5HT-1B, 5HT-1D, 5HT-2A, 5HT-2C, or opioid receptors (Artigas,

c) The in vitro activity of antidepressants has not always been predictive duloxetine compared to venlafaxine may not imply greater clinical efficacy duloxetine in inhibiting 5HT and norepinephrine reuptake (Wong et al, 19 serotonin/norepinephrine reuptake inhibitors (SNRIs) are essential to dete

d) Duloxetine has increased neural sphincter activity and bladder capacit has been investigated in urinary incontinence.

2) Review Articles

a) A review of the pharmacology, pharmacokinetic profile, and clinical eff al, 2005).

b) Advances in the treatment of depression, including duloxetine (Leonar

c) Mechanisms, pharmacology, pharmacokinetics, and clinical efficacy of

minutes; p=0.002). Quality of life, as measured on a scale of 0 (l
Quality of Life Questionnaire, increased more in duloxetine patie
95% CI of difference between groups, 1.36 to 6.31; p=0.002), an
much better" or "much better" according to the Patient Global Im
subjects (p=0.001). A significantly greater number of placebo pat
patients (78%), with adverse effects being the most common rea
(TEAEs) occurred in 61.3% of duloxetine subjects vs 44.8% of pl
common complaint in both groups (18% vs 4.5%, respectively; p
duloxetine patients and at a rate greater than 5% included dry m
(6.7%) (Bent et al, 2008).

2) Stress Urinary Incontinence

a) The Duloxetine Efficacy and Safety for Incontinence in Racial
label, multicenter study, demonstrated non-inferiority efficacy in A
receiving duloxetine for stress urinary incontinence compared to
and Hispanic women with characteristics similar to Caucasian w
older, at least 7 incontinence episodes per week at baseline, and
included in the study. Baseline characteristics of patients in the A
and Hispanic (mean age, 47.4 years; range, 20-86 years) subgro
years; range, 18-97 years) were significantly different ($p < 0.05$)
Incontinence Quality of Life (I-QOL) and Patient Global Impressi
number of pads used per week. All patients received duloxetine
week lead-in period. Non-inferiority efficacy was determined by c
episode frequency in the African-American and Hispanic subgrou
treatment. All three subgroups had significant improvement ($p <$
baseline (African-American group, 7 versus (vs) 21 episodes/we
Caucasian group, 5 vs 19.25 episodes/week (-75%)). Additionall
less than 0.001) in quality of life questionnaire scores after treatr
scale (African-American group, 71.5 vs 51.7 points; Hispanic gro
and the Patient Global Impression of Improvement (African-Ame
Caucasian group, 66.6% improved); however, significantly less (
reduction in incontinence episode frequency compared with Cau
of patients completed the study, and the most common reason fo
common adverse event occurring in 21.8 to 28% of patients and
(African-American group, 6.6%; Hispanic group, 5.7%; Caucasia
(p less than 0.05) in Hispanic patients compared to Caucasian p
7.4%), and somnolence (12.2% vs 7%) (Weinstein et al, 2006).

b) Incontinence episode frequency (IEF) was reduced following
urinary incontinence in a randomized, double-blind, placebo-con
urinary incontinence of at least 3 months duration and experienc
duloxetine 40 milligrams twice daily or placebo for 12 weeks. The
than half of patients averaged two or more episodes daily. From
in the duloxetine group as compared with the placebo group (per
this effect was even stronger in patients with a baseline IEF of 14
respectively; p=0.022). In addition, the average voiding interval i
compared with those who received placebo (20.4 vs 8.5 minutes
patients in the duloxetine group also showed greater improveme
questionnaire as compared with patients in the placebo group (m
were significantly more frequent with duloxetine treatment than v
and resulted in significantly higher discontinuation rates in the du
respectively; p less than 0.001). In duloxetine-treated patients, th

headache (14.5%), insomnia (13.7%), constipation (12.8%), dry
(8.4%), anorexia (6.6%), vomiting (6.2%), and increased sweatin
c) Duloxetine was effective in the treatment of stress urinary inc
blind, placebo-controlled, multicenter trial. Women (n=683) 22 to
experiencing 7 or more episodes weekly received duloxetine 80
Incontinence episode frequency decreased by 50% to 100% in 5
placebo-treated patients (p less than 0.001). Mean improvement
score was also significantly better for patients in the duloxetine g
respectively; p less than 0.001). Adverse events occurred more f
24.1% vs 4.1%; p less than 0.001) and included nausea (22.7%)
constipation (9.6%), somnolence (8.7%), dizziness (7.6%), head

4.6 Comparative Efficacy / Evaluation With Other Therapies

Escitalopram

Paroxetine

Venlafaxine

4.6.A Escitalopram

4.6.A.1 Major depressive disorder

a) In an 8-week randomized, double-blind, placebo- and active-comparat
(n=684) with major depressive disorder (MDD), onset of efficacy for dulox
escitalopram 10 mg daily, and patients in both active treatment groups we
Patients aged 18 years or older (range, 18 to 79 years), meeting the DSM
Depression Rating Scale (MADRS) total score of 22 or greater and a Clini
greater were included. Patients were randomized to receive either duloxe
Hamilton Rating Scale for Depression (HAMD) Maier subscale score, 17.6
mean baseline HAMD score, 17.8), or placebo (n=137; mean age, 42.5 ye
acute treatment period. Onset of efficacy (primary endpoint) was defined a
week 2 that was sustained for the remainder of the acute treatment period
efficacy onset criteria was similar in the duloxetine and escitalopram grou
confidence interval (CI), -1.3% to 16.2%; p=0.097), and patients in both gr
placebo patients (21.5%; duloxetine vs placebo, p less than 0.001; escital
escitalopram was maintained following a per-protocol analysis. In an anal
were pooled, a significantly greater proportion of duloxetine patients achie
greater proportion of patients in both active treatment groups achieved eff
0.018 for both). The median time to onset was significantly shorter among
placebo-treated patients (23 days vs 41 days vs 55 days, respectively; du
less than 0.001), and median time to onset did not differ between escitalo
achieving a treatment response (secondary endpoint) by week 8, defined
similar among the duloxetine (48.7%), escitalopram (45.3%), and placebo
score of 7 or less) also did not differ between the groups (40.1% vs 33% v
complete the study were evenly distributed among the groups, and a simil
effects. Nausea more commonly caused discontinuation among duloxetin
respectively; p=0.02). Both nausea and dry mouth occurred more often in
patients and at a rate greater than 10% (nausea, 23.8% vs 12% vs 8.8%;
Although this study focused on the acute 8-week treatment period, subjec
for an additional 6 months (Nierenberg et al, 2007). During the 6-month ex
mg/day and the escitalopram dose ranged from 10 to 20 mg/day; placebo
assigned in a double-blind fashion to active treatment. Among the 431 pa
no significant differences in antidepressant efficacy between the duloxetin
probability of remission was 70% and 75% among the duloxetine and esc
significant difference between the groups was on the HAMD sleep subsca
improvement in insomnia than duloxetine-treated patients (mean change
discontinuation rates over the 8-month study were higher in the duloxetine
discontinuation due to adverse events were similar (12.8% vs 12%, respe
b) In a randomized, double-blind, fixed-dose, noninferiority trial (n=294), a
for the long term treatment of major depressive disorder (MDD), escitalop
outpatients aged 18 to 73 years old with MDD according to the DSM-IV (T
Rating Scale (MADRS) total score of 26 or greater, and with a Clinical Glo
were included. With the exception of obsessive-compulsive disorder, post

secondary, current, comorbid anxiety disorder were included. Study patie
(n=151) or escitalopram 20 mg (initial dose, 10 mg/day; increased after 2
MADRS scores were 32.1 +/- 4.4 and 32.5 +/- 4.3 in the duloxetine and es
study, the mean change from baseline in MADRS score in the intent-to-tre
duloxetine were -23.4 and -21.7, respectively (p=0.055). Based on a per-p
(escitalopram minus duloxetine) in MADRS scores at 24 weeks was 0.67
which met the prespecified noninferiority criteria (ie, upper limit of the one
escitalopram was evident (ie, upper limit of the one-sided CI did not inclu
treatment differences of 2.54 (95% CI, p=0.011) and 2.21 (p=0.027), resp
81.6% (n=115) of escitalopram-treated patients were considered to be res
total score) compared with 73% (n=112) of duloxetine-treated patients. An
effective than duloxetine in CGI-I (p=0.039) score reduction from baseline
duloxetine in the Sheehan Disability Scale (SDS) work score reduction at
less than 0.05 for all). Significantly more patients on duloxetine reported in
compared to escitalopram, with almost twice the withdrawal rate due to ad
0.05) (Wade et al, 2007).

4.6.B Paroxetine

4.6.B.1 Major depressive disorder

a) Duloxetine therapy was more effective than placebo and non-inferior to
physical symptoms of depression. In a randomized, double-blind, placebo
depressive disorder, a Hamilton Depression Rating Scale (HAM-D) total s
(CGI) Severity rating (score of at least 4) received oral duloxetine 80 millig
divided doses), paroxetine 20 mg daily, or placebo for 8 weeks. Response
HAM-D total score and remission was defined as a HAM-D score of 7 or l
duloxetine produced significantly greater reductions in HAM-D scores fror
points, 95% CI 1.38, 5.86; p=0.002 and 2.34 points, 95% CI 0.19, 4.66; p=
D total scores was also observed with duloxetine 80 mg therapy as compa
95% CI 0.14, 4.65; p=0.037). Paroxetine therapy was not significantly diffe
paroxetine treatment was superior to placebo. The response rate at endpo
80 mg as compared with placebo (51% vs 31%, p=0.009, respectively). A
(50%) was significantly higher at endpoint as compared with remission rat
and the placebo group (30%; p=0.008), but was not superior to patients in
baseline to endpoint in overall pain severity were observed in patients trea
points on VAS scale, 95%CI -25, 1; p=0.005), as compared with placebo,
or duloxetine 40 mg therapy as compared with placebo. Both duloxetine a
was reported significantly more often in duloxetine-treated (80 mg) patient
respectively; p=0.031) (Goldstein et al, 2004).

4.6.C Venlafaxine

4.6.C.1 Major depressive disorder

a) A meta-analysis of published, peer-reviewed, randomized, placebo-co
venlafaxine extended-release (XR) are significantly superior compared to
disorder and although there was a trend in favor of venlafaxine XR the dif
to duloxetine. A systematic literature search of Cochrane, EMBASE, and
independent reviewers. Data was obtained from 8 trials to evaluate efficac
a one week placebo lead-in period followed by either duloxetine 40 to 120
day for a minimum of 8 weeks. The primary outcomes were remission and
the Hamilton Rating Scale for Depression (HAM-D) score to less than or e
(MADRS) score of less than or equal to 10. Response was defined as an
MADRS scores. The secondary outcomes evaluated were dropout rates a
improved for duloxetine and venlafaxine XR and were statistically significa
difference was found for remission and response rates when duloxetine a
had a higher dropout rate due to lack of efficacy compared to those patien
0.001). More patients in the active drug treatment groups dropped out due
venlafaxine XR p less than 0.001). Again, when duloxetine and venlafaxin
were found for dropout rates due to lack of efficacy or adverse drug reacti
drugs. A sensitivity analysis was also performed and included 2 additional
with comorbid anxiety and one study for duloxetine dealing with patients v
results with both drugs having a statistically significant difference from pla

DRUGDEX® Evaluations

VALPROIC ACID

0.0 Overview

1) Class

a) This drug is a member of the following class(es):

Anticonvulsant
Antimanic
Antimigraine
Valproic Acid (class)

2) Dosing Information

a) Valproic Acid

1) Adult

a) Absence seizure, Simple and complex

1) initial, 15 mg/kg/day ORALLY (give in 2 to 3 divided doses if total daily dose exceeds 250 mg) (Prod I (R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008)

2) maintenance, may increase dosage 5 to 10 mg/kg/day ORALLY at one week intervals until seizures a side effects preclude further increases (give in 2 to 3 divided doses if total daily dose exceeds 250 mg)(M or less with a therapeutic serum range of 50 to 100 mcg/mL) (Prod Info DEPAKENE(R) oral capsules, or Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Complex partial epileptic seizure

1) monotherapy, initial 10 to 15 mg/kg/day ORALLY (give in 2 to 3 divided doses if total daily dose exce increase dosage 5 to 10 mg/kg/week to achieve optimal clinical response (MAX 60 mg/kg/day or less wit serum range of 50 to 100 mcg/mL) (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info delayed release oral capsules, 2008)

2) conversion to monotherapy, 10 to 15 mg/kg/day ORALLY (give in 2 to 3 divided doses if total daily do mg), may increase dosage 5 to 10 mg/kg/week to achieve optimal clinical response (MAX 60 mg/kg/day therapeutic serum range of 50 to 100 mcg/mL); reduce concomitant antiepilepsy drug dosage by approxi 2 weeks (reduction may be started at initiation of therapy or delayed by 1 to 2 weeks if there is a concern likely to occur with a reduction) (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STA release oral capsules, 2008)

3) adjunct, may be added to the patient's regimen at an initial dosage of 10 to 15 mg/kg/day ORALLY (g divided doses if total daily dose exceeds 250 mg), may increase dosage 5 to 10 mg/kg/week to achieve response (MAX 60 mg/kg/day or less with a therapeutic serum range of 50 to 100 mcg/mL) (Prod Info DE capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008)

c) Manic bipolar I disorder

1) initial, delayed-release 750 mg ORALLY daily, in divided doses; may increase dose to achieve desire or desired range of plasma concentrations (MAX 60 mg/kg/day or less with a therapeutic serum range of mcg/mL) (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

d) Migraine; Prophylaxis

1) delayed-release 250 mg ORALLY twice daily; MAX dose 1000 mg/day (Prod Info STAVZOR(R) delay capsules, 2008)

e) Seizure, Multiple seizure types; Adjunct

1) 10 to 15 mg/kg/day ORALLY (give in 2 to 3 divided doses if total daily dose exceeds 250 mg), may in to 10 mg/kg/week to achieve optimal clinical response (MAX 60 mg/kg/day or less with a therapeutic ser 100 mcg/mL) (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed capsules, 2008)

2) Pediatric

a) increased risk of fatal hepatotoxicity in patients under the age of 2 years (Prod Info DEPAKENE(R) oral ca 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) safety and efficacy of delayed-release valproic acid (Stavzor(R)) for the treatment of acute mania associat disorder and for migraine prophylaxis have not been established in pediatric patients (Prod Info STAVZOR(R oral capsules, 2008)

1) Absence seizure, Simple and complex

a) (10 yr and older) initial, 15 mg/kg/day ORALLY (give in 2 to 3 divided doses if total daily dose exc (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release 2008)

b) (10 yr and older) maintenance, may increase dosage 5 to 10 mg/kg/day ORALLY at one week in seizures are controlled or side effects preclude further increases (give in 2 to 3 divided doses if total exceeds 250 mg)(MAX 60 mg/kg/day or less with a therapeutic serum range of 50 to 100 mcg/mL) (DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsu

2) Complex partial epileptic seizure

a) (10 yr and older) monotherapy, initial 10 to 15 mg/kg/day ORALLY (give in 2 to 3 divided doses i exceeds 250 mg), may increase dosage 5 to 10 mg/kg/week to achieve optimal clinical response (M

or less with a therapeutic serum range of 50 to 100 mcg/mL) (Prod Info DEPAKENE(R) oral capsule 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) (10 yr and older) conversion to monotherapy, 10 to 15 mg/kg/day ORALLY (give in 2 to 3 divided dose exceeds 250 mg), may increase dosage 5 to 10 mg/kg/week to achieve optimal clinical respon mg/kg/day or less with a therapeutic serum range of 50 to 100 mcg/mL); reduce concomitant antiepi by approximately 25% every 2 weeks (reduction may be started at initiation of therapy or delayed by there is a concern that seizures are likely to occur with a reduction) (Prod Info DEPAKENE(R) oral c syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008)

c) (10 yr and older) adjunct, may be added to the patient's regimen at an initial dosage of 10 to 15 r ORALLY (give in 2 to 3 divided doses if total daily dose exceeds 250 mg), may increase dosage 5 to achieve optimal clinical response (MAX 60 mg/kg/day or less with a therapeutic serum range of 50 t (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release 2008)

3) Seizure, Multiple seizure types; Adjunct

a) (10 yr and older) 10 to 15 mg/kg/day ORALLY (give in 2 to 3 divided doses if total daily dose exc may increase dosage 5 to 10 mg/kg/week to achieve optimal clinical response (MAX 60 mg/kg/day therapeutic serum range of 50 to 100 mcg/mL) (Prod Info DEPAKENE(R) oral capsules, oral syrup, STAVZOR(R) delayed release oral capsules, 2008)

b) Divalproex Sodium

1) Adult

a) converting from valproic acid: initiate divalproex sodium sprinkle capsules at the same daily dose and dos stabilized, divalproex sodium given 2 or 3 times a day may be instituted (Prod Info DEPAKOTE(R) sprinkle o 2008).

b) converting delayed-release to extended-release: administer extended-release tablets (Depakote(R) ER) o 8% to 20% higher than the total daily dose of divalproex sodium delayed-release tablets (Prod Info DEPAKO extended-release oral tablets, 2008)

1) Absence seizure, Simple and complex

a) initial, 15 mg/kg/day ORALLY, may increase dosage by 5 to 10 mg/kg/day at 1-week intervals un controlled or side effects preclude further increases (MAX 60 mg/kg/day; usual therapeutic range, 5(total daily doses greater than 250 mg should be given in divided doses for delayed-release and spri DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral caps Info DEPAKOTE(R) delayed-release oral tablets, 2006)

2) Complex partial epileptic seizure

a) monotherapy, initial, 10 to 15 mg/kg/day ORALLY, may increase dosage 5 to 10 mg/kg/week to a clinical response (MAX 60 mg/kg/day; therapeutic range, 50 to 100 mcg/mL) (Prod Info DEPAKOTE release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAK release oral tablets, 2006)

b) adjunct, initial, 10 to 15 mg/kg/day ORALLY, may increase dosage 5 to 10 mg/kg/week to achiev response (MAX 60 mg/kg/day; therapeutic range, 50 to 100 mcg/mL) (Prod Info DEPAKOTE(R) ER oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAKOTE(R) oral tablets, 2006)

c) conversion to monotherapy, initial, 10 to 15 mg/kg/day ORALLY, may increase dosage 5 to 10 m achieve optimal clinical response (MAX 60 mg/kg/day; therapeutic range, 50 to 100 mcg/mL); reduc antiepileptic dosage by approximately 25% every 2 weeks (reduction may be started at initiation of t by 1 to 2 weeks if there is a concern that seizures are likely to occur with a reduction) (Prod Info DE extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Inf delayed-release oral tablets, 2006)

3) Manic bipolar I disorder

a) (Depakote (R) ER, extended-release) initial, 25 mg/kg/day ORALLY once daily; increase dose as possible to clinical effect; usual trough plasma level, 85 to 125 mcg/mL; MAX 60 mg/kg/day (Prod In ER extended-release oral tablets, 2008)

b) (Depakote (R), delayed-release) initial, 750 mg ORALLY daily in divided doses; increase dose as possible to clinical effect; usual trough plasma level, 50 to 125 mcg/mL; MAX 60 mg/kg/day (Prod In delayed-release oral tablets, 2006)

4) Migraine; Prophylaxis

a) (Depakote (R) ER, extended-release) initial, 500 mg ORALLY once daily for 1 week, thereafter ir mg once daily (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008)

b) (Depakote (R) delayed-release) initial, 250 mg ORALLY twice daily; may increase to a MAX 100 Info DEPAKOTE(R) delayed-release oral tablets, 2006)

2) Pediatric

a) safety and efficacy for the treatment of epilepsy in children less than 10 years of age have not been estab DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 200

b) efficacy for use in pediatric population for the treatment of mania or migraine prophylaxis has not been es Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

c) converting from valproic acid: initiate divalproex sodium sprinkle capsules at the same daily dose and dos stabilized, divalproex sodium given 2 or 3 times a day may be instituted (Prod Info DEPAKOTE(R) sprinkle o 2008).

d) converting delayed-release to extended-release: administer extended-release tablets (Depakote(R) ER) o

8% to 20% higher than the total daily dose of divalproex sodium delayed-release tablets (Prod Info DEPAKO capsules, 2008)

1) Absence seizure, Simple and complex

a) 10 years and older, initial, 15 mg/kg/day ORALLY, may increase dosage 5 to 10 mg/kg/day at 1- seizures are controlled or side effects preclude further increases (MAX 60 mg/kg/day; usual therape 100 mcg/mL; total daily doses greater than 250 mg should be given in divided doses for delayed-rel (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkl 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006)

2) Complex partial epileptic seizure

a) 10 yr and older, monotherapy, initial, 10 to 15 mg/kg/day ORALLY, may increase dosage 5 to 10 achieve optimal clinical response (MAX 60 mg/kg/day; therapeutic range, 50 to 100 mcg/mL) (Prod (R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; DEPAKOTE(R) delayed-release oral tablets, 2006)

b) 10 yr and older, adjunct, initial, 10 to 15 mg/kg/day ORALLY, may increase dosage 5 to 10 mg/k optimal clinical response (MAX 60 mg/kg/day; therapeutic range, 50 to 100 mcg/mL) (Prod Info DEP extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Inf delayed-release oral tablets, 2006)

c) 10 yr and older, conversion to monotherapy, initial, 10 to 15 mg/kg/day ORALLY, may increase c mg/kg/week to achieve optimal clinical response (MAX 60 mg/kg/day; therapeutic range, 50 to 100 r concomitant antiepileptic dosage by approximately 25% every 2 weeks (reduction may be started at therapy or delayed by 1 to 2 weeks if there is a concern that seizures are likely to occur with a reduc DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral caps Info DEPAKOTE(R) delayed-release oral tablets, 2006)

c) Valproate Sodium

1) Adult

a) Absence seizure, Simple and complex

1) 15 mg/kg/day IV, may increase dosage 5 to 10 mg/kg/day at one week intervals until seizures are cor effects preclude further increases (MAX 60 mg/kg/day or less with a therapeutic range of 50 to 100 mcg/ DEPACON(R) IV injection, 2006)

b) Complex partial epileptic seizure

1) monotherapy, 10 to 15 mg/kg/day IV, may increase dosage 5 to 10 mg/kg/week to achieve optimal cli (MAX 60 mg/kg/day or less with a therapeutic range of 50 to 100 mcg/mL) (Prod Info DEPACON(R) IV ir

2) conversion to monotherapy, 10 to 15 mg/kg/day IV, may increase dosage 5 to 10 mg/kg/week to achi response (MAX 60 mg/kg/day or less with a therapeutic range of 50 to 100 mcg/mL); reduce concomitan dosage by approximately 25% every 2 weeks (reduction may be started at initiation of therapy or delaye there is a concern that seizures are likely to occur with a reduction) (Prod Info DEPACON(R) IV injection

3) adjunct, may be added to the patient's regimen at an initial dosage of 10 to 15 mg/kg/day IV, may inc 10 mg/kg/week to achieve optimal clinical response (MAX 60 mg/kg/day or less with a therapeutic range mcg/mL) (Prod Info DEPACON(R) IV injection, 2006)

c) Seizure, Multiple seizure types; Adjunct

1) 10 to 15 mg/kg/day IV, may increase 5 to 10 mg/kg/week to achieve optimal clinical response (MAX 6 less with a therapeutic range of 50 to 100 mcg/mL) (Prod Info DEPACON(R) IV injection, 2006)

2) Pediatric

a) safety and effectiveness in pediatric patients under age 10 have not been established

1) Complex partial epileptic seizure

a) (10 yr and older) monotherapy, 10 to 15 mg/kg/day IV, may increase dosage 5 to 10 mg/kg/week optimal clinical response (MAX 60 mg/kg/day or less with a therapeutic range of 50 to 100 mcg/mL) DEPACON(R) IV injection, 2006)

b) (10 yr and older) conversion to monotherapy, 10 to 15 mg/kg/day IV, may increase dosage 5 to 1 achieve optimal clinical response (MAX 60 mg/kg/day or less with a therapeutic range of 50 to 100 r concomitant antiepilepsy drug dosage by approximately 25% every 2 weeks (reduction may be start therapy or delayed by 1 to 2 weeks if there is a concern that seizures are likely to occur with a reduc DEPACON(R) IV injection, 2006)

c) (10 yr and older) adjunct, may be added to the patient's regimen at an initial dosage of 10 to 15 r increase dosage 5 to 10 mg/kg/week to achieve optimal clinical response (MAX 60 mg/kg/day or les therapeutic range of 50 to 100 mcg/mL) (Prod Info DEPACON(R) IV injection, 2006)

2) Seizure, Multiple seizure types; Adjunct

a) 10 yr and older, 10 to 15 mg/kg/day IV, may increase 5 to 10 mg/kg/week to achieve optimal clin (MAX 60 mg/kg/day or less with a therapeutic range of 50 to 100 mcg/mL) (Prod Info DEPACON(R)

3) Contraindications

a) Valproic Acid

1) hepatic disease or significant hepatic dysfunction (Prod Info STAVZOR(R) delayed release oral capsules, 200 DEPACON(R) IV injection, 2006; Prod Info DEPAKENE(R) oral capsules, syrup, 2006; Prod Info DEPAKOTE(R) oral tablets, 2006; Prod Info DEPAKOTE(R) ER extended-release tablet, 2006; Prod Info DEPAKOTE(R) sprinkle 2003)

2) hypersensitivity to sodium valproate, divalproex sodium, or valproic acid (Prod Info STAVZOR(R) delayed rele 2008; Prod Info DEPACON(R) IV injection, 2006; Prod Info DEPAKENE(R) oral capsules, syrup, 2006; Prod Info delayed-release oral tablets, 2006; Prod Info DEPAKOTE(R) ER extended-release tablet, 2006; Prod Info DEPAK

oral capsules, 2003)
3) urea cycle disorders, known; hyperammonemic encephalopathy, including fatalities, has occurred (Prod Info S delayed release oral capsules, 2008; Prod Info DEPACON(R) IV injection, 2006; Prod Info DEPAKENE(R) oral ca 2006; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006; Prod Info DEPAKOTE(R) ER extended-releas Prod Info DEPAKOTE(R) sprinkle oral capsules, 2003)

b) Divalproex Sodium
1) hepatic disease or significant hepatic dysfunction (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Proc (R) ER extended-release oral tablets, 2008)
2) hypersensitivity to divalproex sodium (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAI extended-release oral tablets, 2008)
3) urea cycle disorders (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAKOTE(R) ER ext tablets, 2008)

c) Valproate Sodium
1) hepatic disease or significant hepatic dysfunction (Prod Info DEPACON(R) IV injection, 2006)
2) hypersensitivity to valproate sodium, valproic acid, or divalproex sodium (Prod Info DEPACON(R) IV injection,
3) known urea cycle disorders; hyperammonemic encephalopathy, including fatalities, has occurred (Prod Info DI injection, 2006)

4) Serious Adverse Effects

a) Valproic Acid
1) Coma, Hyperammonemia-induced
2) Hematemesis
3) Hyperammonemia
4) Hyperammonemic encephalopathy
5) Immune hypersensitivity reaction
6) Ototoxicity - deafness
7) Palpitations
8) Pleural effusion
9) Pulmonary hemorrhage
10) Tachycardia
11) Thrombocytopenia, Dose-related

b) Divalproex Sodium
1) Hyperammonemia
2) Hyperammonemic encephalopathy
3) Immune hypersensitivity reaction
4) Liver failure
5) Ototoxicity - deafness
6) Palpitations
7) Pancreatitis
8) Tachycardia
9) Thrombocytopenia, Dose-related

c) Valproate Sodium
1) Liver failure, Children under the age of two years are at increased risk
2) Pancreatitis, Life-threatening
3) Thrombocytopenia, Dose-related

5) Clinical Applications

a) Valproic Acid
1) FDA Approved Indications
a) Absence seizure, Simple and complex
b) Complex partial epileptic seizure
c) Manic bipolar I disorder
d) Migraine; Prophylaxis
e) Seizure, Multiple seizure types; Adjunct

b) Divalproex Sodium
1) FDA Approved Indications
a) Absence seizure, Simple and complex
b) Complex partial epileptic seizure
c) Manic bipolar I disorder
d) Migraine; Prophylaxis

c) Valproate Sodium
1) FDA Approved Indications
a) Absence seizure, Simple and complex
b) Complex partial epileptic seizure
c) Seizure, Multiple seizure types; Adjunct

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms

Divalproex Na
Divalproex Sodium
Sodium Valproate
Valproate Na
Valproate Sodium
Valproic Acid

1.2 Storage and Stability

A) Valproic Acid

1) Preparation

a) Oral route

1) Valproic acid capsules should be swallowed whole without chewing to avoid local irritation of the mou Divided doses should be given if the total daily dose exceeds 250 milligrams. A slow titration from the ini giving with food may help to decrease gastrointestinal irritation in patients who experience it (Prod Info D capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008).

B) Divalproex Sodium

1) Preparation

a) Oral route

1) Extended-Release

a) Extended-release formulations are for once daily dosing and should be swallowed whole and not chewed. Patients who experience gastrointestinal irritation should take divalproex sodium with food titration from the initial dose (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

2) Delayed-Release

a) The delayed-release formulation may be taken with or without food. Patients who experience gas irritation should take divalproex sodium with food or utilize slow dose titration from the initial dose (P DEPAKOTE(R) delayed-release oral tablets, 2006).

3) Sprinkle-Capsules

a) The sprinkle-capsules may be swallowed whole, or opened and contents sprinkled on a small an teaspoonful) of soft food such as applesauce or pudding. The drug/food mixture should not be store but should be swallowed immediately without chewing. Patients who experience gastrointestinal irrit divalproex sodium with food or utilize slow dose titration from the initial dose (Prod Info DEPAKOTE capsules, 2008).

C) Valproic Acid

1) Oral route

a) Capsule, Delayed Release

1) Store delayed-release capsules at controlled room temperature, 25 degrees Celsius (77 degrees Fah excursions permitted between 15 and 30 degrees Celsius (59 and 86 degrees Fahrenheit) (Prod Info ST delayed release oral capsules, 2008).

b) Capsule, Liquid Filled

1) Store liquid-filled capsules between 15 and 25 degrees Celsius (59 and 77 degrees Fahrenheit) (Proc (R) capsules and syrup, 2003).

c) Syrup

1) Store syrup below 30 degrees Celsius (86 degrees Fahrenheit) (Prod Info DEPAKENE(R) capsules a

D) Divalproex Sodium

1) Oral route

a) Capsule

1) Divalproex sodium sprinkle capsules should be stored below 77 degrees Fahrenheit (25 degrees Cel DEPAKOTE(R) oral sprinkle capsule, 2003).

b) Tablet, Delayed Release

1) Divalproex sodium delayed-release tablets should be stored below 86 degrees Fahrenheit (30 degree Info Depakote(R) Tablets, 2002).

c) Tablet, Extended Release

1) Divalproex sodium extended-release tablets should be stored at 77 degrees Fahrenheit (25 degrees excursions permitted between 59 and 86 degrees Fahrenheit (15 and 30 degrees Celsius) (Prod Info DE Tablets, 2005).

E) Valproate Sodium

1) Injection route
a) Solution
1) Valproate sodium injection should be stored at room temperature, 15 to 30 degrees Celsius (59 to 86 Fahrenheit) (Prod Info Depacon(R), , 2003).
2) Valproate sodium injection is stable in 5% dextrose injection, 0.9% sodium chloride injection and lacta injection for at least 24 hours in glass or polyvinyl chloride chloride (PVC) bags at 15 to 30 degrees Celsi degrees Fahrenheit) (Prod Info Depacon(R), , 2003).

1.3 Adult Dosage

1.3.1.A Divalproex Sodium

Oral route

Alcohol withdrawal syndrome

1.3.1.A.1 Oral route

Absence seizure, Simple and complex

Complex partial epileptic seizure

Manic bipolar I disorder

Migraine; Prophylaxis

1.3.1.A.1.a Absence seizure, Simple and complex
1) The recommended initial dose is 15 milligrams/kilogram/day (mg/kg/day), increasing at 1-week ir mg/kg/day until the desired therapeutic effect is reached or adverse effects occur. The maximum rec is 60 mg/kg/day. The usual therapeutic serum concentration ranges from 50 to 100 micrograms/milli there is no good correlation between daily dose, serum concentrations, and therapeutic effect. Some experience seizure control with higher or lower serum levels. For the delayed-release tablets and sp total daily doses exceeding 250 mg should be given in divided doses. As divalproex sodium doses a upwards, the blood levels of phenobarbital and/or phenytoin may be affected (Prod Info DEPAKOTE release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAK release oral tablets, 2006).

1.3.1.A.1.b Complex partial epileptic seizure

1) Initial Monotherapy

a) The recommended initial oral dosage for monotherapy is 10 to 15 milligrams/kilogram/day (r increasing by 5 to 10 mg/kg/week until the desired therapeutic effect is reached or adverse effe clinical response is typically achieved at daily doses below 60 mg/kg/day. If a satisfactory respo obtained, plasma levels should be measured to determine whether or not they are in the accept range (50 to 100 mcg/mL). Doses above 60 mg/kg/day are not recommended (Prod Info DEPAI extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prc (R) delayed-release oral tablets, 2006).

2) Adjunctive Therapy

a) The recommended oral dosage when adding valproic acid to a patient's regimen is 10 to 15 milligrams/kilogram/day (mg/kg/day) increasing by 5 to 10 mg/kg/week until the desired therape reached or adverse effects occur. Optimal clinical response is typically achieved at daily doses mg/kg/day. If a satisfactory response has not been obtained, plasma levels should be measure whether or not they are in the accepted therapeutic range (50 to 100 mcg/mL). Doses above 60 recommended (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DE sprinkle oral capsules, 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006).

3) Conversion to Monotherapy

a) When converting to monotherapy, the recommended initial oral dosage is 10 to 15 milligram (mg/kg/day) increasing by 5 to 10 mg/kg/week until the desired therapeutic effect is reached or occur. Optimal clinical response is typically achieved at daily doses below 60 mg/kg/day. If a sa has not been obtained, plasma levels should be measured to determine whether or not they are therapeutic range (50 to 100 mcg/mL). The concomitant antiepileptic dosage may be reduced a valproic acid therapy or after 1 to 2 weeks of therapy. The dosage of the concomitant antiepilep reduced by approximately 25% every 2 weeks. Valproic acid doses above 60 mg/kg/day are no (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sp capsules, 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006).

1.3.1.A.1.c Manic bipolar I disorder

1) Depakote (R) ER, extended-release: The initial dose is 25 milligrams/kilogram/day (mg/kg/day) a once daily with increases in dose done as quickly as possible to achieve the desired clinical effect. I the target trough plasma level range was 85 to 125 micrograms/milliliter. The maximum recommend mg/kg/day (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

2) Depakote (R), delayed-release: The initial dose is 750 mg orally per day in divided doses with inc done as quickly as possible to achieve the desired clinical effect. In clinical studies, the target trough 50 to 125 micrograms/milliliter. The maximum recommended dose is 60 mg/kg/day (Prod Info DEPA release oral tablets, 2006)

3) A divalproex loading dose of 20 milligrams/kilogram/day (mg/kg/day) has been given to achieve s concentrations of 80 milligrams/liter. This dosage strategy has been used to rapidly achieve therape patients with acute psychotic manic symptoms (McElroy et al, 1996).

4) Another accelerated loading regimen used divalproex 30 milligrams per kilogram per day (mg/kg and 2 followed by 20 mg/kg/day for days 3 through 10, which resulted in 16 of 19 (84%) of patients a therapeutic serum valproate levels of 50 micrograms/milliliter by day 3 of the study (Hirschfeld, 1999

1.3.1.A.1.d Migraine; Prophylaxis

1) The recommended initial dose of extended-release tablets is 500 milligrams (mg) orally once a d followed by an increase to 1000 mg orally once daily (Prod Info DEPAKOTE(R) ER extended-releas 2008).

2) The recommended initial dose of delayed-release tablets is 250 milligrams (mg) twice daily. In sc up to 1000 mg/day are beneficial (Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006).

1.3.1.A.1.e Conversion From Valproic Acid

1) When converting patients from valproic acid, initiate divalproex sodium sprinkle capsules at the s and dosing schedule. Once stabilized, a schedule of divalproex sodium 2 or 3 times a day may be ir DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets,

1.3.1.A.1.f Conversion From Delayed-Release To Extended-Release Formulations

1) When converting from divalproex sodium delayed-release tablets (Depakote(R) Tablets), adminis sodium extended-release tablets (Depakote(R) ER) once daily in doses 8% to 20% higher than the t divalproex sodium delayed-release tablets (Depakote(R) Tablets). Due to pharmacokinetic variation patients, monitor plasma levels if satisfactory clinical response has not been achieved.

Divalproex Sodium Dose Conversion	
Delayed-release (Depakote(R)) total daily dose (mg)	Extended-release (Depakote(R) ER) (mg)
500* - 625	750
750* - 875	1000
1000* - 1125	1250
1250 - 1375	1500

1500 - 1625	1750
1750	2000
1875 - 2000	2250
2125 - 2250	2500
2375	2750
2500 - 2750	3000
2875	3250
3000 - 3125	3500
* these total daily doses cannot be directly converted to extended-release since the required dosing strengths are not available	

In cases where the total daily dose of delayed-release product cannot be directly converted to a release product because the required dosing strengths are not available, consider increasing th the next higher dosage before converting to the appropriate total daily dose of the extended-rele (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

1.3.1.A.1.g Withdrawal Schedule

1) The risk factors associated with withdrawal of anticonvulsants in 92 patients who had been free o years with single agent therapy were evaluated. The dose of each anticonvulsant was reduced by 1 2 weeks (1 unit equivalent to 200 milligrams of carbamazepine or valproic acid or 100 milligrams of mean follow-up period of 26 months (range, 6 to 62 months). Relapse occurred in 31 patients, with 6 remaining free of seizures (relapse rate 33.7%) (Callaghan et al, 1988).

1.3.1.A.2 Alcohol withdrawal syndrome

See Drug Consult reference: DRUG THERAPY OF ETHANOL WITHDRAWAL

1.3.1.B Valproate Sodium

Intravenous route

Rectal route

1.3.1.B.1 Intravenous route

Absence seizure, Simple and complex

Complex partial epileptic seizure

Seizure, Multiple seizure types; Adjunct

1.3.1.B.1.a Absence seizure, Simple and complex

1) The initial dosage is 15 milligrams/kilogram/day (mg/kg/day), increasing at 1-week intervals by 5 until the desired therapeutic effect is reached or adverse effects occur. Total daily doses exceeding given in divided doses, and the maximum recommended dosage is 60 mg/kg/day (Prod Info DEPAC injection, 2006).

1.3.1.B.1.b Complex partial epileptic seizure

1) Initial Monotherapy

a) The usual recommended initial intravenous dosage for monotherapy is 10 to 15 milligrams/k (mg/kg/day), increasing at 1-week intervals by 5 to 10 mg/kg/day until the desired therapeutic e adverse effects occur. Total daily doses exceeding 250 milligrams should be given in divided do maximum recommended dose is 60 mg/kg/day (Prod Info DEPACON(R) IV injection, 2006).

2) Adjunctive Therapy

a) The usual recommended intravenous dosage when adding valproic acid to a patient's regim milligrams/kilogram/day (mg/kg/day), increasing at 1-week intervals by 5 to 10 mg/kg/day until t therapeutic effect is reached or adverse effects occur. Total daily doses exceeding 250 milligrar in divided doses, and the maximum recommended dose is 60 mg/kg/day (Prod Info DEPACON 2006).

3) Conversion to Monotherapy

a) Concomitant antiepilepsy drug dosage may be reduced by approximately 25% every 2 week of valproic acid therapy or after 1 to 2 weeks of therapy (Prod Info DEPACON(R) IV injection, 2

1.3.1.B.1.c Seizure, Multiple seizure types; Adjunct

1) Administer 10 to 15 milligrams per kilograms (mg/kg) per day intravenously. The dose may be in
mg/kg/week to achieve optimal clinical response, which is typically seen at a therapeutic range of 5(
The maximum recommended dose is 60 mg/kg/day (Prod Info DEPACON(R) IV injection, 2006).

1.3.1.B.1.d Important Note

1) Valproate sodium injection is for intravenous use only and should be used in patients who are te
use the oral form of valproic acid. Use of valproate sodium injection for periods of more than 14 day
studied. As soon as it is clinically feasible, patients should be switched back to oral valproic acid. Va
injection should be administered as a 60 minute infusion and not faster than 20 milligrams/minute. It
with at least 50 milliliters of a compatible diluent. The same frequency of administration should be us
products. Plasma concentrations should be monitored (Prod Info Depacon(R), 2003).

2) There have been reports of hyperammonemic encephalopathy (including fatalities) in patients wi
disorders (UCD) who have received valproate therapy. UCD is a genetic disorder with an estimated
1:8000 to 1:30,000 births. Patients suspected of having UCD should not receive valproic acid, divalp
valproate sodium (Prod Info Depakote(R), 2003; Prod Info Depakote ER(R), 2003; Prod Info Depako
2003; Prod Info Depakene(R), 2003; Prod Info Depacon(R), 2003).

a) To achieve high therapeutic levels of valproic acid, RAPID INTRAVENOUS INFUSION at 3
milligrams/kilogram (mg/kg)/minute for a duration of 4.17 or 8.34 minutes, respectively, has bee
21 to 28 mg/kg (mean dose 24.2 mg/kg) were given to 21 patients (2 to 54 years old). Peak ser
concentrations measured 20 minutes post-infusion were 105 to 204 micrograms/milliliter. The ir
tolerated and no cardiac or central nervous system adverse effects were reported (Venkataram
1999).

b) Intravenous valproic acid was used in 4 patients (3 children and 1 adult) for the treatment of
WAVE STATUS EPILEPTICUS. Loading doses of 30 milligrams/kilogram were given over an h
dosages required in the 3 pediatric patients ranged from 120 to 160 mg/kg/day divided every 6
1999).

3) Valproate sodium injection should be administered as a 60 minute infusion and not faster than 2(
milligrams/minute. It should be diluted with at least 50 milliliters of a compatible diluent. The same fr
administration should be used as the oral products. Plasma concentrations should be monitored (Pr
(R), 2003).

e) The total daily dose of valproate sodium injection should be equivalent to the total daily dose of the o
product and should be administered as a 60 minute infusion with the same frequency as the oral product
concentration monitoring and dosage adjustments may be necessary. Infusions should not exceed 20 m
(mg)/minute. If the total daily dose exceeds 250 mg, it should be given in divided doses (Prod Info Depac

f) The manufacturer states that the equivalence shown between valproate sodium injection and oral valp
at steady state was only evaluated in an every 6 hour dosing regimen. If valproate sodium injection is giv
trough levels may fall below those measured using the oral route. Close monitoring of trough plasma lev
if valproate sodium injection is given only 2 or 3 times daily (Prod Info Depacon(TM), 1999).

1.3.1.B.2 Rectal route

a) In one patient, a 65-year-old male, status epilepticus did not respond to commonly used anticonvulsa
completely controlled by SODIUM VALPROATE syrup given rectally (250 to 500 milligrams every 6 to 8
was mixed with 30 milliliters of water and given as a retention enema. It was well-absorbed rectally and c
respiratory depression than other agents (Thorpy, 1980).

1.3.1.B.3 Withdrawal Schedule

a) The risk factors associated with withdrawal of anticonvulsants in 92 patients who had been free of sei
with single agent therapy were evaluated. The dose of each anticonvulsant was reduced by 1 unit at inte
unit equivalent to 200 milligrams of CARBAMAZEPINE or VALPROIC ACID, or 100 milligrams of PHEN
mean follow-up period of 26 months (range, 6 to 62 months). Relapse occurred in 31 patients, with 61 pa
free of seizures (relapse rate 33.7%) (Callaghan et al, 1988).

1.3.1.C Valproic Acid

Oral route

Hiccoughs

1.3.1.C.1 Oral route

Absence seizure, Simple and complex

Complex partial epileptic seizure

Manic bipolar I disorder

Migraine; Prophylaxis

Myoclonic seizure

Seizure, Multiple seizure types; Adjunct

1.3.1.C.1.a Absence seizure, Simple and complex

1) The usual recommended dosage is 15 milligrams/kilogram/day (mg/kg/day) orally, increasing at
5 to 10 mg/kg/day until the desired therapeutic effect is reached or adverse effects occur. The maxi
recommended dosage is 60 mg/kg/day . Total daily doses of valproic acid exceeding 250 mg should
divided doses. Therapeutic valproate serum concentrations for most patients with absence seizures
range from 50 to 100 micrograms/milliliter (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006
STAVZOR(R) delayed release oral capsules, 2008).

2) The initial dose should be determined by weight and not age. The manufacturer of (Depakene(R)
following dosage schedule based on body weight (Prod Info DEPAKENE(R) oral capsules, oral syru

Pounds (lbs)	Kilograms (kg)	Daily dose
22 to 54.9 lbs	10 to 24.9 kg	250 mg
55 to 87.9 lbs	25 to 39.9 kg	500 mg
88 to 131.9 lbs	40 to 59.9 kg	750 mg
132 to 164.9 lbs	60 to 74.9 kg	1000 mg
165 to 197.9 lbs	75 to 89.9 kg	1250 mg

1.3.1.C.1.b Complex partial epileptic seizure

1) Initial Monotherapy

a) The usual recommended initial oral dosage for monotherapy is 10 to 15 milligrams/kilogram/
increasing at 1 week intervals by 5 to 10 mg/kg/week until the desired therapeutic effect is reac
optimal clinical response is achieved at daily doses below 60 mg/kg/day. If a satisfactory respor
obtained, plasma levels should be measured to determine whether or not they are in the accept
serum range (50 to 100 mcg/mL). Doses above 60 mg/kg/day are not recommended. Total dail
acid exceeding 250 milligrams should be given in 2 to 3 divided doses (Prod Info DEPAKENE(F
oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008) .

2) Conversion to Monotherapy

a) When converting to monotherapy, the usual recommended initial oral dosage is 10 to 15
milligrams/kilogram/day (mg/kg/day) increasing at 1 week intervals by 5 to 10 mg/kg/week until
therapeutic effect is reached. Usually, optimal clinical response is achieved at daily doses belov
a satisfactory response has not been obtained, plasma levels should be measured to determine
they are in the accepted therapeutic serum range (50 to 100 mcg/mL). Concomitant antiepileps
be reduced at the initiation of valproic acid therapy or after 1 to 2 weeks of therapy. The dosage
concomitant antiepilepsy drug can be reduced by approximately 25% every 2 weeks. Valproic a
60 mg/kg/day are not recommended. Total daily doses of valproic acid exceeding 250 milligram
in 2 to 3 divided doses (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STA
release oral capsules, 2008).

3) Adjunctive Therapy

a) The usual recommended oral dosage when adding valproic acid to a patient's regimen is 10
milligrams/kilogram/day (mg/kg/day), increasing at 1 week intervals by 5 to 10 mg/kg/week until
therapeutic effect is reached. Usually, optimal clinical response is achieved at daily doses belov
a satisfactory response has not been obtained, plasma levels should be measured to determine
they are in the accepted therapeutic serum range (50 to 100 mcg/mL). Doses above 60 mg/kg/d
recommended. Total daily doses of valproic acid exceeding 250 milligrams should be given in 2
(Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed rele
2008).

1.3.1.C.1.c Manic bipolar I disorder

1) The recommended initial dose of delayed-release valproic acid is 750 milligrams (mg) orally daily
The dose should be increased as quickly as possible to achieve the lowest therapeutic dose that wil
desired clinical response or desired range of plasma concentrations. The maximum recommended d
mg/kilogram/day or less with a therapeutic serum range of 50 to 125 micrograms/milliliter (Prod Info
delayed release oral capsules, 2008).

1.3.1.C.1.d Migraine; Prophylaxis

1) For the prophylaxis of migraine, the recommended initial dose of delayed-release valproic acid (S
milligrams (mg) orally twice daily. Some patients may benefit from doses up to 1000 mg/day. Higher
to greater efficacy in clinical trials (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

1.3.1.C.1.e Myoclonic seizure

1) A starting dose of 15 milligrams/kilogram/day (mg/kg/day) provided seizure control for 63% of 76 juvenile myoclonic epilepsy. Twenty-five percent of patients were controlled at 20 mg/kg/day, 4% at 8% required addition of a second drug. After a 2-year seizure-free period, 22% of patients could be 5 mg/kg/day, 33% on 6 to 8 mg/kg/day, and 42% required more than 9 mg/kg/day (Panagariya et al,

1.3.1.C.1.f Seizure, Multiple seizure types; Adjunct

1) The recommended initial dose is 10 to 15 milligrams/kilogram/day (mg/kg) orally. The dose may to 10 mg/kg/week to achieve optimal clinical response. If total daily dose exceeds 250 mg, give in 2 Maximum daily dose is 60 mg/kg/day or less with a therapeutic serum range of 50 to 100 microgram Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral ca

1.3.1.C.1.g Withdrawal Schedule

1) The risk factors associated with withdrawal of anticonvulsants in 92 patients who had been free o years with single agent therapy were evaluated. The dose of each anticonvulsant was reduced by 1 2 weeks (1 unit equivalent to 200 milligrams of carbamazepine or valproic acid, or 100 milligrams of mean follow-up period of 26 months (range, 6 to 62 months). Relapse occurred in 31 patients, with 6 remaining free of seizures (relapse rate 33.7%) (Callaghan et al, 1988).

1.3.1.C.2 Hiccoughs

See Drug Consult reference: HICCUPS - ETIOLOGY AND TREATMENT

1.3.2 Dosage in Renal Failure

A) Valproic Acid

1) Renal excretion of sodium valproate as the unchanged drug is 1.8% (Hardman et al, 1996a). A 27% reduc unbound clearance of valproate has been reported in patients with a creatinine clearance of less than 10 milli however, hemodialysis typically decreases valproate concentrations by about 20%. Therefore, dosage adjust unnecessary in patients with renal failure. Monitoring total concentrations of valproic acid may be misleading renal failure because protein binding in these patients is significantly reduced (Prod Info DEPAKENE(R) oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008).

B) Divalproex Sodium

1) Dose adjustments are not required in renal failure (Prod Info DEPAKOTE(R) ER extended-release oral tal Bennett et al, 1994). However, increased free levels of valproic acid have been reported, and monitoring of to may be misleading (Lapierre et al, 1999). Renal excretion of sodium valproate as the unchanged drug is 1.8% 1996a). A 27% reduction in the unbound clearance of valproate has been reported in patients with a creatinir less than 10 milliliters/minute (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

C) Valproate Sodium

1) Dosage adjustments are not required in renal failure (Prod Info Depakote(R) Tablets, 2002a; Bennett et al increased free levels of valproic acid have been reported and monitoring of total concentrations may be misle al, 1999). Renal excretion of SODIUM VALPROATE as the unchanged drug is 1.8% (Hardman et al, 1996a). in the unbound clearance of valproate has been reported in patients with a creatinine clearance of less than 1 milliliters/minute.

1.3.3 Dosage in Hepatic Insufficiency

A) Valproic Acid

1) Valproic acid should not be administered to patients with hepatic disease or significant hepatic insufficienc impairs the capacity to eliminate valproate. In one study, the clearance of free valproate was decreased by 5(cirrhosis and by 16% in patients with acute hepatitis. Patients with liver disease have decreased albumin con larger unbound fractions by a 2 to 2.6 fold increase. Monitoring of total concentrations may be misleading sin concentrations may be significantly elevated in patients with hepatic disease, with total concentrations appea (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral caps

2) Mean serum half-life of valproic acid was shown to increase in 7 patients with alcoholic cirrhosis or recove hepatitis. Single doses of 450 milligrams orally (solution) were administered (Klotz et al, 1978).

B) Divalproex Sodium

1) Divalproex sodium should not be administered to patients with hepatic disease or significant hepatic insuf disease impairs the capacity to eliminate valproate. In one study, the clearance of free valproate was decreas patients with cirrhosis and by 16% in patients with acute hepatitis. Patients with liver disease have decreased concentrations and larger unbound fractions by a 2- to 2.6-fold increase. Monitoring of total concentrations m (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral cap Info DEPAKOTE(R) delayed-release oral tablets, 2006).

2) Mean serum half-life of valproic acid was shown to increase in 7 patients with alcoholic cirrhosis or recove hepatitis (Klotz et al, 1978). Single doses of 450 milligrams orally (solution) were administered.

C) Valproate Sodium

1) VALPROIC ACID or DIVALPROEX should not be administered to patients with hepatic disease or signific insufficiency (Prod Info Depakene(R), 1999)(Prod Info Depakote(R) Tablets, 2002a). Liver disease impairs th eliminate valproate. In one study, the clearance of free valproate was decreased by 50% in patients with cirrh in patients with acute hepatitis. Patients with liver disease have decreased albumin concentrations and larger by a 2 to 2.6 fold increase. Monitoring of total concentrations may be misleading.

2) Mean serum half-life of VALPROIC ACID was shown to increase in 7 patients with alcoholic cirrhosis or re acute hepatitis (Klotz et al, 1978). Single doses of 450 milligrams orally (solution) were administered.

1.3.4 Dosage in Geriatric Patients

A) Valproic Acid

1) The manufacturer recommends that the starting dose be reduced due to a decrease in unbound clearanc a potential increase in sensitivity to somnolence in the elderly. Slow dosage titration and close monitoring of f intake, dehydration and adverse effects are also recommended. In patients with decreased food or fluid intak with excessive somnolence, dose reductions or discontinuation of therapy should be considered. Maintenanc based on clinical response (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R oral capsules, 2008).

B) Divalproex Sodium

1) Due to a 39% decrease in intrinsic clearance and a 44% increase in free fraction, decrease the initial dose patients. Slow dosage titration and close monitoring of fluid and nutritional intake, dehydration, and adverse e recommended. Maintenance doses should be based on clinical response (Prod Info DEPAKOTE(R) ER exte tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAKOTE(R) delayed-relea 2006).

C) Valproate Sodium

1) The manufacturer recommends that the starting dose be reduced due to a decrease in unbound clearanc a potential increase in sensitivity to somnolence in the elderly. Slow dosage titration and close monitoring of f intake, dehydration and adverse effects are also recommended. Maintenance doses should be based on clin (Prod Info Depakote(R) Tablets, 2002a).

1.3.5 Dosage Adjustment During Dialysis

A) Valproic Acid

1) Hemodialysis typically reduces valproate concentrations by about 20%, but a 27% reduction in the unbou valproate has been reported in patients with a creatinine clearance of less than 10 milliliters/minute. Therefor supplementation is required in patients following hemodialysis, peritoneal dialysis, or continuous arteriovenou Monitoring total concentrations of valproic acid may be misleading in patients with renal failure because prote patients is significantly reduced (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZO release oral capsules, 2008).

B) Divalproex Sodium

1) No dosage supplementation is required in patients following hemodialysis, peritoneal dialysis, or continuo hemofiltration (Bennett et al, 1994). Hemodialysis typically reduces valproate concentrations by about 20% a is substantially reduced. Monitoring total concentrations may be misleading (Prod Info DEPAKOTE(R) ER ex oral tablets, 2008).

C) Valproate Sodium

1) No dosage supplementation is required in patients following hemodialysis, peritoneal dialysis, or continuo hemofiltration (Prod Info Depakote(R) Tablets, 2002a; Bennett et al, 1994). Hemodialysis typically reduces va concentrations by about 20% and protein binding is substantially reduced. Monitoring total concentrations ma (Prod Info Depakote(R) Tablets, 2002a).

1.4 Pediatric Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage Adjustment During Dialysis

1.4.1 Normal Dosage

Divalproex Sodium

Valproate Sodium

Valproic Acid

1.4.1.A Divalproex Sodium

1.4.1.A.1 Oral route

Absence seizure, Simple and complex

Complex partial epileptic seizure

1.4.1.A.1.a Absence seizure, Simple and complex

1) The recommended initial dose is 15 milligrams/kilogram/day (mg/kg/day), increasing at 1-week ir mg/kg/day until the desired therapeutic effect is reached or adverse effects occur. The maximum rec dosage is 60 mg/kg/day. The usual therapeutic serum concentration ranges from 50 to 100 microgra however, there is no good correlation between daily dose, serum concentrations, and therapeutic ef patients may experience seizure control with higher or lower serum levels. For the delayed-release t capsules, total daily doses exceeding 250 mg should be given in divided doses. As divalproex sodiu titrated upwards, the blood levels of phenobarbital and/or phenytoin may be affected (Prod Info DEP extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Inf delayed-release oral tablets, 2006).

1.4.1.A.1.b Complex partial epileptic seizure

1) Initial Monotherapy

a) Initial monotherapy (children 10 years of age or older): The recommended initial oral dosage is 10 to 15 milligrams/kilogram/day (mg/kg/day), increasing by 5 to 10 mg/kg/week until the des effect is reached or adverse effects occur. Optimal clinical response is typically achieved at dail mg/kg/day. If a satisfactory response has not been obtained, plasma levels should be measure whether or not they are in the accepted therapeutic range (50 to 100 mcg/mL). Doses above 60 recommended (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DE sprinkle oral capsules, 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006).

2) Adjunctive Therapy

a) Adjunctive therapy (children 10 years of age or older): The recommended initial oral dosage valproic acid to a patient's current regimen is 10 to 15 milligrams/kilogram/day (mg/kg/day), incr mg/kg/week until the desired therapeutic effect is reached or adverse effects occur. Optimal clir typically achieved at daily doses below 60 mg/kg/day. If a satisfactory response has not been o levels should be measured to determine whether or not they are in the accepted therapeutic rar mcg/mL). Doses above 60 mg/kg/day are not recommended (Prod Info DEPAKOTE(R) ER exte tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAKOTE(R) oral tablets, 2006).

3) Conversion To Monotherapy

a) Conversion to monotherapy (children 10 years of age or older): The recommended initial ora monotherapy is 10 to 15 milligrams/kilogram/day (mg/kg/day), increasing by 5 to 10 mg/kg/wee therapeutic effect is reached or adverse effects occur. Optimal clinical response is typically achi doses below 60 mg/kg/day. If a satisfactory response has not been obtained, plasma levels sho to determine whether or not they are in the accepted therapeutic range (50 to 100 mcg/mL). Do mg/kg/day are not recommended. The concomitant antiepileptic drug dosage may be reduced a valproic acid therapy or after 1 to 2 weeks of therapy and can be reduced by approximately 25% (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sp capsules, 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006).

1.4.1.A.1.c Safety and Efficacy

1) The safety and efficacy for the treatment of epilepsy in children less than 10 years of age have n established (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOT capsules, 2008).

2) The efficacy for use in the pediatric population for the treatment of mania or migraine prophylaxis established (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

1.4.1.A.1.d Conversion From Valproic Acid

1) When converting patients from valproic acid, initiate divalproex sodium sprinkle capsules at the s and dosing schedule. Once stabilized, a schedule of divalproex sodium 2 or 3 times a day may be ir DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets,

1.4.1.A.1.e Conversion From Delayed-Release To Extended-Release Formulations

1) When converting from divalproex sodium delayed-release tablets (Depakote(R) Tablets), adminis sodium extended-release tablets (Depakote(R) ER) once daily in doses 8% to 20% higher than the t divalproex sodium delayed-release tablets (Depakote(R) Tablets). Due to pharmacokinetic variation patients, monitor plasma levels if satisfactory clinical response has not been achieved.

Divalproex Sodium Dose Conversion	
Delayed-release (Depakote(R)) total daily dose (mg)	Extended-release (Depakote(R) ER) (mg)
500* - 625	750

750* - 875	1000
1000* - 1125	1250
1250 - 1375	1500
1500 - 1625	1750
1750	2000
1875 - 2000	2250
2125 - 2250	2500
2375	2750
2500 - 2750	3000
2875	3250
3000 - 3125	3500
* these total daily doses cannot be directly converted to extended-release since the required dosing strengths are not available	

In cases where the total daily dose of delayed-release product cannot be directly converted to a release product because the required dosing strengths are not available, consider increasing th the next higher dosage before converting to the appropriate total daily dose of the extended-rel (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

1.4.1.A.1.f Withdrawal Schedule

1) The risk factors associated with withdrawal of anticonvulsants in 92 patients who had been free o years with single agent therapy were evaluated. The dose of each anticonvulsant was reduced by 1 2 weeks (1 unit equivalent to 200 milligrams of carbamazepine or valproic acid, or 100 milligrams of mean follow-up period of 26 months (range, 6 to 62 months). Relapse occurred in 31 patients, with 6 remaining free of seizures (relapse rate 33.7%) (Callaghan et al, 1988).

1.4.1.B Valproate Sodium

Intravenous route

Oral route

1.4.1.B.1 Intravenous route

Absence seizure, Simple and complex

Complex partial epileptic seizure

Seizure, Multiple seizure types; Adjunct

1.4.1.B.1.a Absence seizure, Simple and complex

1) For children 10 years of age and older, the initial dosage is 15 milligrams/kilogram/day (mg/kg/da week intervals by 5 to 10 mg/kg/day until the desired therapeutic effect is reached or adverse effects doses exceeding 250 mg should be given in divided doses, and the maximum recommended dosag (Prod Info DEPACON(R) IV injection, 2006).

1.4.1.B.1.b Complex partial epileptic seizure

1) Initial Monotherapy (children 10 years of age or older)

a) The usual recommended initial dosage for monotherapy is 10 to 15 milligrams/kilogram/day increasing at 1 week intervals by 5 to 10 mg/kg/day until the desired therapeutic effect is reache effects occur. Total daily doses exceeding 250 milligrams should be given in divided doses, and recommended dose is 60 mg/kg/day (Prod Info DEPACON(R) IV injection, 2006).

2) Adjunctive Therapy (children 10 years of age or older)

a) The usual recommended dosage when adding valproic acid to a patient's regimen is 10 to 1 milligrams/kilogram/day (mg/kg/day), increasing at 1 week intervals by 5 to 10 mg/kg/day until t therapeutic effect is reached or adverse effects occur. Total daily doses exceeding 250 milligra in divided doses, and the maximum recommended dose is 60 mg/kg/day (Prod Info DEPACON 2006).

3) Conversion to Monotherapy

a) Concomitant antiepilepsy drug dosage may be reduced by approximately 25% every 2 week of valproic acid therapy or after 1 to 2 weeks of therapy (Prod Info DEPACON(R) IV injection, 2

1.4.1.B.1.c Seizure, Multiple seizure types; Adjunct

1) For children 10 years and older, administer 10 to 15 milligrams per kilograms (mg/kg) per day int dose may be increased by 5 to 10 mg/kg/week to achieve optimal clinical response, which is typicall therapeutic range of 50 to 100 mcg/mL. The maximum recommended dose is 60 mg/kg/day (Prod Ir IV injection, 2006).

1.4.1.B.1.d Important Note

1) Valproate sodium injection is for intravenous use only and should be used in patients who are ter use the oral form of valproic acid. Use of valproate sodium injection for periods of more than 14 days studied. As soon as it is clinically feasible, patients should be switched back to oral valproic acid. Va injection should be administered as a 60 minute infusion and not faster than 20 milligrams/minute. It with at least 50 milliliters of a compatible diluent. The same frequency of administration should be us products. Plasma concentrations should be monitored (Prod Info Depacon(R), 2003).

2) There have been reports of hyperammonemic encephalopathy (including fatalities) in patients wi disorders (UCD) who have received valproate therapy. UCD is a genetic disorder with an estimated 1:8000 to 1:30,000 births. Patients suspected of having UCD should not receive valproic acid, divalp valproate sodium (Prod Info Depakote(R), 2003; Prod Info Depakote ER(R), 2003; Prod Info Depako 2003; Prod Info Depakene(R), 2003; Prod Info Depacon(R), 2003).

e) Two patients (ages 10 years and 34 months) receiving multiple antiepileptic inducing agents including coma required a loading dose of valproate 20 milligrams/kilogram (mg/kg). A maintenance infusion of 4 r required to maintain a level of approximately 75 mg/Liter (Hovinga et al, 1999).

f) To achieve high therapeutic levels of valproic acid, RAPID INTRAVENOUS INFUSION at 3 or 6 millig (mg/kg)/minute for a duration of 4.17 or 8.34 minutes, respectively, has been used. Doses of 21 to 28 mg 24.2 mg/kg) were given to 21 patients (2 to 54-years-old). Peak serum valproate concentrations measure post-infusion were 105 to 204 micrograms/milliliter. The infusions were well-tolerated and no cardiac or c system adverse effects were reported (Venkataraman & Wheless, 1999).

1.4.1.B.1.g Intravenous valproic acid was used in 4 patients (3 children and 1 adult) for the treatment o WAVE STATUS EPILEPTICUS. Loading doses of 30 milligrams/kilogram were given over an hour. Main required in the 3 pediatric patients ranged from 120 to 160 mg/kg/day divided every 6 hours (Chez et al,

1) Equivalent Doses

a) The total daily dose of valproate sodium injection should be equivalent to the total daily dose valproic acid product and should be administered as a 60 minute infusion with the same freque products. Plasma concentration monitoring and dosage adjustments may be necessary. Infusio exceed 20 milligrams(mg)/minute. If the total daily dose exceeds 250 mg, it should be given in c (Prod Info Depacon(TM), 1999).

b) The manufacturer states that the equivalence shown between valproate sodium injection an products at steady state was only evaluated in an every 6 hour dosing regimen. If valproate soc given less frequently, trough levels may fall below those measured using the oral route. Close m trough plasma levels may be needed if valproate sodium injection is given only 2 or 3 times dail Depacon(TM), 1999).

2) Intravenous Rate of Administration

a) Valproate sodium injection should be administered as a 60 minute infusion and not faster tha milligrams/minute. It should be diluted with at least 50 milliliters of a compatible diluent. The sar administration should be used as the oral products. Plasma concentrations should be monitored Depacon(R), 2003).

b) In a prospective pilot study involving 4 hospitalized and acutely ill children, intravenous sodi safely administered at an infusion rate of 1 milligram/kilogram/minute. The patients ranged from age and weighed between 17.2 to 60 kilograms. Before and during the infusion, vital signs and were recorded every 5 minutes. Blood samples were also collected pre-infusion, at 0.5 hours ar hours post-infusion. Doses ranged between 8.3 to 15.4 milligrams/kilogram (mg/kg) and the dur infusions ranged from 8 to 15 minutes. Intravenous sodium valproate was diluted 1:1 (v/v) with 5 sterile water. The investigators found no clinically significant changes in blood pressure, heart ra rate (values not reported). The only reported adverse reaction was local inflammation at the inje in 1 patient. Unbound valproate acid concentrations were greater at 0.5 hours post-infusion than infusion (median percent of unbound valproate acid 22% vs 15%, respectively). Study investiga being cautious when using rapid infusions to acutely ill patients as higher unbound drug levels r excessive toxicity although total drug levels are within the target range (Birnbaum et al, 2003).

c) To achieve high therapeutic levels of valproic acid, RAPID INTRAVENOUS INFUSION at 3 milligrams/kilogram (mg/kg)/minute for a duration of 4.17 or 8.34 minutes, respectively, has bee 21 to 28 mg/kg (mean dose 24.2 mg/kg) were given to 21 patients (2 to 54-years-old). Peak ser concentrations measured 20 minutes post-infusion were 105 to 204 micrograms/milliliter. The in tolerated and no cardiac or central nervous system adverse effects were reported (Venkataram 1999).

d) Two patients (ages 10 years and 34 months) receiving multiple antiepileptic inducing agents phenobarbital, required a loading dose of valproate 20 milligrams/kilogram (mg/kg). A maintena 6 mg/kg/hour was required to maintain a level of approximately 75 mg/Liter (Hovinga et al, 199

1.4.1.B.2 Oral route

1.4.1.B.2.a West syndrome

1) Monotherapy with VALPROIC ACID was effective in the treatment of INFANTILE SPASMS in a p involving 22 children aged 4 to 11 months (Siemes et al, 1988). VALPROIC ACID (as SODIUM VAL given initially in oral doses of 15 milligrams/kilogram/day; this was increased every second day by 1(milligrams/kilogram until seizures ceased or a maximum dose of 100 milligrams/kilogram/day was a(were not controlled or reduced after 4 to 6 weeks of treatment, oral DEXAMETHASONE 0.4 to 0.5 m added to the regimen. The doses of SODIUM VALPROATE ranged from 40 to 100 milligrams/kilogra 74).

1.4.1.C Valproic Acid

Oral route

Rectal route

1.4.1.C.1 Oral route

Absence seizure, Simple and complex

Complex partial epileptic seizure

Migraine; Prophylaxis

Seizure, Multiple seizure types; Adjunct

1.4.1.C.1.a Absence seizure, Simple and complex

1) In children, 10 years and older, the usual recommended dosage is 15 milligrams/kilogram/day (m increasing at 1 week intervals by 5 to 10 mg/kg/day until the desired therapeutic effect is reached or occur. The maximum recommended dosage is 60 mg/kg/day. Total daily doses of valproic acid exce should be given in 2 to 3 divided doses. Therapeutic valproate serum concentrations for most patien seizures is considered to range from 50 to 100 micrograms/milliliter (Prod Info DEPAKENE(R) oral c syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008).

2) The initial dose should be determined by weight and not age. The manufacturer of (Depakene(R) following dosage schedule based on body weight (Prod Info DEPAKENE(R) oral capsules, oral syru

Pounds (lbs)	Kilograms (kg)	Daily dose
22 to 54.9 lbs	10 to 24.9 kg	250 mg
55 to 87.9 lbs	25 to 39.9 kg	500 mg
88 to 131.9 lbs	40 to 59.9 kg	750 mg
132 to 164.9 lbs	60 to 74.9 kg	1000 mg
165 to 197.9 lbs	75 to 89.9 kg	1250 mg

1.4.1.C.1.b Complex partial epileptic seizure

1) Initial Monotherapy

a) In children 10 years and older, the usual recommended initial oral dosage for monotherapy i milligrams/kilogram/day (mg/kg/day) increasing at 1 week intervals by 5 to 10 mg/kg/week until therapeutic effect is reached. Usually, optimal clinical response is achieved at daily doses belov a satisfactory response has not been obtained, plasma levels should be measured to determine they are in the accepted therapeutic serum range (50 to 100 mcg/mL). Doses above 60 mg/kg/d recommended. Total daily doses of valproic acid exceeding 250 milligrams should be given in 2 (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed rele 2008) .

2) Conversion to Monotherapy

a) When converting to monotherapy in children 10 years and older, the usual recommended ini 10 to 15 milligrams/kilogram/day (mg/kg/day) increasing at 1 week intervals by 5 to 10 mg/kg/w desired therapeutic effect is reached or adverse effects occur. Usually, optimal clinical response daily doses below 60 mg/kg/day. If a satisfactory response has not been obtained, plasma level measured to determine whether or not they are in the accepted therapeutic serum range (50 to Concomitant antiepilepsy drug dosage may be reduced at the initiation of valproic acid therapy weeks of therapy. The dosage of the concomitant antiepilepsy drug can be reduced by approxi 2 weeks. Valproic acid doses above 60 mg/kg/day are not recommended. Total daily doses of v

exceeding 250 milligrams should be given in 2 to 3 divided doses (Prod Info DEPAKENE(R) ora syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3) Adjunctive Therapy

a) In children 10 years and older, the usual recommended oral dosage when adding valproic a regimen is 10 to 15 milligrams/kilogram/day (mg/kg/day), increasing at 1 week intervals by 5 to until the desired therapeutic effect is reached. Usually, optimal clinical response is achieved at 60 mg/kg/day. If a satisfactory response has not been obtained, plasma levels should be measu whether or not they are in the accepted therapeutic serum range (50 to 100 mcg/mL). Doses ab are not recommended. Total daily doses of valproic acid exceeding 250 milligrams should be gi divided doses (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R oral capsules, 2008).

1.4.1.C.1.c Migraine; Prophylaxis

1) Valproic acid 15 to 30 milligrams/kilogram/day divided into 2 doses has been used for the prophy children (Hamalainen, 1998). However, the efficacy has not been confirmed in clinical trials (Prod In delayed release oral capsules, 2008; Prod Info DEPAKOTE(R) ER extended-release oral tablets, 20

1.4.1.C.1.d Seizure, Multiple seizure types; Adjunct

1) In children, 10 years and older, the recommended initial dose is 10 to 15 milligrams/kilogram/day The dose may be increased by 5 to 10 mg/kg/week to achieve optimal clinical response. If total daily 250 mg, give in 2 to 3 divided doses. Maximum daily dose is 60 mg/kg/day or less with a therapeutic 50 to 100 micrograms/milliliter (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info S delayed release oral capsules, 2008).

e) There is an increased risk of fatal hepatotoxicity in patients under 2 years of age (Prod Info DEPAKEI capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008). The safety an delayed-release valproic acid (Stavzor(R)) in patients under 18 years of age for the treatment of acute m with bipolar disorder and for the prophylaxis of migraines have not been established (Prod Info STAVZO release oral capsules, 2008).

1.4.1.C.1.f Withdrawal Schedule

1) The risk factors associated with withdrawal of anticonvulsants in 92 patients who had been free o years with single agent therapy were evaluated. The dose of each anticonvulsant was reduced by 1 2 weeks (1 unit equivalent to 200 milligrams of carbamazepine or valproic acid, or 100 milligrams of mean follow-up period of 26 months (range, 6 to 62 months). Relapse occurred in 31 patients, with 6 remaining free of seizures (relapse rate 33.7%) (Callaghan et al, 1988).

1.4.1.C.2 Rectal route

a) The bioavailability of diluted valproic acid syrup given rectally is comparable to that following oral adm are, therefore, the same for rectal or oral administration. Rectal administration of valproic acid syrup app alternative to oral administration when the oral route is not available (Cloyd & Kriel, 1981).

b) Rectal administration of valproic acid has been successful in the treatment of intractable status epilep Commercially available valproic acid syrup (Depakene(R) 250 mg/5 mL) was diluted 1:1 with tap water a retention enema in a loading dose of 10 to 20 milligrams/kilogram. Maintenance doses were started 8 ho initial loading dose (10 to 15 milligrams/kilogram every 8 hours. Five of 7 children (mean age, 7.7 years) seizures within 24 hours after starting rectal therapy. Duration of therapy ranged from 1 to 8 days (mean authors suggest that loading doses of 20 milligrams/kilogram be administered which will attain plasma le approximately 50 mcg/mL. Marked increases in aspartate aminotransferase activity occurred in 3 of the requiring cessation of valproic acid therapy (Snead & Miles, 1985).

c) The successful use of rectal anticonvulsants was described as an alternative route to oral drug therap seizures undergoing gastrointestinal surgery. Perioperative rectal therapy was employed for clonazepam valproate (retention enema in tap water or saline), and given until the patients could again receive oral m duration of use was generally 48 to 72 hours. All patients maintained excellent seizure control without to rectally administered preparations (Woody et al, 1989).

1.4.2 Dosage in Renal Failure

A) Valproic Acid

1) Renal excretion of sodium valproate as the unchanged drug is 1.8% (Hardman et al, 1996a). A 27% reduc unbound clearance of valproate has been reported in patients with a creatinine clearance of less than 10 milli however, hemodialysis typically decreases valproate concentrations by about 20%. Therefore, dosage adjust unnecessary in patients with renal failure. Monitoring total concentrations of valproic acid may be misleading renal failure because protein binding in these patients is significantly reduced (Prod Info DEPAKENE(R) oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008).

B) Divalproex Sodium

1) Dose adjustments are not required in renal failure (Prod Info DEPAKOTE(R) ER extended-release oral tal Bennett et al, 1994). However, increased free levels of valproic acid have been reported and monitoring of to may be misleading (Lapierre et al, 1999). Renal excretion of sodium valproate as the unchanged drug is 1.8% 1996a). A 27% reduction in the unbound clearance of valproate has been reported in patients with a creatinir less than 10 milliliters/minute (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

C) Valproate Sodium

1) Renal excretion of SODIUM VALPROATE as the unchanged drug is 1.8% (Hardman et al, 1996a). A 27% unbound clearance of valproate has been reported in patients with a creatinine clearance of less than 10 milli Dosage adjustments are not required in renal failure (Prod Info Depakote(R) Tablets, 2002a; Bennett et al, 19 increased free levels of valproic acid have been reported and monitoring of total concentrations may be misle al, 1999).

1.4.3 Dosage in Hepatic Insufficiency

A) Valproic Acid

1) Valproic acid should not be administered to patients with hepatic disease or significant hepatic insufficienc impairs the capacity to eliminate valproate. In one study, the clearance of free valproate was decreased by 5(cirrhosis and by 16% in patients with acute hepatitis. Patients with liver disease have decreased albumin con larger unbound fractions by a 2 to 2.6 fold increase. Monitoring of total concentrations may be misleading sin concentrations may be significantly elevated in patients with hepatic disease, with total concentrations appea (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral caps

B) Divalproex Sodium

1) Divalproex sodium should not be administered to patients with hepatic disease or significant hepatic insuf disease impairs the capacity to eliminate valproate. In one study, the clearance of free valproate was decreas patients with cirrhosis and by 16% in patients with acute hepatitis. Patients with liver disease have decreased concentrations and larger unbound fractions by a 2- to 2.6-fold increase. Monitoring of total concentrations m (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral ca Info DEPAKOTE(R) delayed-release oral tablets, 2006).

C) Valproate Sodium

1) VALPROIC ACID or DIVALPROEX should not be administered to patients with hepatic disease or signific insufficiency (Prod Info Depakene(R), 1999; Prod Info Depakote(R), 1999). Liver disease impairs the capacity valproate. In one study, the clearance of free valproate was decreased by 50% in patients with cirrhosis and with acute hepatitis. Patients with liver disease have decreased albumin concentrations and larger unbound f 2.6 fold increase. Monitoring of total concentrations may be misleading.

1.4.4 Dosage Adjustment During Dialysis

A) Valproic Acid

1) Hemodialysis typically reduces valproate concentrations by about 20%, but a 27% reduction in the unbou valproate has been reported in patients with a creatinine clearance of less than 10 milliliters/minute. Therefor supplementation is required in patients following hemodialysis, peritoneal dialysis, or continuous arteriovenou Monitoring total concentrations of valproic acid may be misleading in patients with renal failure because prote patients is significantly reduced (Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZO release oral capsules, 2008).

B) Divalproex Sodium

1) No dosage supplementation is required in patients following hemodialysis, peritoneal dialysis, or continuo hemofiltration (Bennett et al, 1994). Hemodialysis typically reduces valproate concentrations by about 20% a is substantially reduced. Monitoring total concentrations may be misleading (Prod Info DEPAKOTE(R) ER ex oral tablets, 2008).

C) Valproate Sodium

1) No dosage supplementation is required in patients following hemodialysis, peritoneal dialysis, or continuo hemofiltration (Prod Info Depakote(R) Tablets, 2002a; Bennett et al, 1994). Hemodialysis typically reduces va concentrations by about 20% and protein binding is substantially reduced. Monitoring total concentrations ma (Prod Info Depakote(R) Tablets, 2002a).

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Peak Response

a) Epilepsy, oral: 2 weeks (Lance & Anthony, 1977a; Lance & Anthony, 1977b).

2.2 Drug Concentration Levels

A) Therapeutic Drug Concentration

1) Epilepsy, 50 to 100 mcg/mL (Prod Info STAVZOR(R) delayed release oral capsules, 2008)(Prod Info Depaken Info Depakote(R), Tablets 2003; Prod Info Depacon(R), 1999)(Turnbull et al, 1983a; Rimmer & Richens, 1985d).

a) A free concentration therapeutic range has not been established (Prod Info Depakene(R), 1999).

b) High concentration valproic acid (80 to 150 mcg/mL) may be needed to reduce seizure frequency of some seizures and secondarily generalized tonic-clonic seizures (Beydoun et al, 1997d).

c) Plasma concentrations fluctuate between doses, varying between 100% and 140% of the steady state co (Schobben et al, 1975a; Loiseau et al, 1975).

d) Comparable plasma levels occur when switching from oral valproate to intravenous valproate sodium (Pro (R), 1999).

2) Acute mania, 50 to 125 mcg/mL (Prod Info STAVZOR(R) delayed release oral capsules, 2008)(Prod Info Depa 2003).

B) Peak Concentration

1) When a single dose of valproic acid delayed release 500 milligram (mg) oral capsules was compared to a sing divalproex sodium delayed release 500 mg oral tablets under fasted conditions, similar plasma concentration-time noted with the exception of median Tmax, which occurred earlier with the delayed release capsules (2 hours vers When valproic acid delayed release capsules were administered with food, there was a 23% decrease in Cmax o median Tmax was increased to 4.8 hours (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

C) Time to Peak Concentration

1) Oral, valproic acid delayed-release capsules, single 500-mg dose, fasted: 2 hr (Prod Info STAVZOR(R) delaye capsules, 2008)

a) When a single dose of valproic acid delayed release 500 milligram (mg) oral capsules was compared to a divalproex sodium delayed release 500 mg oral tablets under fasted conditions, similar plasma concentration noted with the exception of median Tmax, which occurred earlier with the delayed release capsules (2 hours (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

2) Oral, valproic acid delayed-release capsules, single 500-mg dose, with food: 4.8 hr (Prod Info STAVZOR(R) d capsules, 2008)

a) When a single dose of valproic acid delayed release 500 milligram capsules was administered with food, t decrease in Cmax of valproic acid and median Tmax was increased to 4.8 hours compared with administratio state (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3) Oral, valproic acid capsules (Depakene(R)): 1 to 4 hours (Prod Info Depakene(R), 1999)(Hardman et al, 1996)

4) Oral, divalproex tablet: 4 to 8 hours (Prod Info Depakote(R) Tablets, 2002; Oelkers et al, 1977).

5) Oral, divalproex sprinkle capsule: 3.3 to 4.8 (Prod Info Depakote(R) Sprinkle Capsules, 1999).

6) Oral, divalproex sodium extended-release tablet: 4 - 17 hours (Prod Info Depakote(R) ER, 2003m)

a) When a single dose of valproic acid delayed release 500 milligram (mg) oral capsules was compared to a divalproex sodium delayed release 500 mg oral tablets under fasted conditions, similar plasma concentration noted with the exception of median Tmax, which occurred earlier with the delayed release capsules (2 hours (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

b) Maximum valproate plasma concentration (Cmax) of divalproex sodium extended-release tablets at stead relative to divalproex sodium delayed-release tablets given twice a day (Prod Info Depakote(R) ER, 2003m).

7) Oral, sodium valproate solution: 1.2 hours (Klotz & Antonin, 1977).

8) Intravenous, Depacon(R): At the end of a 1 hour infusion (Prod Info Depacon(R), 1999).

9) Rectal, diluted valproic acid syrup: 3.1 hours (Holmes et al, 1989).

D) Area Under the Curve

1) When a single dose of valproic acid delayed release 500 milligram (mg) oral capsules was compared to a sing divalproex sodium delayed release 500 mg oral tablets under fasted conditions, the plasma concentration-time pr in terms of valproic acid. Coadministration with food did not alter systemic exposure of valproic acid (Prod Info ST delayed release oral capsules, 2008).

2) Equivalent areas under the curve were achieved at steady state, when divalproex sodium tablets and valproat given as a one hour infusion, were administered at 250 mg every 6 hours for 4 days (Prod Info Depacon(R), 1999

3) The area under the curve and the maximum concentration resulting from a valproate sodium injection 500 mg and a 500 mg dose of valproic acid syrup were equivalent (Prod Info Depacon(R), 1999).

4) When extended release divalproex sodium tablets (Depakote(R) ER) are administered once daily in doses 8 t the total daily dose of delayed release divalproex sodium tablets (Depakote(R) Tablets), equivalent areas under t achieved (Prod Info Depakote(R) ER, 2003m).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

Extracorporeal Elimination

2.3.1 Absorption

A) Bioavailability

1) Oral, extended-release tablets: 90% (Prod Info Depakote(R) ER, 2003m)

a) The absolute bioavailability of divalproex sodium extended- release tablet administered as a single do was approximately 90% relative to intravenous infusion (Prod Info Depakote(R) ER, 2003m).

b) Divalproex sodium extended-release tablets given on an empty stomach produced an average bioava 89% relative to divalproex sodium delayed-release tablets given twice a day (Prod Info Depakote(R) ER,

B) Effects of Food

1) No significant effect on systemic availability (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

a) When a single dose of valproic acid delayed release 500 milligram capsules was administered with fo 23% decrease in Cmax of valproic acid and median Tmax was increased from 2 to 4.8 hours compared v under a fasted state but there was no change in systemic exposure (Prod Info STAVZOR(R) delayed rel capsules, 2008).

b) Coadministration of oral valproate products with food is not expected to have any significant clinical e management of patients with epilepsy (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding

a) 90% (primarily to albumin) (Prod Info Depakene(R), 1999) (Prod Info STAVZOR(R) delayed release o 2008; Prod Info Depakote(R) Tablets, 2002; Hardman et al, 1996; Klotz & Antonin, 1977).

1) Protein binding is concentration-dependent and decreases at high valproate concentrations (Pro (R), 1999). Free fraction plasm protein concentration increases from approximately 10% at 40 mcg/m mcg/mL (Prod Info STAVZOR(R) delayed release oral capsules, 2008; Prod Info Depakote(R) ER, 2

2) Plasma protein binding decreased in the elderly resulting in an increase in the free fraction by 44 Depakote(R) ER Tablets, 2003)(Rimmer & Richens, 1985d). Liver disease is associated with 2 to 2.5 unbound valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008)(Prod Info Depako 2003)(Klotz et al, 1978a). Plasma protein binding is also decreased in patients with renal disease (L (Marbury et al, 1980; Gugler & Mueller, 1978), in hyperlipidemic patients (Prod Info Depakote(R) ER and in the presence of other drugs such as aspirin (Prod Info STAVZOR(R) delayed release oral cap Conversely, valproate may displace other protein-bound medications such as phenytoin, carbamaze tolbutamide (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3) A 108% increase in free valproic acid was observed in the sera of patients with HIV (Dasgupta &

2) Tissues and Fluids

a) CEREBROSPINAL FLUID, 10% (Prod Info STAVZOR(R) delayed release oral capsules, 2008; Pinde

1) Valproate concentration in cerebrospinal fluid is approximately 10% of the total concentration (Pr (R) delayed release oral capsules, 2008).

B) Distribution Kinetics

1) Volume of Distribution

a) 0.14 to 0.23 L/kg (Puentas et al, 1999)(Bennett et al, 1994a).

1) Differences in volume of distribution occur between young and elderly (0.13 and 0.19 L/kg, respe et al, 1984; Bryson et al, 1983).

2) The volume of distribution for total valproate is 11 L/1.73 m(2), free valproate is 92 L/1.73 m(2) (F STAVZOR(R) delayed release oral capsules, 2008; Prod Info Depakote(R) ER, 2003m).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) Liver, rapidly and extensively (Prod Info STAVZOR(R) delayed release oral capsules, 2008)(Prod Info De (Prod Info Depakote(R) Tablets, 2002).

a) Valproate undergoes conjugation (30% to 50%), mitochondrial beta oxidation (40%), and microsomal numerous metabolites (15% to 20%). Less than 3% of an administered dose is excreted unchanged in th STAVZOR(R) delayed release oral capsules, 2008; Prod Info Depakote(R) ER, 2003m); (Prod Info Depa (Prod Info Depakote(R) Tablets, 2002).

b) A cytochrome P450 microsomal enzyme appears to metabolize valproic acid (Zaccara et al, 1988).

B) Metabolites

1) 2-propyl-3-keto-pentanoic acid, activity unknown (Prod Info Depakene(R), 1999)(Prod Info Depakote(R) T

2) 2-propyl-hydroxypentanoic acids, activity unknown (Prod Info Depakene(R), 1999)(Prod Info Depakote(R)

a) Approximately 70% of a dose is excreted as the glucuronide (Nau & Loscher, 1984; Loscher, 1981; B 1979).

2.3.4 Excretion

A) Kidney

1) Renal Clearance (rate)

a) Total valproate, adults: 0.56 L/hr/1.73 square meter (Prod Info STAVZOR(R) delayed release oral cap

b) Free valproate, adults: 4.6 L/hr/1.73 square meter (Prod Info STAVZOR(R) delayed release oral caps

2) Renal Excretion (%)

a) 70% to 80% (Bruni & Wilder, 1979; Schobben et al, 1975a).

b) In adult patients on monotherapy, 30% to 50% of an administered dose appears in the urine as glucu (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) Less than 3% of an administered dose of valproate is excreted unchanged in the liver total valproate, square meter (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

B) Bile

1) Bile, 7% (Pinder et al, 1977d).

C) Other

1) TOTAL PLASMA CLEARANCE

a) 0.9 L/hr (Puentes et al, 1999).

1) Clearance decreases with increasing age (Snachez-Alcaraz et al, 1998). Clearances in specific a found to be: 24.5 ml/kg/hr for less than 2 years old, 19.9 ml/kg/hr for 2 to 4 years old, 12.7 ml/kg/hr f years old.

2) Children between 3 months and 10 years have 50% higher clearance rates when compared to a the age of 10, pharmacokinetic parameters of children are similar to those of adults (Prod Info STAV release oral capsules, 2008).

3) Intrinsic clearance in the elderly (age ranged from 68 to 89 years) is reduced by 39% and free fra by 44% when compared with young adults (age ranged from 22 to 26 years) (Prod Info STAVZOR(R oral capsules, 2008; Prod Info Depakote(R) ER, 2003m).

4) Clearance is increased by 10% with coadministration of phenobarbital (Yukawa et al, 1997a).

5) Clearance is increased by coadministration of carbamazepine (dose-related) (Yukawa et al, 199

6) There are no differences in the body surface area adjusted unbound clearance between male an L/hr/1.73 m(2) and 4.7 L/hr/1.73 m(2), respectively) (Prod Info Depakote(R) ER, 2003m). However, clearance in female patients is 10% less than in male patients (Yukawa et al, 1997a).

7) Clearance of free valproate is decreased in patients with liver disease. One study demonstrated clearance in 7 patients with cirrhosis and a 16% decrease in clearance in 4 patients with acute hepa 6 healthy subjects (Prod Info STAVZOR(R) delayed release oral capsules, 2008; Prod Info Depakot 2002).

8) There is a 27% decrease in the unbound clearance of valproate in patients with a creatinine clea mL/minute (Prod Info STAVZOR(R) delayed release oral capsules, 2008)(Prod Info Depakote(R) EF

2) OTHER EXCRETION

a) Lung, 2 to 18% (Pinder et al, 1977d).

1) Excreted in expired air as carbon dioxide (Pinder et al, 1977d).

2.3.5 Elimination Half-life

A) Parent Compound

1) Adults: 6 to 17 hours (Prod Info STAVZOR(R) delayed release oral capsules, 2008)(Prod Info Depakene(R et al, 1996; Rimmer & Richens, 1985d; Perucca et al, 1984; Bryson et al, 1983).

a) The mean terminal half-life for valproate monotherapy ranged from 9 to 16 hours following oral dosing to 1000 milligrams (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

b) In one study, the half life of valproate was increased from 12 to 18 hours in patients with liver disease Depakote(R) Tablets, 2002).

2) Adults, liver disease: 18 hours (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

a) Compared with 6 healthy subjects, the half-life of valproate in patients with liver disease increased fro in one study involving 7 patients with cirrhosis and 4 patients with acute hepatitis (Prod Info STAVZOR(R oral capsules, 2008; Prod Info Depakote(R) Tablets, 2002).

3) Neonates less than 10 days old: 10 to 67 hours (Prod Info STAVZOR(R) delayed release oral capsules, 2

a) Children within the first 2 months of life have decreased ability to eliminate valproate compared to old adults. This is due to reduced clearance and increased volume of distribution (Prod Info STAVZOR(R) de capsules, 2008).

4) Neonates greater than 2 months old: 7 to 13 hours (Prod Info STAVZOR(R) delayed release oral capsules

a) Children within the first 2 months of life have decreased ability to eliminate valproate compared to old adults. This is due to reduced clearance and increased volume of distribution (Prod Info STAVZOR(R) de capsules, 2008).

2.3.6 Extracorporeal Elimination

A) Hemodialysis

1) Dialyzable: Yes (Prod Info STAVZOR(R) delayed release oral capsules, 2008; Johnson et al, 1999); (Frar (Marbury et al, 1980).

a) Hemodialysis of 4 hours duration removed 15% to 22% of valproic acid in chronic renal failure patient 1980).

b) Acute valproic acid overdose (serum concentration greater than 1200 mcg/mL) in a 25-year-old woma suicide attempts was successfully treated with high-flux hemodialysis using a highly permeable polysulfo membrane. High- flux hemodialysis was performed for 4 hours and lowered the valproic acid half-life to 2 increased the calculated elimination rate constant to 0.2522 h(-1). The authors concluded that high-flux h as effective as combination hemodialysis and charcoal hemoperfusion and avoided the attendant risks o hemoperfusion (Kane et al, 2000).

c) A 43-year-old woman who ingested approximately 19 grams of valproic acid had 15.5 grams removed hemodialysis (high-flux polysulfone hemodialysis membrane) (Johnson et al, 1999). Her valproic acid se

decreased from 940 to 164 micrograms/milliliter. The half-life of valproic acid was reduced from 7.2 to 2.

B) Peritoneal

1) Dialyzable: Yes (Orr et al, 1983).

a) In a 9-year-old boy receiving chronic peritoneal dialysis, only an average of 4.5% of the valproic acid over 12- or 24-hour dialysis periods (Orr et al, 1983).

C) Hemoperfusion

1) Dialyzable: Yes (Franssen et al, 1999).

a) A 27-year-old male was successfully treated with serial hemodialysis, and hemoperfusion with resin a following a valproic acid overdose (Franssen et al, 1999). The patient was dialyzed during two 3-hour se highly permeable polysulfone hemodialysis membrane. A charcoal hemoperfusion column was added dc first session and a resin column for the second. The hemodialysis was effective while the hemofiltration v in the first hour. This was due to rapid saturation of the column. The resin column appeared to be more e charcoal.

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING

1) Valproic Acid

a) Oral (Syrup; Capsule, Liquid Filled)

Hepatotoxicity

Hepatic failure resulting in fatalities has occurred in patients receiving valproic acid and its derivatives. E indicated that children under the age of two years are at a considerably increased risk of developing fata especially those on multiple anticonvulsants, those with congenital metabolic disorders, those with sever accompanied by mental retardation, and those with organic brain disease. When valproic acid is used in they should be used with extreme caution and as a sole agent. The benefits of therapy should be weighe risks. Above this age group, experience in epilepsy has indicated that the incidence of fatal hepatotoxicit considerably in progressively older patient groups.

These incidents usually have occurred during the first six months of treatment. Serious or fatal hepatoto preceded by non-specific symptoms such as malaise, weakness, lethargy, facial edema, anorexia, and v patients with epilepsy, a loss of seizure control may also occur. Patients should be monitored closely for these symptoms. Liver function tests should be performed prior to therapy and at frequent intervals there during the first six months.

Pancreatitis

Cases of life-threatening pancreatitis have been reported in both children and adults receiving valproate. cases have been described as hemorrhagic with a rapid progression from initial symptoms to death. Cas reported shortly after initial use as well as after several years of use. Patients and guardians should be w abdominal pain, nausea, vomiting, and/or anorexia can be symptoms of pancreatitis that require prompt evaluation. If pancreatitis is diagnosed, valproate should ordinarily be discontinued. Alternative treatmen medical condition should be initiated as clinically indicated.

Teratogenicity

Valproate can produce teratogenic effects such as neural tube defects (eg, spina bifida). Accordingly, the products in women of childbearing potential requires that the benefits of its use be weighed against the r fetus. This is especially important when the treatment of a spontaneously reversible condition not ordinar permanent injury or risk of death (eg, migraine) is contemplated (Prod Info DEPACON(R) IV injection, 20 DEPAKENE(R) oral capsules, syrup, 2006; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006; DEPAKOTE(R) ER extended-release tablet, 2006; Prod Info DEPAKOTE(R) sprinkle oral capsules, 200

b) Oral (Capsule, Delayed Release)

Hepatotoxicity

Hepatic failure resulting in fatalities has occurred in patients receiving valproic acid and its derivatives. C age of two years are at a considerably increased risk of developing fatal hepatotoxicity, especially those anticonvulsants, those with congenital metabolic disorders, those with severe seizure disorders accompa retardation, and those with organic brain disease. When valproic acid is used in this patient group, it sho extreme caution and as a sole agent. The benefits of therapy should be weighed against the risks. The ir hepatotoxicity decreases considerably in progressively older patient groups.

These incidents usually have occurred during the first six months of treatment. Serious or fatal hepatoto

preceded by non-specific symptoms such as malaise, weakness, lethargy, facial edema, anorexia, and v
patients with epilepsy, a loss of seizure control may also occur. Patients should be monitored closely for
these symptoms. Liver function tests should be performed prior to therapy and at frequent intervals there
during the first six months.

2) Divalproex Sodium

a) Oral (Tablet, Enteric Coated; Tablet, Extended Release; Capsule, Delayed Release)

Hepatotoxicity

Hepatic failure resulting in fatalities has occurred in patients receiving valproic acid and its derivatives. C
age of two years are at a considerably increased risk of developing fatal hepatotoxicity, especially those
anticonvulsants, those with congenital metabolic disorders, those with severe seizure disorders accompa
retardation, and those with organic brain disease. When divalproex sodium is used in this patient group,
with extreme caution and as a sole agent. The benefits of therapy should be weighed against the risks. T
fatal hepatotoxicity decreases considerably in progressively older patient groups.

These incidents usually have occurred during the first six months of treatment. Serious or fatal hepatotox
preceded by non-specific symptoms such as malaise, weakness, lethargy, facial edema, anorexia, and v
patients with epilepsy, a loss of seizure control may also occur. Patients should be monitored closely for
these symptoms. Liver function tests should be performed prior to therapy and at frequent intervals there
during the first six months.

Teratogenicity

Valproate can produce teratogenic effects such as neural tube defects (eg, spina bifida). Accordingly, the
sodium in women of childbearing potential requires that the benefits of its use be weighed against the ris
fetus. This is especially important when the treatment of a spontaneously reversible condition not ordinar
permanent injury or risk of death (eg, migraine) is contemplated.

An information sheet describing the teratogenic potential of valproate is available for patients.

Pancreatitis

Cases of life-threatening pancreatitis have been reported in both children and adults receiving valproate.
cases have been described as hemorrhagic with a rapid progression from initial symptoms to death. Cas
reported shortly after initial use as well as after several years of use. Patients and guardians should be w
abdominal pain, nausea, vomiting, and/or anorexia can be symptoms of pancreatitis that require prompt
evaluation. If pancreatitis is diagnosed, valproate should ordinarily be discontinued. Alternative treatmen
medical condition should be initiated as clinically indicated (Prod Info DEPAKOTE(R) sprinkle oral capsu
Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

3) Valproate Sodium

a) Intravenous (Solution)

HEPATOTOXICITY

Hepatic failure resulting in fatalities has occurred in patients receiving valproic acid and its derivatives. E
indicated that children under the age of two years are at a considerably increased risk of developing fata
especially those on multiple anticonvulsants, those with congenital metabolic disorders, those with sever
accompanied by mental retardation, and those with organic brain disease. When valproate sodium is use
group, it should be used with extreme caution and as a sole agent. The benefits of therapy should be we
risks. Above this age group, experience in epilepsy has indicated that the incidence of fatal hepatotoxicit
considerably in progressively older patient groups.

These incidents usually have occurred during the first six months of treatment. Serious or fatal hepatotox
preceded by non-specific symptoms such as malaise, weakness, lethargy, facial edema, anorexia, and v
patients with epilepsy, a loss of seizure control may also occur. Patients should be monitored closely for
these symptoms. Liver function tests should be performed prior to therapy and at frequent intervals there
during the first six months(Prod Info DEPACON(R) IV injection, 2006).

PANCREATITIS

Cases of life-threatening pancreatitis have been reported in both children and adults receiving valproate.
cases have been described as hemorrhagic with a rapid progression from initial symptoms to death. Cas
reported shortly after initial use as well as after several years of use. Patients and guardians should be w
abdominal pain, nausea, vomiting, and/or anorexia can be symptoms of pancreatitis that require prompt
evaluation. If pancreatitis is diagnosed, valproate should ordinarily be discontinued. Alternative treatmen
medical condition should be initiated as clinically indicated (Prod Info DEPACON(R) IV injection, 2006).

TERATOGENICITY

Valproate can produce teratogenic effects such as neural tube defects (eg, spina bifida). Accordingly, the

products in women of childbearing potential requires that the benefits of its use be weighed against the r
fetus. This is especially important when the treatment of a spontaneously reversible condition not ordinar
permanent injury or risk of death (eg, migraine) is contemplated (Prod Info DEPACON(R) IV injection, 20

3.1 Contraindications

A) Valproic Acid

1) hepatic disease or significant hepatic dysfunction (Prod Info STAVZOR(R) delayed release oral capsules, 200

3.3.1 Cardiovascular Effects

Valproic Acid

Divalproex Sodium

3.3.1.A Valproic Acid

Chest pain

Hypertension

Hypotension

Palpitations

Peripheral edema

Tachycardia

3.3.1.A.1 Chest pain

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Chest pain was reported in more than 1% but less than 5% of patients receiving valproate during plac clinical trials of migraine and acute mania and during monotherapy treatment of complex partial seizures causality could not be attributed to valproate alone in the complex partial seizures trial, as patients were another antiepilepsy drug during the first part of the study (Prod Info STAVZOR(R) delayed release oral

3.3.1.A.2 Hypertension

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Hypertension was reported in more than 1% but less than 5% of patients receiving valproate during p clinical trials of acute mania and during monotherapy treatment of complex partial seizures. In many cas not be attributed to valproate alone in the complex partial seizures trial, as patients were titrated off of an drug during the first part of the study (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.1.A.3 Hypotension

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Hypotension and postural hypotension was reported in more than 1% but less than 5% of 89 patients valproate during two clinical trials of valproate treatment of manic episodes associated with bipolar disor STAVZOR(R) delayed release oral capsules, 2008).

c) A mentally retarded 11-year-old girl experienced profound hypotension during an IV valproate infusio given to treat status epilepticus. Upon arrival in the emergency department, the girl was given IV diazepa the seizure temporarily. When the seizures began again, the girl was given IV lorazepam and started on mg. Her blood pressure 5 minutes prior to the start of the valproate infusion was 130/80 mmHg, but decr mmHg 39 minutes after the start of the infusion. She was given IV fluids and her blood pressure ranged mmHg and 60/30 mmHg. She was intubated and given dopamine and recovered 10 days later without fu (White & Santos, 1999)

3.3.1.A.4 Palpitations

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Palpitations were reported in more than 1% but less than 5% of patients receiving valproate during pl clinical trials of acute mania and during monotherapy treatment of complex partial seizures. In many cas not be attributed to valproate alone in the complex partial seizures trial, as patients were titrated off of an drug during the first part of the study (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.1.A.5 Peripheral edema

a) Incidence: 3% to 8% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, peripheral edema was re patients receiving high-dose valproate (n=131) compared with 3% of patients receiving low-dose valproa many cases, causality could not be determined as patients were being titrated off another antiepilepsy dr part of the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.1.A.6 Tachycardia

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Tachycardia was reported in more than 1% but less than 5% of patients receiving valproate during pl clinical trials of acute mania and during monotherapy treatment of complex partial seizures. In many cas not be attributed to valproate alone in the complex partial seizures trial, as patients were titrated off of an drug during the first part of the study (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.1.B Divalproex Sodium

Chest pain

Hypertension

Palpitations

Peripheral edema

Tachycardia

3.3.1.B.1 Chest pain

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Chest pain was reported in more than 1% but less than 5% of patients receiving divalproex sodium (r

monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.1.B.2 Hypertension

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Hypertension was reported in more than 1% but less than 5% of patients receiving divalproex sodium monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.1.B.3 Palpitations

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Palpitations were reported in more than 1% but less than 5% of patients receiving divalproex sodium monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.1.B.4 Peripheral edema

a) Incidence: 3% to 8% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Peripheral edema was reported in 8% of patients receiving high-dose divalproex sodium (n=131) com patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.1.B.5 Tachycardia

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Tachycardia was reported in more than 1% but less than 5% of patients receiving divalproex sodium monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.2 Dermatologic Effects

Valproic Acid

Divalproex Sodium

3.3.2.A Valproic Acid

Alopecia

Cutaneous pseudolymphoma

Injection site disorder

Rash

Stevens-Johnson syndrome

3.3.2.A.1 Alopecia

a) Incidence: 6% to 24% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia alopecia was reported in 6% of patients receiving valproate (n=77) compared with 1% of patients receivi In most cases, causality could not be determined as patients also received other antiepilepsy drugs conc valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) During a clinical trial of valproate monotherapy for complex partial seizures, alopecia was reported in receiving high-dose valproate (n=131) compared with 13% of patients receiving low-dose valproate (n=1 cases, causality could not be determined as patients were being titrated off another antiepilepsy drug du the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

d) Alopecia was reported in 7% of migraine patients receiving valproate (n=202) compared with 1% of p placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) delayed r

capsules, 2008).
e) In a double-blind, concentration-response clinical trial using valproic acid as monotherapy, high conce
acid (n=96, target level 80 to 150 mcg/mL) caused alopecia in 27 patients (28%) versus 2 patients (4%)
to low concentration valproic acid (n=47, target range of 25 to 50 mcg/mL) (Beydoun et al, 1997c).

3.3.2.A.2 Cutaneous pseudolymphoma

a) Cutaneous pseudolymphoma erupted on the left shoulder of a 41-year-old man after sodium valproat
recurred when the patient was switched to carbamazepine. Valproate 500 mg twice daily was ordered af
experienced an extradural hematoma secondary to cranial trauma. His lesion was an itchy infiltrated eryt
histologically mimicking a non-epidermotropic T-cell lymphoma. Applying polymerase chain reaction to th
produced monoclonal rearrangement of the T-cell gamma gene. Valproate was discontinued and replace
carbamazepine 400 mg twice daily (the patient was using no other medications). The lesion became pro
infiltrated, but did not totally disappear. Approximately 6 months later, two additional papules appeared in
Cutaneous biopsy showed a pattern histologically identical to the original papule. Carbamazepine was w
other antiepileptic drugs were prescribed. All 3 skin lesions disappeared after 3 months; no relapse occu
of follow-up (Cogrel et al, 2001).

3.3.2.A.3 Injection site disorder

a) The manufacturer reports that injection site reactions including inflammation and pain have been repo
acid intravenous therapy (Prod Info Depacon(TM), 1999).

3.3.2.A.4 Rash

a) Incidence: 6% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)
b) During two clinical trials of valproate treatment of manic episodes associated with bipolar disorder, ra
6% of patients receiving valproate (n=89) compared with 3% of patients receiving placebo (n=97) (Prod I
delayed release oral capsules, 2008).

3.3.2.A.5 Stevens-Johnson syndrome

a) After 45 days of valproate 400 mg 3 times daily, a 20-year-old man developed lip ulcerations and targ
on the trunk. Liver function tests were elevated with an aspartate aminotransferase level of 3550 units/L,
aminotransferase 5770 units/L and alkaline phosphatase level of 421 units/L. Stevens-Johnson syndrom
and with 2 weeks of prednisolone therapy his skin lesions cleared. After 30 days, liver function tests retu
(Tsai & Chen, 1998). Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) have beer
occasionally during the early stages of valproic acid therapy. In a case-control study of patients taking va
agents, 73 cases of SJS or TEN were identified; of these, 13 were due to valproic acid ingestion. SJS/TE
occurred during the first 8 weeks of valproic acid therapy (Rzany et al, 1999).

3.3.2.B Divalproex Sodium

Alopecia

Petechiae

Rash

3.3.2.B.1 Alopecia

a) Incidence: 6% to 24% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, alopecia was reported in 6% of pat
divalproex sodium (n=77) compared with 1% of patients receiving placebo (n=70) (Prod Info DEPAKOTE
capsules, 2008).
c) Alopecia was reported in 24% of patients receiving high-dose divalproex sodium (n=131) compared w
patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei
cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep
the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.2.B.2 Petechiae

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Petechia was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n=
monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d
patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT
capsules, 2008).

3.3.2.B.3 Rash

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Rash was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n=358

treatment of complex partial seizures. In many cases, causality could not be attributed to divalproex alon titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOTE(R) sprinkle 2008).

3.3.3 Endocrine/Metabolic Effects

Valproic Acid

Divalproex Sodium

3.3.3.A Valproic Acid

Acute intermittent porphyria

Carnitine nutritional deficiency

Finding of thyroid function

Hyperglycinemia

Hyperhomocysteinemia

Hyperprolactinemia

Increased appetite

Lipids abnormal

Syndrome of inappropriate antidiuretic hormone secretion

Weight gain

Weight loss

3.3.3.A.1 Acute intermittent porphyria

See Drug Consult reference: DRUGS CONSIDERED UNSAFE- ACUTE PORPHYRIAS

3.3.3.A.2 Carnitine nutritional deficiency

a) A case of carnitine deficiency associated with hyperammonemia (venous ammonia level of 377 mcm (Glasgow Coma Scale score 8) without hepatic dysfunction, and with a therapeutic serum valproic acid c reported in a 41-year-old male on chronic valproic acid therapy. His venous ammonia level dropped to 4 after the administration of 10 g of L-carnitine IV over 1 hour. The patient was alert, with a normal physica within 24 hours (Barrueto & Hack, 2001).

b) Chronic therapeutic use of valproic acid in young children may cause a carnitine deficiency resulting i symptoms of lethargy, weakness or hypotonia, hepatotoxicity, and hyperammonemia. An incidence of fa children under the age of two years of 1/800 has been reported (Raskind & El-Chaar, 2000).

c) Decreased plasma carnitine was reported in 14 children. Thirteen children were symptomless, yet on signs of valproic acid hepatotoxicity (appearing as a Reye's-like syndrome). After withdrawal of valproic a symptomatic patient recovered. The mechanism is believed to be increased excretion of carnitine in the and valproyl metabolites (Murphy et al, 1985).

d) A 3-year-old girl developed acute liver disease along with the typical features of Reye's syndrome aft valproate for 6 months. Serum free carnitine was decreased as well as 3-keto-valproic acid, the main me oxidation of valproate. The possible importance of carnitine in the pathogenesis of liver disease induced (Bohles et al, 1982).

e) An inverse relationship was found between plasma carnitine concentrations and the dosage of valpro between plasma carnitine and blood ammonia values (Ohtani et al, 1982).

3.3.3.A.3 Finding of thyroid function

a) One study found valproic acid slightly increased serum thyrotropin hormone (TSH) levels in girls with effects were reversible upon discontinuation of therapy. Patients, between the ages of 8 and 18 years, w 54 age-matched controls. Mean TSH levels in were 3.3 milliunits/L compared to 2.5 milli-units/L in the co than 0.01). Thyroxine (T4), free thyroxine (FT4), and free triiodothyronine (FT3) levels were not significar between the groups. Patients had been on therapy for a mean of 3 years (range 0.8 to 10.3 years). A se taken a mean of 5.8 years later was performed. Thyroid hormone levels in patients who had discontinue did not significantly differ from the controls. Patients had been off therapy for a mean of 7 years (Vainion

3.3.3.A.4 Hormone level - finding, Sex

a) Antiepileptic agents have been associated with changes in serum concentrations of male reproductiv compared to healthy controls (n=41), carbamazepine-treated men with partial epilepsy (n=15) had lower dehydroepiandrosterone sulfate concentrations (3068 nanogram/mL for controls versus 1952 nanograms carbamazepine; p less than 0.001). No statistically significant differences in dehydroepiandrosterone lev between controls and oxcarbazepine treated (n=18) or valproic acid treated (n=27) men with generalized also found that men in the valproic acid group had higher androstenedione levels (5.9 nanograms/mL) w the control group (2.2 nanograms/mL; p less than 0.001) whereas the other arms did not. Serum testoste hormone binding globulin, free androgen index, luteinizing hormone, follicle stimulating hormone, prolact measurements were not statistically significantly different between all 4 groups. Whether the differences hormones are epilepsy-induced changes or antiepileptic agent-induced changes remains to be determin 2004).

b) Carbamazepine and (to a lesser extent) valproic acid were found to alter serum concentrations of sex young male epileptic patients (aged 15 to 18 years; n=48) treated at least 2 years with these drugs; how were not permanently changed and soon after the drugs were withdrawn, hormone levels normalized (Ve Compared with concentrations in normal healthy male controls, subjects treated with carbamazepine mo had decreased levels of free testosterone (FT) (p less than 0.05) and dehydro- epiandrosterone sulphate than 0.001); concentrations of sex hormone-binding globulin were significantly increased (p less than 0.0 treated with valproic acid monotherapy (n=18) had insignificantly decreased levels of FT and DHEAS. Su combination carbamazepine and valproic acid (n=10) had the same significant alterations as those on ca monotherapy. At least four months after withdrawal of these drugs, all values had returned to normal. Le testosterone, luteinizing hormone, follicle stimulating hormone, and prolactin were normal throughout the ovaries, hyperandrogenism, and menstrual disorders were more common among women being treated f valproate (n=37) than among women being treated for epilepsy with carbamazepine (n=35) or among co (n=52). Seventy-nine percent of obese valproate-treated women and 65% of lean valproate- treated wom ovaries or hyperandrogenism or both, compared to 20% of carbamazepine-treated women and 19% of c Seventy-nine percent of obese and 48% of lean valproate- treated women had menstrual disorders, whe and 17% of lean control women had menstrual disorders (p less than 0.001) (Isojarvi et al, 2001).

c) Reproductive hormone levels in men with epilepsy may be affected by use of valproic acid or carbam some effect shown by oxcarbazepine at high doses. In valproate-treated men (n=21), androstenedione le significantly increased compared with controls (n=25) (p less than 0.001), and more than half of the coho (57%) had serum concentrations of testosterone, androstenedione, or dehydroepiandrosterone (DHEA) reference range (p less than 0.001). Follicle stimulating hormone levels were abnormally low in valproate less than 0.05). Among carbamazepine-treated men (n=40), serum concentrations of DHEA were low (p and sex hormone-binding globulin (SHBG) levels were high (p less than 0.05). In men taking high doses (900 milligrams/day or more), serum concentrations of testosterone, luteinizing hormone, and SHBG wer p=0.02, p=0.005, respectively). The authors noted that serum insulin levels were high across all groups (2001).

d) Hyperandrogenism has been reported in girls taking valproic acid. Evaluation of testosterone levels ir years old, taking valproic acid revealed significantly higher serum testosterone levels compared to contro same pubertal stage. Of girls receiving valproic acid, 38% of prepubertal girls, 36% of pubertal girls, and postpubertal girls were hyper-androgenic (Vainionpaa et al, 1999).

e) Evidence is strongly suggestive of a causative link between reproductive endocrine disorders and val treatment in women with epilepsy. In a study of 238 adult epileptic women, 27% of those who received v 20 or later, and 80% of those who received valproic acid before the age of 20, demonstrated polycystic o serum testosterone levels. In both age groups, the incidence of hyper-androgenic effects was significantl valproic acid than for other antiepileptic medications (p less than 0.01) (Isojarvi et al, 1993).

3.3.3.A.5 Hyperammonemia

a) Hyperammonemia, sometimes present despite normal liver function tests, has been reported with val Patients who develop symptoms of hyperammonemia (hypothermia, unexplained lethargy and vomiting, changes) while receiving valproate therapy should receive prompt treatment (including discontinuation of therapy) and be evaluated for underlying urea cyclic disorder (Prod Info STAVZOR(R) delayed release o 2008).

b) An 88-year-old man developed hyperammonemia and worsening confusion two months after starting four times a day for a presumed seizure disorder. His liver function tests were within normal limits except

concentration of 836 mcg/dL (reference range 19 to 60 mcg/dL). His trough valproate serum concentratio
His medication was changed to phenytoin 150 mg twice day and his confusion resolved. One week later
was 63 mcmol/L (reference range 11 to 35 mcmol/L) and his phenytoin and valproate concentrations we
and less than 10 mcg/mL, respectively. He was inadvertently started on valproate again at the former do
days his ammonia concentration increased to 130 mcmol/L. He became confused and lethargic and his l
bilateral 5 to 7 hertz (Hz) slowing and abnormal, irregular 2-Hz to 3-Hz activity on the right. Valproate wa
his ammonia concentration decreased to 60 mcmol/L after one day and on the second day his confusion
baseline (Feil et al, 2002).

c) A 37-year-old man with previously unknown ornithine transcarbamylase deficiency developed plasma
of up to 800 mcmol/L (normal less than 40 mcmol/L) after beginning sodium valproate therapy. He had b
with spinocerebellar degeneration and was having severe pain in the region of a sural-nerve biopsy whe
prescribed valproate 200 mg 3 times daily. After 9 days he appeared drowsy and confused with a 3-day
and vomiting. It was noted that plasma ammonia levels were increased and valproate was discontinued.
hospital however, he died. It was not established until after his death that he had ornithine transcarbamy
(Ellaway et al, 1999).

d) One study reported significantly higher postprandial plasma ammonia levels in children who received
other anticonvulsant(s) as compared to the control group (average 34 versus 20 mcg/dL, respectively). T
did find a positive correlation between serum valproic acid and plasma ammonia levels. Oral L-carnitine
reduced ammonia levels to normal within 15 to 45 days of therapy (Altunbasak et al, 1997).

e) The frequency of hyperammonemia in asymptomatic children receiving valproic acid was evaluated. V
concentrations were evaluated in three groups of children (receiving valproic acid only, receiving valproic
anticonvulsants, and control patients receiving other anticonvulsants). Hyperammonemia was reported ir
receiving valproic acid alone or in combination with anticonvulsants (ammonia levels exceeding 45 micro
(mcg%)), as compared to 28% of the controlled group. Valproic acid serum concentrations ranged from 2
and there was no correlation with ammonia levels and drug serum concentrations. The authors suggest t
mild elevations in ammonia levels in adults can result in subtle neurologic dysfunction, that monitoring of
concentrations in valproic acid treated patients is desirable (Wyllie et al, 1983).

f) A case of a Reye-like syndrome was reported in a 13-year-old female who had received valproic acid
Hyperammonemia and severe hepatic damage, as well as diffuse small droplets in liver biopsy material,
demonstrated. It is suggested that valproic acid or its metabolites may decrease the activity on N-acetylg
can decrease the activity of carbamyl phosphate synthetase I, inducing hyperammonemia (Sugimoto et a

3.3.3.A.6 Hyperglycinemia

a) In a patient with preexistent nonketotic hyperglycinemia, hyperglycinemia occurred with valproic acid
associated with a fatal outcome (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.3.A.7 Hyperhomocysteinemia

a) In a study of 60 adolescent epileptic patients (aged 14 to 18 years), a one-year course of carbamazep
therapy was found to produce significantly higher plasma concentrations of homocysteine compared with
prior to therapy and compared with levels in a healthy age- and sex-matched control group (p less than 0
comparisons). The finding of hyperhomocystinemia held true with both fasting and post-methionine homo
measurements. For the patients taking carbamazepine or valproate, serum concentrations of folate and p
5-phosphate (PLP) were significantly decreased with respect to pretreatment values and to values in the
less than 0.01, folate; p less than 0.001, PLP). Levels of vitamin B12 and erythrocyte folate remained in t
(Verrotti et al, 2000a).

3.3.3.A.8 Hyperprolactinemia

a) Sodium valproate was given to 20 normal and 15 hyperprolactinemic patients. Prolactin levels were s
lowered in both groups following valproate administration; however, prolactin levels in the hyperprolactin
decreased in those patients without evidence of prolactinoma. This study suggests that enhancement of
is followed by inhibition of prolactin secretion (Melis et al, 1982).

3.3.3.A.9 Increased appetite

a) Incidence: 6% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Increased appetite was reported in 6% of migraine patients receiving valproate (n=202) compared wit
receiving placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R)
oral capsules, 2008).

3.3.3.A.10 Lipids abnormal

a) In a study evaluating lipids in children and adolescents receiving carbamazepine (n=14), valproic acid
phenobarbital (n=20), serum lipid and lipoprotein levels returned completely to normal at 1 to 1.5 years a
discontinued. During therapy patients receiving carbamazepine demonstrated increased levels of total ch
triglycerides, LDL cholesterol, and HDL as compared to a control group (n=110)(all p less than 0.01). Ch
valproic acid had low triglycerides (p less than 0.05) and LDL (p less than 0.05) and high levels of HDL (p
as compared to the control group. Children receiving phenobarbital had high concentrations of total chole
cholesterol and low concentrations of triglycerides as compared to the control group (all p less than 0.01
1998).

b) Serum lipids and lipoproteins in 33 epileptic children were measured. All of the children were being cl

with phenobarbital, valproate and carbamazepine. HDL cholesterol was significantly higher in the epilept 2 control groups (healthy nonepileptic children and epileptic children before starting anticonvulsant thera indicate that anticonvulsant drugs should be added to the list of substances that affect serum HDL (Held 1983).

3.3.3.A.11 Syndrome of inappropriate antidiuretic hormone secretion

a) Syndrome of inappropriate secretion of antidiuretic hormone (SIADH) in a 62-year-old man was attrib long-term use of sodium valproate. At age 56, the man had his first generalized tonic-clonic seizure, and mg/day was initiated. Symptoms such as hyponatremia, elevated serum concentrations of antidiuretic ho cloudiness of consciousness, disorientation, psychomotor excitement, and a tonic-clonic seizure occurre year. These episodes were different from his original tonic-clonic convulsion, as originally hyponatremia, and cloudiness of consciousness were not present. Laboratory findings included serum sodium of 127 m picograms (pg)/mL, an increase in urinary sodium excretion, and slight elevation of urinary osmosity. Se concentrations were 10.5 mcg/mL. SIADH was diagnosed. The patient was switched from valproate to z 18 months, his serum ADH had normalized (0.8 pg/mL); he had no symptoms of SIADH and he no longe type of seizures. The authors concluded that SIADH in this case was due to long-term administration of v weakness in the CNS (bilateral hippocampal atrophy) (Miyaoka et al, 2001).

b) A 50-year-old male with Henoch-Schonlein nephritis was discovered to have hyponatremia (serum so mEq/L) during a routine follow-up. His only medication was valproate 2000 mg/day. He had no complaint volume depletion, hypothyroidism, or renal or adrenal insufficiency. His plasma osmolality was low at 26 Repeated water loading at different valproate doses confirmed the ability to excrete water was reduced i dependent manner. The authors concluded that the valproate caused syndrome of inappropriate secretio hormone (SIADH). Water restriction corrected the hyponatremia (Branten et al, 1998).

3.3.3.A.12 Weight gain

a) Incidence: 4% to 9% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Weight gain was reported in 8% of migraine patients receiving valproate (n=202) compared with 2% o receiving placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) oral capsules, 2008).

c) During a clinical trial of valproate monotherapy for complex partial seizures, weight gain was reported receiving high-dose valproate (n=131) compared with 4% of patients receiving low-dose valproate (n=13 causality could not be determined as patients were being titrated off another antiepilepsy drug during the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

d) A retrospective, longitudinal study revealed that epileptic children between the ages of 2 and 8 years 0.8 yr; 53% male) experienced a significant increase in BMI z-scores following valproic acid treatment. H percentage of patients who were overweight or obese at the end of 3.1 yr follow-up was not statistically s BMI z-score of 0.1 was calculated at initiation of treatment, which increased to 0.8 (p=0.001) at 3.1 years therapy, 6.9% of the patients were overweight, which increased to 16% (p=0.081) following 3.1 yr of valp treatment. A total of 3.5% of patients were obese at baseline, which increased to 5.7% following 3.1 yr of however this increase in weight was also not statistically significant (p=0.8). This study data suggests tha occurred during the first 16 months of treatment but leveled off with continued treatment. Over the cours significant increases in serum triglyceride levels, total serum cholesterol levels, or fasting blood glucose l reported (Grosso et al, 2009).

e) Obesity in children treated with valproate was common in a study of 55 children. Body mass index wa 90th percentile-for-age in 14 patients at baseline which increased to 20 patients at follow-up. The risk of gain with valproate was significant as seen in changes in weight Z-score and in body mass index (p=0.0 respectively). Also seen was impaired growth in girls as measured by height Z-score (p=0.001) (Novak e et al, 1977c).

f) In a retrospective study of 70 epileptic patients treated with long-term valproic acid (mean 27 months) weight gain in excess of 10% over their baseline measurement, and another 24% gained an additional 5 control group of patients treated with carbamazepine monotherapy, 14% of patients had weight gain grea 28% had weight gain between 5% and 10% (Corman et al, 1997). In another study of patients treated lon valproic acid for epilepsy (female patients only), 11 of 22 (50%) experienced marked weight gain (mean indisputable despite preexisting obesity. Weight gain was frequently associated with hyperinsulinemia ar growth factor-binding protein 1 (Isojarvi et al, 1996).

3.3.3.A.13 Weight loss

a) Incidence: 6% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia loss was reported in 6% of patients receiving valproate (n=77) compared with 0% of patients receiving pl most cases, causality could not be determined as patients also received other antiepilepsy drugs concur valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.3.B Divalproex Sodium

Hyperammonemia

Increased appetite

Weight gain

Weight loss

3.3.3.B.1 Hyperammonemia

a) Hyperammonemia, sometimes present despite normal liver function tests, has been reported with val
Patients who develop symptoms of hyperammonemia (hypothermia, unexplained lethargy and vomiting,
changes) while receiving valproate therapy should receive prompt treatment (including discontinuation o
therapy) and be evaluated for underlying urea cyclic disorder (Prod Info DEPAKOTE(R) sprinkle oral cap

3.3.3.B.2 Increased appetite

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Increased appetite was reported in more than 1% but less than 5% of patients receiving divalproex so
monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d
patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT
capsules, 2008).

3.3.3.B.3 Weight gain

a) Incidence: 4% to 9% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Weight gain was reported in 9% of patients receiving high-dose divalproex sodium (n=131) compared
patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei
cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep
the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.3.B.4 Weight loss

a) Incidence: 6% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, weight loss was reported in 6% of
divalproex sodium (n=77) compared with 0% of patients receiving placebo (n=70) (Prod Info DEPAKOTE
capsules, 2008).

3.3.4 Gastrointestinal Effects

Valproic Acid

Divalproex Sodium

3.3.4.A Valproic Acid

Abdominal pain

Constipation

Diarrhea

Hematemesis

Indigestion

Loss of appetite

Nausea

Pancreatitis

Vomiting

3.3.4.A.1 Abdominal pain

a) Incidence: 9% to 23% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During two clinical trials of valproate treatment of manic episodes associated with bipolar disorder, ab reported in 9% of patients receiving valproate (n=89) compared with 8% of patients receiving placebo (n= STAVZOR(R) delayed release oral capsules, 2008).

c) Abdominal pain was reported in 9% of migraine patients receiving valproate (n=202) compared with 4 receiving placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) oral capsules, 2008).

d) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia abdominal pain was reported in 23% of patients receiving valproate (n=77) compared with 6% of patients (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

e) During a clinical trial of valproate monotherapy for complex partial seizures, abdominal pain was repo patients receiving high-dose valproate (n=131) compared with 9% of patients receiving low-dose valproa many cases, causality could not be determined as patients were being titrated off another antiepilepsy dr part of the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.4.A.2 Constipation

a) Incidence: 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia constipation was reported in 5% of patients receiving valproate (n=77) compared with 1% of patients rec (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.4.A.3 Diarrhea

a) Incidence: 12% to 23% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Diarrhea was reported in 12% of migraine patients receiving valproate (n=202) compared with 7% of placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) delayed r capsules, 2008).

c) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia diarrhea was reported in 13% of patients receiving valproate (n=77) compared with 6% of patients receiv (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

d) During a clinical trial of valproate monotherapy for complex partial seizures, diarrhea was reported in receiving high-dose valproate (n=131) compared with 19% of patients receiving low-dose valproate (n=1 cases, causality could not be determined as patients were being titrated off another antiepilepsy drug du the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.4.A.4 Hematemesis

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Hematemesis was reported in more than 1% but less than 5% of patients receiving valproate (n=265) treatment of complex partial seizures. In many cases, causality could not be attributed to valproate alone titrated off of another antiepilepsy drug during the first part of the trial (Prod Info STAVZOR(R) delayed re capsules, 2008).

3.3.4.A.5 Indigestion

a) Incidence: 8% to 13% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During two clinical trials of valproate treatment of manic episodes associated with bipolar disorder, dy reported in 9% of patients receiving valproate (n=89) compared with 8% of patients receiving placebo (n= STAVZOR(R) delayed release oral capsules, 2008).

c) Dyspepsia was reported in 13% of migraine patients receiving valproate (n=202) compared with 9% o receiving placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) oral capsules, 2008).

d) During a clinical trial of valproate monotherapy for complex partial seizures, dyspepsia was reported i receiving high-dose valproate (n=131) compared with 10% of patients receiving low-dose valproate (n=1 cases, causality could not be determined as patients were being titrated off another antiepilepsy drug du the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

e) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia dyspepsia was reported in 8% of patients receiving valproate (n=77) compared with 4% of patients receiv (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.4.A.6 Loss of appetite

a) Incidence: 4% to 12% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia anorexia was reported in 12% of patients receiving valproate (n=77) compared with 0% of patients receiv (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) During a clinical trial of valproate monotherapy for complex partial seizures, anorexia was reported in receiving high-dose valproate (n=131) compared with 4% of patients receiving low-dose valproate (n=13 causality could not be determined as patients were being titrated off another antiepilepsy drug during the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.4.A.7 Nausea

a) Incidence: 22% to 48% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During two clinical trials of valproate treatment of manic episodes associated with bipolar disorder, na in 22% of patients receiving valproate (n=89) compared with 15% of patients receiving placebo (n=97) (P STAVZOR(R) delayed release oral capsules, 2008).

c) Nausea was reported in 31% of migraine patients receiving valproate (n=202) compared with 10% of placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) delayed r capsules, 2008).

d) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia was reported in 48% of patients receiving valproate (n=77) compared with 14% of patients receiving plac most cases, causality could not be determined as patients also received other antiepilepsy drugs concur valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

e) During a clinical trial of valproate monotherapy for complex partial seizures, nausea was reported in 3 receiving high-dose valproate (n=131) compared with 26% of patients receiving low-dose valproate (n=1 cases, causality could not be determined as patients were being titrated off another antiepilepsy drug du the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.4.A.8 Pancreatitis

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Life-threatening pancreatitis has been reported with valproate use in both children and adults shortly after several years of therapy. Some cases of hemorrhagic pancreatitis with rapid progression from initia death have been described. Symptoms of pancreatitis requiring prompt medical evaluation include abdo nausea, vomiting, and anorexia. There were 2 cases of pancreatitis reported among 2416 patients receiv during clinical trials, representing 1044 patient-years of experience. Pancreatitis has recurred upon recha valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) Pancreatitis was reported in more than 1% but less than 5% of patients receiving valproate (n=265) fo treatment of complex partial seizures. In many cases, causality could not be attributed to valproate alone titrated off of another antiepilepsy drug during the first part of the trial (Prod Info STAVZOR(R) delayed re capsules, 2008).

d) Of 45 published cases of valproic acid-induced pancreatitis, 3 cases were found to be definite (by the drug reaction probability scale), 32 probable, and 10 possible. There was no correlation between valproic plasma concentration and development of pancreatitis. Thirty percent of patients developed symptoms w starting valproic acid, 58% within 12 months, and 30% 2 years or more after starting valproic acid. Many with discontinuation of valproic acid. However, 13 (29%) died (Chapman et al, 2001).

e) A 22-year-old woman who been taking valproic acid for 19 years for epiloia developed an acute exac pancreatitis. At the time, her valproic acid dosage was 25 mg/kg/day. She also took other medications fo She was treated conservatively, with discontinuation of valproic acid and increased doses of other agent seizures. Serum markers of pancreatitis normalized by 4 days and she was discharged on day 22. A day readmitted because of recurrent pancreatitis, which required surgical resection of the pancreatic head ar preservation of the stomach and pyloric ring. The resected specimens were notable for a large volume o in the pancreatic head and fibrosis around the main pancreatic duct. Findings suggested that the cause was flow disturbance of pancreatic juice due to calculi in the main pancreatic duct. There had been no re pancreatitis at 2 years postsurgery (Taira et al, 2001).

f) A 35-year-old man demonstrated signs and symptoms of pancreatitis 17 months after beginning valpr and again upon rechallenge. Signs and symptoms included abdominal pain, increased enzymes, and ult computed tomographic scan showing thickening of the body and tail of the pancreas. Rechallenge was c after valproic acid discontinuance due to increased seizure frequency and irritability. Pancreatitis develop restarting valproic acid (Fecik et al, 1999).

g) A 23-year-old male, on hemodialysis for endstage renal disease secondary to hemolytic uremic syndr pancreatitis following a 3 month course of valproic acid (2500 mg/day) and phenobarbital (200 mg/day). valproic acid and administering symptomatic therapy, the pancreatitis resolved. Phenobarbital was contin further pancreatic symptoms (Plaza et al, 1999).

h) Two pediatric cases of valproic acid-associated pancreatitis occurred in the presence of endstage ren amylase levels were 232 units/L and 465 units/L, respectively, in a 14-year-old female on peritoneal dialy figures were 880 units/L and 530 units/L in a 12-year-old male on hemodialysis. Both had received valpr for seizure disorder (doses not given). The 14-year-old also developed hepatotoxicity and subsequently old recovered with valproic acid discontinuation (Levin et al, 1997).

i) Development of VPA (valproic acid)-associated pancreatitis is a relative contraindication to further trea routine monitoring of serum amylase is not necessary in asymptomatic patients. Other cases of fatal and induced pancreatitis have been described (Evans et al, 1995)(Pinkston & Walker, 1997).

j) Four cases of pancreatitis secondary to valproic acid were described. Doses of valproic acid were ran mg/kg/day for 7 months to 4.5 years (age of patients, 3, 7, 18, and 27 years). Complications of pancreati pseudocyst, pericardial effusion, laparotomy wound infection, and coagulopathy occurred in one patient;

one other patient. Withdrawal of valproic acid resulted in recovery (Wyllie et al, 1984).
k) Fourteen cases of valproate-associated pancreatitis are reviewed. None of the cases experienced oth effects and pancreatitis was not dose-related. It developed as early as one week and as late as 4.5 years treatment. Two of 14 patients died. Of 7 rechallenged with valproic acid, 6 had recurrence of pancreatitis 1984).
l) Attacks of pancreatitis were described in an 11-year-old girl receiving valproic acid 15 mg/kg/day. Trai discomfort occurred at this dosage (exact duration of therapy unspecified), and 2 days after beginning 45 daily) the patient developed severe abdominal pain. Laparotomy for suspected appendicitis was institute mesenteric fat necrosis. Postoperative serum amylase was 225 units/dL (normal less than 160). The pat after a period of 2 weeks. Valproic acid was initiated again after a period of 4 weeks and was again asso abdominal pain and elevated serum amylase (696 units/dL) after the dosage was increased from 20 to 2 patient recovered fully upon discontinuation of valproic acid. The second case, a 1-year-old boy, develop abdominal pain following meals at doses of 55 mg/kg/day (900 mg daily) with serum amylase increasing units/dL. The patient recovered 2 weeks after discontinuation of valproic acid. It is not possible to attribut pancreatitis in these children to the use of valproic acid. However, signs of unusual abdominal discomfor followed by serum amylase examination in order to rule out the possibility of acute pancreatitis (Camfield

3.3.4.A.9 Vomiting

a) Incidence: 11% to 27% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)
b) During two clinical trials of valproate treatment of manic episodes associated with bipolar disorder, vo reported in 12% of patients receiving valproate (n=89) compared with 3% of patients receiving placebo (r STAVZOR(R) delayed release oral capsules, 2008).
c) Vomiting was reported in 11% of migraine patients receiving valproate (n=202) compared with 1% of placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) delayed r capsules, 2008).
d) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia vomiting was reported in 27% of patients receiving valproate (n=77) compared with 7% of patients receiv (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).
e) During a clinical trial of valproate monotherapy for complex partial seizures, vomiting was reported in receiving high-dose valproate (n=131) compared with 15% of patients receiving low-dose valproate (n=1 cases, causality could not be determined as patients were being titrated off another antiepilepsy drug du the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.4.B Divalproex Sodium

Abdominal pain

Constipation

Diarrhea

Hematemesis

Indigestion

Loss of appetite

Nausea

Pancreatitis

Vomiting

3.3.4.B.1 Abdominal pain

a) Incidence: 9% to 23% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, abdominal pain was reported in 23 receiving divalproex sodium (n=77) compared with 6% of patients receiving placebo (n=70) (Prod Info DI sprinkle oral capsules, 2008).
c) Abdominal pain was reported in 12% of patients receiving high-dose divalproex sodium (n=131) comp patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep

the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.4.B.2 Constipation

a) Incidence: 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, constipation was reported in 5% of divalproex sodium (n=77) compared with 1% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

3.3.4.B.3 Diarrhea

a) Incidence: 13% to 23% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, diarrhea was reported in 13% of pa divalproex sodium (n=77) compared with 6% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

c) Diarrhea was reported in 23% of patients receiving high-dose divalproex sodium (n=131) compared w patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.4.B.4 Hematemesis

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Hematemesis was reported in more than 1% but less than 5% of patients receiving divalproex sodium monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.4.B.5 Indigestion

a) Incidence: 8% to 11% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, dyspepsia was reported in 8% of p divalproex sodium (n=77) compared with 4% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

c) Dyspepsia was reported in 11% of patients receiving high-dose divalproex sodium (n=131) compared patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.4.B.6 Loss of appetite

a) Incidence: 4% to 12% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, anorexia was reported in 12% of p divalproex sodium (n=77) compared with 0% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

c) Anorexia was reported in 11% of patients receiving high-dose divalproex sodium (n=131) compared w receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial seizures. In causality could not be attributed to divalproex alone, as patients were titrated off of another antiepilepsy first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.4.B.7 Nausea

a) Incidence: 26% to 48% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, nausea was reported in 48% of pa divalproex sodium (n=77) compared with 14% of patients receiving placebo (n=70) (Prod Info DEPAKOT capsules, 2008).

c) Nausea was reported in 34% of patients receiving high-dose divalproex sodium (n=131) compared wi receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial seizures. In causality could not be attributed to divalproex alone, as patients were titrated off of another antiepilepsy first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.4.B.8 Pancreatitis

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Life-threatening pancreatitis has been reported with valproate use in both children and adults shortly after several years of therapy. Some cases of hemorrhagic pancreatitis with rapid progression from initia death have been described. Symptoms of pancreatitis requiring prompt medical evaluation include abdo nausea, vomiting, and anorexia. There were 2 cases of pancreatitis reported among 2416 patients receiv during clinical trials, representing 1044 patient-years of experience. Pancreatitis may recur upon rechalle (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

c) Pancreatitis was reported in more than 1% but less than 5% of patients receiving divalproex sodium (monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.4.B.9 Vomiting

a) Incidence: 15% to 27% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, vomiting was reported in 27% of pa divalproex sodium (n=77) compared with 7% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

c) Vomiting was reported in 23% of patients receiving high-dose divalproex sodium (n=131) compared w patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.5 Hematologic Effects

Valproic Acid

Thrombocytopenia, Dose-related

von Willebrand factor inhibitor disorder

3.3.5.A.1 Acute promyelocytic leukemia, FAB M3

a) Valproic acid therapy produced hematopoietic changes consistent with acute promyelocytic leukemia year-old Native American female. The patient had received 65 mg/kg/day for seizure disorder for 1 year presentation with anemia, thrombocytopenia, leukocytosis, and coagulopathy. The valproic acid serum le normal range (82 mcg/mL). Abnormal/immature myeloid precursor cells appeared in the bone marrow ar Although the diagnosis of APML was considered, the patient gradually recovered after valproic acid disc (Bottom et al, 1997).

3.3.5.A.2 Blood coagulation disorder

a) Summary

1) Sodium valproate has been shown to inhibit the secondary phase of platelet aggregation. This ca increased bleeding times and hemorrhage (Prod Info STAVZOR(R) delayed release oral capsules, 2 Bruni & Wilder, 1979a; Gerber et al, 1979; Addison & Gordon, 1980; Hintze et al, 1987; Gidal et al, 1 inhibition of platelet aggregation is usually of no clinical significance unless patients are receiving otl

affect hemostasis (aspirin, warfarin) or undergoing surgery. Children appear to be particularly susce
1977c).

b) Hemostatic disturbances occurred in a 9-year-old female receiving oral valproate sodium 600 mg dail
3 years for grand mal epilepsy. During valproate therapy, the patient developed an acute pulmonary infe
resulted in severe nasal bleeding, hemoptysis, thrombocytopenia and abnormal clotting tests. Partial thro
74.8 seconds (normal 50), fibrinogen was 420 mg% (normal 160 to 400) and hemoglobin was 6 gram%.
and antibiotics were administered resulting in complete recovery (Klose et al, 1977).

c) The effects of sodium valproate on platelet function in 20 children with seizures was evaluated. Clinic
hemorrhagic disease including petechiae, epistaxis, otorrhagia, and prolonged bleeding after surgery we
several patients. Bleeding time was increased in 6 patients and platelet adhesiveness was found to be d
patients (von Voss et al, 1976).

3.3.5.A.3 Ecchymosis

a) Incidence: 4% to 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, ecchymosis was reporte
receiving high-dose valproate (n=131) compared with 4% of patients receiving low-dose valproate (n=13
causality could not be determined as patients were being titrated off another antiepilepsy drug during the
trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.5.A.4 Factor VII deficiency

a) A 3-year-old boy with a history of afebrile convulsions developed acquired factor VII deficiency while
with valproate 20 mg/kg for 7 months. There was no reported personal or family history of hematologic d
other drug treatments, toxic compound exposure, infection, or immunization. The child had experienced
bruising over his body 1 month after beginning valproate treatment. Neurological examination revealed h
tendon reflexes in both lower extremities and positive Babinski sign and clonus. The patient's laboratory
normal with the exception of prolonged prothrombin time (PT, 15.6 sec) and reduced factor VII concentra
the parents had factor VII levels within normal range. Twelve months following discontinuation of valproa
institution of phenobarbital), bruising resolved and factor VII concentrations and PT intervals returned to
range (50% and 13 sec, respectively) (Unalp et al, 2008).

3.3.5.A.5 Hematology finding

a) Valproic acid therapy resulted in myelodysplastic hematologic changes including macrocytosis, throm
pelger-huet neutrophils in two case reports. Neither had folate or vitamin B12 deficiencies. The patients i
48-year-old female on valproic acid 6000 mg/day for 3 years for refractory bipolar disorder, with a serum
of 95.4 mcg/mL, and a 2-year-old female with congenital anomalies and seizure disorder on valproic acid
(duration unknown), with a serum level of 125 mcg/mL. Hematology profiles improved in both cases with
(Fawcett, 1997; Hongeng et al, 1997).

b) In a cohort study involving 29,357 recipients of anticonvulsive therapy (receiving 684,706 prescription
drugs, one being valproate), serious blood dyscrasias were rarely found in these patients. Among the 4 c
appear different. An overall rate of blood dyscrasias was reported to be 3 to 4 per 100,000 prescriptions
(Blackburn et al, 1998).

3.3.5.A.6 Myelosuppression

a) Valproate-associated dysmyelopoiesis was reported in a 62-year-old man and in a 62-year-old woma
received valproate 200 mg twice a day for seizure control. Two weeks later he developed a mild pancyto
bone marrow aspirate showed mild dysmyelopoiesis. His blood cell counts normalized 12 days after disc
valproate. The woman had received valproate 1500 mg/day for 10 years and developed a mild, persister
thrombocytopenia. Following an increase in dosage to 1500 mg twice a day her valproate concentration
therapeutic level to 1447 mcmol/L (therapeutic range, 347 to 693 mcmol/L). Severe pancytopenia occurr
and a diagnosis of dysmyelopoiesis was made following examination of her bone marrow aspirate. She v
carbamazepine and her blood counts normalized in 6 weeks (So & Wong, 2002).

b) Valproic acid therapy resulted in myelodysplastic hematologic changes including macrocytosis, throm
Pelger-Huet neutrophils in two case reports. Neither had folate or B12 deficiencies. The patients involve
old female on valproic acid 6000 mg/day for 3 years for refractory bipolar disorder, with a serum valproic
mcg/mL; and a 2-year-old female with congenital anomalies and seizure disorder on valproic acid 90 mg
unknown), with a serum level of 125 mcg/mL. Hematology profiles improved in both cases with valproic a
reduction (Fawcett, 1997; Hongeng et al, 1997).

c) In a study of 1,251 hospitalized patients receiving valproate therapy, 6 developed moderate to severe
less than 4000/mm(3)); 2 of these patients were also taking carbamazepine (Tohen et al, 1995).

3.3.5.A.7 Neutropenia

a) In a case report, valproic acid use was associated with severe neutropenia that resolved after drug di
56-year-old female was hospitalized for seizure activity secondary to a superior frontoparietal cortex abs
initially treated with phenytoin, however it was replaced with valproic acid due to an adverse reaction. Va
titrated to a dose of 500 mg 3 times daily. Concomitant medications included ceftriaxone and metronidaz
absolute neutrophil count (ANC) prior to the administration of valproic acid was 2064 cells/mm(3). Two d
patient's ANC decreased to 735 cells/mm(3). The following day the ceftriaxone was discontinued and lev
started. On day 4 of valproic acid use the ANC dropped to 56 cells/mm(3) despite a dose of filgrastim. Th

was then discontinued. The next day, the ANC dropped to its nadir of 47 cells/mm(3) and the patient rec
of filgrastim. From that point forward the ANC continued to rise and the neutropenia resolved (Vesta & M

3.3.5.A.8 Pancytopenia

a) Pancytopenia occurred in a 65-year-old man taking valproate 1000 mg daily for bipolar mood disorde
of therapy his WBC count was 6.8, RBC count was 4.52 and platelets (PLT) were 160. He then started ta
750 mg daily. At 10 weeks of treatment his hematological values were: WBC 4.7, RBC 4.21, PLT 137. H
increased to 1000 mg daily and at 14 weeks the hematologic values were: WBC 3.5, RBC 4.18, PLT 132
valproate was discontinued, the indices were: WBC 3.2, RBC 3.83, and PLT 106. The pancytopenia app
related and reversible, disappearing on the valproate was stopped (Oluboka et al, 2000).

b) Fatal pancytopenia developed in a 3-year-old child administered high-dose valproate therapy (Rajant

3.3.5.A.9 Protein C deficiency disease

a) Protein C deficiency may be associated with use of valproic acid, based on a comparison of children
(n=20) and those using other anticonvulsants (n=20), such as carbamazepine, phenytoin, and lamotrigin
group, 19 of 20 children had normal values for coagulation proteins (protein C antigen, protein C functior
protein S free, antithrombin). In the valproic acid group, 45% (9 of 20) had abnormally low values for prot
(p=0.001 compared with other anticonvulsant group), and 40% (8 of 20) had abnormally low values for p
(p=0.002). The authors decided to investigate a potential relationship between valproic acid and protein
a stroke occurred in an 18-month-old child being treated with valproic acid for a seizure disorder. Ruling
which might have caused the child's stroke (a stroke seemingly consistent with ischemic injury) led to a f
abnormally low protein C and related low anticoagulation activity seemed to be the most plausible cause
(Gruppo et al, 2000).

3.3.5.A.10 Pure red cell aplasia

a) Pure red cell aplasia has been associated with sodium valproate therapy. A case of pure red cell apla
9-year-old girl following sodium valproate therapy with 200 mg three times a day for a period of 6 months
previously, the girl had an attack of measles followed immediately by severe chicken pox. It has been su
infective episodes may have sensitized the patient to a potentially hematotoxic drug (valproic acid) that h
been well tolerated. Within one month of drug withdrawal regeneration of bone marrow erythroid precurs
The patient was rechallenged with sodium valproate 200 mg 3 times daily. Within 6 weeks there was evi
aplasia, and the drug was withdrawn. Over the next 6 weeks, the child improved, and red cell aplasia res
(MacDougall, 1982).

3.3.5.A.11 Thrombocytopenia

a) Summary

1) The most common hematologic abnormality with valproic acid is thrombocytopenia, possibly rela
autoimmune mechanism (Rimmer & Richens, 1985f; Covanis et al, 1982; Barr et al, 1982). The inci
induced thrombocytopenia has been reported to vary from 1% to 30% (Allarakhia et al, 1996a; Hoffr
al, 1982; Morris et al, 1981; Smith & Boots, 1980). The rate of occurrence of thrombocytopenia amo
was nearly double that among younger patients (Conley et al, 2001). The risk of thrombocytopenia i
increasing doses of valproic acid and with coadministration of aspirin (Conley et al, 2001). The risk i
total valproate plasma trough levels above 110 mcg/mL in females and 135 mcg/mL in males (Prod
Tablets, 2002a). Nadir platelet counts after valproate administration ranged from 15,000/mm(3) to 8
the time course was variable. A thrombocytopenia rate of 1.6 per 100,000 valproic acid prescriptions
reported by the United Kingdom Department of Health's General Practice Research Database with 5
6465 valproic acid recipients (Blackburn et al, 1998). Valproate-induced thrombocytopenia may be t
related. Platelet aggregation inhibition has also been described (Rimmer & Richens, 1985f; Prod Inf
Tablets, 2002a).

b) In a double-blind, concentration-response clinical trial using valproic acid as monotherapy, high conc
acid (n=96, target level 80 to 150 mcg/mL) caused thrombocytopenia (platelet count of less than 75,000
patients (31%) versus 0 patients in those assigned to low concentration valproic acid (n=47, target range
mcg/mL). Although none of the patients were symptomatic, 12 patients were withdrawn for this adverse
al, 1997c).

c) The effects of valproate in 30 patients ranging in age from 26 years to 76 years were studied. Patient
valproate doses of 1200 mg to 3000 mg. No other anticonvulsants were administered. Following valproa
significant reductions in platelet counts of 49,000/mm(3) from baseline was reported with moderate dose
1700 mg) and a reduction of 69,000/mm(3) was reported with high doses (2100 mg to 3000 mg). Platele
reduced to the lower limit of normal in 10 patients. All patients were asymptomatic. After discontinuation
platelet counts returned to baseline within 4 to 12 days (Neophytides et al, 1979).

d) Children receiving valproic acid had lower platelet counts as compared to control subjects. Patients r
acid mean dose of 20 mg/kg and mean level of 60 mcg/mL. After 6 months of therapy, children receiving
(n=20) had significantly lower platelet counts than age-matched controls (n=15) (194,000/mcL versus 29
than 0.01). Platelet counts were significantly correlated with dose (r=-0.49, p less than 0.05) and plasma
0.52, p less than 0.01). Decreased platelet aggregation and ATP release impairment was also noted in t
group. Discontinuation of valproic acid was not necessary since the decreases were not clinically importa
1999).

e) The incidence of thrombocytopenia (defined as a platelet count of less than 200,000/mm(3)) in childre

Serum valproic acid concentrations of greater than 90 mcg/mL and older adolescent age (16 to 21 years predictive of thrombocytopenia. The degree of thrombocytopenia was mild; the authors concluded that th thrombocytopenia with valproic acid therapy is low and that drug discontinuation is not necessary in the (Allarakhia et al, 1996).

f) A one-year prospective study of 45 children (median age of 6 years) was conducted in which the incid induced thrombocytopenia was evaluated. Twelve patients also received treatment with other anticonvul cases of thrombocytopenia (defined as a platelet count less than 150,000/mm(3) occurring 3 to 8 months of valproate) were noted that were reported to be transient and self-limited. In 82% of cases, thrombocyt associated with an increase in platelet-associated IgG antibodies. There was an inverse relationship in t and the serum concentration of platelet-associated IgG antibody. There was not a significant difference b serum concentrations in patients with or without thrombocytopenia. It was concluded that immune-media thrombocytopenia may be common, but appears to be transient and self-limited despite continuations of (Barr et al, 1982).

g) A case of thrombocytopenia-induced fatal pulmonary hemorrhage was reported in a 30-year-old fema valproate monotherapy. Its been suggested that viral infections may be associated with thrombocytopeni receiving valproate therapy (Sleiman et al, 2000).

3.3.5.A.12 Thrombocytopenia, Dose-related

a) Incidence: 1% to 27% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During clinical trials of patients with epilepsy, thrombocytopenia (at least 1 platelet value of 75 x 10(9) reported in 27% (34/126) of patients receiving valproate monotherapy at approximately 50 mg/kg/day. Pl returned to normal in all patients regardless of whether the drug was withdrawn or continued. Higher tota concentrations (110 mcg/mL or greater in females and 135 mcg/mL or greater in males) were significantl thrombocytopenia occurrence. Monitoring of platelet counts and coagulation is recommended prior to va and at periodic intervals during therapy (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) During a clinical trial of valproate monotherapy for complex partial seizures, thrombocytopenia was re patients receiving high-dose valproate (n=131) compared with 1% of patients receiving low-dose valproa many cases, causality could not be determined as patients were being titrated off another antiepilepsy dr part of the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.5.A.13 von Willebrand factor inhibitor disorder

a) Below-normal levels of von Willebrand factor activity was observed in 6 of 29 (21%) children who had valproic acid for at least 6 months for treatment of epilepsy. The 6 children were regarded as having "acc Willebrand's Disease." No correlation was found between von Willebrand factor activity and dose or bloo acid or duration of therapy. The authors cautioned that when surgery is necessary, factor VIII von Willebr concentrations should be supplemented (Serdaroglu et al, 2002).

3.3.5.B Divalproex Sodium

Ecchymosis

Thrombocytopenia, Dose-related

3.3.5.B.1 Ecchymosis

a) Incidence: 4% to 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Ecchymosis was reported in 5% of patients receiving high-dose divalproex sodium (n=131) compared patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.5.B.2 Thrombocytopenia, Dose-related

a) Incidence: 1% to 27% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) During clinical trials of patients with epilepsy, thrombocytopenia (at least 1 platelet value of 75 x 10(9) reported in 27% (34/126) of patients receiving divalproex sodium monotherapy at approximately 50 mg/k counts returned to normal in all patients regardless of whether the drug was withdrawn or continued. Hig concentrations (110 mcg/mL or greater in females and 135 mcg/mL or greater in males) were significantl thrombocytopenia occurrence. Monitoring of platelet counts and coagulation is recommended prior to div initiation and at periodic intervals during therapy, especially prior to planned surgery. Drug discontinuatio reduction is recommended if patient experiences hemorrhage, bruising, or a hemostasis/coagulation disc divalproex sodium therapy (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

c) Thrombocytopenia was reported in 24% of patients receiving high-dose divalproex sodium (n=131) co of patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial s cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.6 Hepatic Effects

Valproic Acid

Divalproex Sodium

3.3.6.A Valproic Acid

ALT (SGPT) level raised

AST/SGOT level raised

Hepatitis

Hepatotoxicity

Increased liver function test

Liver failure

3.3.6.A.1 ALT (SGPT) level raised

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Increased SGPT was reported in more than 1% but less than 5% of patients receiving valproate durir (n=202) and during monotherapy treatment of complex partial seizures (n=265). In many cases, causalit attributed to valproate alone, as patients were titrated off of another antiepilepsy drug during the first par monotherapy trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.6.A.2 AST/SGOT level raised

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Increased SGOT was reported in more than 1% but less than 5% of patients receiving valproate durir (n=202) and during monotherapy treatment of complex partial seizures (n=265). In many cases, causalit attributed to valproate alone, as patients were titrated off of another antiepilepsy drug during the first par monotherapy trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.6.A.3 Hepatitis

a) An 8-year-old boy taking valproate 40 mg/kg daily for epilepsy died from a normally benign viral hepa acquired from his sister. The boy presented with jaundice, decreased consciousness, lethargy, hyperam increased valproate level. Despite aggressive medical treatment and discontinuation of the valproate the liver enzymes decreased while his bilirubin level and bleeding time increased and the patient died 12 da to the hospital. The authors postulate that the additive hepatotoxicity associated with the increased valpr have contributed to the development of fulminant liver failure and death in this patient (Fayad et al, 2000)

3.3.6.A.4 Hepatotoxicity

a) Fatal hepatotoxicity is reported in 1/800 children under the age of 2 years following antiepileptic thera acid. It is suggested that valproic acid may induce a carnitine deficiency in young children and result in n symptoms of deficiency, hepatotoxicity, and hyperammonemia. Carnitine supplementation may help prev hepatotoxicity (Raskind & El-Chaar, 2000).

b) A 52-year-old male with no known risk factors developed fulminant hepatotoxicity that progressed to while taking valproic acid 500 mg twice daily for migraine prophylaxis. He presented with altered mental jaundice and anuria. An exhaustive diagnostic work-up failed to reveal an etiology. The patient had asso as well as acute tubular necrosis with renal failure and rhabdomyolysis. He fully recovered after 16 days and supportive care (Pinkston & Walker, 1997).

c) One study indicated that the greatest risk of fatal hepatotoxicity occurred in children between the age who were receiving multiple anticonvulsant therapy. The incidence of fatal hepatotoxicity in this group wa greater than the overall incidence of fatal hepatotoxicity of 1/10,000). The incidence of fatal hepatotoxicit age group was 1/7000. No hepatic fatalities were described in patients over the age of 10 years who rec as monotherapy. The risk of fatal hepatotoxic reactions in children over the age of 2 years receiving poly considerably lower (1/12,000), with the risk of fatal hepatic dysfunction in patients above 2 years of age r acid as monotherapy being 1/45,000. Thus, the risk of fatal hepatic reactions appears to be greatest in v (0 to 2 years of age) and declines significantly with age (Dreifuss et al, 1987).

3.3.6.A.5 Increased liver function test

a) Summary

1) Elevated liver enzymes have been reported following chronic administration of valproate (Lewis, Wilder, 1979a; Gerber et al, 1979; Addison & Gordon, 1980; Coulter & Allen, 1981; Rawat et al, 198 elevations in transaminases (aspartate aminotransferase (AST; SGOT) and alanine aminotransferas and lactate dehydrogenase are frequently seen and are dose-related. Increased serum bilirubin and function tests may also be seen. These may reflect a more serious problem. It is speculated that val normally toxic substance, but in the presence of metabolic abnormalities such as an inborn error of r administration with other drugs, it may become toxic (Rimmer & Richens, 1985f).

3.3.6.A.6 Liver failure

a) Serious hepatotoxicity and hepatic failure have been reported in patients receiving valproic acid and i usually in the first 6 months of treatment. Serious or fatal hepatic toxicity may be preceded by symptoms lethargy, anorexia, malaise, facial edema, weakness, or loss of seizure control (in epileptic patients). Mo function tests should be initiated prior to therapy and at frequent intervals during treatment, mainly during months. However, abnormal serum biochemistry may not be present in all cases. Children under the age increased risk of developing hepatotoxicity, especially if they are taking multiple anticonvulsants, have co disorders, have severe seizure disorders accompanied by mental retardation, or have organic brain dise dysfunction has progressed in some cases, even with the discontinuation of drug (Prod Info STAVZOR(R oral capsules, 2008).

b) A case of fulminant liver failure induced by valproate therapy was reported in a 39-year-old woman w bilateral ptosis and chronic progressive external ophthalmoplegia (CPEO). The patient developed fulmina months after she was treated with valproate for status epilepticus and died due to multiorgan failure and syndrome. The patient's 2 siblings also had congenital bilateral ptosis and CPEO, a typical sign of mitoch cytopathies, but none of them had any previous signs of liver disease. This report suggested that mitoch should be considered a risk factor for valproate-induced liver failure and should be excluded before valpr (Krahenbuhl et al, 2000).

c) It is speculated that valproic acid is not a normally toxic substance, but in the presence of metabolic a as an inborn error of metabolism or administration with other drugs, it may become toxic (Rimmer & Rich one case, medium chain acyl-CoA dehydrogenase deficiency, resulting in abnormal fatty acid beta-oxida in a 10-year-old male who died of liver failure 3 months after valproic acid initiation (Njolstad et al, 1997).

d) In one report, hepatic failure occurred in a 15-year-old boy following approximately 5 years of valproic epilepsy. The patient had also been receiving phenytoin and phenobarbital. The patient developed cereb in a 24-hour period. These data suggest that hepatic failure secondary to valproic acid can also occur aft therapy (van Egmond et al, 1987).

e) Acute hepatic failure resulting in fatality in 2 children (5 years and 11.5 years) following 650 mg daily months and 250 mg to 1000 mg daily over approximately 7 weeks (with other anticonvulsants), respectiv described. Autopsy revealed mixed toxic cholestatic hepatitis with diffuse hepatocellular injury which tern centrolobular microvesicular fatty changes and submassive necrosis. The site of injury appeared to be bi apparatus, canaliculi and ducts of Hering (Suchy et al, 1979).

3.3.6.B Divalproex Sodium

ALT (SGPT) level raised

AST/SGOT level raised

Liver failure

3.3.6.B.1 ALT (SGPT) level raised

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Increased SGPT was reported in more than 1% but less than 5% of patients receiving divalproex sod monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.6.B.2 AST/SGOT level raised

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Increased SGOT was reported in more than 1% but less than 5% of patients receiving divalproex soc monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.6.B.3 Liver failure

a) Serious hepatotoxicity and hepatic failure have been reported in patients receiving valproic acid and i

usually in the first 6 months of treatment. Serious or fatal hepatic toxicity may be preceded by symptoms lethargy, anorexia, malaise, facial edema, weakness, or loss of seizure control (in epileptic patients). Mo function tests should be initiated prior to therapy and at frequent intervals during treatment, mainly during months. However, abnormal serum biochemistry may not be present in all cases. Children under the age increased risk of developing hepatotoxicity, especially if they are taking multiple anticonvulsants, have co disorders, have severe seizure disorders accompanied by mental retardation, or have organic brain dise dysfunction has progressed in some cases, even with the discontinuation of drug (Prod Info DEPAKOTE capsules, 2008).

3.3.7 Immunologic Effects

Valproic Acid

Divalproex Sodium

3.3.7.A Valproic Acid

HIV infection, Progression

Immune hypersensitivity reaction

Immunology finding

Systemic lupus erythematosus

3.3.7.A.1 HIV infection, Progression

a) Valproate therapy may reduce intracellular levels of glutathione and inhibit activity of glutathione redu red blood cells. There may be a link between intracellular levels of glutathione and the progression of hu immunodeficiency virus (HIV) disease. Decreased glutathione levels may activate the replication of HIV. with cell lines infected with HIV showed the addition of valproate increased viral expression and replicati drug concentrations (Hardy & Nardacci, 1999).

3.3.7.A.2 Immune hypersensitivity reaction

a) Incidence: rare (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Multiorgan hypersensitivity reactions (eg, fever and rash associate with other organ system involvem rarely reported between 1 and 40 days following initiation of valproate therapy in both adult and pediatric reactions have led to hospitalization and at least one death. If a hypersensitivity reaction occurs, disconti therapy and begin an alternative treatment (Prod Info STAVZOR(R) delayed release oral capsules, 2008

c) A 6-year-old boy developed hypersensitivity syndrome after receiving valproic acid for about 1.5 mon ethosuximide for 1 month. Both drugs were in the therapeutic range. He developed a diffuse morbilliform edema of the face, high fever, and enlarged lymph nodes. He also had a leukocytosis, eosinophilia, lymp monocytosis, and stimulated lymphocytes. Liver enzymes were also slightly elevated. Since the authors infections may contribute to the pathogenesis of hypersensitivity, the child was tested for reactivation of l 6. Titers were significantly increased within 15 days. Patch testing revealed hypersensitivity to both valpr ethosuximide (Conilleau et al, 1999).

3.3.7.A.3 Immunology finding

a) IgA deficiency was reported in 29% of 41 epileptic patients receiving 1 or more anticonvulsants (valpr phenytoin, phenobarbital, carbamazepine) was reported. Patients receiving valproate sodium exhibited s mean IgA levels than nonusers of valproate sodium (Joubert et al, 1977).

3.3.7.A.4 Systemic lupus erythematosus

a) A case of systemic lupus erythematosus, marked by increased antihistone antibody level, arthralgias, weakness, fatigue and fever, was reported in a 30-year-old female epileptic patient after 1 year of treatm acid. The laboratory and clinical symptoms disappeared after discontinuation of valproic acid (Gigli et al, See Drug Consult reference: DRUG-INDUCED SYSTEMIC LUPUS ERYTHEMATOSUS

3.3.7.B Divalproex Sodium

3.3.7.B.1 Immune hypersensitivity reaction

a) Incidence: rare (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Multi-organ hypersensitivity reactions (eg, fever and rash associate with other organ system involvem

rarely reported between 1 and 40 days following initiation of valproate therapy in both adult and pediatric reactions have led to hospitalization and at least one death. If a hypersensitivity reaction occurs, disconti therapy and begin an alternative treatment (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.8 Musculoskeletal Effects

Valproic Acid

Divalproex Sodium

3.3.8.A Valproic Acid

Asthenia

Backache

Osteomalacia

Secondary myopathy

3.3.8.A.1 Asthenia

a) Incidence: 10% to 27% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During two clinical trials of valproate treatment of manic episodes associated with bipolar disorder, as reported in 10% of patients receiving valproate (n=89) compared with 7% of patients receiving placebo (n STAVZOR(R) delayed release oral capsules, 2008).

c) Asthenia was reported in 20% of migraine patients receiving valproate (n=202) compared with 9% of placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) delayed re capsules, 2008).

d) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia asthenia was reported in 27% of patients receiving valproate (n=77) compared with 7% of patients receiv (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

e) During a clinical trial of valproate monotherapy for complex partial seizures, asthenia was reported in receiving high-dose valproate (n=131) compared with 10% of patients receiving low-dose valproate (n=1 cases, causality could not be determined as patients were being titrated off another antiepilepsy drug du the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.8.A.2 Backache

a) Incidence: 8% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Back pain was reported in 8% of migraine patients receiving valproate (n=202) compared with 6% of placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) delayed re capsules, 2008).

3.3.8.A.3 Osteomalacia

a) A 2-year cross-sectional and retrospective study concluded that lumbar spine bone mineral density va significantly reduced in prepubertal children treated with valproic acid and carbamazepine compared to c children treated with antiepileptics (valproic acid: 17 boys, 16 girls; mean age 8.8 +/- 2 years; carbamaze girls; mean age 9.7 +/-1.6 years) were compared to age- and sex-matched controls (13 boys, 9 girls; me years). Patients were ambulatory with normal activity and had adequate nutritional intake, which exclude could reduce BMD or biochemical markers of bone turnover. Mean length of treatment was 33.72 +/- 15 acid and 35.52 +/- 12.84 months for carbamazepine. Mean BMD z-scores at lumbar spine were -1.28 +/- acid, -1.69 +/- 0.85 for carbamazepine, and -0.23 +/- 0.87 for the control group. Differences in serum insu factor (IGF)-I and IGF binding protein (IGFBP)-3 levels, which affect bone metabolism and BMD, betwee receiving antiepileptics compared to controls were not significant (Kumandas et al, 2006).

3.3.8.A.4 Secondary myopathy

a) A 4-year-old male child developed myopathy with symptoms of progressive weakness in all limbs 16 starting valproate sodium for epilepsy. Over 1 year the valproate sodium dose was gradually increased fr 40 mg/kg. Four months after starting on 40 mg/kg, he developed lower limb weakness resulting in difficu jumping, climbing up stairs, and standing from a sitting position. Examination revealed weakness in prox muscles of all four limbs (more pronounced in the lower limbs), lordosis, a waddling gait, and normal sen tendon reflexes. No hypertrophy or atrophy was noted. Serum valproate and creatinine phosphokinase c

were within normal limits. The findings on electromyogram (EMG) were suggestive of myopathy. Plasma was below normal at 16 mcmol/L (normal, 20 to 43 mcmol/L). Valproate-induced-myopathy secondary to deficiency was suspected. Carbamazepine replaced valproate and L-carnitine 100 mg/kg/day was initiate there was improvement and within 2 months complete recovery. Complete recovery was further demons months later (Kasturi & Sawant, 2005).
b) Chronic therapeutic use of valproic acid in young children may cause a carnitine deficiency resulting i symptoms of lethargy, weakness or hypotonia, hepatotoxicity, and hyperammonemia. An incidence of fa children under the age of two years of 1/800 has been reported (Raskind & El-Chaar, 2000). An inverse found between plasma carnitine concentrations and the dosage of valproic acid, and between plasma ca ammonia values (Ohtani et al, 1982).
c) The syndrome known as MELAS, including mitochondrial myopathy, encephalopathy, lactic acidosis episodes, was precipitated by valproic acid therapy in a 12-year-old male. Signs and symptoms included exacerbation, hemiparesis, hypotonia, elevated deproteinized blood lactate and pyruvate, and brain infar was found to have a point mutation in mitochondrial DNA. He stabilized upon valproic acid withdrawal (L

3.3.8.B Divalproex Sodium

Arthralgia

Backache

Generalized myasthenia

Myalgia

3.3.8.B.1 Arthralgia
a) Incidence: 1% to 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Arthralgia was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n= monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.8.B.2 Backache
a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Back pain was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n= monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.8.B.3 Generalized myasthenia
a) Incidence: 1% to 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Myasthenia was reported in more than 1% but less than 5% of patients receiving divalproex sodium (monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.8.B.4 Myalgia
a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Myalgia was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n=3 monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.9 Neurologic Effects

Valproic Acid

Divalproex Sodium

3.3.9.A Valproic Acid

Abnormal behavior

Amnesia

Ataxia

Cerebral atrophy

Coma, Hyperammonemia-induced

Dementia

Demyelinating disease of central nervous system

Dizziness

Extrapyramidal disease

Feeling nervous

Headache

Hyperammonemic encephalopathy

Insomnia

Paresthesia

Seizure

Somnolence

Tremor

3.3.9.A.1 Abnormal behavior

a) Behavioral changes were seen in 56 out of 88 pediatric patients receiving sodium valproate monothe included irritability, longer and deeper sleep, superficial sleep, hyperactivity, increased alertness, lassitu increased sociability, calmness, increased sadness, happiness, and aggression. It was emphasized that reactions with valproic acid were as frequent as depressive effects (Herranz et al, 1984b).

3.3.9.A.2 Amnesia

a) Incidence: 4% to 7% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, amnesia was reported in receiving high-dose valproate (n=131) compared with 4% of patients receiving low-dose valproate (n=13 causality could not be determined as patients were being titrated off another antiepilepsy drug during the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.9.A.3 Ataxia

a) Incidence: 8% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia was reported in 8% of patients receiving valproate (n=77) compared with 1% of patients receiving placeb cases, causality could not be determined as patients also received other antiepilepsy drugs concurrently (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.9.A.4 Cerebral atrophy

a) In a series of 16 patients treated with valproate in whom cranial computer tomography (CT) were perf demonstrated new or progressive cerebral atrophy. The atrophy improved in the two patients in whom cr repeated after valproate was discontinued (Armon et al, 1996).

3.3.9.A.5 Coma, Hyperammonemia-induced

a) A 56-year-old woman experienced life-threatening hyperammonemic coma following a moderate dos divalproex sodium. The patient had been poorly controlled while receiving divalproex sodium for 6 years

phenobarbital, phenytoin, carbamazepine, and gabapentin. The divalproex sodium dose was increased f to 2500 mg/day, and the phenobarbital, phenytoin, carbamazepine and gabapentin were slowly discontir initially presented with a 3-hour period of unresponsiveness on divalproex sodium monotherapy. Her am mcg/dL (reference range 22 to 78). The divalproex sodium dose was increased to 3000 mg/day. The pat after 10 hours of the dose escalation. Her venous ammonia level was 921 mcg/dL, and the arterial amm mcg/dL (reference range 22 to 78). Possible causes of hyperammonemia and coma were excluded by e gastrointestinal bleeding or portosystemic shunt and other metabolic, toxic, and structural factors respec divalproex sodium was discontinued and within 48 hours, the ammonia level normalized to 69 mcg/dL ar regained consciousness. A possible urea enzyme deficiency may have contributed to the development o hyperammonemic coma. The Naranjo probability scale conducted stated that the causal relationship bet and hyperammonemic coma was probable (Cuturic, 2005).

3.3.9.A.6 Dementia

a) Long-term therapy with valproic acid was associated with the occurrence of a reversible dementia in a with epilepsy. Withdrawal of the drug resulted in dramatic improvement in memory and other tasks of int It is suggested that valproic acid may induce a dementia-like syndrome via either a direct toxic central ne (CNS) effect, a paradoxical epileptogenic effect, or an indirect CNS effect via production of hyperammon Cohen, 1986).

3.3.9.A.7 Demyelinating disease of central nervous system

a) A 23-year-old male with fulminant demyelinating disease experienced an acute progression after an e valproate-induced hyperammonemic encephalopathy. He had been experiencing uncontrolled seizures v phenytoin and phenobarbital when valproic acid 500 mg twice daily was added to his regimen. After 3 da progressively lethargic and was eventually unresponsive. His venous ammonia level was 524 mcmol/L (r mcmol/L) with normal liver enzymes. Serum carnitine levels were also low. After 15 days, a repeat crania extensive progression of his demyelinating disease. He expired 3 weeks thereafter. The authors specula hyperammonemia may have exacerbated his disease. They conclude that valproic acid should be avoide of seizures in patients with demyelinating disease (Blindauer et al, 1998).

3.3.9.A.8 Dizziness

a) Incidence: 12% to 25% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, dizziness was reported ir receiving high-dose valproate (n=131) compared with 13% of patients receiving low-dose valproate (n=1 cases, causality could not be determined as patients were being titrated off another antiepilepsy drug du the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) During two clinical trials of valproate treatment of manic episodes associated with bipolar disorder, diz reported in 12% of patients receiving valproate (n=89) compared with 4% of patients receiving placebo (r STAVZOR(R) delayed release oral capsules, 2008).

d) Dizziness was reported in 12% of migraine patients receiving valproate (n=202) compared with 6% o placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) delayed r capsules, 2008).

e) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia dizziness was reported in 25% of patients receiving valproate (n=77) compared with 13% of patients rec (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.9.A.9 Extrapyramidal disease

a) Summary

1) A 77-year-old man, with a diagnosis of dementia of the Alzheimer's type, developed an acute Pa movement disorder 1 week after starting valproate therapy. This man, who had no prior history of m was started on valproate due to an increase in aggressive and violent behaviors. The valproate dos increased to 300 mg per day over one week and resulted in a serum level of 11 mcg/mL. At this time experienced resting tremors, rigidity, gait disturbance, and bradykinesis and his Unified Parkinson's Scale (UPDRS) score increased from 18 to 59. Valproate was discontinued 2 weeks later when ther lessening in the Parkinsonian symptoms. Movement disorder signs gradually resolved following disc valproate (Iijima, 2002).

2) Parkinson's syndrome has been associated with chronic valproate therapy. In a series of 36 patie valproate, 27 (75%) had clinical evidence of Parkinsonism (Armon et al, 1996). Of these patients 19 of instability, 16 (44%) reported tremor, 30 (80%) demonstrated cognitive impairment, 22 (62%) had (55%) had abulia and 16 (44%) had upper motor neuron signs (Armon et al, 1996). Most patients im valproate was discontinued. An extrapyramidal syndrome, unresponsive to antiparkinson medicatior developed in a 52-year-old man with schizophrenia who was given sodium valproate 1 to 2 g/day (L

3.3.9.A.10 Feeling nervous

a) Incidence: 7% to 11% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, nervousness was reporte patients receiving high-dose valproate (n=131) compared with 7% of patients receiving low-dose valproa many cases, causality could not be determined as patients were being titrated off another antiepilepsy dr

part of the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.9.A.11 Headache

a) Incidence: 5% to 31% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia headache was reported in 31% of patients receiving valproate (n=77) compared with 21% of patients rec (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) During a clinical trial of valproate monotherapy for complex partial seizures, headache was the only a reported in at least 5% of patients receiving high-dose (n=131) valproate and occurring at an equal or gr patients receiving low-dose valproate (n=134). In many cases, causality could not be determined as pati titrated off another antiepilepsy drug during the first part of the trial (Prod Info STAVZOR(R) delayed rele 2008).

3.3.9.A.12 Hyperammonemic encephalopathy

a) Hyperammonemic encephalopathy, sometimes fatal, has been reported with valproic acid use in pati cycle disorders (particularly ornithine transcarbamylase deficiency) and in patients receiving concomitant Patients who develop symptoms of hyperammonemic encephalopathy (unexplained lethargy and vomitin changes) while receiving valproate therapy should receive prompt treatment (including discontinuation of therapy) and be evaluated for underlying urea cyclic disorder. Most patients receiving concomitant topira resolution of hyperammonemia upon discontinuation of either drug (Prod Info STAVZOR(R) delayed rele 2008).

b) An 88-year-old man developed hyperammonemia and worsening confusion two months after starting four times a day for a presumed seizure disorder. His liver function tests were within normal limits except concentration of 836 mcg/dL (reference range 19 to 60 mcg/dL). His trough valproate serum concentratio His medication was changed to phenytoin 150 mg twice day and his confusion resolved. One week later was 63 mcmol/L (reference range 11 to 35 mcmol/L) and his phenytoin and valproate concentrations we and less than 10 mcg/mL, respectively. He was inadvertently started on valproate again at the former do days his ammonia concentration increased to 130 mcmol/L. He became confused and lethargic and his E bilateral 5 to 7 hertz (Hz) slowing and abnormal, irregular 2-Hz to 3-Hz activity on the right. Valproate wa his ammonia concentration decreased to 60 mcmol/L after 1 day and on the second day his confusion de baseline (Feil et al, 2002).

c) Clinicians reported two adult cases of valproate-induced hyperammonemic encephalopathy, which oc combination therapy including valproate and topiramate. The patients were a 32-year-old man who had l epilepsy with complex partial and secondarily generalized seizures and a 37-year-old woman with focal e right parietal angioma. Among the patient's symptoms were sudden somnolence, slurred speech, ataxia, horizontal nystagmus, and nausea. One day after admission, the man was reacting only to strong stimuli experienced 2 secondarily generalized tonic-clonic seizures (the first time in 10 years for the woman). EE revealed continuous generalized slowing for both. The patients had previously tolerated valproate in com medications (phenobarbital, carbamazepine, lamotrigine). The encephalopathy occurred in both instance and topiramate were given concurrently in a combination regimen. Both had serum levels of valproate be therapeutic range (ie, 38 and 47 mcg/mL, respectively; therapeutic range, 50 to 100 mcg/mL) and elevat ammonia concentrations (116 and 88 mcmol/L, respectively; normal range 11 to 60 mcmol/L). One patie by discontinuation of valproate and the other, by withdrawal of topiramate. The authors suggested that to increase ammonia levels by its inhibition of carbonic anhydrase and cerebral glutamine synthetase (Ham

d) Ten days following initiation of valproic acid (10 mg/kg/day), a 51-year-old female presented with a ra level of consciousness (Glasgow coma score 5/15). EEG showed triphasic waves consistent with hepatic Serum valproic acid and liver enzyme levels were normal; blood arterial ammonia concentration was sign (234 mcmol/L) 10 hours after presentation. Following discontinuation of valproic acid and administration her neurological condition improved within 18 hours (Borbath et al, 2000).

e) A 16-year-old girl with undiagnosed heterozygous ornithine transcarbamylase deficiency (OTC) devel hyperammonemic encephalopathy after valproic acid therapy. OTC deficiency is an X-linked disorder wh common inherited cause of hyperammonemia. The child was experiencing frequent seizures and had va to her carbamazepine therapy. After 7 days, she became deeply somnolent. Her plasma ammonia level (normal less than 50 mcmol) with normal serum transaminases and fibrinogen. Valproic acid was discon deficiency diagnosis was based on non-detectable serum citrulline and high urinary excretion of orotic ac treated with a low-protein diet, sodium benzoate, sodium phenylbutyrate, and substitution of L-arginine. A ammonia levels fell to 55 mcmol (Ochsner et al, 1998).

f) A 23-year-old male with fulminant demyelinating disease experienced an acute progression after an e valproate-induced hyperammonemic encephalopathy. He had been experiencing uncontrolled seizures v phenytoin and phenobarbital when valproic acid 500 mg twice daily was added to his regimen. After 3 da progressively lethargic and was eventually unresponsive. His venous ammonia level was 524 mcmol/L (n mcmol/L) with normal liver enzymes. Serum carnitine levels were also low. After 15 days, a repeat crania extensive progression of his demyelinating disease. He expired 3 weeks thereafter. The authors specula hyperammonemia may have exacerbated his disease. They conclude that valproic acid should be avoide of seizures in patients with demyelinating disease (Blindauer et al, 1998).

g) A 31-year-old woman with systemic lupus erythematous and a seizure disorder treated with valproic a developed fatal hyperammonemia. The woman had also been receiving aspirin 81 mg and cimetidine 40

elevation in anti-cardiolipin-beta2-glycoprotein-1Ab. After 15 months of valproic acid therapy, she was di
nephritis and treated with repeated steroid pulse therapy. This was ineffective and hemodialysis was inst
and finally coma developed and she was found to have a serum ammonia level of 500 mcmol/L. Despite
her ammonia level continued to rise and she died of hyperammonemic encephalopathy (Ichikawa et al, 1

3.3.9.A.13 Insomnia

a) Incidence: 9% to 15% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, insomnia was reported ir
receiving high-dose valproate (n=131) compared with 9% of patients receiving low-dose valproate (n=13
causality could not be determined as patients were being titrated off another antiepilepsy drug during the
trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.9.A.14 Paresthesia

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Paresthesia was reported in more than 1% but less than 5% of patients receiving valproate during pla
clinical trials of migraine and acute mania and during monotherapy treatment of complex partial seizures
causality could not be attributed to valproate alone in the complex partial seizures trial, as patients were
another antiepilepsy drug during the first part of the study (Prod Info STAVZOR(R) delayed release oral

3.3.9.A.15 Seizure

a) In 2 children, ages 5 and 10 years old, valproic acid therapy for infrequent absence seizures resulted
deterioration to absence status with atonic generalized seizures, along with drop attacks in the younger
experienced an increase in the frequency and duration of absences and progressive disorientation. The
effects of valproic acid occurred at doses of 80 to 120 mg twice per day for the 5-year-old patient and 50
for the 10-year-old patient. After valproic acid administration was stopped, both patients experienced a d
absence frequency and duration (to pretreatment levels) along with a clearing of disorientation (Shahar e

b) A 14-year-old boy receiving phenobarbital for tonic-clonic seizures presented with status epilepticus a
valproic acid added. Initially, tonic seizures occurred which increased after 13 days to status. Serum plas
of both valproic acid and phenobarbital were within the therapeutic range. Valproic acid was discontinue
a later date with similar results (Capocchi et al, 1998).

c) Increasing generalized spike and wave activity with increasing somnolence to the point of absence st
25-year-old woman after beginning valproic acid therapy. The woman suffered from multiple seizure type
generalized tonic-clonic, gelastic, absence, and drop attacks. She was being treated with carbamazepine
and fluphenazine. Valproic acid (maximum dose 2500 mg after 4 days) was added for hallucinations ass
frequent seizures. Spike and wave activity during wakefulness was noted to increase as the blood conce
acid increased. Her ammonia level also increased to 104 mcmol/L. Valproic acid was discontinued and la
started (Stecker & Kita, 1998).

d) A breakthrough seizure occurred in a 19-year-old epileptic girl following substitution of Depakene(R)
generic form of valproic acid capsules. Re-initiation of Depakene(R) therapy resulted in no recurrence of
months of follow-up (MacDonald, 1987).

3.3.9.A.16 Somnolence

a) Incidence: 17% to 30% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) In a double-blinded study involving elderly patients with dementia (mean age of 83 years), the occurr
somnolence was significantly higher in the valproate arm (target dose of 20 mg/kg/day) compared with p
approximately half of the affected patients, somnolence was associated with reduced nutritional intake, v
baseline albumin concentration, lower valproate clearance, and higher BUN. When dosing elderly patien
recommended to increase doses more slowly and to monitor fluid and nutritional intake, dehydration, and
adverse reactions (including somnolence) on a regular basis. Consider dose reductions or discontinuatio
excessive somnolence or in patients with reduced fluid or nutritional intake (Prod Info STAVZOR(R) dela
capsules, 2008).

c) During a clinical trial of valproate monotherapy for complex partial seizures, somnolence was reporte
patients receiving high-dose valproate (n=131) compared with 18% of patients receiving low-dose valpro
many cases, causality could not be determined as patients were being titrated off another antiepilepsy dr
part of the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

d) During two clinical trials of valproate treatment of manic episodes associated with bipolar disorder, so
reported in 19% of patients receiving valproate (n=89) compared with 12% of patients receiving placebo
STAVZOR(R) delayed release oral capsules, 2008).

e) Somnolence was reported in 17% of migraine patients receiving valproate (n=202) compared with 5%
receiving placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R)
oral capsules, 2008).

f) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partial
somnolence was reported in 27% of patients receiving valproate (n=77) compared with 11% of patients r
(n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru
with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

g) Due to a higher risk of somnolence among the elderly, the valproate starting dose should be reduced
adjustment should be conservative (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.9.A.17 Tremor

a) Incidence: 9% to 57% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, tremor was reported in 5 receiving high-dose valproate (n=131) compared with 19% of patients receiving low-dose valproate (n=1 cases, causality could not be determined as patients were being titrated off another antiepilepsy drug du the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia was reported in 25% of patients receiving valproate (n=77) compared with 6% of patients receiving place cases, causality could not be determined as patients also received other antiepilepsy drugs concurrently (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

d) Tremor was reported in 9% of migraine patients receiving valproate (n=202) compared with 0% of pa placebo (n=81) during two clinical trials and their long-term extension (Prod Info STAVZOR(R) delayed r capsules, 2008).

e) In 28 consecutive valproic acid-treated patients (mean duration: 3.8 years, mean dose: 1259 mg), 3 h parkinsonism, 15 had intentional tremor, and 16 had postural tremor. None of the patients with parkinsor levodopa (Nouzeilles et al, 1999).

f) In a double-blind, concentration-response clinical trial using valproic acid as monotherapy, high conce acid (n=96, target level 80 to 150 mcg/mL) caused tremor in 61 patients (64%) versus 3 patients (6%) in low concentration valproic acid (n=47, target range of 25 to 50 mcg/mL) (Beydoun et al, 1997c).

g) The effects of propranolol, amantadine, diphenhydramine, benztropine, and cyproheptadine on valpro patients were studied. Propranolol was clearly the most therapeutic. Amantadine was moderately effecti cyproheptadine, diphenhydramine and benztropine gave little or no relief (Karas et al, 1983).

3.3.9.B Divalproex Sodium

Amnesia

Asthenia

Ataxia

Dizziness

Feeling nervous

Headache

Hyperammonemic encephalopathy

Insomnia

Nystagmus

Paresthesia

Somnolence

Tremor

3.3.9.B.1 Amnesia

a) Incidence: 4% to 7% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, amnesia was reported in 5% of pa divalproex sodium (n=77) compared with 1% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

c) Amnesia was reported in 7% of patients receiving high-dose divalproex sodium (n=131) compared wi receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial seizures. In causality could not be attributed to divalproex alone, as patients were titrated off of another antiepilepsy first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.9.B.2 Asthenia

a) Incidence: 10% to 27% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, asthenia was reported in 27% of p divalproex sodium (n=77) compared with 7% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).
c) Asthenia was reported in 21% of patients receiving high-dose divalproex sodium (n=131) compared v patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.9.B.3 Ataxia
a) Incidence: 8% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, ataxia was reported in 8% of patie divalproex sodium (n=77) compared with 1% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

3.3.9.B.4 Dizziness
a) Incidence: 13% to 25% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, dizziness was reported in 25% of p divalproex sodium (n=77) compared with 13% of patients receiving placebo (n=70) (Prod Info DEPAKOT capsules, 2008).
c) Dizziness was reported in 18% of patients receiving high-dose divalproex sodium (n=131) compared patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.9.B.5 Feeling nervous
a) Incidence: 7% to 11% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Nervousness was reported in 11% of patients receiving high-dose divalproex sodium (n=131) compa patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.9.B.6 Headache
a) Incidence: 31% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, headache was reported in 31% of divalproex sodium (n=77) compared with 21% of patients receiving placebo (n=70) (Prod Info DEPAKOT capsules, 2008).

3.3.9.B.7 Hyperammonemic encephalopathy
a) Hyperammonemic encephalopathy, sometimes fatal, has been reported with valproic acid use in patie cycle disorders (particularly ornithine transcarbamylase deficiency) and in patients receiving concomitant Patients who develop symptoms of unexplained hyperammonemic encephalopathy (unexplained letharg mental status changes) while receiving valproate therapy should receive prompt treatment (including dis valproate therapy) and be evaluated for underlying urea cyclic disorder. Most patients receiving concomi experienced resolution of hyperammonemia upon discontinuation of either drug (Prod Info DEPAKOTE(R capsules, 2008).

3.3.9.B.8 Insomnia
a) Incidence: 9% to 15% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Insomnia was reported in 15% of patients receiving high-dose divalproex sodium (n=131) compared v receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial seizures. In causality could not be attributed to divalproex alone, as patients were titrated off of another antiepilepsy first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.9.B.9 Nystagmus
a) Incidence: 1% to 8% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, nystagmus was reported in 8% of divalproex sodium (n=77) compared with 1% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).
c) Nystagmus was reported in 7% of patients receiving high-dose divalproex sodium (n=131) compared patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.9.B.10 Paresthesia
a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) Paresthesia was reported in more than 1% but less than 5% of patients receiving divalproex sodium monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT

capsules, 2008).

3.3.9.B.11 Somnolence

a) Incidence: 18% to 30% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, somnolence was reported in 27% receiving divalproex sodium (n=77) compared with 11% of patients receiving placebo (n=70) (Prod Info D sprinkle oral capsules, 2008).

c) Somnolence was reported in 30% of patients receiving high-dose divalproex sodium (n=131) compar patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

d) Due to a higher risk of somnolence among the elderly, the starting dose should be reduced and dose be conservative (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.9.B.12 Tremor

a) Incidence: 19% to 57% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, tremor was reported in 25% of pati divalproex sodium (n=77) compared with 6% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

c) Tremor was reported in 57% of patients receiving high-dose divalproex sodium (n=131) compared wi receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial seizures. In causality could not be attributed to divalproex alone, as patients were titrated off of another antiepilepsy first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.10 Ophthalmic Effects

Valproic Acid

Divalproex Sodium

3.3.10.A Valproic Acid

Amblyopia

Blurred vision

Diplopia

Nystagmus

3.3.10.A.1 Amblyopia

a) During a clinical trial of valproate monotherapy for complex partial seizures, amblyopia/blurred vision 8% of patients receiving high-dose valproate (n=131) compared with 4% of patients receiving low-dose v In many cases, causality could not be determined as patients were being titrated off another antiepilepsy first part of the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia amblyopia/blurred vision was reported in 12% of patients receiving valproate (n=77) compared with 9% receiving placebo (n=70). In most cases, causality could not be determined as patients also received oth drugs concurrently with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.10.A.2 Blurred vision

a) During a clinical trial of valproate monotherapy for complex partial seizures, amblyopia/blurred vision 8% of patients receiving high-dose valproate (n=131) compared with 4% of patients receiving low-dose v In many cases, causality could not be determined as patients were being titrated off another antiepilepsy first part of the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia amblyopia/blurred vision was reported in 12% of patients receiving valproate (n=77) compared with 9% receiving placebo (n=70). In most cases, causality could not be determined as patients also received oth drugs concurrently with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.10.A.3 Diplopia

a) Incidence: 16% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia was reported in 16% of patients receiving valproate (n=77) compared with 9% of patients receiving place cases, causality could not be determined as patients also received other antiepilepsy drugs concurrently (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.10.A.4 Nystagmus

a) Incidence: 1% to 8% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, nystagmus was reported receiving high-dose valproate (n=131) compared with 1% of patients receiving low-dose valproate (n=13 causality could not be determined as patients were being titrated off another antiepilepsy drug during the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia nystagmus was reported in 8% of patients receiving valproate (n=77) compared with 1% of patients rece (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.10.B Divalproex Sodium

Abnormal vision

Amblyopia

Blurred vision

Diplopia

3.3.10.B.1 Abnormal vision

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Abnormal vision was reported in more than 1% but less than 5% of patients receiving divalproex sodi monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.10.B.2 Amblyopia

a) In a clinical trial of adjunctive therapy for complex partial seizures, amblyopia/blurred vision was repo patients receiving divalproex sodium (n=77) compared with 9% of patients receiving placebo (n=70) (Pro (R) sprinkle oral capsules, 2008).

b) Amblyopia/blurred vision was reported in 8% of patients receiving high-dose divalproex sodium (n=13 4% of patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex part many cases, causality could not be attributed to divalproex alone, as patients were titrated off of another during the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.10.B.3 Blurred vision

a) In a clinical trial of adjunctive therapy for complex partial seizures, amblyopia/blurred vision was repo patients receiving divalproex sodium (n=77) compared with 9% of patients receiving placebo (n=70) (Pro (R) sprinkle oral capsules, 2008).

b) Amblyopia/blurred vision was reported in 8% of patients receiving high-dose divalproex sodium (n=13 4% of patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex part many cases, causality could not be attributed to divalproex alone, as patients were titrated off of another during the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.10.B.4 Diplopia

a) Incidence: 16% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, diplopia was reported in 16% of pa divalproex sodium (n=77) compared with 9% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

3.3.11 Otic Effects

Valproic Acid

Divalproex Sodium

3.3.11.A Valproic Acid

Ototoxicity - deafness

Tinnitus

3.3.11.A.1 Ototoxicity - deafness

a) Incidence: 1% to less than 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Deafness was reported in more than 1% but less than 5% of patients receiving valproate during acute (n=89) and during monotherapy treatment of complex partial seizures (n=265). In many cases, causality attributed to valproate alone, as patients were titrated off of another antiepilepsy drug during the first part monotherapy trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.11.A.2 Tinnitus

a) Incidence: 1% to 7% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, tinnitus was reported in 7 receiving high-dose valproate (n=131) compared with 1% of patients receiving low-dose valproate (n=13 causality could not be determined as patients were being titrated off another antiepilepsy drug during the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) A 52-year-old man experienced tinnitus after receiving valproic acid for treatment of bipolar disorder. admitted to a psychiatric unit for bipolar disorder; symptoms included agitation, loudness, pressured spe grandiose delusions, and paranoia. His treatment included olanzapine 10 mg and divalproex sodium 500 day, and lorazepam as needed. Two days later, he complained of noises in his head. This complaint was worsening of his psychotic symptoms. By day 8, he was calm and coherent but continued to report increa ears. At that time, his serum valproic acid level was 67.5 mcg/mL (within the therapeutic range). The pati that he had experienced the same problem when he had taken valproate several years earlier. Valproate and his tinnitus resolved over a period of 10 days (Reeves et al, 2000).

3.3.11.B Divalproex Sodium

Otitis media

Ototoxicity - deafness

Tinnitus

3.3.11.B.1 Otitis media

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Otitis media was reported in more than 1% but less than 5% of patients receiving divalproex sodium (monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.11.B.2 Ototoxicity - deafness

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Deafness was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n= monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.11.B.3 Tinnitus

a) Incidence: 1% to 7% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Tinnitus was reported in 7% of patients receiving high-dose divalproex sodium (n=131) compared wit receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial seizures. In causality could not be attributed to divalproex alone, as patients were titrated off of another antiepilepsy first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.12 Psychiatric Effects

Valproic Acid

Divalproex Sodium

Valproate Sodium

3.3.12.A Valproic Acid

Depression

Disturbance in thinking

Mood swings

Psychiatric sign or symptom

Suicidal thoughts

3.3.12.A.1 Depression

a) Incidence: 4% to 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) Depression was reported in 5% of patients receiving high-dose valproate (n=131) compared with 4% receiving low-dose valproate (n=134) for monotherapy treatment of complex partial seizures. In many ca could not be attributed to valproate alone, as patients were titrated off of another antiepilepsy drug during the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.12.A.2 Disturbance in thinking

a) Incidence: 6% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia abnormal thinking was reported in 6% of patients receiving valproate (n=77) compared with 0% of patien placebo (n=70). In most cases, causality could not be determined as patients also received other antiepil concurrently with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.12.A.3 Mood swings

a) Incidence: 6% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, emotional lability was reported in 6 receiving valproate (n=77) compared with 4% of patients receiving placebo (n=70). In most cases, causa determined as patients also received other antiepilepsy drugs concurrently with valproate (Prod Info STA release oral capsules, 2008).

3.3.12.A.4 Psychiatric sign or symptom

a) Behavioral changes were reported 1 week after starting therapy in a 34-year-old male who was receiv valproic acid per day as part of a controlled study. The valproic acid was discontinued and 5 days later th recovered (Alvarez et al, 1982).

b) A psychotic reaction in a 14-year-old male who received valproate sodium 1600 mg daily for 14 days described. The patient at this time was seizure-free but experienced confusion, bizarre behavior, and hal Plasma levels of valproate at the time were 13 mcg/mL. The drug was discontinued and restarted at 800 patient remained seizure-free with no further psychotic episodes (Bellman & Ross, 1977).

3.3.12.A.5 Suicidal thoughts

a) Data reviewed by the US Food and Drug Administration suggest an increased risk of suicidal behavio exist in patients receiving therapy with antiepileptic drugs (AEDs). The analysis included 199 placebo-co studies covering 11 different AEDs used for several different indications such as epilepsy, selected psych and other conditions, including migraine and neuropathic pain syndromes. The analysis included 27,863 with AEDs and 16,029 patients who received placebo, and patients were aged 5 years and older. There suicides among patients in the AED treatment groups versus (vs) none in the placebo groups. Suicidal b occurred in 0.43% of patients in the AED treatment groups compared to 0.22% of patients in the placebo corresponded to an estimated 2.1 per 1000 (95% confidence interval, 0.7 to 4.2) more patients in the AE groups having suicidal behavior or ideation than the placebo groups. The increased risk of suicidality wa after starting an AED and continued to at least 24 weeks. When compared to placebo, results were gene among the drugs and were seen in all demographic subgroups. Patients treated for epilepsy, psychiatric conditions were all at an increased risk for suicidality compared to placebo. Closely monitor patients trea emergence or worsening of depression, suicidality and other unusual changes in behavior, which may in such as anxiety, agitation, hostility, mania, and hypomania (US Food and Drug Administration, 2008).

3.3.12.B Divalproex Sodium

Anxiety

Confusion

Depression

Disturbance in thinking

Mood swings

Suicidal thoughts

3.3.12.B.1 Anxiety

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Anxiety was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n=3
monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d
patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT
capsules, 2008).

3.3.12.B.2 Confusion

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Confusion was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n
monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d
patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT
capsules, 2008).

3.3.12.B.3 Depression

a) Incidence: 4% to 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Depression was reported in 5% of patients receiving high-dose divalproex sodium (n=131) compared
patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei
cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep
the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.12.B.4 Disturbance in thinking

a) Incidence: 6% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, abnormal thinking was reported in
receiving divalproex sodium (n=77) compared with 0% of patients receiving placebo (n=70) (Prod Info DI
sprinkle oral capsules, 2008).

3.3.12.B.5 Mood swings

a) Incidence: 6% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, emotional lability was reported in 6
receiving divalproex sodium (n=77) compared with 4% of patients receiving placebo (n=70) (Prod Info DI
sprinkle oral capsules, 2008).

3.3.12.B.6 Suicidal thoughts

a) Data reviewed by the US Food and Drug Administration suggest an increased risk of suicidal behavio
exist in patients receiving therapy with antiepileptic drugs (AEDs). The analysis included 199 placebo-co
studies covering 11 different AEDs used for several different indications such as epilepsy, selected psyc
and other conditions, including migraine and neuropathic pain syndromes. The analysis included 27,863
with AEDs and 16,029 patients who received placebo, and patients were aged 5 years and older. There
suicides among patients in the AED treatment groups versus (vs) none in the placebo groups. Suicidal b
occurred in 0.43% of patients in the AED treatment groups compared to 0.22% of patients in the placebo
corresponded to an estimated 2.1 per 1000 (95% confidence interval, 0.7 to 4.2) more patients in the AE
groups having suicidal behavior or ideation than the placebo groups. The increased risk of suicidality wa
after starting an AED and continued to at least 24 weeks. When compared to placebo, results were gene
among the drugs and were seen in all demographic subgroups. Patients treated for epilepsy, psychiatric
conditions were all at an increased risk for suicidality compared to placebo. Closely monitor patients trea
emergence or worsening of depression, suicidality and other unusual changes in behavior, which may in
such as anxiety, agitation, hostility, mania, and hypomania (US Food and Drug Administration, 2008).

3.3.12.C Valproate Sodium

3.3.12.C.1 Suicidal thoughts

a) Data reviewed by the US Food and Drug Administration suggest an increased risk of suicidal behavic exist in patients receiving therapy with antiepileptic drugs (AEDs). The analysis included 199 placebo-co studies covering 11 different AEDs used for several different indications such as epilepsy, selected psyc and other conditions, including migraine and neuropathic pain syndromes. The analysis included 27,863 with AEDs and 16,029 patients who received placebo, and patients were aged 5 years and older. There suicides among patients in the AED treatment groups versus (vs) none in the placebo groups. Suicidal b occurred in 0.43% of patients in the AED treatment groups compared to 0.22% of patients in the placebc corresponded to an estimated 2.1 per 1000 (95% confidence interval, 0.7 to 4.2) more patients in the AE groups having suicidal behavior or ideation than the placebo groups. The increased risk of suicidality wa after starting an AED and continued to at least 24 weeks. When compared to placebo, results were gene among the drugs and were seen in all demographic subgroups. Patients treated for epilepsy, psychiatric conditions were all at an increased risk for suicidality compared to placebo. Closely monitor patients trea emergence or worsening of depression, suicidality and other unusual changes in behavior, which may in such as anxiety, agitation, hostility, mania, and hypomania (US Food and Drug Administration, 2008).

3.3.13 Renal Effects

Fanconi syndrome

Nocturnal enuresis

3.3.13.A Fanconi syndrome

1) The manufacturer reports that rare reports of Fanconi's syndrome have occurred mainly in children (Prod delayed release oral capsules, 2008). A case of Fanconi's syndrome occurred in a young girl following 18 an therapy of valproic acid and clobazam, respectively. The patient presented with hypophosphatemia, phospha glycosuria, mild metabolic acidosis, aminoaciduria, and evidence of rickets. Symptoms slowly improved follov discontinuation of both drugs. It is difficult to determine from this report whether this adverse reaction occurre therapy with one of the drugs, or possibly, a combination of both agents (Smith et al, 1995).

3.3.13.B Nocturnal enuresis

1) Summary

a) Enuresis has occurred with valproic acid therapy (Prod Info STAVZOR(R) delayed release oral capsu et al, 1979; Suchy et al, 1979). Nocturnal enuresis was described as a side effect of valproic acid in 2 Gr treated for seizures. Enuresis developed within 2 to 3 days after initiation of valproic acid treatment and c seizure-free period; enuresis remitted upon reduction of the dose or withdrawal of valproic acid (Panayio

3.3.14 Reproductive Effects

Semen finding

Testicular hypofunction

3.3.14.A Semen finding

1) Antiepileptic agents have been associated with changes in sperm morphology and motility. A lower freque morphologically normal sperm was found in carbamazepine treated men with partial epilepsy (n=15), in valpr men with generalized epilepsy and in oxcarbazepine treated men with partial epilepsy (n=18) (p less than 0.0 carbamazepine and valproic acid and p less than 0.05 for oxcarbazepine) compared to healthy controls (n=4 significant decrease in the frequency of motile sperm was also found with all treatment groups combined whe healthy controls (p less than 0.05). Within the various treatment groups, valproic acid treated patients had a s significant decrease in the frequency of motile sperm than in the control group (p less than 0.05). Carbamaze had high frequencies of abnormally low sperm concentration (p less than 0.001) and poorly motile sperm (p l when compared to controls (Isojarvi et al, 2004).

3.3.14.B Testicular hypofunction

1) When compared to healthy controls (n=41), valproic acid treated men with generalized epilepsy (n=27) ha volumes (p=0.01). Within the same study however, the testicular volumes of carbamazepine treated men with (n=15) or oxcarbazepine treated men with generalized epilepsy (n=18) did not differ from controls. When furth valproic acid treated men with abnormal sperm morphology had smaller testicular volumes than control wher volumes of valproic acid treated men with normal sperm were similar to controls (Isojarvi et al, 2004).

3.3.15 Respiratory Effects

Valproic Acid

Divalproex Sodium

3.3.15.A Valproic Acid

Bronchitis

Dyspnea

Pharyngitis

Pleural effusion

Pulmonary hemorrhage

Respiratory tract infection

Rhinitis

3.3.15.A.1 Bronchitis

a) Incidence: 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia bronchitis was reported in 5% of patients receiving valproate (n=77) compared with 1% of patients receiv (n=70). In most cases, causality could not be determined as patients also received other antiepilepsy dru with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.15.A.2 Dyspnea

a) Incidence: 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, dyspnea was reported in receiving high-dose valproate (n=131) compared with 1% of patients receiving low-dose valproate (n=13 causality could not be determined as patients were being titrated off another antiepilepsy drug during the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.15.A.3 Pharyngitis

a) Incidence: 8% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial of valproate monotherapy for complex partial seizures, pharyngitis was reported receiving high-dose valproate (n=131) compared with 2% of patients receiving low-dose valproate (n=13 causality could not be determined as patients were being titrated off another antiepilepsy drug during the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.15.A.4 Pleural effusion

a) Incidence: rare

b) Recurrent transudative pleural effusion associated with sodium valproate therapy was diagnosed in a with a history of smoking, atrial fibrillation (treated with digoxin), and posttraumatic epilepsy (treated with 500 mg/day for one year). The patient had his first occurrence 8 months earlier when he was diagnosed pleural effusion containing 700 mL of neutrophilic transudate. Current symptoms included a 5-day fever dry cough, and dyspnea and laboratory examination revealed mild anemia and slightly increased erythro rate and C-reactive protein. Chest X-ray and thoracentesis revealed a right-sided pleural effusion with 12 neutrophilic transudative. One day after the fluid was drained, a CT showed pleural fluid in both pleural c was switched from sodium valproate to gabapentin 300 mg/day and the patient had no recurrence of ple months follow-up. After 7 months, an epileptic episode caused the patient to resume sodium valproate th month later the patient experienced a recurrence of right-sided pleural effusion with transudative effusion relapse, gabapentin was increased to 400 mg twice daily and no pleural fluid recurrence was observed u (Tryfon et al, 2009).

c) Eosinophilic pleural effusion developed in a 34-year-old male treated with valproic acid 1500 mg/day. months after the initiation of therapy, the patient presented with fever and nonproductive cough. Upon ho medications were discontinued and a full medical workup was conducted. There was no evidence of pne hemothorax, pulmonary infiltrates, lymphadenopathy or infection. The symptoms resolved and the patien Rechallenge with valproic acid resulted in the reappearance of symptoms (Kravetz & Federman, 2003).

3.3.15.A.5 Pulmonary hemorrhage

a) Incidence: rare

b) A case of thrombocytopenia-induced fatal pulmonary hemorrhage was reported in a 30-year-old fema valproate monotherapy, with a history of a viral illness 3 weeks earlier. Initial serum valproate level was 1 (normal 50 to 100 mcg/mL). The authors suggested that viral infections may be associated with thrombo patients on valproate therapy (Sleiman et al, 2000).

3.3.15.A.6 Respiratory tract infection

a) Incidence: 12% to 20% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) During a clinical trial where valproate was given as adjunctive therapy for treatment of complex partia respiratory tract infection was reported in 12% of patients receiving valproate (n=77) compared with 6% receiving placebo (n=70). In most cases, causality could not be determined as patients also received oth drugs concurrently with valproate (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

c) During a clinical trial of valproate monotherapy for complex partial seizures, respiratory tract infection 20% of patients receiving high-dose valproate (n=131) compared with 13% of patients receiving low-dos (n=134). In many cases, causality could not be determined as patients were being titrated off another an during the first part of the trial (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.15.A.7 Rhinitis

a) Incidence: 5% (Prod Info STAVZOR(R) delayed release oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, rhinitis was reported in 5% of patie valproate (n=77) compared with 4% of patients receiving placebo (n=70) (Prod Info STAVZOR(R) delaye capsules, 2008).

3.3.15.B Divalproex Sodium

Bronchitis

Dyspnea

Epistaxis

Pharyngitis

Pneumonia

Rhinitis

Sinusitis

3.3.15.B.1 Bronchitis

a) Incidence: 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, bronchitis was reported in 5% of p divalproex sodium (n=77) compared with 1% of patients receiving placebo (n=70) (Prod Info DEPAKOTE capsules, 2008).

3.3.15.B.2 Dyspnea

a) Incidence: 1% to 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Dyspnea was reported in 1% of patients receiving high-dose divalproex sodium (n=131) compared wi receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial seizures. In causality could not be attributed to divalproex alone, as patients were titrated off of another antiepilepsy first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.15.B.3 Epistaxis

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Epistaxis was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n= monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.3.15.B.4 Pharyngitis

a) Incidence: 2% to 8% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Pharyngitis was reported in 8% of patients receiving high-dose divalproex sodium (n=131) compared

patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei
cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep
the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.15.B.5 Pneumonia

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Pneumonia was reported in more than 1% but less than 5% of patients receiving divalproex sodium (
monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d
patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT
capsules, 2008).

3.3.15.B.6 Rhinitis

a) Incidence: 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) In a clinical trial of adjunctive therapy for complex partial seizures, rhinitis was reported in 5% of patie
divalproex sodium (n=77) compared with 4% of patients receiving placebo (n=70) (Prod Info DEPAKOTE
capsules, 2008).

3.3.15.B.7 Sinusitis

a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Sinusitis was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n=3
monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d
patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT
capsules, 2008).

receiving valproate (n=77) compared with 9% of patients receiving placebo (n=70). In many cases, causa
attributed to valproate alone, as patients were titrated off of another antiepilepsy drug during the first part
Info STAVZOR(R) delayed release oral capsules, 2008).

3.3.16.A.3 Reye's syndrome

a) Summary

1) Valproic acid has been associated with a Reye-like syndrome (RLS). In some reports, there was
decreased serum carnitine levels. Clinical signs and symptoms were similar among patients with rev
fatal outcomes. Most patients presented with nausea, vomiting and apathy. Increase in seizure frequ
concurrent febrile illness also occur. Patients developing any signs of RLS should have valproic acid
immediately (Sugimoto et al, 1983; Gerber et al, 1979).

b) A case of Reye-like syndrome (RLS) was reported in a 6-month-old infant who received valproic acid
This infant became unresponsive to therapy for seizure control and developed signs of valproic acid-indu
hepatotoxicity. Laboratory values revealed increased plasma ammonia levels, increased liver enzymes a
plasma carnitine. Valproic acid was discontinued and the patient recovered. This report supported the vi

acid-associated RLS may be mediated by carnitine depletion (Murphy et al, 1985).
c) A case of a Reye-like syndrome was reported in a 13-year-old female who had received valproic acid
Hyperammonemia and severe hepatic damage, as well as diffuse small droplets in liver biopsy material,
demonstrated. It was suggested that valproic acid or its metabolites may decrease the activity on N-acet
can decrease the activity of carbamyl phosphate synthetase I, inducing hyperammonemia (Sugimoto et a
d) Features of Reye's syndrome were reported in a 3-year-old girl receiving valproic acid 600 mg daily.
attack, which caused unconsciousness and subsequent recovery, the patient became increasingly drows
Blood ammonia levels and bilirubin were elevated, but liver enzymes were within a normal to slightly elev
serum carnitine was decreased. Postmortem liver biopsy revealed microvesicular steatosis of hepatocyte
suggested that valproic acid and its metabolites needed to be investigated for their influence on carnitine
the resultant storage of free fatty acids as lipid particles (Bohles et al, 1982).
e) Reye-like syndrome (RLS) associated with valproic acid was reported in a 40-month-old mentally reta
severe refractory multifocal seizure disorder. The patient was receiving phenytoin and ethosuximide in a
acid. Increased liver enzymes were noted 2 weeks prior to admission. A low-grade fever and loose, foul
were noted shortly before onset of generalized seizure activity. Blood ammonia levels were increased. Li
widespread disorganization of the parenchyma with swelling of the hepatocytes and compression of the
diffuse fatty infiltration, including macrovacuoles and microvacuoles was also identified (Keene et al, 198
f) A fatal case of Reye-like syndrome was reported in an 8-year-old boy receiving valproic acid 375 mg t
seizure episode, the boy became febrile and tachypneic; liver enzymes and blood ammonia levels were
Postmortem examination revealed panlobular microvesicular fatty changes in the liver and renal tubules.
appeared swollen, but did not have other gross or microscopic pathological changes (Young et al, 1980)
g) Reye-like syndrome (RLS) associated with valproic acid was reported in a 12-year-old girl. The patien
multiple medications including valproic acid 250 mg three times daily, phenobarbital 60 mg daily, phenyto
and acetazolamide 125 mg twice daily. The patient developed a viral respiratory infection and steadily de
increasing temperature and loss of consciousness. Liver enzymes and blood ammonia levels were eleva
examination revealed a bronchopneumonia and an enlarged, yellow, greasy liver with a mottled appeara
of venous congestion. Biopsy showed marked fatty changes in the liver with fat formed vacuoles which fi
in most of the cells; kidney biopsy revealed numerous small lipid vacuoles in most proximal tubular cells
1979).

3.3.16.B Divalproex Sodium

Fever

Infectious disease

Influenza

Malaise

3.3.16.B.1 Fever
a) Incidence: 6% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, fever was reported in 6% of patien
divalproex sodium (n=77) compared with 4% of patients receiving placebo (n=70) (Prod Info DEPAKOTE
capsules, 2008).

3.3.16.B.2 Infectious disease
a) Incidence: 12% to 20% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, infection was reported in 12% of pa
divalproex sodium (n=77) compared with 6% of patients receiving placebo (n=70) (Prod Info DEPAKOTE
capsules, 2008).
c) Infection was reported in 20% of patients receiving high-dose divalproex sodium (n=131) compared w
patients receiving low-dose divalproex sodium (n=134) for monotherapy treatment of complex partial sei
cases, causality could not be attributed to divalproex alone, as patients were titrated off of another antiep
the first part of the trial (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008).

3.3.16.B.3 Influenza
a) Incidence: 12% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)
b) In a clinical trial of adjunctive therapy for complex partial seizures, flu syndrome was reported in 12%
receiving divalproex sodium (n=77) compared with 9% of patients receiving placebo (n=70) (Prod Info DI
sprinkle oral capsules, 2008).

3.3.16.B.4 Malaise
a) Incidence: 1% to less than 5% (Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008)

b) Malaise was reported in more than 1% but less than 5% of patients receiving divalproex sodium (n=3 monotherapy treatment of complex partial seizures. In many cases, causality could not be attributed to d patients were titrated off of another antiepilepsy drug during the first part of the trial (Prod Info DEPAKOT capsules, 2008).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category D (Prod Info DEPAKOTE(R) ER extende tablets, 2006) (All Trimesters)

a) There is positive evidence of human fetal risk, but the benefits from use in pregnant women may be accep risk (e.g., if the drug is needed in a life-threatening situation or for a serious disease for which safer drugs car ineffective).

2) Australian Drug Evaluation Committee's (ADEC) Category: D (Batagol, 1999)

a) Drugs which have caused, are suspected to have caused, or may be expected to cause an increased inci fetal malformations or irreversible damage. These drugs may also have adverse pharmacological effects. Acc should be consulted for further details.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

3) Crosses Placenta: Yes

4) Clinical Management

a) As valproic acid can be teratogenic and cause congenital malformations such as neural tube defects, cons valproic acid or its salt form, sodium divalproex in women of childbearing potential only after the risks have be discussed with the patient and the potential benefits outweigh the risk of injury to the fetus. This is particularly treating a spontaneously reversible condition which does not bear a risk of permanent injury or risk of death (cases where the severity and frequency of the seizure disorder may permit removal of the drug without posin therapy to the patient, clinicians may consider discontinuation of the drug prior to or during pregnancy. Where unavoidable or unanticipated, the pregnant mother should be advised of possible consequences to the fetus. neural tube defects is recommended and clotting parameters should be routinely monitored. Although it is un folic acid supplementation in pregnant women receiving valproate can reduce risk of neural tube defects in th should be routinely recommended in patients contemplating pregnancy, both prior to and during pregnancy (P DEPAKOTE(R) ER extended-release oral tablets, 2006; Prod Info DEPAKOTE(R) oral sprinkle capsules, 200 DEPAKOTE(R) delayed-release oral tablets, 2006a; Prod Info DEPACON(R) IV injection, 2006; Prod Info DE capsules, oral syrup, 2006). Infants born to mothers treated with valproate during pregnancy should have blo monitored during the first several hours of life (Ebbesen et al, 2000).

5) Literature Reports

a) Data collected from the Antiepileptic Drug (AED) Pregnancy Registry revealed 16 cases of congenital mal infants born of pregnant women (n=149) exposed valproate monotherapy (doses of approximately 1,000 mg/ first trimester. The prevalence rate of birth defects was 10.7% (95% confidence interval (CI), 6.3% to 16.9%). defects occurred in 2% of the infants (n=3/149) while 4% of the infants (n=6/149) had less severe malformatic (n=1,048) exposed to other AED monotherapies, the malformation rate was 2.9% (95% CI, 2% to 4.1%). Con malformations in valproic acid-exposed mothers was 4-fold higher compared to those treated with other AED a group (odds ratio, 4.0; 95% CI, 2.1% to 7.4%) (Prod Info DEPAKOTE(R) ER extended-release oral tablets, DEPAKOTE(R) oral sprinkle capsules, 2006; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006a; P DEPACON(R) IV injection, 2006; Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006).

b) Data collected from the Antiepileptic Drug (AED) Pregnancy Registry for over 3,000 pregnant women exp included 123 completed pregnancies exposed to valproate monotherapy (Holmes et al, 2003). The prevalenc was 8.9% in this subset compared to 2.8% (RR 3.5; 95% CI 2.0 to 6.2) of women exposed to monotherapy w to 1.6% (RR 6.0; 95% CI 3.5 to 10.2) of an external comparison group. Anomalies reported in order of freque neural tube, hypospadias, polydactyly, bilateral inguinal hernia, dysplastic kidneys, and club foot. Similarly, a retrospective cohort study (n=1411) showed an increased risk of major congenital abnormalities in the offspri treated with either carbamazepine (relative risk (RR) 2.6) or valproate (RR 4.1) monotherapy during the first t pregnancy (Samren et al, 1999). Risk associated with valproate was dose-dependent. Valproate alone and in other AEDs were associated with an increased risk of neural tube defects (RR 4.0, p=0.03; RR 5.4, p=0.004, risk of hypospadia was similarly higher in the monotherapy and combination therapy groups (RR 4.8, p=0.05; respectively).

c) Numerous cases have been reported of fetal neural tube defects, primarily spina bifida, and/or cardiac def of Fallot, patent ductus arteriosus, valvular aortic stenosis, and ventricular septal defect). There is an increas neural tube defects with exposure during the first trimester of pregnancy. Risk of spina bifida in children of wo valproic acid during pregnancy is estimated to be 1% to 2% by the CDC. While the American College of Obst Gynecologists estimates the general risk for congenital neural tube defects to be 0.14% to 0.2%, data from th Drug (AED) Pregnancy Registry showed that neural tube defects occurred at a rate of 2% (n=3/149) (Prod In ER extended-release oral tablets, 2006; Prod Info DEPAKOTE(R) oral sprinkle capsules, 2006; Prod Info DE delayed-release oral tablets, 2006a; Prod Info DEPACON(R) IV injection, 2006; Prod Info DEPAKENE(R) ora syrup, 2006; Ardinger et al, 1988; Bertollini et al, 1987; Jager-Roman et al, 1986; Bailey et al, 1983; Jeavons Guibaud, 1982; Thomas & Buchanan, 1981; Clay et al, 1981; Dalens et al, 1980).

d) Various other reports of fetal abnormalities resemble those seen in fetal hydantoin syndrome, including cr skeletal or limb defects (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2006; Prod Info DEPAK sprinkle capsules, 2006; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006a; Prod Info DEPACON 2006; Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006; DiLiberti et al, 1984; Jager-Roman et al, 198

1988). It is not clearly established, however, whether these anomalies constitute a fetal valproic acid syndrom of other factors such as genetic or environmental factors, combination therapy with other anticonvulsants, an episodes during gestation. A case-control study in which 57 of 22,294 malformed infants and 10 of 21,937 co exposed to valproic acid estimated a risk for limb deficiencies to be about 0.42% (Rodriguez-Pinilla et al, 200 analysis calculated an odds ratio of 6.17 (confidence interval 1.28-29.66, p = 0.023) for limb deficiencies afte prenatal exposure to valproic acid. The types of limb deficiencies reported included overlapping digits, talipes clinodactyly, arachnodactyly, hip dislocation, and others.

e) The relationship of first-trimester plasma antiepileptic drug (AED) concentrations and pregnancy outcome women was assessed, including 44 women on valproic acid monotherapy (Canger et al, 1999). Valproic acid significantly higher rate of malformations (p less than 0.02) compared to monotherapy with other AEDs such carbamazepine, phenobarbital, phenytoin, and clonazepam. In addition, the mothers of malformed fetuses us valproic acid during their first trimester than did mother of nonmalformed fetuses.

f) Twenty-two infants with in utero exposure to a median daily dose of 1 g valproate in the first trimester and third trimester were described by (Ebbesen et al, 2000). In 13 of the 22 infants, blood glucose dropped below the first hypoglycemic episode occurring within one hour of birth in seven infants and within 2 hours in three i infants exhibited withdrawal symptoms within 12 to 24 hours including irritability, jitteriness, hypertonia, seizu problems.

g) Other reported fetotoxic effects include a case of an infant with afibrinogenemia who died of hemorrhage, hepatic failure that resulted in death of a newborn infant (Prod Info DEPAKOTE(R) ER extended-release oral Prod Info DEPAKOTE(R) oral sprinkle capsules, 2006; Prod Info DEPAKOTE(R) delayed-release oral tablets DEPACON(R) IV injection, 2006; Prod Info DEPAKENE(R) oral capsules, oral syrup, 2006).

h) If phenytoin or carbamazepine (or any prodrugs) is used in pregnant women, there is a substantially incre teratogenicity with many combinations of other anticonvulsants. The teratogenicity of these drugs is largely o the levels of the reactive epoxide metabolites (Buehler et al, 1990c; Van Dyke et al, 1991c; Finnell et al, 1992 epoxide/parent drug ratio is generally increased when phenytoin or carbamazepine is combined with each otl drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide hydrolase, su acid, progabide, and lamotrigine (Bianchetti et al, 1987c; Ramsay et al, 1990c; Spina et al, 1996c). Such com the risk of major birth defects 3- to 4-fold over monotherapy and about 10-fold over background rates.

B) Breastfeeding

1) American Academy of Pediatrics Rating: Maternal medication usually compatible with breastfeeding. (Anon, 2

2) World Health Organization Rating: Compatible with breastfeeding. Monitor infant for side effects. (Anon, 2002)

3) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk wh breastfeeding. Weigh the potential benefits of drug treatment against potential risks before prescribing this dr breastfeeding.

4) Clinical Management

a) Valproate is excreted into breast milk, with levels reported to be 1% to 10% of maternal serum levels. The recommends to consider discontinuing nursing when valproic acid is administered to a nursing woman (Prod (R) ER extended-release oral tablets, 2006; Prod Info DEPAKOTE(R) oral sprinkle capsules, 2006; Prod Info delayed-release oral tablets, 2006a; Prod Info DEPACON(R) IV injection, 2006; Prod Info DEPAKENE(R) ora syrup, 2006).However, valproic acid is considered to be compatible with breastfeeding by the American Acad (Anon, 2001). Children younger than two years of age who use valproic acid may, however, be at risk of fatal (Zimmerman, 1993). Additionally, a case report described thrombocytopenia and anemia in a 3-month-old inf mother received sodium valproate (Stahl et al, 1997). Therefore, nursing mothers should monitor their infants toxicity such as drowsiness, petechiae, vomiting, and/or diarrhea (Iqbal et al, 2001).

5) Literature Reports

a) Early data indicated that valproic acid was excreted in breast milk in significant levels (approximately 10% levels) (Pinder et al, 1977a), but the number of women studied was low (16 in the largest study) (Chaudron & Data from other studies have supported the findings that the drug is not contraindicated during the breastfeed (Rimmer & Richens, 1985c; Von Uhruh et al, 1984; Dickinson et al, 1979).

b) One report describes a 3-month-old infant presenting with thrombocytopenia and anemia caused by sodiu administration to the nursing mother. The infant's serum valproate level was 6.6 mcg/mL. Breastfeeding was hematologic abnormalities resolved within 35 days(Stahl et al, 1997).

3.5.1.A Acyclovir

1) Interaction Effect: decreased valproic acid plasma concentrations and potential increased seizure activity

2) Summary: A case report from the University of Bologna in Italy documents a reduction in plasma levels of and valproic acid when combined with acyclovir treatment. This reduction resulted in increased seizure activi approximately one per month to 25 in one day. Phenytoin dosage was increased and plasma levels returned ranges after 10 days (Parmeggiani et al, 1995a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor patients for reduction in antiepileptic plasma levels. Consider alternative an

7) Probable Mechanism: increased gastrointestinal transit or change in gastrointestinal fluid pH

8) Literature Reports

a) According to a case report from the University of Bologna in Italy, a seven-year-old child with a histor experienced increased seizure activity after being treated with acyclovir in addition to his antiepileptic me patient's trough plasma levels of phenytoin and valproic acid were 17 and 32 mcg/mL, respectively, 10 d acyclovir treatment for viral throat and mouth lesions. Four days after initiation of acyclovir treatment, the were 5.0 and 22 mcg/mL, respectively. Acyclovir treatment was discontinued after six days. Three and si acyclovir withdrawal, phenytoin and valproic acid plasma levels were still low, and the patient experience seizures five days after discontinuation. Phenytoin dosage was increased to reach therapeutic plasma le frequency of seizures was reduced to two or three per week. The authors suggest that further study of th interaction is warranted (Parmeggiani et al, 1995).

3.5.1.B Amitriptyline

1) Interaction Effect: increased serum concentrations of amitriptyline and its metabolite nortriptyline

2) Summary: A controlled study observed increases in the area under the concentration-time curve (AUC) ar concentration (Cmax) for amitriptyline and its active metabolite, nortriptyline, when given concurrently with div (Wong et al, 1996a). Monitor amitriptyline levels in patients taking valproate concomitantly. Consideration sho lowering the dose of amitriptyline in the presence of valproate (Prod Info Depakote(R) ER, 2003).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical
6) Clinical Management: Monitor amitriptyline levels and nortripyline concentrations in patients taking valproa with amitriptyline. A lower dose of amitriptyline may be necessary if given concurrently with valproate.
7) Probable Mechanism: decreased amitriptyline plasma clearance
8) Literature Reports
a) In an open-label study of 15 healthy volunteers, the pharmacokinetic interactions between divalproex amitriptyline were studied. Subjects were given amitriptyline 50 mg alone and two hours after receiving n divalproex sodium 500 mg, which was given every 12 hours. Coadministration of amitriptyline with divalp resulted in a 17% increase in amitriptyline maximum concentration (Cmax) and a 31% increase in the an under the concentration-time curve (AUC). Time to maximum concentration (Tmax) for amitriptyline was coadministration with divalproex sodium. For nortriptyline, the metabolite of amitriptyline, AUC was incre Cmax was increased by 28%, and Tmax was unaffected. The authors postulated that divalproex sodium amitriptyline and nortriptyline disposition, possibly through inhibition of hepatic metabolism (Wong et al, 1
b) The addition of valpromide to a stable amitriptyline regimen may result in an increase of antidepressa concentrations. Twenty patients with major depressive illness (DSM - III criteria) were divided into two gr with amitriptyline alone and one treated with both amitriptyline and valpromide. All patients received oral mg once daily in the evening for 20 days. Only benzodiazepines (diazepam, lorazepam, bromazepam, cl dipotassique), 5-30 mg/day, were also administered. Ten patients also received 600 mg valpromide daily amitriptyline to avoid relapses and/or to decrease irritability and agitation. No statistically significant differ amitriptyline and nortriptyline plasma levels were determined on days 10 and 20, respectively in ten patie amitriptyline 125 mg daily. In the ten patients who received valpromide 600 mg, amitriptyline and nortript increased. The mean amitriptyline level increased from 70.5 +/- 35.9 nanograms/milliliter (ng/mL) to 105. (p less than 0.0003, paired Student's t test), and the mean nortriptyline level rose from 61.0 +/- 34.3 to 1(less than 0.01). No significant relationship was seen between the percentage increase of amitriptyline lev plasma level of valproic acid, the main valpromide metabolite. There was a significant linear relationship plasma levels of amitriptyline before and after valpromide (r equal to 0.94, p less than 0.001) and betwee plasma levels before and after valpromide (r equal to 0.87, p less than 0.001). Tricyclic antidepressant pl increase above the therapeutic window after addition of valpromide. Monitoring of plasma levels of tricyc is advisable to control this interaction (Vandel et al, 1988).

3.5.1.C Aspirin

1) Interaction Effect: increased free valproic acid concentrations
2) Summary: Salicylates have been shown to alter both the metabolism and protein binding of valproic acid. in increased free valproate free fractions (Prod Info Depakote(R) ER, 2003j) by 30% to 65% (Abbott et al, 198 1987).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: An occasional single dose of aspirin would not likely present a problem; however, w doses, monitoring of valproic acid concentrations might be considered. An alternative analgesic such as acet be considered if appropriate.
7) Probable Mechanism: altered binding and metabolism
8) Literature Reports
a) Six epileptic children who were taking valproic acid received antipyretic doses of aspirin. The steady-s of valproate rose from 12% to 43% in the presence of salicylate in five of these patients. Half-life of valpr total and free valproate concentrations, increased. Renal excretion of unchanged valproate decreased w Salicylates appear to displace valproate from serum protein binding sites and alter valproate metabolism Farrell et al, 1982).

3.5.1.D Betamipron

1) Interaction Effect: decreased valproic acid efficacy
2) Summary: Three case reports describe a decrease in valproic acid serum concentrations when panipener therapy was instituted, resulting in the recurrence of seizures in two patients. Although the exact mechanism is not known, panipenem/betamipron should be avoided in patients treated with valproic acid (Yamagata et a
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Patients receiving valproic acid anticonvulsant therapy should not be treated with panipenem/betamipron. An alternative antibiotic which does not affect valproic acid serum levels should be c
7) Probable Mechanism: unknown
8) Literature Reports
a) A 4-year-old female with spastic quadriplegia, epilepsy, and mental retardation was receiving valproic mg/kg/day and phenobarbital 5 mg/kg/day with serum levels of 55.1 mg/dL and 28.4 mg/dL, respectively admitted to the hospital for pneumonia, and her valproic acid dose was increased to 30 mg/kg/day while was decreased to 4.5 mg/kg/day. Panipenem/betamipron therapy was initiated at 60 mg/kg/day in three daily, and the serum valproic acid level decreased to 22.9 mg/mL by day 6. Although no seizures develo this decrease, panipenem/betamipron was discontinued, and the valproic acid serum concentration incre mg/dL (Yamagata et al, 1998).

b) A 3-year-old girl with quadriplegia, epilepsy, and mental retardation was receiving valproic acid 35 mg carbamazepine 11 mg/kg/day, and phenytoin 10 mg/kg/day for two months before a hospital admission f pneumonia. Valproic acid serum concentration was 88.7 mg/mL prior to the start of panipenem/betamipr and amikacin 5 mg/kg/day. Three days later, generalized tonic-clonic seizures began to occur once or tw valproic acid level had decreased to 30.9 mg/mL and further dropped to 26.8 mg/mL two days later. Des the valproic acid dose to 42 mg/kg/day, the serum concentration continued to decrease to 15.3 mg/mL o treatment with panipenem/betamipron. The valproic acid level started to increase within 24 hours of disc panipenem/betamipron. The phenytoin serum level was undetectable on day 3 of panipenem/betamipror carbamazepine level was not significantly altered (Yamagata et al, 1998).

c) Panipenem/betamipron 30 mg/kg/day resulted in intense, generalized seizures and frequent myoclon year-old male who had previously been stabilized on valproic acid 32 mg/kg/day, clonazepam 0.9 mg/kg phenytoin 5 mg/kg/day. Prior to panipenem/betamipron therapy, his valproic acid serum level ranged fro 108.9 mg/mL. However, by day 5 of panipenem/betamipron treatment, the valproic acid level was 26.7 m the valproic acid dose was increased to 34 mg/kg/day, serum levels were undetectable by day 25 of panipenem/betamipron therapy. After the antibiotic was discontinued, the serum valproic acid concentrat 55 mg/mL and the frequency of the seizures was decreased. Incidentally, in this patient, the phenytoin a levels were not significantly altered by the presence of panipenem/betamipron (Yamagata et al, 1998).

3.5.1.E Carbamazepine

1) Interaction Effect: carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vomiting, apnea, seizur decreased valproic acid effectiveness

2) Summary: The literature contains conflicting data regarding the effects of combined carbamazepine and v Carbamazepine may decrease valproic acid levels by 15% to 25% while increasing clearance by up to 30% (1979a; Rimmer & Richens, 1985b; Mahaly et al, 1979a; Jann et al, 1988a). Furthermore, the conversion of va ene-VPA (thought to be the most toxic metabolite with potential for hepatotoxicity and teratogenicity) is signifi with coadministration of carbamazepine (Kondo et al, 1990a). Valproic acid may increase, decrease, or caus carbamazepine concentrations (Mattson et al, 1982a; Levy et al, 1984a; Pisani et al, 1990a; Anderson et al, 1

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor patients for signs of carbamazepine toxicity such as nausea, vomiting, drow when valproic acid is added. Serum carbamazepine concentrations should also be measured, though clinicia aware of the increase in the concentration of the active metabolite, carbamazepine-epoxide, which is not rout but does contribute to the efficacy and toxicity of the drug. If carbamazepine is added to valproic acid therapy acid levels; increased valproic acid dosage may be required.

7) Probable Mechanism: increased valproic acid clearance; variable effects on carbamazepine metabolism

8) Literature Reports

a) Significant increases (59%) in valproic acid serum concentrations have been reported following the w carbamazepine in six epileptic patients. A new plateau for the valproic acid serum level was observed at weeks after withdrawal of the carbamazepine (Jann et al, 1988).

b) Several reports have indicated conflicting effects of valproic acid on carbamazepine serum levels (Ri 1985a; Flachs et al, 1979; Adams et al, 1978). In an in vitro study of protein binding, valproic acid compe carbamazepine plasma protein binding sites, resulting in significant increases in free carbamazepine (Ma Concurrent therapy of valproic acid and carbamazepine in seven patients was found to decrease levels o by 3% to 59% and protein binding decreased. The plasma concentration ratio of carbamazepine-10,11-e carbamazepine increased in all patients by 11% to 500% (Levy et al, 1984; Pisani et al, 1990) probably d epoxide hydroxylase by valproic acid (Robbins et al, 1990). In addition, carbamazepine may cause a red valproic acid half-life with increased clearance secondary to enzyme induction and increased hepatic me et al, 1979; Rimmer & Richens, 1985a; Mahaly et al, 1979). Infrequent reports have indicated symptoms nausea, or confusion when valproic acid was added to carbamazepine therapy (Lhermitte et al, 1978; Ha A single case of psychosis following the addition of carbamazepine to valproic acid has been reported in refractory epilepsy (McKee et al, 1989).

c) Select patients with suspected genetic deficiencies may tolerate poorly the effects of valproic acid on certain amino and fatty acids, which may impact anticonvulsant therapy based on carbamazepine-valpro these individuals (Anderson et al, 1994a).

d) The pharmacokinetics of valproic acid and its metabolites when coadministered with carbamazepine epileptic patients. The ratio of valproic acid concentration to dose was significantly lower in those patient acid with carbamazepine compared with those receiving only valproic acid. Additionally, the ratio of 4-en concentration to valproic acid concentration was significantly higher in those receiving combined carbam acid compared with those on valproic acid monotherapy. 4-ene-VPA, reported to be the most toxic of val metabolites, may manifest as hepatotoxicity and teratogenicity (Kondo et al, 1990).

e) If phenytoin or carbamazepine (or any prodrug) is used in pregnant women, there is a substantially in teratogenicity with many combinations of other anticonvulsants. The teratogenicity of these drugs is large related to the levels of the reactive epoxide metabolites (Buehler et al, 1990a; Van Dyke et al, 1991a; Fir The epoxide/parent drug ratio is generally increased when phenytoin or carbamazepine is combined with other drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide hyc valproic acid, progabide, and lamotrigine (Bianchetti et al, 1987a; Ramsay et al, 1990a; Spina et al, 1996 combinations increase the risk of major birth defects 3- to 4-fold over monotherapy and about 10-fold ov

rates.

3.5.1.F Cholestyramine

1) Interaction Effect: decreased serum valproic acid concentrations

2) Summary: A controlled study observed that the concurrent administration of valproic acid and cholestyram significantly reduced valproic acid area under the concentration-time curve (AUC) and maximum concentratic However, administration of valproic acid three hours before taking cholestyramine resulted in no significant pl changes (Malloy et al, 1996a).

3) Severity: moderate

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Clinicians should be aware that valproic acid taken concurrently with cholestyramin serum valproic acid concentrations. If these drugs are to be given together, administer cholestyramine at leas valproic acid, and monitor patients for valproic acid therapeutic efficacy.

7) Probable Mechanism: decreased absorption of valproic acid

8) Literature Reports

a) In an open-label, three-way crossover study, the effects of cholestyramine on the plasma concentrati were investigated in six healthy volunteers. Subjects participated in three treatment phases, with a minim washout period between phases. During phase 1, the subjects received a single dose of valproic acid 25 phase 2, subjects received cholestyramine 4 g twice daily for one day, followed by valproic acid 250 mg dose of cholestyramine. Phase 3 was identical to phase 2 except that the valproic acid 250 mg was take before the morning dose of cholestyramine. When valproic acid was given concurrently with cholestyram acid area under the concentration-time curve (AUC) decreased by 21% and the valproic acid maximum c (Cmax) decreased by 15% compared to valproic acid alone. When valproic acid was given three hours b cholestyramine, no significant changes in AUC or Cmax were observed. Based on this data, decreases i concentrations can be partially avoided by taking the cholestyramine three hours after valproic acid (Mall

3.5.1.G Clarithromycin

1) Interaction Effect: increased serum levels of valproate

2) Summary: There have been reports of interactions of clarithromycin with drugs not thought to be metaboli P450 3A4, such as valproate (Prod Info Biaxin(R), 2002).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Monitor plasma concentrations of valproate closely in patients receiving concomitar therapy.

7) Probable Mechanism: unknown

3.5.1.H Clomipramine

1) Interaction Effect: an increased risk of clomipramine toxicity (agitation, confusion, hallucinations, urinary re tachycardia, seizures, coma)

2) Summary: Comedication with clomipramine and valproic acid may increase serum levels of clomipramine increased side effects. Clomipramine toxicity developed in a patient twelve days after valproic acid therapy w Metabolism of clomipramine is mediated through N-demethylation, hydroxylation, and glucuronidation, and va appears to inhibit the enzymes responsible for this mode of metabolism (Fehr et al, 2000a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor serum clomipramine levels to avoid overdosing as a result of elevated conc clomipramine when comedicating with valproic acid. The clomipramine dose may need to be reduced when v added to therapy.

7) Probable Mechanism: inhibition of cytochrome P450 2C-mediated metabolism of clomipramine

8) Literature Reports

a) A case report describes a 46-year-old female with personality disorder whose serum clomipramine cc became elevated after she began concomitant therapy with valproic acid. Antidepressant therapy with cl lorazepam was initiated while being hospitalized for treatment of her psychiatric disorder. These two age reduce the frequency of panic attacks and to improve symptoms of suicidal and self-destructive behavior clomipramine 150 mg/day resulted in serum clomipramine levels in the normal range. Lorazepam was in 2 mg/day After two weeks of therapy valproate was initiated at 1000 mg/day because emotional instabilit destructive behavior remained unimproved. After five days of therapy the serum levels of clomipramine a desmethylclomipramine increased to 447 ng/mL and 85 ng/mL, respectively. Valproate serum concentra mcg/mL. The valproate dose was subsequently adjusted to 1400 mg/day. Seven days after the increase clomipramine and desmethylclomipramine serum concentrations were 479 ng/mL and 269 ng/mL respec the valproate serum level was 55 mcg/mL. The patient noted a feeling of numbness and exaggerated sle After the clomipramine dose was reduced to 75 mg/day, these symptoms resolved. The author conclude in serum clomipramine concentrations was primarily due to comedication with valproate (Fehr et al, 200

3.5.1.I Dehydroepiandrosterone

1) Interaction Effect: reduced effectiveness of valproic acid
2) Summary: Dehydroepiandrosterone (DHEA) in a single case report was noted to cause mania in a patient personal or family history of bipolar disorder (Markowitz et al, 1999a). Elevated DHEA levels have been found mental disorders; DHEA suppression has lead to improvement in psychotic symptoms (Howard, 1992). Patie medication for bipolar disorder or patients with a personal and/or family history of bipolar disorder should not further data is available to characterize this drug-herb interaction.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If valproic acid is being used for manic symptoms, concomitant use of dehydroepian (DHEA) may cause a return of symptoms. Patients with a personal or family history of bipolar disorder should avoid DHEA use.
7) Probable Mechanism: proserotonergic activity of dehydroepiandrosterone may predispose patients to mar dehydroepiandrosterone is a precursor to androgenic steroids, which in high doses may precipitate mania
8) Literature Reports
a) A 68-year-old male with no documented psychiatric history initiated dehydroepiandrosterone (DHEA) (mg) daily and increased the dose to 200 to 300 mg daily for 6 months. Within 3 months, family members of odd behavior with prominent symptoms of agitation, delusional thinking, decreased sleep and appetite sprees. The patient was not taking any prescribed medication but did ingest alcohol in amounts up to 1 c Another 3 months elapsed, leading to involuntary inpatient admission secondary to rapid, loud, pressured grandiose thoughts. At admission, the patient reported that he had decreased alcohol intake to 2 beers c concerns about his behavior changes. There was no family history of bipolar disorder. Urinary drug scree Over the seven-day hospital stay, with the institution of valproic acid 500 mg twice daily, the patient's beh patterns improved, and the patient believed DHEA led to his symptoms. There were no ethanol withdraw patient was discharged with follow-up care from his primary care physician with a diagnosis of substance disorder (Markowitz et al, 1999).

3.5.1.J Doripenem

1) Interaction Effect: reduced valproic acid serum concentrations
2) Summary: Frequently monitor valproic acid concentrations after starting doripenem as coadministration re valproic acid concentrations and may result in loss of seizure control. If valproic acid concentrations cannot b within the therapeutic range or a seizure occurs, alternative antibiotic or anticonvulsant therapy should be con DORIBAX(R) IV injection, 2009).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Frequently monitor valproic acid concentrations after starting doripenem as coadmi result in reduced valproic acid concentrations and possibly a loss of seizure control. If valproic acid concentra maintained within the therapeutic range or a seizure occurs, alternative antibiotic or anticonvulsant therapy sh considered (Prod Info DORIBAX(R) IV injection, 2009).
7) Probable Mechanism: unknown
8) Literature Reports
a) Valproic acid AUC was reduced by 63% in healthy volunteers following coadministration of doripenem DORIBAX(R) IV injection, 2009).

3.5.1.K Ertapenem

1) Interaction Effect: decreased valproic acid plasma concentrations and loss of anticonvulsant effect
2) Summary: Clinically significant reductions in serum valproic acid levels have been reported in patients rec carbapenem antibiotics concomitantly. Two case reports describe significant decreases in serum valproic aci with coadministration of ertapenem, leading to seizures in one (Lunde et al, 2007; CabanesMariscal et al, 20 exact mechanism is not understood, in vitro and animal data suggest that carbapenems may inhibit valproic a hydrolysis. If ertapenem is initiated in patients receiving valproic acid, frequent monitoring of valproic acid lev recommended. Use alternative antibacterial or anticonvulsant therapy if valproic acid blood levels drop below or if a seizure occurs (Prod Info INVANZ(R) IV, IM injection, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: If concomitant administration of valproic acid and ertapenem is required, monitor va concentration frequently. Consider alternative antibiotic or anticonvulsant therapy if serum valproic acid levels therapeutic range or if a seizure occurs (Prod Info INVANZ(R) IV, IM injection, 2008).
7) Probable Mechanism: unknown
8) Literature Reports
a) A 41-year-old man maintained on divalproex sodium for seizure prophylaxis experienced recurrent to on day 7 of concomitant ertapenem (1000 mg) every 24 hours) therapy. His medical history was significa hypertension controlled with metoprolol, seizure disorder secondary to traumatic brain injury, and chronic osteomyelitis. Approximately 3 months prior to starting ertapenem, the patient's serum valproic acid conc therapeutic at 130 mcg/mL while taking divalproex sodium 2000 mg/day. He was admitted to the emerge 3 seizure episodes, the last of which was a witnessed tonic-clonic seizure lasting longer than one minute

valproic acid concentration was 70 mcg/mL. The dose of divalproex sodium was increased to 2750 mg/d was discharged. He returned 4 days later with recurrent seizures and a serum valproic acid concentratio Intravenous valproic acid 1000 mg was administered along with one oral dose of divalproex sodium 100 was discontinued, and intravenous ampicillin-sulbactam 3 grams every 6 hours was begun. The followin serum valproic acid concentration increased to 55 mcg/mL. Oral divalproex sodium was again increased and 2 days later his level was 88.1 mcg/mL. Five days after ertapenem was discontinued his serum valp concentration reached 146 mcg/mL, necessitating a decrease in divalproex sodium dose. He subsequen seizure-free (Lunde et al, 2007; Personal Communication, 04/28/2008).

b) An 80-year-old woman, chronically treated with valproic acid solution 1100 mg/day for complex partia secondary to severe cerebrovascular disease, experienced significantly reduced serum valproic acid cor beginning 4 days after the initiation of ertapenem 1000 mg every 24 hours. Approximately, 1.5 months p exposure, her total serum valproic acid concentration was 72 mcg/mL. Admitted to the hospital for aspira the patient was treated with ertapenem. Four days later serum valproic acid concentration was reported mcg/mL, and her valproic acid dose was increased to 1600 mg/day. Two days later serum valproic acid mcg/mL and the drug dose increased to 2000 mg/day. A level of 1.04 mcg/mL was measured 4 days afte increase. Ertapenem was discontinued. With intravenous administration of valproic acid (800 mg loading 400 mg every 6 hours), the patient's serum concentration gradually returned to therapeutic range over th She was subsequently maintained on oral valproic acid 1400 mg/day (CabanesMariscal et al, 2006).

3.5.1.L Erythromycin

1) Interaction Effect: valproic acid toxicity (CNS depression, seizures)

2) Summary: One case report described the concurrent use of erythromycin and valproic acid resulting in inc acid concentration and symptoms of valproate toxicity. Discontinuation of erythromycin led to lowered valproa resolution of the symptoms (Redington et al, 1992a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: If erythromycin and valproic acid are used concurrently, monitor patient for signs of (CNS depression, seizures). Monitor valproic acid serum concentrations during and after erythromycin therap

7) Probable Mechanism: decreased valproic acid metabolism

8) Literature Reports

a) One study describes a 38-year-old female outpatient receiving valproate 3500 mg daily, clorazepate mg four times daily, and lithium carbonate 300 mg twice daily; her valproate level was 88.8 mg/L (therap 100 mg/L). Erythromycin 250 mg four times daily was prescribed for a respiratory infection; within a weel difficulty in walking, confusion, lethargy, slurred speech, and poor concentration. Her valproate level was admission; at that time both erythromycin and valproate were discontinued. Fifteen hours later the valpro mg/L, and valproate was restarted at the original dosage. All signs of adverse reaction resolved (Redingt

3.5.1.M Ethosuximide

1) Interaction Effect: an increased risk of ethosuximide toxicity

2) Summary: Concomitant valproic acid and ethosuximide therapy does not appear to influence the pharmac parameters of ethosuximide. This was demonstrated in an evaluation in which valproic acid was added to a c ethosuximide regimen. There was no apparent change in total or nonrenal clearance of ethosuximide (Bauer However, the above combination did result in elevated ethosuximide levels (Mattson & Cramer, 1980). Admir ethosuximide in patients receiving valproic acid therapy was reported to result in significant increases in etho (from 44 to 54 hours) and a significant decrease in total body clearance (11.2 to 9.5 mL/minute) (Pisani et al, suggest that valproic acid is capable of inhibiting the metabolism of ethosuximide.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor patients receiving valproate and ethosuximide concomitantly for alterations concentrations of both drugs.

7) Probable Mechanism: inhibition of ethosuximide metabolism

8) Literature Reports

a) Valproate inhibits the metabolism of ethosuximide. Administration of a single ethosuximide 500 mg d (800 to 1600 mg/day) to six healthy volunteers resulted in a 25% increase in elimination half-life of ethos 15% decrease in valproate total clearance compared to ethosuximide alone. Patients on concomitant val ethosuximide should be monitored for alterations in serum concentrations of both drugs (Prod Info Depal 2003k).

3.5.1.N Evening Primrose

1) Interaction Effect: reduced anticonvulsant effectiveness

2) Summary: Theoretically, evening primrose oil may reduce the effectiveness of anticonvulsants by lowering threshold. Evening primrose oil is contraindicated in patients with epilepsy (Barber, 1998; Newall et al, 1996).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Avoid concomitant use of evening primrose oil with anticonvulsants.

7) Probable Mechanism: evening primrose oil may reduce the seizure threshold

3.5.1.O Felbamate

1) Interaction Effect: increased valproic acid concentrations

2) Summary: Coadministration of felbamate (1200 mg to 2400 mg daily) and valproic acid resulted in an incr valproic acid AUC (28% and 54%), peak concentrations (34% and 55%), and average steady-state concentra 54%) (Wagner et al, 1992; Prod Info Felbatol(R), 2000). A decrease in valproate dosage may be necessary v therapy is initiated (Prod Info Depakote(R) ER, 2003e).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor valproic acid levels when initiating or discontinuing felbamate. Tremor, irrita and restlessness are more common when valproic acid serum levels exceed 100 mcg/mL. A decrease in the acid may be necessary.

7) Probable Mechanism: decreased valproic acid clearance

3.5.1.P Fosphenytoin

1) Interaction Effect: altered valproate levels or altered phenytoin levels

2) Summary: Fosphenytoin is a prodrug of phenytoin and the same interactions that occur with phenytoin are occur with fosphenytoin (Prod Info Cerebyx(R), 1999). Valproic acid may initially cause a decrease in total ph displacement of phenytoin from protein binding sites (Levy & Koch, 1982; Bruni et al, 1980; Monks et al, 1978 decrease in the bound fraction of phenytoin; the phenytoin which is displaced by valproic acid re-equilibrates capacity of the tissue compartment such that the unbound plasma concentration remains unchanged (Winter al, 1978). The degree of displacement appears to be valproic acid dose related (Monks & Richens, 1980). Va also inhibit phenytoin metabolism (Levy & Koch, 1982; Bruni et al, 1980; Patel et al, 1980; Winter, 1988; de W

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Due to the complex situation involving displacement of protein-bound phenytoin and phenytoin metabolism, as well as the potential for decreased valproic acid concentrations, patients should be phenytoin toxicity and therapeutic efficacy. Free plasma phenytoin levels should be measured if possible to p accurate assessment of phenytoin activity early in therapy. At steady-state free phenytoin concentrations and concentrations should be normalized.

7) Probable Mechanism: altered clearance and protein binding of both drugs

8) Literature Reports

a) If phenytoin or carbamazepine (or any prodrugs) is used in pregnant women, there is a substantially i teratogenicity with many combinations of other anticonvulsants. The teratogenicity of these drugs is large related to the levels of the reactive epoxide metabolites (Buehler et al, 1990; Van Dyke et al, 1991; Finne epoxide/parent drug ratio is generally increased when phenytoin or carbamazepine is combined with eac drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide hydrolase acid, progabide, and lamotrigine (Bianchetti et al, 1987; Ramsay et al, 1990; Spina et al, 1996). Such co increase the risk of major birth defects 3- to 4-fold over monotherapy and about 10-fold over background

3.5.1.Q Ginkgo

1) Interaction Effect: decreased anticonvulsant effectiveness

2) Summary: In a case report, 2 patients with epilepsy previously well controlled by valproate sodium develo of seizures after ingesting ginkgo extract. Seizure control was regained after ginkgo was withdrawn (Granger developed seizures after exposure to 4'-O-methylpyridoxine arising from ingestion of ginkgo seeds (Yagi et a compound 4'-O-methylpyridoxine, a neurotoxin, is found in ginkgo seeds (used as food in Japan) as well as i ginkgo component from which commercially available extracts are derived (Arenz et al, 1996a). The majority products should not contain sufficient amounts of 4'-O-methylpyridoxine to cause seizures. However, ginkgo commonly assayed to assure that 4'-O-methylpyridixone is not contained in the commercial product. Of conc instances where, depending on the harvest season and the potential introduction of contamination, 4'-O-meth be present in sufficient amounts to be problematic in vulnerable populations (eg, infants or those with known

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Avoid concomitant use of ginkgo and anticonvulsants in patients with epilepsy. If se the first time or recur in patients previously controlled by anticonvulsant medication, inquire about the use of g extract. If possible, an assay should be conducted on the specific product to ascertain if 4'-O-methylpyridoxin

7) Probable Mechanism: neurotoxin 4'-O-methylpyridoxine (found in leaves and seeds of ginkgo biloba) may

8) Literature Reports

a) The serum of a 21-month-old patient with gin-nan food poisoning was assayed for 4'-O-methylpyridox serum concentration was 0.9 micrograms/milliliter (mcg/mL) at 8.5 hours after ingesting ginkgo seeds, de mcg/mL at 15.5 hours. The authors concluded that the 4'-O-methylpyridoxine content was responsible fo convulsions and loss of consciousness observed. They further observed that infants are particularly vuln 1993).

b) Four to six milligrams of the neurotoxin 4'-O-methylpyridoxine have been isolated from 2 kilograms of

leaves which is the source of commercially-available products. Highest amounts were found in seeds (85 (mcg)/seed) and leaves (5 mcg/leaf) derived from the tree at the end of July and beginning of August. Th seed can contain 105.15 mcg/gram dry weight, but this is reduced to 0.75-1.32 mcg/gram dry weight whe unprocessed seed coats contain from 5.44-7.15 mcg/gram dry weight. The neurotoxin in ginkgo leaf was medications and it was even detectable in homeopathic preparations. Specifically, 8.13 mcg/mL of 4'-O-m was found in Tebonin Forte(R), 9.77 mcg/mL in Rokan(R), 3.80 mcg/mL in Kaveri Forte(R), and 7.18 mc (R). Based on recommended daily intake, this translates into a maximum daily intake of 4'-O-methylpyrid mcg, 58.62 mcg, 11.40 mcg, and 43.08 mcg for Tebonin Forte(R), Rokan(R), Kaveri Forte(R), and Gingi respectively. Among the homeopathic products, Ginkgo biloba Urtinktur Hanosan(R) and Ginkgo biloba U contained 0.301 mcg/mL and 0.589 mcg/mL of 4'-O-methylpyridoxine, respectively. However, the author amount contained in medicinal extracts of ginkgo leaves may be too low to be of clinical significance. Co the variance in 4'-O-methylpyridoxine content depending on the season during which the ginkgo was har al, 1996).

c) Seizures recurred in 2 patients, both with epilepsy that was well controlled prior to ingesting ginkgo bi patients (an 84-year-old woman and a 78-year-old man) had been free of seizures for at least 18 months therapy with Gb 120 milligrams daily to treat cognitive decline. Both patients developed seizures within 2 beginning Gb therapy, and both remained seizure-free (without changing anticonvulsant therapy) after di (Granger, 2001).

3.5.1.R Imipenem

1) Interaction Effect: decreased valproic acid plasma concentrations and loss of anticonvulsant effect

2) Summary: Clinically significant reductions in serum valproic acid levels have been reported in patients rec carbapenem antibiotics concomitantly. If imipenem is initiated in patients receiving valproic acid, frequent mo acid levels is recommended. Use alternative antibacterial or anticonvulsant therapy if valproic acid blood leve therapeutic range or if a seizure occurs (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: If concomitant administration of valproic acid and imipenem is required, monitor val concentration frequently. Consider alternative antibiotic or anticonvulsant therapy if serum valproic acid levels therapeutic range or if a seizure occurs (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

7) Probable Mechanism: unknown

3.5.1.S Isoniazid

1) Interaction Effect: valproic acid or isoniazid toxicity

2) Summary: In a case report, the concurrent use of valproic acid and isoniazid resulted in increased SGPT l and a higher incidence of tonic-clonic seizures. Isoniazid may inhibit the metabolism of valproic acid, or valpr increase the risk of isoniazid toxicity (Dockweiler, 1987).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Consider monitoring liver function tests periodically with therapy, as well as continu therapeutic efficacy of valproic acid. Monitor serum valproic acid trough concentrations as indicated. If toxicity alternative anticonvulsant may be appropriate.

7) Probable Mechanism: altered metabolism

3.5.1.T Lamotrigine

1) Interaction Effect: increased elimination half-life of lamotrigine leading to lamotrigine toxicity (fatigue, drow an increased risk of life-threatening rashes

2) Summary: Valproic acid interferes with the metabolic clearance of lamotrigine. The normal elimination half is approximately 24 hours; in patients receiving concomitant valproic acid therapy, the half-life increases to ap 60 hours. The mechanism of this interaction is thought to be competition of the two drugs for hepatic metabol 1986; Peck, 1991; Eriksson et al, 1996; Sallustio & Morris, 1997). Fever, rash, multiorgan dysfunction, dissem intravascular coagulation, and fatal toxic necrolysis have been reported with this combination in adults and pe (Chattergoon et al, 1997a; Page II et al, 1998a). Given the increased risk of rash in pediatric patients, careful lamotrigine serum concentrations may be advisable for children younger than 16 years of age, for whom the i lamotrigine is restricted to those who have been diagnosed with either partial seizures or Lennox-Gastaut syn of lamotrigine should be reduced when coadministered with valproate (Prod Info Depakote(R) ER, 2003c; Pro oral tablets, 2006).

3) Severity: major

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: Dosage reductions of lamotrigine are necessary with concurrent valproic acid thera in conjunction with other enzyme-inducing medications. The manufacturer recommends a lamotrigine dose o other day for the first two weeks, increasing to 25 mg once daily for the next two weeks, advancing to a maint 100 mg to 400 mg daily in increments of 25 mg to 50 mg daily every one to two weeks. If valproic acid is the antiepileptic medication, the usual maintenance dose of lamotrigine is 100 to 200 mg daily. Discontinue use o first sign of a rash unless the rash is clearly not drug related (Prod Info lamotrigine oral tablets, 2006).

7) Probable Mechanism: decreased lamotrigine metabolism
8) Literature Reports
a) A 23-year-old woman presented to the emergency room with generalized rash, redness and swelling lips, fever, weakness, blisters, and a sore throat 3 weeks after lamotrigine was added to her anti-epilepsy initial regimen consisted of carbamazepine 400 mg twice a day. Valproic acid 500 mg twice daily was ad lamotrigine 50 mg twice daily was added 3 weeks prior to current presentation. The patient had an eleva sedimentation rate and C-reactive protein. However, serum carbamazepine and valproic acid levels were range. Serum lamotrigine concentrations were not measured. She was diagnosed with lamotrigine-induc Johnson syndrome (SJS), with a Naranjo Adverse Drug Reactions Probability Scale score of 6 (probably Lamotrigine was discontinued and treatment was initiated for the SJS. She was discharged on day 18 or carbamazepine 400 mg twice daily and oral valproic acid 1500 mg/day. At the one month follow-up, she significant improvement in oromucosal and skin lesions, with areas of hyperpigmentation. The patient's i developing SJS may have potentially been a result of either the combination of lamotrigine and valproic a decreased metabolism of lamotrigine, or due to initiation of lamotrigine at a dose higher than the manufa recommended starting dose of 25 mg per day (Kocak et al, 2007).
b) Fever, rash, multiorgan dysfunction, and disseminated intravascular coagulation were reported in two with valproic acid and lamotrigine. Both children were receiving valproic acid for treatment of seizures. La added because of poor control. Symptoms developed within nine days of starting lamotrigine, but did not lamotrigine was discontinued (Chattergoon et al, 1997).
c) A 54-year-old male presented to the hospital with a five-day history of facial swelling, intermittent feve and pruritic rash on the chest, upper extremities, neck, and back. He had been taking allopurinol 100 mg 50 mg daily for four years prior to admission. Because of a glioblastoma multiforme brain tumor, valproic lamotrigine therapy was begun and the doses were titrated to valproic acid 500 mg three times daily and twice daily approximately four weeks prior to his hospital admission. By hospital day 7, the patient was e extensive sloughing of his skin along his back, face, and trunk, accounting for more than 60% of his total area. He continued to deteriorate and was withdrawn from life support on hospital day 12. His death was epidermal necrolysis probably due to lamotrigine therapy and possibly enhanced by valproic acid (Page
d) A study including 28 patients with intractable epilepsy was conducted to determine whether the dose serum concentrations (Css) of valproic acid were inversely related to lamotrigine clearance. Valproic acid 500 mg/day for 3 days and increased to 750 mg/day on day 4, depending on tolerance and response. Th dose was increased 125 to 250 mg every 3 weeks, until patients became seizure-free or developed adve initiation of valproic acid, the dose of lamotrigine was decreased by 50%, so as to maintain lamotrigine C levels to those reached during monotherapy. A 50% reduction in lamotrigine clearance was reported in th dose of lamotrigine needs to be decreased by 50% at the start of valproic acid therapy to maintain comp Css. However, additional increases in valproic acid dose would not require further reductions of lamotrigi stable lamotrigine Css. Seizure-free periods were significantly longer during treatment with both lamotrig acid than during lamotrigine monotherapy, an indication that therapeutic synergism exists between lamot acid (Kanner & Frey, 2000).
e) A study involving eight patients with epilepsy found a significant increase in lamotrigine area under th time curve (AUC) and longer half-life with concomitant valproic acid administration. Dosages of valproic a mg/day resulted in mean increases in lamotrigine AUC of more than 2.5-fold. Even low doses of valproic resulted in significant increases in lamotrigine AUC (mean 84%). Significant increases in plasma lamotrig by inhibiting lamotrigine metabolism and increased half-life has been achieved with the use of low to mod valproic acid (Morris et al, 2000).
f) Lamotrigine decreased valproic acid steady-state concentrations by 25% in 18 healthy volunteers ove and then stabilized. Adding lamotrigine to the existing therapy did not cause a change in plasma valproat in adult or pediatric patients in controlled clinical trials. The addition of valproate increased lamotrigine st concentrations in normal volunteers by more than 2-fold (Prod Info Lamictal(R), 2004).
g) In a black box warning from the manufacturer, the incidence of severe rash may be higher in patients administered valproic acid and lamotrigine (Prod Info Lamictal(R), 2003).

3.5.1.U L-Methylfolate

1) Interaction Effect: decreased valproic acid serum levels
2) Summary: Concomitant administration of first-generation anticonvulsants, including valproic acid, with high may lead to decreased serum levels of the anticonvulsant, thereby decreasing valproic acid efficacy and incre seizures. Although there have been no such reports with the use of l-methylfolate and valproic acid, caution is agents are used concomitantly (Prod Info DEPLIN(R) oral tablets, 2006; Prod Info Zervalx(R) oral tablets, 20 patients for loss of valproic acid efficacy.
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if l-methylfolate is prescribed to patients receiving valproic acid a folate may theoretically result in decreased serum valproic acid levels, thereby reducing valproic acid efficacy the frequency of seizures (Prod Info DEPLIN(R) oral tablets, 2006; Prod Info Zervalx(R) oral tablets, 2008). If used concomitantly, monitor patients for loss of valproic acid efficacy.
7) Probable Mechanism: unknown

3.5.1.V Lopinavir

1) Interaction Effect: decreased valproic acid serum concentrations
2) Summary: Coadministering lopinavir/ritonavir with valproic acid may decrease the plasma concentration o
case report suggests the mechanism may be due to ritonavir induction of VPA metabolism via glucuronidatio
2006). Monitoring of valproic acid plasma concentrations is recommended (Prod Info NORVIR(R), 2005).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor therapeutic concentrations of valproic acid when coadministering with lopin
valproic acid dose increase may be needed.
7) Probable Mechanism: ritonavir-induced metabolism of valproic acid
8) Literature Reports
a) A case report describes a 30-year-old man with bipolar disorder and HIV who became increasingly m
addition of lamivudine 150 mg/zidovudine 300 mg twice a day and lopinavir 133 mg/ritonavir 33 mg (3 ca
day) to his drug regimen. The patient had been maintained on valproic acid (VPA) 250 mg 3 times a day
concentration of 495 mcmol/L, when the antiretrovirals were prescribed during a hospital admission for m
Paroxetine 10 mg/day was simultaneously given for the depressive episode. The patient became hypom
and the paroxetine was switched to sertraline 50 mg/day. Twenty-one days after the initiation of antiretro
became increasingly manic and was again admitted. He had continued all medications except sertraline
including the same VPA dose. Serum VPA concentration 6 to 10 hours post-dose was subtherapeutic at
decrease of 48% from the previous documented concentration. Olanzapine and an increase in VPA to 1
effectively managed the manic episode. The patient adhered to this new drug regimen, including the pre
antiretrovirals, and 10 days later a 14-hour post-dose VPA level measured in the therapeutic range at 39
the patient was not taking concomitant medications known to affect VPA metabolism, it was hypothesize
decrease in VPA concentrations was due to ritonavir induction of VPA metabolism (via glucuronidation)
2006).

3.5.1.W Lorazepam

1) Interaction Effect: increased lorazepam concentrations
2) Summary: In a small study of healthy subjects (n=8), valproic acid was found to decrease lorazepam clea
compared to controls (Anderson et al, 1994). When lorazepam and valproic acid are coadministered, the dos
should be reduced by 50% (Prod Info Ativan(R), 1997a).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: When lorazepam and valproic acid are coadministered, the dose of lorazepam shou
50%. The patient should then still be monitored for evidence of lorazepam toxicity, including excessive sedati
depression.
7) Probable Mechanism: decreased lorazepam metabolism
8) Literature Reports
a) In a study involving six healthy male subjects, the coadministration of intravenous lorazepam 2 mg wi
acid 250 twice daily for three days resulted in a decrease of 40% in the total clearance of lorazepam. The
glucuronide formation rate was also decreased by 55%. Plasma concentrations of lorazepam were appro
times higher for at least 12 hours following concurrent administration. The manufacturer of lorazepam re
reducing the dose of lorazepam by 50% during valproic acid coadministration (Prod Info Ativan(R), 1997

3.5.1.X Mefloquine

1) Interaction Effect: loss of seizure control
2) Summary: The concomitant use of mefloquine in patients taking an anticonvulsant may cause reduced se
lowering plasma levels of the anticonvulsant (Prod Info Lariam(R), 2003). One case report describes a male v
an increase in the frequency of his seizures after he was prescribed mefloquine for malaria prophylaxis. His a
medication included carbamazepine and sodium valproate. Pharmacokinetic studies determined that the half
valproate was significantly reduced by the administration of mefloquine, while carbamazepine was not affecte
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: If mefloquine and valproic acid must be administered concurrently, monitor the leve
Adjustments of the valproic acid dose may be required. Also monitor the patient for seizure control.
7) Probable Mechanism: unknown
8) Literature Reports
a) A 38-year old male epileptic controlled by carbamazepine 1200 mg daily and sodium valproate 1 grar
mefloquine 250 mg weekly. The patient began to experience multiple partial seizures. The pharmacokine
antiepileptic drugs were studied to determine the cause of this patient's seizures. A reduction in the half-
valproate (from 8-20 hours to 5.6 hours) was observed, although that of carbamazepine was unchanged
mefloquine accelerated the metabolism of sodium valproate, since they both share the same hepatic me
(Jallon, 1988).

3.5.1.Y Meropenem

1) Interaction Effect: decreased valproic acid plasma concentrations and loss of anticonvulsant effect

2) Summary: As described in a case report, the coadministration of meropenem with valproic acid produced in valproic acid (VPA) plasma concentrations, causing recurrent seizure activity (Coves-Orts et al, 2005) . Sin VPA serum concentrations were reported in several other patients receiving concomitant treatment with VPA No patient developed seizures (Nacarkucuk et al, 2004; De Turck et al, 1998). A single retrospective study of confirms that the concurrent use of valproic acid with meropenem results in subtherapeutic VPA plasma conc corresponding increases in seizure activity and electroencephalogram changes (Spriet et al, 2007).
3) Severity: major
4) Onset: rapid
5) Substantiation: established
6) Clinical Management: Patients receiving valproic acid anticonvulsant therapy should avoid being treated v Consider an alternative antibiotic which does not affect valproic acid serum levels. If concomitant administrati and meropenem is unavoidable, monitor valproic acid serum concentration closely (Spriet et al, 2007).
7) Probable Mechanism: unknown
8) Literature Reports

a) A retrospective study of 39 patients with concurrent treatment with valproic acid (VPA) and meropene an average decrease of valproic acid levels of 66% within 24 hours. In patients receiving meropenem aft the mean plasma concentrations of VPA decreased from 64.3 milligrams/liter (mg/L) to 22.5 mg/L. Thera plasma concentrations range from 50 to 100 (mg/L). Patients receiving VPA after meropenem did not ac plasma levels of VPA, with mean levels of 11.8 mg/L. Despite additional loading doses and increased ma only one patient achieved therapeutic plasma levels after the maintenance dose was increased to 12 gra adverse patient outcomes or incomplete data, 20 patients were evaluated for causality and clinical releva interaction. The interaction was rated probable in 16 and possible in 4 of the 20 patients. Eleven of these experienced an increase in seizures, electroencephalogram changes, or both. VPA concentrations achie range approximately 8 days after concurrent use of the two medications ceased, and seizure activity was et al, 2007).

b) The coadministration of meropenem with valproic acid produced a pronounced decline in valproic aci concentrations. In a case report, a 21-year-old woman was administered valproic acid (VPA) 1920 milligı continuous intravenous (I.V.) infusion over 24 hours in an attempt to control recurrent tonic-clonic seizure concentration of 52.5 micrograms/milliliter (mcg/mL) was attained on treatment day 6, with therapeutic se concentrations maintained on days 8, 10, and 12. On day 13, the patient developed a fever for which intı meropenem 1 gram 3 times daily was started. Two days later, numerous myoclonic events were observe arms and face; VPA serum concentration was measured at 42 mcg/mL. VPA dose was increased to 288 I.V. infusion over 24 hours), yet tonic-clonic seizures recurred on day 17 in conjunction with a further dec concentration to 7 mcg/mL. VPA dose was increased the following day to 3600 mg; however, VPA serun did not exceed 10 mcg/mL. Intravenous ceftazidime and ciprofloxacin were substituted for meropenem o which serum concentration of VPA increased over the next several days, eventually attaining therapeutic cessation of seizure activity (Coves-Orts et al, 2005).

c) As described in a series of case reports, serum concentration levels of valproic acid were substantiall the concurrent administration of meropenem. In the first case, a 14-year-old boy with epilepsy had been with valproic acid (VPA) 50 milligrams/kilogram (mg/kg)/day, prior to receiving meropenem and tobramyc unspecified) for treatment of Acinetobacter pneumonia. VPA serum concentrations subsequently decline therapeutic levels (nadir of 15 micrograms/milliliter (mcg/mL)) despite an increase in VPA dose to 200 m after completing meropenem therapy, VPA serum concentrations returned to therapeutic levels (114 mcg patient was a 7-month-old girl with West syndrome, receiving anticonvulsant treatment with VPA 75 mg/k VPA plasma concentrations were within therapeutic range (69 to 90 mcg/mL) prior to receiving concomit meropenem and vancomycin to treat an Acinetobacter nosocomial pneumonia. VPA was increased to 13 plasma VPA declined to as low as 18 mcg/mL. The patient continued to receive meropenem for 14 days, activity, and sustained an increase in plasma VPA concentrations to 81 mcg/mL on the third day after co meropenem therapy. The third patient, a 14-month-old girl, was receiving VPA 75 mg/kg/day for anticonv West syndrome symptoms. Baseline VPA serum concentrations were 85 mcg/mL. The patient received ı therapy for treatment of an Acinetobacter urinary tract infection; within 3 days of beginning meropenem t plasma concentrations decreased to a nadir of 10 mcg/mL, yet returned to within therapeutic range 3 day the course of meropenem treatment (Nacarkucuk et al, 2004).

d) In 2 patients, substantial reductions occurred in valproic acid (VPA) plasma concentrations when mer added to previously stable dose regimens of VPA. The first patient, a 65-year-old woman, received an in intravenous VPA 1200 milligrams (mg) over 24 hours following shunt placement for management of a su hemorrhage. Therapeutic VPA concentration levels were maintained with a dose range of 1200 mg to 16 approximately 23 days, intravenous meropenem 1 gram 3 times daily was administered with amikacin to negative bacillus infection. On the day following initiation of meropenem, the VPA serum concentration d approximately 55 mg/mL to 25 mg/L (per graphic analysis), despite supplementation of VPA dose. In the report, a 57-year-old woman was given a prophylactic infusion of intravenous VPA (dose unspecified) alc 100 mg 3 times daily administered on postop days 9-15. Due to development of a lung infection with Klel Pseudomonas organisms, intravenous meropenem and amikacin were administered at an indeterminate during the postoperative course, accompanied by an unspecified supplementation of VPA dose. Despite augmentation, serum concentration of VPA declined from 44 mg/L to 5 mg/L within 24 hours of beginning this second patient, the plasma elimination half life of VPA was found to have declined from an expected to only 4 hours (De Turck et al, 1998).

3.5.1.Z Nifedipine

1) Interaction Effect: increased plasma concentration of nifedipine

2) Summary: Nifedipine plasma concentrations may be increased by the presence of valproic acid. Clinical n nifedipine toxicity is recommended (Prod Info Adalat(R) CC Extended Release Tablets, 2004).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Concomitant administration of nifedipine and valproic acid may increase exposure t Monitor for clinical signs of nifedipine toxicity, including hypotension, peripheral edema, and bradycardia. Cor reduction of nifedipine.

7) Probable Mechanism: unknown

3.5.1.AA Nimodipine

1) Interaction Effect: nimodipine toxicity (dizziness, headache, flushing, peripheral edema)

2) Summary: A single dose study has shown that concurrent use of valproic acid with nimodipine results in ir nimodipine AUC with no change in half-life (Tartara et al, 1991a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for clinical or toxic effects of nimodipine (hypotension is most likely). Downv adjustment may be necessary to maintain desired cardiovascular response.

7) Probable Mechanism: decreased nimodipine metabolism

8) Literature Reports

a) Three groups of eight subjects were studied (Tartara et al, 1991). Group 1 was comprised of healthy had epileptic patients treated at least four months with carbamazepine, phenobarbital, phenytoin (all enz a combination, and group 3 included epileptic patients treated for at least four months with sodium valpro the control group, nimodipine AUCs averaged a 7-fold decrease in the enzyme inducer group, probably d first-pass metabolism. The nimodipine AUCs were increased by 50% in the valproate-treated group.

3.5.1.AB Nortriptyline

1) Interaction Effect: increased serum nortriptyline levels

2) Summary: The manufacturer reports a 34% decrease in plasma clearance of nortriptyline and a 21% decr clearance of amitriptyline following the administration of amitriptyline 50 mg (single dose) and valproate 500 r 15 healthy volunteers. However, concurrent use of valproate and amitriptyline (nortriptyline precursor) has ra associated with overt toxicity (Prod Info Depacon(R), 2002). Monitor nortriptyline levels in patients taking valp concomitantly. Consider lowering the dose of nortriptyline in the presence of valproate (Prod Info Depakote(R

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor nortriptyline levels in patients taking valproate concomitantly. Consider lowe nortriptyline in the presence of valproate.

7) Probable Mechanism: inhibition of nortriptyline metabolism

8) Literature Reports

a) In an open-label study of 15 healthy volunteers, the pharmacokinetic interactions between divalproex amitriptyline were studied. Subjects were given amitriptyline 50 mg alone and two hours after receiving n divalproex sodium 500 mg, which was given every 12 hours. Coadministration of amitriptyline with divalp resulted in a 17% increase in amitriptyline maximum concentration (Cmax) and a 31% increase in the an under the concentration-time curve (AUC). Time to maximum concentration (Tmax) for amitriptyline was coadministration with divalproex sodium. For nortriptyline, the metabolite of amitriptyline, AUC was increa Cmax was increased by 28%, and Tmax was unaffected. The authors postulated that divalproex sodium amitriptyline and nortriptyline disposition, possibly through inhibition of hepatic metabolism (Wong et al, 1

b) The combination of valproic acid and nortriptyline has resulted in toxic levels of nortriptyline. A 33-yea bipolar disorder had elected to discontinue her lithium treatment which she had been maintained on for 8 developed severe depression two months later. Nortriptyline 25 mg at bedtime was initiated on day 1 of l day 10, the dosage was increased to nortriptyline 100 mg at bedtime. Valproate 250 mg three times daily day 7 and increased to 500 mg twice daily on day 10. On day 13 of the patient noticed marked tremulous and fingers, which worsened over the next 3 days. After 15 days of nortriptyline treatment the nortriptylin ng/nL (range, 40 to 130 ng/mL). The valproate level was 105 mg/liter (range, 50 to 100 mg/liter). Both me discontinued and the patient's tremulousness decreased over the next 2 days (Fu et al, 1994).

c) A 36-year old male with bipolar disorder was treated initially with lithium but had terminated his lithium of suspected lithium-induced hypothyroidism. His current regimen consisted of thioridazine 75 mg/day ar mg/day. His nortriptyline level at that time was 146 ng/mL. His thioridazine dose was tapered over a 20-d then discontinued due to difficulties with sexual dysfunction. One month later his mood became dysphori presentation to the emergency room, he was restarted on thioridazine 75 mg/day and nortriptyline was ir mg/day. His nortriptyline level was 218 ng/mL, and his nortriptyline was decreased to 75 mg/day. Valproa times daily was subsequently added to the patient's regimen to provide mood stabilization. Valproate wa 1250 mg/day within a few weeks. The patient then stopped thioridazine and started loxapine 10 mg/day. level of nortriptyline was 345 ng/mL. Nortriptyline was titrated down to 25 mg/day and a subsequent drug

ng/mL. This was within the therapeutic range (Fu et al, 1994).
d) The addition of valpromide to a stable amitriptyline regimen may result in an increase of antidepressa
Twenty patients with major depressive illness (DSM - III criteria) were divided into two groups, one treate
alone and one treated with both amitriptyline and valpromide. All patients received oral amitriptyline 125
the evening for 20 days. Only benzodiazepines (diazepam, lorazepam, bromazepam, clorazepate dipota
mg/day, were also administered. Ten patients also received 600 mg valpromide daily after 10 days on ar
relapses and/or to decrease irritability and agitation. No statistically significant difference between amitrip
nortriptyline plasma levels were determined on days 10 and 20, respectively in ten patients treated with a
mg daily. In the ten patients who received valpromide 600 mg, amitriptyline and nortriptyline plasma leve
mean amitriptyline level increased from 70.5 +/- 35.9 nanograms/milliliter (ng/mL) to 105.5 +/- 49.4 ng/m
0.0003, paired Student's t test), and the mean nortriptyline level rose from 61.0 +/- 34.3 to 100.5 +/- 65.1
No significant relationship was seen between the percentage increase of amitriptyline levels and the plas
valproic acid, the main valpromide metabolite. There was a significant linear relationship between the pla
amitriptyline before and after valpromide (r equal to 0.94, p less than 0.001) and between the nortriptylin
before and after valpromide (r equal to 0.87, p less than 0.001). Tricyclic antidepressant plasma levels m
the therapeutic window after addition of valpromide. Monitoring of plasma levels of tricyclic antidepressa
control this interaction (Vandel et al, 1988a).

3.5.1.AC Oxcarbazepine

1) Interaction Effect: decreased plasma concentration of the active 10-monohydroxy metabolite of oxcarbaze
2) Summary: Concurrent administration of oxcarbazepine (600 to 1,800 milligrams (mg)/day) in patients rece
with valproic acid (400 to 2,800 mg/day) resulted in a 18% decrease (90% confidence interval, 13% decrease
in the plasma concentration of oxcarbazepine's 10-monohydroxy derivative (MHD) and a less than 10% chan
acid concentration (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005). Although, the clinical signif
interaction is unknown, decreased plasma MHD concentrations may result in a potential loss of oxcarbazepin
oxcarbazepine and valproic acid are administered concurrently, clinical response to oxcarbazepine may need
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Coadministration of oxcarbazepine and valproic acid may result in a decreased con
active 10-monohydroxy metabolite of oxcarbazepine. Monitor patients for clinical response to oxcarbazepine.
7) Probable Mechanism: unknown

3.5.1.AD Panipenem

1) Interaction Effect: decreased valproic acid efficacy
2) Summary: Three case reports describe a decrease in valproic acid serum concentrations when panipener
therapy was instituted, resulting in the recurrence of seizures in two patients. Although the exact mechanism
is not known, panipenem/betamipron should be avoided in patients treated with valproic acid (Yamagata et a
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Patients receiving valproic acid anticonvulsant therapy should not be treated with
panipenem/betamipron. An alternative antibiotic which does not affect valproic acid serum levels should be c
7) Probable Mechanism: unknown
8) Literature Reports
a) A 4-year-old female with spastic quadriplegia, epilepsy, and mental retardation was receiving valproic
mg/kg/day and phenobarbital 5 mg/kg/day with serum levels of 55.1 mg/dL and 28.4 mg/dL, respectively
admitted to the hospital for pneumonia, and her valproic acid dose was increased to 30 mg/kg/day while
was decreased to 4.5 mg/kg/day. Panipenem/betamipron therapy was initiated at 60 mg/kg/day in three
daily, and the serum valproic acid level decreased to 22.9 mg/mL by day 6. Although no seizures develo
this decrease, panipenem/betamipron was discontinued, and the valproic acid serum concentration incre
mg/dL (Yamagata et al, 1998).
b) A 3-year-old girl with quadriplegia, epilepsy, and mental retardation was receiving valproic acid 35 mg
carbamazepine 11 mg/kg/day, and phenytoin 10 mg/kg/day for two months before a hospital admission f
pneumonia. Valproic acid serum concentration was 88.7 mg/mL prior to the start of panipenem/betamipr
and amikacin 5 mg/kg/day. Three days later, generalized tonic-clonic seizures began to occur once or tw
valproic acid level had decreased to 30.9 mg/mL and further dropped to 26.8 mg/mL two days later. Des
the valproic acid dose to 42 mg/kg/day, the serum concentration continued to decrease to 15.3 mg/mL o
treatment with panipenem/betamipron. The valproic acid level started to increase within 24 hours of disc
panipenem/betamipron. The phenytoin serum level was undetectable on day 3 of panipenem/betamipror
carbamazepine level was not significantly altered (Yamagata et al, 1998).
c) Panipenem/betamipron 30 mg/kg/day resulted in intense, generalized seizures and frequent myoclon
year-old male who had previously been stabilized on valproic acid 32 mg/kg/day, clonazepam 0.9 mg/kg/
phenytoin 5 mg/kg/day. Prior to panipenem/betamipron therapy, his valproic acid serum level ranged fro
108.9 mg/mL. However, by day 5 of panipenem/betamipron treatment, the valproic acid level was 26.7 m
the valproic acid dose was increased to 34 mg/kg/day, serum levels were undetectable by day 25 of
panipenem/betamipron therapy. After the antibiotic was discontinued, the serum valproic acid concentrat
55 mg/mL and the frequency of the seizures was decreased. Incidentally, in this patient, the phenytoin a

levels were not significantly altered by the presence of panipenem/betamipron (Yamagata et al, 1998).

3.5.1.AE Phenobarbital

1) Interaction Effect: phenobarbital toxicity or decreased valproic acid effectiveness

2) Summary: Concurrent administration of valproic acid and phenobarbital results in decreased phenobarbita increased serum concentrations (Prod Info Depakote(R) ER, 2003g; Bourgeois, 1988; Fernandez de Gatta et al, 1980a). It may be necessary to decrease the phenobarbital dosage with concomitant use. Conversely, val may decrease significantly with concurrent use (May & Rambeck, 1985).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: With the addition of valproic acid therapy in a patient stabilized on phenobarbital, th be monitored for signs of phenobarbital toxicity and a serum phenobarbital level obtained. Phenobarbital dos be decreased in some cases. Due to increased valproic acid metabolism, periodic determinations of valproic barbiturate concentrations should be considered.

7) Probable Mechanism: decreased phenobarbital metabolism or increased valproic acid metabolism

8) Literature Reports

a) Elevations in serum phenobarbital levels have occurred with concurrent sodium valproate administrat secondary to inhibition of phenobarbital metabolism (Schobben et al, 1975; Johannessen, 1977; Richens Suganuma et al, 1981; Kapetanovic et al, 1981; Bruni et al, 1980a; Anon, 1978). Conversely, phenobarb the serum half-life of sodium valproate due to the induction of liver enzymes (Pinder et al, 1977; Rimmer Furlanut et al, 1982). A 10% increase in clearance of valproic acid has been observed in patients taking (Yukawa et al, 1997).

b) Phenobarbital metabolism is inhibited by valproate. Six subjects received valproate 250 mg twice dail phenobarbital which resulted in a 50% increase in half-life and a 30% decrease in plasma clearance of p mg single dose). The fraction of phenobarbital dose excreted unchanged increased by 50% in presence Info Depakote(R) ER, 2003f).

3.5.1.AF Phenytoin

1) Interaction Effect: altered valproate levels or altered phenytoin levels

2) Summary: Valproic acid may initially cause a decrease in total phenytoin level by displacement of phenytc binding sites (Prod Info Depakote(R) ER, 2003l; Levy & Koch, 1982a; Bruni et al, 1980a; Monks et al, 1978a) decrease in the bound fraction of phenytoin; the phenytoin which is displaced by valproic acid re-equilibrates capacity of the tissue compartment such that the unbound plasma concentration remains unchanged (Winter et al, 1978a). The degree of displacement appears to be valproic acid dose related (Monks & Richens, 1980a may also inhibit phenytoin metabolism (Levy & Koch, 1982a; Bruni et al, 1980a; Patel et al, 1980b; Winter, 19 al, 1982a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Due to the complex situation involving displacement of protein-bound phenytoin and phenytoin metabolism, as well as the potential for decreased valproic acid concentrations, patients should be phenytoin toxicity and therapeutic efficacy. Free plasma phenytoin levels should be measured if possible to p accurate assessment of phenytoin activity early in therapy. At steady-state free phenytoin concentrations and concentrations should be normalized.

7) Probable Mechanism: altered clearance and protein binding of both drugs

8) Literature Reports

a) If phenytoin or carbamazepine (or any prodrugs) is used in pregnant women, there is a substantially i teratogenicity with many combinations of other anticonvulsants. The teratogenicity of these drugs is large related to the levels of the reactive epoxide metabolites (Buehler et al, 1990b; Van Dyke et al, 1991b; Fir The epoxide/parent drug ratio is generally increased when phenytoin or carbamazepine is combined with other drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide hyc valproic acid, progabide, and lamotrigine (Spina et al, 1996b; Bianchetti et al, 1987b; Ramsay et al, 1990 combinations increase the risk of major birth defects 3- to 4-fold over monotherapy and about 10-fold ove rates.

3.5.1.AG Primidone

1) Interaction Effect: severe central nervous system depression

2) Summary: The concurrent use of valproic acid and phenobarbital may result in severe central nervous sys possibly due to the impairment of non-renal phenobarbital clearance. Serum concentrations of phenobarbital significantly increased. Since primidone is metabolized to phenobarbital, the same interaction may be possibl Depakote(R) ER, 2003b; Prod Info Depakene(R), 1998).

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: All patients receiving concurrent primidone and valproic acid therapy should be mor excessive central nervous system depression and neurological toxicity. Serum primidone and derived phenob should be monitored and the dosage of primidone decreased, if necessary.

7) Probable Mechanism: impairment of phenobarbital clearance
8) Literature Reports
a) One hundred epileptic patients taking primidone alone or in combination with other anticonvulsants w studied (Yukawa et al, 1989). Primidone doses ranged from 1.45 mg per kg to 27.03 mg per kg. All patie taking the same dosage for at least three weeks prior to blood sampling. Results showed no significant c primidone serum level when given concomitantly with valproate sodium, but there was a significant incre phenobarbital serum level.

3.5.1.AH Rifampin
1) Interaction Effect: reduced valproate levels
2) Summary: A 40% increase in the oral clearance of valproate was observed in a study involving the admini dose of valproate (7 mg per kg) 36 hours after five nights of daily dosing with rifampin (600 mg) (Prod Info De When coadministered with rifampin, valproate dosage adjustment may be required (Prod Info Depakote(R) E
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor valproate levels and the patient for seizure control. An adjustment in the do may be necessary when coadministered with rifampin.
7) Probable Mechanism: increased valproate oral clearance

3.5.1.AI Rifapentine
1) Interaction Effect: decreased anticonvulsant effectiveness
2) Summary: The efficacy of anticonvulsants may be impaired with concomitant use of rifapentine. Rifapentir the metabolism of other coadministered drugs that are metabolized by cytochrome P450 3A4 or 2C8/9. Dosa anticonvulsants may be necessary if given concurrently with rifapentine (Prod Info Priftin(R), 2000).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor serum anticonvulsant levels and with concomitant use and adjust doses ac
7) Probable Mechanism: increased hepatic metabolism

3.5.1.AJ Risperidone
1) Interaction Effect: increased plasma valproic acid concentrations
2) Summary: The addition of risperidone to valproic acid produces a significant increase in the peak plasma (Cmax) of valproic acid (Prod Info Risperdal(R) Consta(TM), 2003a) as well as marked increases in ammonia al, 2007). The high protein capacity of risperidone could lead to a competition for protein-binding with the high capacity of valproic acid, leading to displacement of valproic acid from plasma protein-binding sites (van Wat However, Valproic acid can be added safely to a treatment regimen consisting of risperidone (Spina et al, 20(ammonia levels may be warranted in patients who exhibited new or increased manic behavior when taking va risperidone, especially in patients vulnerable to valproic acid-induced hyperammonemia, including the young, polytherapy, severely handicapped, or suffering from malnutrition, protein load, and decreased free serum ca al, 2007). In patients prescribed this combination of drugs, monitoring of plasma risperidone or 9-OH-risperid does not appear to be warranted.
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Monitor for increased ammonia levels and plasma valproic acid concentrations with risperidone to drug therapy or changes in risperidone dose.
7) Probable Mechanism: unknown
8) Literature Reports
a) In 2 case reports of 11 year-old boys, there were marked exacerbations in manic behavior and a 2 to serum ammonia levels when risperidone and valproic acid were concomitantly administered. The first pa history of Asperger's disorder, attention-deficit/hyperactivity disorder (ADHD), psychosis, and manic sym admitted for increasing aggressive behavior. Chlorpromazine was added as needed and risperidone was his aripiprazole. Following the initiation of valproic acid 250 mg twice daily, the patient experienced a qua exacerbation of manic behavior. The risperidone dosage was eventually adjusted to 2 mg/day and valpro mg/day. The patient's valproate level ranged from 87 to 90 and ammonia level was 213. When valproic a discontinued, and the ammonia level fell to 55, his manic behavior stopped. The second patient, with a h epilepsy and ADHD, was on stable doses of valproic acid. Because of his psychotic symptoms, risperido and increased to 1.125 mg/day over 5 weeks. The patients exhibited markedly pronounced manic behav serum ammonia level of 113, despite a normal valproic acid level of 71. Upon discontinuation of risperid acid, the ammonia level normalized to 55 and the manic behavior resolved. One month later when the pa rechallenged with risperidone (in the absence of valproic acid), there was no return of either mania or hy (Carlson et al, 2007).
b) A study was performed to evaluate the pharmacokinetic interaction between risperidone and valproic plasma concentrations of risperidone and 9-hydroxyrisperidone (9-OH risperidone) were compared in pa risperidone alone or in patients comedicated with valproic acid. Thirty-three patients with a DSM-IV diagr schizophrenia, schizoaffective disorder or bipolar disorder, were stabilized with risperidone alone or in co

valproic acid. The results demonstrate that valproic acid given at doses up to 1200-1500 mg/day had clir effects on plasma concentrations of risperidone and its active metabolite. Valproic acid can be added sat regimen consisting of risperidone. In patients prescribed this combination of drugs, monitoring of plasma OH-risperidone concentrations does not appear to be warranted (Spina et al, 2000).

c) The combination of valproic acid and risperidone led to significantly increased levels of valproic acid i year-old male suffered from mood swings and increasingly aggressive behavior. Valproic acid treatment titrated up to 1750 mg/day. Valproate serum levels were in the therapeutic range. After 10 days of treatm mg/day was added, which was increased to 3 mg/day on day 4. On day 5 after risperidone was started, t symptoms improved but valproic acid levels were above the therapeutic range at 191 mg/L. Valproic acic 1000 mg/day and the level normalized to 108 mg/L within 3 days and subsequently stabilized. The autho the high-protein-binding capacity of risperidone could lead to a competition for protein-binding with the hi capacity of valproic acid, leading to displacement of valproic acid from plasma protein-binding sites (Van

d) In 21 patients, repeated oral doses of risperidone 4 mg daily did not affect the pre-dose or average pl concentrations or exposure (area under the concentration-time curve) of valproate 1000 mg daily compa There was, however, a 20% increase in valproate maximum plasma concentration (Cmax) after risperidc coadministration (Prod Info Risperdal(R) Consta(TM), 2003).

3.5.1.AK Ritonavir

1) Interaction Effect: decreased valproic acid serum concentrations

2) Summary: Coadministering ritonavir with valproic acid may decrease the plasma concentration of valproic report suggests the mechanism may be due to ritonavir induction of VPA metabolism via glucuronidation (Sh Monitoring of valproic acid plasma concentrations is recommended (Prod Info NORVIR(R), 2005).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor therapeutic concentrations of valproic acid when coadministering with ritona acid dose increase may be needed.

7) Probable Mechanism: ritonavir-induced metabolism of valproic acid

8) Literature Reports

a) A case report describes a 30-year-old man with bipolar disorder and HIV who became increasingly m addition of lamivudine 150 mg/zidovudine 300 mg twice a day and lopinavir 133 mg/ritonavir 33 mg (3 ca day) to his drug regimen. The patient had been maintained on valproic acid (VPA) 250 mg 3 times a day concentration of 495 mcmol/L, when the antiretrovirals were prescribed during a hospital admission for m Paroxetine 10 mg/day was simultaneously given for the depressive episode. The patient became hypom and the paroxetine was switched to sertraline 50 mg/day. Twenty-one days after the initiation of antiretro became increasingly manic and was again admitted. He had continued all medications except sertraline including the same VPA dose. Serum VPA concentration 6 to 10 hours post-dose was subtherapeutic at decrease of 48% from the previous documented concentration. Olanzapine and an increase in VPA to 1! effectively managed the manic episode. The patient adhered to this new drug regimen, including the pre antiretrovirals, and 10 days later a 14-hour post-dose VPA level measured in the therapeutic range at 39 the patient was not taking concomitant medications known to affect VPA metabolism, it was hypothesize decrease in VPA concentrations was due to ritonvavir induction of VPA metabolism (via glucuronidation) 2006).

3.5.1.AL Rufinamide

1) Interaction Effect: increased rufinamide plasma concentrations

2) Summary: Concomitant administration of rufinamide and valproate may result in rufinamide concentration 70%. Larger increases in rufinamide plasma concentrations were observed in children with higher valproate doses/concentrations (Prod Info BANZEL(TM) oral tablets, 2008).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Caution is advised if rufinamide and valproate are coadministered as this may resul rufinamide plasma concentrations. Risk is increased in children with higher valproate doses/concentrations (F (TM) oral tablets, 2008).

7) Probable Mechanism: unknown

3.5.1.AM Tipranavir

1) Interaction Effect: decreased valproic acid plasma concentrations and potential for decreased efficacy

2) Summary: Coadministration of tipranavir and valproic acid may result in decreased valproic acid concentra decrease the efficacy of valproic acid (Prod Info APTIVUS(R) oral capsules, 2007). Valproic acid doses may adjusted and frequent monitoring of valproic acid levels for efficacy may be required.

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Use caution when prescribing valproic acid to patients who are taking tipranavir. Va less effective due to decreased valproic acid concentrations in patients taking concomitant tipranavir (Prod In oral capsules, 2007). Monitor patients for loss of valproic acid efficacy and adjust doses as necessary.

7) Probable Mechanism: unknown

3.5.1.AN Topiramate

1) Interaction Effect: decreased topiramate or valproic acid concentrations, and increased risk of hyperammo encephalopathy

2) Summary: Controlled, clinical pharmacokinetic studies in patients with epilepsy showed an 11% decrease concentration of valproic acid when topiramate was added. However, when topiramate was given alone, the topiramate decreased by 14% when valproic acid was added (Prod Info TOPAMAX(R) oral tablets, oral sprin 2008). In two controlled studies involving a total of seven epileptic patients already receiving valproic acid, the topiramate did not significantly change the serum concentration of valproic acid or valproic acid trough conce et al, 1996; Floren et al, 1989a). The coadministration of valproic acid and topiramate has also been implicate development of hyperammonemic encephalopathy (Hamer et al, 2000a). As described in a series of case rep encephalopathy developed in 5 patients with drug-resistant epilepsy, shortly after beginning a combination ar regimen comprising topiramate and valproic acid. Symptoms largely resolved after either drug was reduced i completely withdrawn (Latour et al, 2004). Although not studied, concomitant use of topiramate and valproic a exacerbate existing defects or unmask deficiencies in susceptible patients. Patients with inborn errors of met hepatic mitochondrial activity may be at an increased risk for hyperammonemia with or without encephalopat TOPAMAX(R) oral tablets, oral sprinkle capsules, 2008).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Concomitant use of topiramate and valproic acid may result in hyperammonemia a encephalopathy. It may also result in decreased plasma concentrations of one or both drugs (Prod Info TOPA tablets, oral sprinkle capsules, 2008). Upon the coadministration of topiramate and valproic acid, dosing adju required for either or both drugs. Consider monitoring patients for seizure control and excessive adverse effe

7) Probable Mechanism: unknown

8) Literature Reports

a) In a controlled study, interactions with topiramate were assessed in six epileptic patients already takir three epileptic patients already taking valproic acid. The patients were given topiramate 100 mg every m increased to the maximum tolerated dose (no greater than 1200 mg per day). Plasma concentration-time observed over the next eight weeks. No apparent changes were observed in either phenytoin or valproic the concentration-time curve (AUC) profiles or trough plasma concentrations (Floren et al, 1989).

b) Stuporous encephalopathy developed in 5 patients with drug-resistant epilepsy, shortly after beginnir anticonvulsant regimens comprising topiramate (TPM) and valproic acid (VPA). Hyperammonemia was the patients (age ranging from 29 to 41 years). Blood ammonia levels ranged from 62 to 146 mcmol/L. A dose or withdrawal of TPM or VPA, blood ammonia levels returned to normal. In the 5th case report, a 1 developed impaired consciousness, 10 days after VPA 1500 mg/day was added to a stable dose regime 300 mg/day, phenytoin (PHT) 300 mg/day, and carbamazepine 6 mg/day. Blood ammonia concentration normal limits; however, elevations were observed in plasma concentrations of gamma glutamyl-transfera phosphatase. The patient's cognitive status returned to baseline after TPM was tapered and withdrawn, a reduction of PHT dose (Latour et al, 2004).

c) A 32-year-old male with centro-temporal epilepsy was controlled on phenobarbital 200 mg daily and t daily when valproic acid was added to his regimen. Two days prior to hospital admission, valproic acid w 1500 mg daily and the patient became drowsy with nausea and slurred speech. The phenobarbital conce mcg/mL (therapeutic range 15 mcg/mL to 40 mcg/mL) and the valproic acid level was 38 mcg/mL (therap mcg/mL to 100 mcg/mL) at hospital admission. The ammonia concentration was elevated at 116 mcmol/ mcmol/L to 60 mcmol/L), as was the gamma glutamyl transpeptidase (GGT) level. Acute valproic acid er suspected, and valproic acid was discontinued. The patient recovered within the next three days and the concentration decreased to within normal limits (Hamer et al, 2000).

d) A 37-year-old female with focal epilepsy was receiving topiramate 400 mg daily, carbamazepine 1000 lamotrigine 150 mg daily with little effect on her seizure frequency. Valproic acid 1200 mg daily was slow lamotrigine, and the patient became somnolent and dysarthric within three weeks. Laboratory results sho acid level of 47 mcg/mL (therapeutic range 50 mcg/mL to 100 mcg/mL) and a carbamazepine level of 5.2 (therapeutic range 8 mcg/mL to 12 mcg/mL). The ammonia level was increased to 88 mmol/L and valpro hyperammonemic encephalopathy was suspected. Topiramate was slowly discontinued over a seven-da patient completely recovered, although the ammonia level remained elevated. Valproic acid was then als and the ammonia concentration returned to a normal range (Hamer et al, 2000).

3.5.1.AO Vorinostat

1) Interaction Effect: severe thrombocytopenia and gastrointestinal bleeding

2) Summary: Severe thrombocytopenia and gastrointestinal bleeding have occurred with the concomitant us other histone deacetylase inhibitors, such as valproic acid. Caution is advised if these agents are coadministe platelet count every 2 weeks for the first 2 months of therapy (Prod Info ZOLINZA(TM) oral capsules, 2006).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Concomitant use of vorinostat with other histone deacetylase inhibitors, such as val resulted in severe thrombocytopenia and gastrointestinal bleeding. Use caution if these agents are coadminis

platelet count every 2 weeks for the first 2 months of therapy (Prod Info ZOLINZA(TM) oral capsules, 2006).
7) Probable Mechanism: unknown

3.5.1.AP Zidovudine
1) Interaction Effect: increased zidovudine plasma concentrations and potential zidovudine toxicity (asthenia hematologic abnormalities)
2) Summary: Coadministered valproic acid increases the bioavailability of zidovudine and may lead to zidovu (Lertora et al, 1994a; Prod Info Retrovir(R), 2003). In six patients who were seropositive for HIV, the clearanc (100 mg q8h) was decreased by 38% after administration of valproate (250 or 500 mg q8h) (Prod Info Depak
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients for signs and symptoms of zidovudine toxicity (asthenia, fatigue, na hematologic abnormalities). It may be necessary to reduce zidovudine doses when valproic acid is added to t increase doses when valproic acid is discontinued.
7) Probable Mechanism: inhibition by valproic acid of zidovudine metabolism
8) Literature Reports
a) Zidovudine pharmacokinetics were studied in six HIV-infected volunteers administered four days of zi and four days of zidovudine combined with valproic acid. Study subjects received zidovudine 100 mg ora hours and valproic acid 250 mg orally every eight hours (one patient was given 500 mg of valproic acid e The area under the concentration-time curve of zidovudine increased by 80%, from 0.65 to 1.17 mcg/hr/l concomitant valproic acid was given. Zidovudine oral clearance decreased 38% from 2351 to 1449 mL/m life of zidovudine was not significantly altered during coadministration. In this short-term study, no chang hematologic parameters or renal and hepatic function tests. The clinical impact of long-term use of this c date unknown. Effects on valproic acid concentrations were not studied. The mechanism of the interactio be inhibition by valproic acid of first-pass glucuronidation of zidovudine (Prod Info Depakote(R) ER, 2003 1994).

3.5.3 Drug-Lab Modifications

Plasma free fatty acid measurement

Urinalysis, acetone or ketone bodies measurement

3.5.3.A Plasma free fatty acid measurement
1) Interaction Effect: falsely elevated plasma free fatty acid levels
2) Summary: In a plasma mixing experiment, free fatty acids falsely increased when measured by a colorime therapeutic concentrations of valproic acid were added (Albani et al, 1982). Consider using a more specific m determine FFA concentration in patients receiving valproic acid.
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Consider avoiding calorimetric methods to determine plasma free fatty acid levels in valproic acid. More specific methods for free fatty acid determination should be used.
7) Probable Mechanism: assay interference
8) Literature Reports
a) When free fatty acids (FFA) are measured by colorimetric methods, false elevations may occur due to valproic acid, a short branched-chain organic acid. In a controlled plasma mixing experiment, the additio micrograms/milliliter valproic acid increased the apparent FFA by an average 246 micromole/liter in 10 re to 705 micromole/liter). Using more specific methods to determine FFA concentrations in patients receivi should avoid this interference (Albani et al, 1982). The concentration of valproic acid used in the experim within the approved therapeutic ranges used for epilepsy (50 to 100 micrograms/milliliter) and acute mar micrograms/milliliter trough concentration), respectively (Prod Info Depakote(R), valproic acid, 2000).

3.5.3.B Urinalysis, acetone or ketone bodies measurement
1) Interaction Effect: a false-positive urine ketone test
2) Summary: In patients receiving valproic acid, false-positive reactions for ketones in the urine may occur b acid is partially eliminated in the urine as a keto-metabolite (Prod Info DEPAKOTE(R) ER extended-release c Use caution when interpreting urine ketone test results in patients receiving concurrent therapy with valproic a
3) Severity: minor
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Valproic acid is partially eliminated in the urine as a keto-metabolite, which may res reactions for ketones in the urine (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008). Interpre results with caution in patients receiving valproic acid therapy.

7) Probable Mechanism: valproic acid being partially eliminated in the urine as a keto-metabolite

3.5.5 Intravenous Admixtures

3.5.5.2 Solutions

3.5.5.2.A Valproate Sodium

DEXTROSE 5%

Lactated Ringer's Injection

SODIUM CHLORIDE 0.9%

3.5.5.2.A.1 DEXTROSE 5%

a) Compatible

1) Valproate sodium injection was found to be physically compatible and chemically stable in d
least 24 hours when stored in glass or polyvinyl chloride bags at controlled room temperature, 1
Celsius (Prod Info Depacon(R), 1999).

3.5.5.2.A.2 Lactated Ringer's Injection

a) Compatible

1) Valproate sodium injection was found to be physically compatible and chemically stable in la
injection for at least 24 hours when stored in glass or polyvinyl chloride bags at controlled room
30 degrees Celsius (Prod Info Depacon(R), 1999).

3.5.5.2.A.3 SODIUM CHLORIDE 0.9%

a) Compatible

1) Valproate sodium injection was found to be physically compatible and chemically stable in s
0.9% for at least 24 hours when stored in glass or polyvinyl chloride bags at controlled room ter
degrees Celsius (Prod Info Depacon(R), 1999).

4.0 Clinical Applications

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters

A) Therapeutic

1) Monitor the reduction in the incidence and severity of seizures.

a) SERUM LEVELS

1) The therapeutic range in epilepsy is 50 to 100 mcg/mL of total valproate (Prod Info Depakene(R), 19
Depakote(R) Tablets, 2002a); (Prod Info Depacon(R), 1999)(Turnbull et al, 1983aa; Rimmer & Richens,

a) A free concentration therapeutic range has not been established (Prod Info Depakene(R), 1999).

b) High concentration valproic acid (80 to 150 mcg/mL) may be needed to reduce seizure frequency
partial seizures and secondarily generalized tonic-clonic seizures (Beydoun et al, 1997c).

2) Studies with valproate in acute mania utilized the following therapeutic range: 50 to 125 mcg/mL (Pro
Tablets, 2002a).

B) Toxic

1) Laboratory Parameters

a) Liver function tests should be monitored prior to the initiation of therapy and at frequent intervals. Liver tox
mainly during the first 6 months of therapy.

1) Ammonia concentrations should be monitored in cases of mental confusion

b) Complete Blood Count

1) Platelet counts and coagulation tests should be undertaken before and during therapy at periodic inte planned surgeries.

c) Amylase levels (serum)

d) Monitor concentrations; increase frequency of monitoring when concomitant antiepileptics are introduced

e) Some healthcare providers recommend against routine monitoring of serum for pancreatic enzymes beca induced pancreatitis has low occurrence, there is wide variability in time to onset, and mild, asymptomatic ele pancreatic enzyme markers occurs frequently without progression to pancreatitis. Those healthcare providers counseling of patients to recognize the signs and symptoms of pancreatitis and advising them to seek immed assistance if those symptoms occur (Chapman et al, 2001).

2) Physical Findings

a) Data reviewed by the US Food and Drug Administration suggest an increased risk of suicidal behavior or in patients receiving therapy with antiepileptic drugs (AEDs). The increased risk of suicidality was noted at 1 w an AED and continued to at least 24 weeks. Patients treated for epilepsy, psychiatric disorders, or other cond an increased risk for suicidality compared to placebo. Closely monitor patients treated with AEDs for emergen of depression, suicidality, and other unusual changes in behavior, which may include symptoms such as anxi hostility, mania, and hypomania (US Food and Drug Administration, 2008).

4.2 Patient Instructions

A) Divalproex (By mouth)

Divalproex Sodium

Treats seizures (epilepsy). Also used to treat the manic phase of bipolar disorder (manic-depressive illness) and t headaches. Belongs to a class of drugs called anticonvulsants.

When This Medicine Should Not Be Used:

You or your child should not use this medicine if you have had an allergic reaction to valproic acid or divalproex, c severe liver disease, a urea cycle disorder (a disease that causes too much ammonia in the blood), or are pregna get pregnant.

How to Use This Medicine:

Long Acting Tablet, Delayed Release Tablet, Coated Tablet, Delayed Release Capsule

Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed order to find out what works best for you. Do not use more medicine or use it more often than your doctor tells May be taken with food to decrease stomach upset.

Swallow the capsule or tablet whole. Do not crush, break or chew it.

You may open the sprinkle capsule and mix the medicine beads with a small amount (about a spoonful) of so applesauce or pudding. Swallow the mixture whole. Do not chew.

If a Dose is Missed:

If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next d then to use the medicine and skip the missed dose. Do not use extra medicine to make up for a missed dose If you miss two or more doses, call your doctor.

How to Store and Dispose of This Medicine:

Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.

Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after your treatment. You will also need to throw away old medicine after the expiration date has passed.

Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:

Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a products.

Make sure your doctor knows if you or your child are taking a blood thinner (such as aspirin, warfarin, or Cou medicines that could make you sleepy, such as sleeping pills (such as alprazolam, lorazepam, Ativan®, Xana medicines (Lorcet®, Percocet®, Tylenol® with Codeine, Vicodin®, Vicoprofen®), or cold medicines. Tell your your child are using any other medicine for seizures.

Tell your doctor if you or your child are taking meropenem (Merrem®), rifampin (Rifadin®, Rimactane®), amit Vanatrip®), topiramate (Topamax®), or zidovudine (Retrovir®).

Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:

Using this medicine while you are pregnant can harm your unborn baby. Use an effective form of birth contro getting pregnant. If you think you have become pregnant while using the medicine, tell your doctor right away

Make sure your doctor knows if you are breastfeeding, or if you or your child have liver disease, pancreas dis disorders. Tell your doctor if you have a family history of urea cycle disorders or unexplained infant deaths.

Because of the risk of increased seizures, do not stop using this medicine suddenly without asking your docto

to slowly decrease your dose before stopping it completely.
If you or your child are taking this medicine in the form of sprinkle capsules, you may see small amounts of th stool. This is normal.
This medicine may make you dizzy or drowsy. Avoid driving, using machines, or doing anything else that cou you are not alert.
Make sure any doctor or dentist who treats you knows that you are using this medicine. This medicine may a certain medical tests.
Your doctor will need to check your blood at regular visits while you are using this medicine. Be sure to keep

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, c trouble breathing.
Changes in vision.
Chest pain.
Dark-colored urine or pale stools.
Fast, pounding heartbeat.
Fever, chills, cough, sore throat, runny or stuffy nose, and body aches.
Lightheadedness, dizziness, drowsiness, or fainting.
Sudden and severe stomach pain, nausea, vomiting, loss of appetite.
Swelling on your face, hands, ankles, or feet.
Tremors or loss of seizure control.
Trouble breathing.
Unusual bleeding or bruising.
Yellowing of your skin or the whites of your eyes.

If you notice these less serious side effects, talk with your doctor:
Back pain.
Diarrhea, constipation, or upset stomach.
Hair loss.
Headache.
Increase in appetite.
Mood changes, unusual thoughts, or memory loss.
Nervousness or depression.
Rash or hives with itching.
Restlessness or irritability.
Ringing in the ears.
Trouble sleeping.
Weight gain or weight loss.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

B) Valproate Sodium (Injection)
Valproate Sodium

Treats different types of seizures (epilepsy). This medicine is an anticonvulsant.

When This Medicine Should Not Be Used:
You should not receive this medicine if you have had an allergic reaction to valproate, or if you have certain liver p should not receive this medicine if you have a genetic (inherited) urea cycle disorder, which causes the body to ha rid of ammonia (a waste product in the blood).

How to Use This Medicine:
Injectable
A nurse or other trained health professional will give you this medicine.Your doctor will prescribe your exact d how often it should be given. This medicine is given through a needle placed in one of your veins.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a products.
Do not use aspirin without your doctor's OK.
There are many other drugs that can interact with valproate. Make sure your doctor knows about all other me using, especially blood thinners, and medicine to treat seizures, depression, or mood problems.
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:
Tell your doctor if you are pregnant or breast feeding, or if you have had a recent head injury. Make sure you you have a history of coma, unexplained mental or behavior problems, frequent vomiting, a family history of u disorders, or a family history of unexplained infant deaths. Tell your doctor if you have HIV or AIDS, or if you

caused by cytomegalovirus (CMV).
If this medicine is to be given to your child, make sure the doctor knows if your child is under the age of two y
using other medicine to treat seizures. Tell the doctor if your child was born with a disease that affects his me
making process of the body). Make sure the doctor knows if your child has mental retardation or a brain disea
Using this medicine while you are pregnant can harm your unborn baby. Use an effective form of birth contro
getting pregnant. If you think you have become pregnant while using the medicine, tell your doctor right away
Make sure any doctor or dentist who treats you knows that you are using this medicine. This medicine may a
certain medical tests.
Your doctor will need to check your blood at regular visits while you are using this medicine. Be sure to keep
This medicine may make you drowsy or less alert. Avoid driving, using machines, or doing anything else that
dangerous if you are not alert.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, c
trouble breathing.
Chest pain or slow heartbeat.
Confusion or hallucinations (sensing things that are not there).
Fever or new coughing.
Lightheadedness, dizziness, severe tiredness, or fainting.
Nausea, vomiting, or sudden and severe stomach pain.
Poor seizure control.
Redness, pain, or swelling at the injection site.
Swelling in your arms or legs, skin rash, or blistering, peeling skin.
Tremors (shaking), or problems with coordination (movement) or posture (remaining upright).
Unusual bleeding or bruising.
Vision changes.
Weakness, loss of appetite, unexplained weight loss, or rapid weight gain.

If you notice these less serious side effects, talk with your doctor:
Dark or bloody urine, pain or burning with urination, or a change in how much or how often you urinate.
Heartburn, diarrhea, or constipation.
Headache.
Hair loss.
Mood changes.
Menstrual (period) changes.
Tiredness or feeling generally unwell.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

C) Valproic Acid (By mouth)
Valproic Acid

Treats seizures (epilepsy). Also used to treat mood disorders and prevent migraine headaches. Belongs to a clas
anticonvulsants.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to valproic acid or divalproex, if you have se
or if you are pregnant.

How to Use This Medicine:
Liquid, Liquid Filled Capsule, Delayed Release Capsule
Your doctor will tell you how much of this medicine to use and how often. Do not use more medicine or use it
your doctor tells you to.
May be taken with food to lessen stomach upset.
Swallow the capsule whole. Do not crush, break or chew.
Measure the oral liquid medicine with a marked measuring spoon, oral syringe, or medicine cup.

If a Dose is Missed:
If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next c
then to use the medicine and skip the missed dose. Do not use extra medicine to make up for a missed dose
If you miss two or more doses, call your doctor.

How to Store and Dispose of This Medicine:
Keep this medicine in the original tightly closed container. Store at room temperature, away from heat and m
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any outdated medicine or n
needed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a products.
Avoid drinking alcohol.
Make sure your doctor knows if you are taking "blood thinners" (medicines such as aspirin or Coumadin®) or other medicines that could make you sleepy such as sleeping pills, cold medicine, or sedatives.

Warnings While Using This Medicine:
Check with your doctor before taking this medicine if you are breastfeeding, or if you have liver disease, kidn blood disorder.
Talk to your doctor before taking this medicine if you are pregnant. If you become pregnant while being treate medicine, tell your doctor right away. This medicine may be harmful to your unborn baby.
Because of the risk of increased seizures, do not suddenly stop taking this medicine without first checking wit
This medicine may cause drowsiness. Be careful when driving or using machinery.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Loss of seizure control
Severe weakness or dizziness
Severe vomiting that doesn't go away
Unusual bleeding or bruising
Yellowing of the skin or eyes
Rash or hives with itching

If you notice these less serious side effects, talk with your doctor:
Nausea, vomiting, or stomach cramps
Drowsiness or dizziness
Restlessness or irritability
Diarrhea or constipation
Trembling of hands or arms
Hair loss

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Valproic Acid

1) Seizures

a) Valproic acid is indicated as monotherapy and adjunctive therapy for complex partial seizures occurring in association with other types of seizures in patients 10 years and older. Valproic acid is also indicated for use and adjunctive therapy in the treatment of complex absence seizures, and adjunctively in patients with multip that include absence seizures (Prod Info STAVZOR(R) delayed release oral capsules, 2008; Prod Info DEPA capsules, oral syrup, 2006).

b) Although valproic acid is considered a first-line therapy for treating generalized tonic-clonic seizures, simp and complex partial seizures, carbamazepine is generally preferred due to its lesser toxicity. Valproic acid is agent for the treatment of absence seizures; ethosuximide is generally preferred, however (Young & Koda-Ki 1989).

c) Valproic acid and carbamazepine appear to have less of an effect on cognitive function and behavioral dis comparison with phenobarbital, phenytoin, and primidone. For this reason, both valproic acid and carbamaze preferred over these other agents for treating seizure disorders in children (Trimble, 1988; Anon, 1985).

2) Bipolar disorder

a) Valproic acid (Stavzor(R)) is indicated for the treatment of the manic episodes associated with bipolar disc week, placebo-controlled, parallel-group studies, valproate had significantly superior results on all measures outcomes for acute mania compared with placebo (Prod Info STAVZOR(R) delayed release oral capsules, 20

b) Valproic acid has been effective in treating mania associated with bipolar disorder in clinical studies (Faw 1989; Post, 1989; McElroy et al, 1989; Calabrese & Delucchi, 1989; Pope et al, 1988; Grunze et al, 1999; Pra

c) Valproic acid has been shown to be effective for the treatment of acute mania. Response has been seen i unresponsive to lithium therapy and to those with mixed mania and rapid cycling (Keck et al, 1998). A greater reduction is seen in approximately 50% of patients. The therapeutic onset correlates with therapeutic plasma Controlled studies are needed to assess valproic acid in the treatment of acute bipolar depression and maint of bipolar disorder.

3) Migraine prophylaxis

a) Valproic acid (Stavzor(R)) is indicated for prophylaxis of migraine in adults and children 16 years and olde randomized, placebo-controlled clinical trials established the efficacy of valproate for prophylaxis of migraine Info STAVZOR(R) delayed release oral capsules, 2008).

B) Divalproex Sodium

1) BIPOLAR DISORDER

a) In a decision analysis model, divalproex was found to be less costly than lithium for the acute and prophyl patients with bipolar disorder over a one-year time period. Four attributes of overall patient management were

model: the response rate to initial therapy; the mean length of hospital stay; the rates of adverse effects; and treatment costs. In the overall analysis, initial therapy with divalproex resulted in costs that were 9% lower tha treatment with lithium, most likely due to a more rapid response with divalproex and shorter length of hospital were most significant in patients with mixed mania and rapid cycling; however, cost savings with lithium thera recognized in patients with classic mania (Keck et al, 1996).

C) Valproate Sodium

1) SEIZURES

a) Valproate sodium injection should be used in patients who temporarily cannot use the oral form of valproic it is clinically feasible, patients should be switched back to oral valproic acid (Prod Info valproate sodium injec

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) Although the mechanism of action is presently unknown, it is postulated that the drug's effects are mediated th the function of brain gamma-aminobutyric acid (GABA), specifically by increasing brain concentrations of this inhil (Prod Info STAVZOR(R) delayed release oral capsules, 2008; Beckner, 1979; Godin et al, 1969; Simler et al, 197

2) The drug has been shown to be an inhibitor of GABA-aminotransferase and succinic semialdehyde dehydroge involved in the synthesis and degradation of GABA (Simler et al, 1973; Loscher, 1980; Sawaya et al, 1975), and s of GABA have been reported to occur in synaptosomes, primarily in areas of high GABA activity (Iadarola & Gale, Richens, 1985d). However, this proposed mechanism of action has been disputed (Rimmer & Richens, 1985d; Hc Concentrations of the drug are reportedly too low for enzyme effects to occur with therapeutic doses, and increas GABA are reportedly too small to account for anticonvulsant effects (Rimmer & Richens, 1985d). Alternately, it ha that valproic acid may selectively enhance postsynaptic GABA responses (Rimmer & Richens, 1985d; MacDonalc Other hypotheses which have been advanced are: (1) direct effect of the drug on neuronal membranes and (2) re excitatory transmission by aspartate (Rimmer & Richens, 1985d; Slater & Johnston, 1978). However, no mechani adequately supported by experimental data (Rimmer & Richens, 1985d).

3) There is some evidence that valproic acid may inhibit the re-uptake of GABA into the glia and nerve endings (E

B) REVIEW ARTICLES

1) Basic reviews of the treatment of seizures have been written; these include treatment of first seizure and statu (Willmore, 1998), treatment of the elderly (Rowan, 1998), and management of epilepsy in adults (Feely, 1999; Ma Pediatric seizure management has also been reviewed (Wolf et al, 1998; Pellock, 1995).

2) A comprehensive review concerning the use of valproate in psychiatric conditions is available (Davis et al, 200

3) The association between valproate therapy and the development of polycystic ovarian syndrome is discussed 1999).

4) A review of clinical trial data on valproic acid's efficacy in migraine prophylaxis is available (Rothrock, 1997).

5) With the addition of the newer antiepileptic drugs, polypharmacy in epilepsy is being revisited (Schneiderman, 1998).

6) The clinical pharmacology, pharmacokinetics, and kinetics of valproic acid in disease states have been extens (Bruni & Albright, 1984).

7) An extensive study of first-dose and steady-state pharmacokinetics with valproic acid in children with seizures al, 1983). A detailed case review of the kinetics of valproic acid in neonates is provided (Irvine-Meek et al, 1982).

8) Pharmacokinetics of valproic acid has been reviewed (Zaccara et al, 1988).

9) The treatment of pediatric malignant glioma with valproic acid has been reviewed (Driever et al, 1999).

10) The clinical studies evaluating the efficacy of valproic acid in bipolar disorder have been reviewed (Guay, 19

Tinnitus

Visual hallucinations

4.5.A.1 Absence seizure, Simple and complex

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (10 years and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid is indicated as adjunct or monotherapy for patients with simple and complex absence s
DEPAKENE(R) oral capsules, oral syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsu

c) Adult:

1) Valproic acid is indicated for use as sole and adjunctive therapy in the treatment of simple and compl seizures. Results of several clinical studies have shown that sodium valproate is effective in patients with seizures (petit mal seizures) with response rates approaching 100% (Rimmer & Richens, 1985g). Result involving 354 patients indicate there is at least a 75% reduction in seizure frequency in about 66% of pat 45 (13%) patients failed to show any significant improvement in this review (Pinder et al, 1977e). Ethosu preferred over valproic acid for treatment of absence seizures as it is equally effective and better tolerate Kimble, 1995a). Combination therapy with valproic acid and ethosuximide was successful in treating abs patients who were refractory to either drug alone (Rowan et al, 1983).

d) Pediatric:

1) Valproic acid monotherapy was reported effective in the treatment of absence epilepsy in 6 of 7 childr patient also responded when clonazepam was added to valproic acid. Prior to therapy, 3 patients had be unsatisfactorily with ethosuximide, alone or in combination with carbamazepine. Valproic acid was given 15 milligrams/kilogram/day for 7 days, followed by 20 to 25 milligrams/kilogram/day for a further 14 days subsequently adjusted based upon seizure response (maximum plasma levels of 700 micromoles/liter). I responding to monotherapy, the EEG normalized completely in 4, with a 95% reduction in epileptic disch remaining two. In these patients, a valproic acid serum level of 440 to 660 micromoles/liter was required 50% reduction of seizures (Braathen et al, 1988). It is suggested that valproic acid is a reasonable altern seizures in children when ethosuximide has failed.

4.5.A.2 Alcohol hallucinosis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproate was effective for the treatment of acute alcohol hallucinosis in a randomized, double-blind conducted in 40 patients (Aliyev & Aliyev, 2008).

c) Adult:

1) Valproate, in the form divalproex sodium, was effective and well-tolerated for the treatment of acute a in a randomized, double-blind, placebo-controlled study of 40 men. Within 24 hours of hospital admissior initiated with valproate or placebo, increasing over 3 days from 1000 mg to 3000 mg in 3 divided doses. evaluated using the Positive and Negative Syndrome Scale (PANSS) subscale for verbal hallucinosis (sc 7 being the most severe), with response defined as at least 50% improvement from baseline after 10 day Study subjects consumed an average of 200 to 300 grams of ethanol per day, and had a history of 10 +/ abuse. At baseline, the mean PANSS verbal hallucinosis subscale scores were 6 +/- 2.3 and 5.9 +/- 0.6 and placebo group, respectively. Based on an intent-to-treat analysis, the mean PANSS score for valpro patients at the end of 10 days improved to 2 +/- 0.9 and 5 +/-1.4 for the placebo group (p=0.001). Secon of response based on the Clinical Global Impression (CGI) determined that 73.68% of valproate-treated "much" or "very much" improved compared to 26.31% of placebo-treated patients (p less than 0.001) (Al 2008).

4.5.A.3 Behavioral syndrome - Dementia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

In an open study, valproic acid therapy provided some improvement in 50% of dementia patients wit (Herrmann, 1998).

Valproic acid decreased behavioral disturbances in 5 of 10 elderly subjects with dementia in an oper (Kasckow et al, 1997).

Benefit was shown in a retrospective chart review of 25 elderly patients with dementia who received alone or in addition to a neuroleptic for behavioral disturbances (Narayan & Nelson, 1997).

c) Adult:

1) In an open study, valproic acid therapy provided some improvement in 50% of dementia patients with Agitated patients (n=16, 68 to 95 years old) with Alzheimer's disease, vascular dementia, or Lewy body d valproic acid 125 milligrams (mg) twice daily. Doses were increased to target serum levels of 350 to 700 Average daily doses were 1438 mg over the average trial length of 9 weeks. Benefits were seen within 4 the Clinical Global Impression Scale, 1 patient was rated as very much improved, 3 patients were much minimally improved and 8 were unchanged (Herrmann, 1998).

2) Valproic acid, initiated at 250 milligrams daily and titrated upward for a 2- to 5-week treatment duratio

behavioral disturbances in 5 of 10 elderly subjects with dementia in an open-label pilot study. The remai
either no change (n=3) or worsened behavior (n=2) (Kasckow et al, 1997).
3) According to a retrospective chart review of 25 elderly patients with dementia who received valproic a
addition to a neuroleptic for behavioral disturbances, 56% showed much or very much improvement on t
Impressions (CGI) scale. The average valproic acid dose and serum level was 1650 milligrams/day and
micrograms/milliliter, respectively (Narayan & Nelson, 1997).

4.5.A.4 Bipolar disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

A randomized, partially blinded trial reported improved efficacy with the combination of valproic acid
serum level of 50 to 125 micrograms/milliliter) and lithium as compared to lithium alone in 12 subject
disorder (Solomon et al, 1997).
A retrospective review of 36 patients with documented bipolar disorders refractory to lithium, neurole
antidepressants, and electroconvulsive treatments who had received valproic acid demonstrated tha
showed a marked response after the addition of valproic acid (McElroy et al, 1987).
Valproic acid was effective in bipolar disorder in mentally retarded adults (Sovner, 1989).
Twelve lithium non-responders suffering from bipolar disorder improved with the addition of valproic
1985).

c) Adult:

1) A randomized, partially blinded trial reported improved efficacy with the combination of valproic acid (
level of 50 to 125 micrograms/milliliter) and lithium as compared to lithium alone in 12 subjects with bipol
the time of enrollment, 50% had depression and 50% had mania. After at least 40 weeks average follow-
combination therapy were significantly less likely to experience a relapse or recurrence, but more likely t
to severe adverse effect(s) than patients on lithium monotherapy (Solomon et al, 1997).
2) Valproic acid was useful in 5 cases of bipolar disorder in mentally retarded adults (1 patient with Frag
with autistic disorder, two with rapidly cycling illness). Valproic acid was used in doses of 1000 to 2000 m
maintain blood levels in the usual therapeutic serum range of 50 to 100 mcg/mL. In 4 of these cases, the
antipsychotic medications was continued. Four of the 5 patients showed a significant response to valproi
improvements in sleep cycle, maladaptive behaviors, distractibility and assaultiveness; the other patient
a moderate response. Antipsychotic medications were successfully tapered or discontinued in all of the p
1989).
3) A retrospective review of 36 patients with documented bipolar disorders refractory to lithium, neurolep
antidepressants, and electroconvulsive treatments who had received valproic acid demonstrated that 44
showed a marked response after the addition of valproic acid . A therapeutic response was generally see
after attaining therapeutic levels (50 to 100 milligrams/liter) (McElroy et al, 1987).
4) Twelve lithium non-responders suffering from bipolar disorder improved with the addition of valproic a
received valproic acid alone as he did not tolerate lithium) . Initial Inpatient Multidimensional Psychiatric S
scores were reduced by an average of 49.6%, and the average improvement ratio comparing the course
valproic acid treatment with prior lithium prophylaxis was 5.3; ratios greater than 1 reflect improvement (E

b) Summary:

Five patients with incapacitating, intractable hiccups were successfully treated with valproic acid, aft
had failed (Jacobson et al, 1981a).

c) Adult:

1) Five patients with incapacitating, intractable hiccups were successfully treated with valproic acid, afte
granulated sugar, carbamazepine, chlorpromazine, and nasopharyngeal stimulation had failed. Valproic
initiated with 15 milligrams/kilogram/day in divided doses. The dose was gradually increased by 250 mg
until hiccups ceased or side effects occurred. Symptoms were eliminated in 4 patients and markedly imp
patient; however, therapy was discontinued after 6 weeks in the fifth patient due to mild gastrointestinal b
patient, hiccups returned to pretreatment levels following withdrawal of valproic acid. Two patients were
off valproic acid; however, 2 patients required continued therapy. Effective peak valproic acid plasma lev
to 96 mcg/mL. It appears that some patients may be successfully treated with valproic acid therapy and
this agent (Jacobson et al, 1981a).

4.5.A.13 Mania

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class III
Strength of Evidence: Adult, Category B; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid was successful in treating AIDS-related mania in 2 cases (RachBeisel & Weintraub, 19
Valproic acid may reduce the frequency, number, and severity of manic episodes in patients with sc
disorders (Puzynski & Klosiewicz, 1984).
Valproic acid was effective in the treatment of severe kleptomania and mixed mania refractory to flu
report (Kmetz et al, 1997).

c) Adult:

1) During the 26 to 51 months of valproic acid treatment of 15 patients with affective and schizoaffective
authors observed reduction in the number, length and severity of affective episodes especially mania. In
fragmentation of long and severe relapses into short and mild mania or depression occurred. The numbe
hospital admissions dropped in all patients (Puzynski & Klosiewicz, 1984).
2) Valproic acid, titrated to a serum level of 94 to 110 micrograms/milliliter, successfully treated AIDS-re
case reports (RachBeisel & Weintraub, 1997).
3) Valproic acid 2000 milligrams/day was effective in the treatment of severe kleptomania and mixed ma
fluoxetine in a 36-year-old female (Kmetz et al, 1997).

4.5.A.14 Manic bipolar I disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes (Stavzor(R) only); Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid, delayed-release ((Stavzor(R)) is indicated for the treatment of the manic episodes ass
bipolar disorder in adults (Prod Info STAVZOR(R) delayed release oral capsules, 2008).
In two 3-week, placebo-controlled, parallel-group studies, valproate had significantly superior results

of assessed outcomes for acute mania compared with placebo (Prod Info STAVZOR(R) delayed rel capsules, 2008).
Valproic acid has been effective in treating mania associated with bipolar disorder in clinical studies Brown, 1989; Post, 1989; McElroy et al, 1989; Calabrese & Delucchi, 1989; Pope et al, 1988; Grunz Prasad, 1984).
Efficacy of valproate for the treatment of children with pediatric bipolar disorder was not established outpatient, double-blind, placebo controlled trial (n=150; 76 on valproate) (Prod Info STAVZOR(R) d oral capsules, 2008; Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).

c) Adult:

1) In two 3-week, placebo-controlled, parallel-group studies, valproate had significantly superior results assessed outcomes for acute mania compared with placebo. In both studies, patients were initiated with milligrams (mg) orally three times a day and adjusted to achieve serum valproate levels in the range of 5 micrograms/milliliter (mcg/mL) in study 1, and 40 to 150 mcg/mL in study 2. At the completion of the stuc receiving a mean dose of 2402 mg/day in study 1 and a mean dose of 2006 mg/day in study 2. The perc who achieved a 30% or greater reduction from baseline in symptom scores in the valproate group compa was 60% vs 26% in study 1, and 58% vs 29% in study 2 (p less than 0.05 for each valproate group comp (Prod Info STAVZOR(R) delayed release oral capsules, 2008).

2) Valproic acid, delayed-release is indicated for the treatment of the manic episodes associated with bi adults (Prod Info STAVZOR(R) delayed release oral capsules, 2008). Valproic acid is effective in the trea suffering from bipolar disorder, even in those who have failed conventional therapy (Fawcett, 1989; Brow 1989; McElroy et al, 1989; Calabrese & Delucchi, 1989), and in bipolar disorder secondary to head injury 1988).

3) Four out of 5 acutely manic patients responded to intravenous valproate loading in an open study. Fiv received valproate 1200 or 1800 milligrams on day 1 followed by dosage individualization based on side mean baseline Bech-Rafaelson Mania Rating Scale score was 30.2 which improved to 8 by day 5. One p been unresponsive to oral valproate. On day 5 most were switched to oral dosing. The authors believe th intravenous loading a quick saturation of plasma-binding proteins occurred which could have contributed action (Grunze et al, 1999).

4) One uncontrolled study reported improvement in 5 of 7 patients with mania given valproic acid (up to daily) for 6 weeks. All patients had not responded to previous therapy with lithium and neuroleptics (Pras

d) Pediatric:

1) Efficacy of valproate for the treatment of children with pediatric bipolar disorder was not established in outpatient, double-blind, placebo controlled trial (n=150; 76 on valproate). Children 10 to 17 years of age bipolar disorder received an initial daily dose of valproate of 15 milligrams/kilogram (mg/kg)(max 750 mg dosing used to achieve a clinical response and/or target serum valproate level of 80 to 125 mcg/mL with of 35 mg/kg. Change from baseline on the YMRS scale at final evaluation was the primary efficacy endp maximum daily dose of 1457 mg (27.1 mg/kg) and mean final serum valproate concentration of 80 mcg/m during the study (Prod Info STAVZOR(R) delayed release oral capsules, 2008; Prod Info DEPAKOTE(R) release oral tablets, 2008).

4.5.A.15 Mental disorder - Mood disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category C; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Although data is limited, valproic acid appears useful in the management of affective disorders in me children and adults (Kastner et al, 1990; Sovner, 1989).

c) Adult:

1) Although data is limited, valproic acid appears useful in the management of affective disorders in mer children and adults. Valproic acid was noted in studies to have advantages over carbamazepine, lithium, antipsychotics for use in mentally retarded patients since it does not carry the same risks of tremor, incor impairment, worsening of mood, and increased seizures associated with other classes of medication (Ka Sovner, 1989).

2) Valproic acid was useful in 5 cases of bipolar disorder in mentally deficient adults (1 patient with Frag with autistic disorder, two with rapidly cycling illness) . Valproic acid was used in doses of 1000 to 2000 r maintain blood levels in the usual therapeutic serum range of 50 to 100 mcg/mL. In 4 of these cases, the antipsychotic medications was continued. Four of the 5 patients showed a significant response to valproi improvements in sleep cycle, maladaptive behaviors, distractibility and assaultiveness; the other patient a moderate response. Antipsychotic medications were successfully tapered or discontinued in all of the p 1989).

d) Pediatric:

1) Significant improvement was seen with valproic acid in 3 mentally deficient children and adolescents disorders characterized by irritability, aggressiveness, self-injurious behavior, hyperactivity and sleep dis symptoms had been unresponsive to previous therapy or the patient had been unable to tolerate side eff with previous medications. Valproic acid 1500 to 3000 milligrams daily, at blood levels of 78 to 111 mcg/

significant improvement in all 3 patients (Kastner et al, 1990).

ADOLESCENTS

c) Adult:

1) Two multicenter, randomized, placebo-controlled clinical trials established the efficacy of valproate fo
migraine headache. In both trials, patients with a history of migraine with or without aura (of at least 6 mo
who were experiencing at least 2 migraine headaches a month during the previous 3 months were recrui
following a 4-week single-blind placebo baseline period, patients were randomized to valproate or placeb
treatment phase, comprised of a 4-week dose titration followed by an 8-week maintenance period. In the
aged 26 to 73 years), 90 patients completed the 8-week maintenance period. Patients in the valproate gr
with doses ranging from 500 to 2500 milligrams (mg) with a mean treatment dose of 1087 mg/day resulti
trough total valproate level of 72.5 micrograms/milliliter (mcg/mL)(range, 31 to 133 mcg/mL). During the t
the mean 4-week migraine headache rate was 5.7 in the placebo group compared to 3.5 in the valproate
significantly different). In the second study (n=176; aged 17 to 76 years), 137 patients completed the 8-w
period. Patients were randomized equally to one of 3 valproate groups (500, 1000, or 1500 mg/day) or p
were initialized with 250 mg and titrated up every 4 to 8 days to the randomized target dose. The mean t
valproate levels during the treatment period were 39.6, 62.5, and 72.5 mcg/mL in the valproate 500, 100
mg/day groups, respectively. During the treatment phase, the mean 4-week migraine headache rates adj
differences in baseline rates, were 4.5 in the placebo group compared to 3.3, 3, and 3.3 in the valproate
1500 mg/day groups, respectively, based on intent-to-treat results. Migraine headache rates in the comb
1000/1500 mg group were significantly lower than in the placebo group (Prod Info STAVZOR(R) delayed
capsules, 2008).

2) Valproic acid in doses adjusted to produce trough valproate concentrations of 70 to 120 milligrams/lite
effective in the prophylaxis of migraine headache. In a double-blind trial, 107 patients were randomized t
either divalproex or placebo for a period of 12 weeks. Forty-eight percent of divalproex-treated patients e
or greater reduction in the frequency of migraine headaches compared to 14% of placebo-treated patien
common side effects noted in patients treated with divalproex were weakness, fatigue, nausea, and vom
only 13% of patients required discontinuation of therapy (Mathew et al, 1995). Another 12-week controlle
demonstrated that 44% of valproic acid-treated patients had at least a 50% reduction in migraine frequer
to 21% of placebo-treated patients. This dose-ranging trial also found no significant difference between t
(mg), 1000 mg, or 1500 mg daily dose in preventing migraine (Klapper et al, 1997). An accompanying ed
that valproic acid be considered for migraine prophylaxis in patients with coexisting epilepsy or mania, or
(s) to beta-blockers (Mathew, 1997).

3) Valproic acid has been effective as prophylaxis against migraine headache (common and classic) . T
in open fashion to 22 patients. Initial doses were 600 milligrams orally twice daily, followed by dosing adj
achieve serum levels of 700 micromol/liter in the morning before the first daily dose. Eleven patients wer
attacks during the duration of follow-up (mean, 6.5 months; range, from 3 to 12 months). Six patients had
headache frequency, and no effect was observed in 1 patient. Four patients were withdrawn from the stu
cooperation. Adverse effects consisted of hepatotoxicity (1 patient), weight gain (3 patients), drowsiness
paresthesias (2 patients who had also used ergotamine suppositories chronically prior to valproic acid) (S

d) Pediatric:

1) Efficacy of valproate was not established for migraine prophylaxis in a single, double-blind, placebo-c
group, four equal armed (placebo, 250 milligrams (mg), 500 mg, and 1000 mg) study (n=304; 231 on val
patients ages 12 to 17 years old. The study consisted of a 4 week baseline period followed by a 12 week

period (including an initial 2 week titration period) with placebo compared to each dose. Reduction from l
week migraine headache rate was the primary efficacy endpoint (Prod Info STAVZOR(R) delayed releas
2008; Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008).
2) Valproic acid 15 to 30 milligrams/kilogram/day divided into 2 doses has been used for the prophylaxis
children . Monitor valproic acid concentrations after 2 to 3 weeks of therapy and after dosage increases.
follow-up should be done with height and weight observations (Hamalainen, 1998).

4.5.A.17 Myelodysplastic syndrome

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid monotherapy resulted in a response rate of 44% in 23 patients with myelodysplastic sy
(Kuendgen et al, 2004).

c) Adult:

1) A 44% response rate was achieved with valproic acid (VPA) monotherapy in 23 patients with myelody
syndromes (MDS) and acute myelogenous leukemia secondary to MDS (sAML/MDS). In an open-label,
patients, aged 35 to 78 years, with MDS for 3 to 122 months, received daily VPA monotherapy (n=18) or
combination with all trans retinoic acid (ATRA) 80 milligrams/meter squared (mg/m(2)) daily (in two divid
1 through 7 every other week (n=5). VPA dose was titrated to maintain serum levels between 50 and 10
micrograms/milliliter (mcg/mL). Patients who failed monotherapy or relapsed were switched to combinati
Response was rated according to the International Working Group (IWG) criteria. A response was obser
(44%) patients receiving VPA monotherapy. The median time to response was 30 days (range, 14 to 38
median VPA dose of 1250 mg (range, 900 to 2550 mg) and median duration of 6 months (range, 2 to 23
Hematologic improvement was observed in 7 patients and a partial response in 1 patient. Relapse occur
a median of 4 months, of which, 4 patients were switched to combination therapy. Two of these 4 patient
therapy for another 11 and 16 months. Stable disease was seen in 4 patients at a median duration of 5 r
patients had progressive disease and were switched to combination therapy without success. None of th
receiving combination therapy initially responded to therapy. Of note, all 3 patients considered low-risk a
international prognostic scoring system showed a major response, while only 1 patient considered high-r
minor response. Furthermore, 3 of 9 patients with an elevated blast count achieved a significant reductio
marrow blasts. Therapy was well tolerated as only one patient discontinued VPA because of vertigo and
and thrombocytopenia were attributed to study medication in 2 patients (Kuendgen et al, 2004).

4.5.A.18 Myoclonic seizure

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Patients with juvenile myoclonic epilepsy (JME) (n=76) were successfully treated with lower than us
valproic acid, and after a period of 2 years free from seizures, could be maintained on still lower dos
al, 2001).
Combination therapy with valproic acid (1500 to 1800 mg daily), clonazepam (6 to 10 mg daily) and
to 100 mg daily) was effective in improving severe progressive myoclonus epilepsy in adults in a lon
clinical study (Iivanainen & Himberg, 1982).

c) Adult:

1) Patients with juvenile myoclonic epilepsy (JME) were successfully treated with lower than usual dose
and after a period of 2 years free from seizures, could be maintained on still lower doses. Seventy-six pa
diagnosed with JME, were initially treated with sodium valproate 15 milligrams/kilogram/day (mg/kg/day)
controlled at that dose continued with the same dose. Doses were increased to 20 to 40 mg/kg/day in th
controlled. In those who were not controlled at 40 mg/kg/day, a second drug was added. Sixty-three perc
were controlled at the 15 mg/kg/day dose, 25% at 20 mg/kg/day, 4% at 40 mg/kg/day, and 8% required a
second drug. After a seizure-free period of 2 years, 22% could be maintained on 3 to 5 mg/kg/day, 33%
mg/kg/day, and 42% required more than 9 mg/kg/day (Panagariya et al, 2001).
2) Combination therapy with valproic acid (1500 to 1800 milligrams (mg) daily), clonazepam (6 to 10 mg
phenobarbital (50 to 100 mg daily) was effective in improving severe progressive myoclonus epilepsy in
term prospective clinical study. All previous medications (phenytoin and other antiepileptic agents) were
to initiation of combination therapy. After 6 years of continuous follow-up, improvement was still observe
not benefited from previous anticonvulsant therapy at optimal doses. Effective plasma levels evaluated i
28 milligrams/liter (mg/L) for valproic acid, 0.05 mg/L for clonazepam, and 19 mg/L for phenobarbital (Iiva
Himberg, 1982).

4.5.A.19 Myoclonus

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid was reported effective in 3 patients with nonepileptic myoclonus (Sotaniemi, 1982).

c) Adult:

1) Valproic acid 900 to 1200 milligrams daily was reported effective in 3 patients with nonepileptic myocl with post-anoxic myoclonus and 2 with nocturnal myoclonus). These patients had no epileptic manifestat seizure activity and no other medications were given. Valproic acid may have a role in the treatment of m however further studies are warranted. The mechanism of action in the condition is unclear (Sotaniemi, 1

4.5.A.20 Nelson syndrome

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Clinical outcomes have varied in studies on the efficacy of valproic acid in the treatment of Nelson's et al, 1984; Buckingham, 1983; Jones et al, 1981; Mercado-Asis et al, 1997a; Loli et al, 1988; Loli et

c) Adult:

1) Numerous studies have documented the efficacy of valproic acid in the treatment of Nelson's syndror Cushing's disease. Decreases in circulating ACTH levels have been documented in patients receiving va or in combination with diazepam, cyproheptadine, or metyrapone (Glaser et al, 1984; Buckingham, 1983 1981). Other studies have failed to find any effects with valproic acid.

2) Valproic acid alone or in combination with cyproheptadine failed to suppress plasma adrenocorticotro (ACTH) secretion in Nelson's Syndrome. Six women with Nelson's Syndrome had their ACTH measured placebo, cyproheptadine, valproic acid, bromocriptine; and the combination of cyproheptadine and valpro combination of bromocriptine, cyproheptadine and valproic acid. Only bromocriptine caused a significant plasma ACTH (P less than 0.05), as did the combination of the 3 drugs (P less than 0.05). However, the the 3 drugs did not significantly exceed the effect of bromocriptine alone (Mercado-Asis et al, 1997a).

3) Chronic valproate acid therapy with 600 milligrams/day was effective in reducing the size of an adren hormone (ACTH)-secreting pituitary macroadenoma in a patient with Nelson's syndrome (Loli et al, 1988 1.5 years, the patient received 2 courses of therapy with valproic acid lasting 4 months each; both treatm tumor reduction that was documented by computed tomography. More studies are required to evaluate t valproic acid in this clinical setting.

4) Another study failed to show the effectiveness of valproic acid in 8 patients with Nelson's syndrome. A unaffected by valproic acid administration. They concluded that the GABAergic system plays a role in the ACTH hypersecretion in Nelson's syndrome (Loli et al, 1984).

4.5.A.21 Obsessive-compulsive disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproate was effective for obsessive compulsive disorder in 1 case report (Cora-Locatelli et al, 199

c) Adult:

1) Valproate was effective for obsessive compulsive disorder in a 35-year-old man who stopped working obsessed with touching his parents 70 to 80 times per day. He had previously discontinued fluoxetine du agitation. Fluoxetine 5 mg was restarted along with valproate 250 milligrams (mg) in the morning and 50 evening to alleviate side effects. After 2 weeks he was able to resume work and felt less anxious and mo control" (Cora-Locatelli et al, 1998).

4.5.A.22 Panic disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid was effective in a case report of a patient with panic disorder associated with multiple s & Cassano, 1996).

c) Adult:

1) Valproic acid was effective in a case report of panic disorder associated with multiple sclerosis. After with alprazolam, imipramine, and clonazepam was ineffective, valproic acid titrated to a dose of 1500 mil caused a complete disappearance of symptoms after two months. The patient remained symptom-free a (Marazziti & Cassano, 1996).

4.5.A.23 Periodic limb movement disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Sleep quality and duration were improved in 6 outpatients given long-term valproate for periodic limb disorder (Ehrenberg et al, 2000).

c) Adult:

1) Sleep quality and duration were improved in 6 outpatients (aged 28 to 62 years, mean 41.5 years) giv valproate for periodic limb movement disorder. After a mean 6 months of therapy, dosages of valproate r 600 milligrams taken at bedtime. Polysomnographic findings included a significant increase in sleep effic significant decrease in stage 1 (light) sleep (p=0.04), significant increases in stages 3 and 4 (deep) sleep change in stage 2 (rapid eye movement-REM) sleep. Mean total sleep time increased from 5.8 to 6.4 hou trend toward a reduction in the number of periodic limb movements per hour of sleep and in the number arousals (p=0.062). Daytime alertness was subjectively reported to be improved. No subject discontinue the end of the study; subsequently 2 patients terminated the drug, 1 due to weight gain and the other du side effects (Ehrenberg et al, 2000).

4.5.A.24 Sedative withdrawal delirium

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Four controlled studies and several case reports and case series suggest that valproate may be effe and benzodiazepine withdrawal (Harris et al, 2000).

c) Adult:

1) Four controlled studies and several case reports and case series suggest that valproate may be effec and benzodiazepine withdrawal. In contrast, one double-blind, controlled trial failed to support the use of benzodiazepine withdrawal. In an open-label study, there were no significant differences in subjective alc symptoms between valproate- and phenobarbital-treated patients, nor were there differences in blood pr rate responses associated with the 2 agents. In another comparative study, valproate and chlormethiazo have similar efficacy in ethanol withdrawal, but physiological effects were poorly documented. A double-l trial might have supported this use of valproate, but dismissed the treatment drug (valproate) because of association with GI distress (probably related to use of the valproic acid form of the drug). In a study com and lorazepam, valproate was found to be effective and well-tolerated in the treatment of ethanol withdra report, two manic schizoaffective patients had successful withdrawal from ethanol when valproate 20 milligrams/kilogram/day was combined with low-dose lorazepam. A patient with panic disorder failed to b clonazepam until valproate was added to therapy. Another report describes 4 cases of protracted withdra during tapering of benzodiazepines; the symptoms were notably eased after the addition of valproate. Tw reported in which valproate prevented alcohol or benzodiazepine relapse (Harris et al, 2000).

4.5.A.25 Seizure, Multiple seizure types; Adjunct

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (10 years and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid is indicated as adjunctive therapy for multiple seizure types (Prod Info DEPAKENE(R) syrup, 2006; Prod Info STAVZOR(R) delayed release oral capsules, 2008).

Valproic acid, orally or rectally, was reported effective in preventing generalized tonic-clonic seizures

withdrawal of anticonvulsant agents in seizure patients undergoing intensive monitoring for diagnost purposes (Rosenfeld et al, 1987).
Valproic acid has been demonstrated effective in a variety of seizure types which include absence s seizures, and tonic-clonic seizures (grand mal), including patients who have been unresponsive to o anticonvulsants (Rimmer & Richens, 1985g; Sato et al, 1982a; Jeavons et al, 1977).

c) Adult:

1) General Information

a) Valproic acid is indicated as adjunctive therapy in patients with multiple seizure types such as ge Valproic acid has been effective in generalized epilepsy (Rimmer & Richens, 1985g; AMA Departme Sato et al, 1982a; Jeavons et al, 1977); however, carbamazepine is generally preferred because of (Young & Koda-Kimble, 1995a).

2) Clinical Trials

a) Valproic acid in loading doses of approximately 12.5 milligrams/kilogram (mg/kg), orally or rectall 15.9 mg/kg) was reported effective in preventing generalized tonic-clonic seizures following withdrav anticonvulsant agents in seizure patients undergoing intensive monitoring for diagnostic and therape Seizure activity was prevented in 23 of 35 patients (66%) following a single loading dose. Serum co ranging from 284 to 458 micromole/L were observed 1.5 hours following administration in 6 of 8 pati These data suggest the benefits of valproic acid given orally or rectally in patients undergoing anticc withdrawal. The rectal route appears to have a place in the treatment of patients unable to take oral to GI disorders, surgery or coma (Rosenfeld et al, 1987).

b) Valproic acid is indicated as adjunctive therapy in patients with multiple seizure types. Valproic a demonstrated effective in a variety of seizure types which include absence seizures, partial seizures seizures (grand mal), including patients who have been unresponsive to other anticonvulsants. The more effective in generalized epilepsy than partial seizures, and appears most useful for the treatme absence seizures (petit mal) and photosensitive epilepsy (Rimmer & Richens, 1985g; Sato et al, 198 1977). Although valproic acid is considered a first-line therapy for treating generalized tonic-clonic s or complex partial seizures, carbamazepine is generally preferred because of its lesser toxicity. Etho generally preferred over valproic acid for treatment of absence seizures because it is equally effectiv tolerated (Young & Koda-Kimble, 1995a). Oral and rectal valproic acid have been effective in refract epilepticus (Vajda et al, 1977; Manhire & Espir, 1974). The drug is usually combined with other antic producing seizure reduction in 75 to 100% in greater than 40% of patients with intractable epilepsy, improvement being seen in myoclonic seizures, absence seizures and grand mal seizures (Simon & However, single-agent therapy has also been effective (Rimmer & Richens, 1985g; Turnbull et al, 19 1983; Covanis et al, 1982a; Callaghan et al, 1982a; Shakir et al, 1981).

c) In 52 severely brain damaged (mental retardation) patients with intractable seizures, valproic aci their drug regimens. Sixty-one percent improved clinically. Valproic acid significantly reduced the fre generalized tonic-clonic seizures, generalized myoclonus, absence and atonic seizures. There was correlation between clinical improvement and reduction of EEG paroxysmal activity (Chayasirisobho 1983).

4.5.A.26 Social phobia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid improved Liebowitz Social Anxiety Scale (LSAS) scores in 17 patients with social anxie open-label, 12-week study (Kinrys et al, 2003).

c) Adult:

1) Valproic acid improved Liebowitz Social Anxiety Scale (LSAS) scores in 17 patients with social anxiet open-label, 12-week study. Valproic acid therapy was initially dosed at 250 milligrams (mg) twice daily, w tolerated, doses were increased to 1000 mg daily. Doses were adjusted according to tolerability and ther however doses were kept between 500 mg daily and 2500 mg daily. Intent to treat analysis demonstrate decrease in the total LSAS score of 19.1 (p less than 0.0001). Individual LSAS scores also showed a sig improvement in fear and avoidance symptoms (p less than 0.0001). Mild cases of nausea, headache, so dizziness, and fatigue were reported with the use of valproic acid in this study group. The authors ackno sample size, and the lack of placebo control and blinding were limitations in study design (Kinrys et al, 2(

4.5.A.27 Stiff-man syndrome

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Sodium valproate showed efficacy for stiff man syndrome in one case report (Spehlmann et al, 1981

c) Adult:

1) Stiff man syndrome was described in a 55-year-old male which was poorly treated by diazepam 130 r clonazepam 18 mg, and baclofen 60 mg in divided doses each day. Valproate was gradually added to th increased to a dose of 2 grams daily. The patient showed marked improvement and was able to walk wit and without his cane. Although the effectiveness of sodium valproate is only cited in one case report, it d trials for this indication (Spehlmann et al, 1981).

4.5.A.28 Tinnitus

See Drug Consult reference: DRUG THERAPY OF TINNITUS

4.5.A.29 Visual hallucinations

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproic acid was efficacious in controlling visual hallucinations associated with Charles Bonnet syn reports (Hori et al, 2000).

c) Adult:

1) Two psychologically normal elderly women (ages 73 and 77) experiencing complex visual hallucinatic sensory deprivation (decreased visual acuity) and mild cerebral dysfunction were successfully treated wi 400 milligrams (mg) to 800 mg daily. The 73-year-old had partial resolution of symptoms at 400 mg daily disappearance of all hallucinations with 800 mg daily. The 77-year-old woman was started on 200 mg da increased to 400 mg daily, at which point she was able to sleep and experienced no more hallucinations. experienced adverse effects (Hori et al, 2000).

Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

May be effective for treatment of alcohol withdrawal and prevention of relapse (Reoux et al, 2001a;

See Drug Consult reference: DRUG THERAPY OF ETHANOL WITHDRAWAL

c) Adult:

1) Divalproex sodium was more effective than placebo in decreasing the need for oxazepam during moc withdrawal. Thirty-six subjects (75% white, 97% male) with a score of at least 10 on the Clinical Institute Assessment-Alcohol revised instrument (CIWA-Ar) completed this 7-day, randomized, double-blind, plac study. All patients received an initial 30 milligram (mg) dose of oxazepam; additional 30 mg doses of oxa every hour if the subject's CIWA-Ar score was 10 or higher. The divalproex group received 500 mg of div (sprinkle formulation) three times a day in addition to the oxazepam. The divalproex group required signi (p=0.033) oxazepam than the placebo group (85 +/- 63.64 mg vs. 111.7 +/- 119.5 mg, respectively) to m withdrawal symptoms. Six percent (1 of 18) of subjects in the divalproex group and 40% (7 of 18) of the p had an increase in withdrawal symptoms (1 point and 3 points respectively) compared to baseline. Adver similar between groups with somnolence reported significantly more frequently (p less than 0.05) in the d (Reoux et al, 2001a).

2) A 51-year-old man with a 30-year history of heavy drinking was successfully withdrawn from alcohol u sodium. On admission, he was found to meet diagnostic criteria for alcohol dependency (DSM-IV), and e liver enzymes and an increased mean corpuscular volume. He had no other mental or physical co-morbi the Clinical Institute Withdrawal Assessment-Alcohol revised instrument (CIWA-Ar) increased from an ini at 8 hours post-admission. He began divalproex detoxification with a loading dose of 750 milligrams (mg) mg/kilogram body weight; the second half of his loading dose 750 mg was given 6 hours later. During the his CIWA-Ar score decreased to below 6, where it remained for the duration of his hospital stay. He was 4 (divalproex level 83 mg/milliliter), and maintained on a dose of divalproex 750 mg twice daily for 6 wee abstinence during the 6 weeks of follow-up. His laboratory results improved. Divalproex was tapered and patient remained abstinent. According to the author, advantages of divalproex over benzodiazepines for include its lack of abuse potential and absence of synergistic reaction with alcohol, and, in contrast to oth anticonvulsants, divalproex can be initiated with an oral loading dose to effect a rapid onset of action (Lo

versus 23.3% divalproex) and stomach pain (10% lithium versus 23.3% divalproex) were also noted, but
significant. Other adverse events reported in over 5% of patients in phase II were tremor, nausea, diarrh
appetite, upper respiratory congestion, fever and sore throat. Five patients withdrew from the study due t
(alopecia, one from each; abnormal thyrotropin blood level, one on divalproex; thrombocytopenia, one or

enuresis, one on lithium) (Findling et al, 2005).

4.5.B.5 Bipolar II disorder, Maintenance

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

No difference in efficacy was found between divalproex sodium and lithium sodium for the maintena pediatric bipolar I or II disorder (Findling et al, 2005).

c) Pediatric:

1) No difference in efficacy was found between divalproex sodium and lithium sodium for the maintenan pediatric bipolar I or II disorder in a double-blind, randomized study. Patients (n=139; mean age 10.8 +/- enrolled if they had a primary diagnosis of bipolar I or II disorder and had experienced at least one manic episode within the past 3 months. In phase I (stabilization phase), all patients received open-label combi immediate release lithium sodium and divalproex sodium for up to 20 weeks. Lithium was titrated to a tar mg/kg/day and adjusted to maintain serum levels of 0.6 to 1.2 millimoles/liter (mmol/L). Divalproex was ti dose of 20 mg/kg/day and adjusted to maintain serum levels of 50 to 100 micrograms/milliliter (mcg/mL). remission criteria (40 or less on the Children's Depression Rating Scale-Revised (CDRS-R), 12.5 or less Mania Rating Scale (YMRS), and at least 51 on the Children's Global Assessment Scale (CGAS)) for 4 c and were able to tolerate the minimum serum concentration levels of lithium or divalproex while receiving stabilizers, antipsychotics, or antidepressants were eligible for enrollment in phase II (double-blind maint phase II, patients were randomized to receive either lithium or divalproex, maintaining desired serum lev weeks. Patients with attention-deficit/hyperactivity disorder were allowed to continue prescribed stimulan (maximum dosage 6 micrograms/kg/day) at stable doses 4 weeks prior to phase II. One hundred thirty-n treated in phase I, with 60 continuing into phase II (lithium, n=30; divalproex, n=30). Sixty-three percent (discontinued the study due to mood-related reasons. Median time to mood relapse was 114 days (stand 57.4 days) for patients treated with lithium and 112 days (SE +/- 56 days) for patients treated with divalpr Median time to discontinuation for any reason was 91 days (SE +/- 30.1 days) for patients treated with lit (SE +/- 19.9 days) for patients treated with divalproex (p=0.72). Statistically significant differences were r frequency of reported emesis (30% lithium versus 10% divalproex; p=0.05), enuresis (30% lithium versus p=0.02), and increased thirst (16.7% lithium versus 0% divalproex). Differences in frequency of headach versus 23.3% divalproex) and stomach pain (10% lithium versus 23.3% divalproex) were also noted, but significant. Other adverse events reported in over 5% of patients in phase II were tremor, nausea, diarrh appetite, upper respiratory congestion, fever and sore throat. Five patients withdrew from the study due t (alopecia, one from each; abnormal thyrotropin blood level, one on divalproex; thrombocytopenia, one or enuresis, one on lithium) (Findling et al, 2005).

4.5.B.6 Borderline personality disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Preliminary results suggest possible efficacy; more studies in larger trials needed (Townsend et al, 2

c) Adult:

1) In a small, prospective, open-label case series, some patients with borderline personality disorder an (DSM-IV) showed improvement during a course of divalproex sodium therapy. Of the 10 patients enrolle 8-week study; one each completed weeks 3, 4, 5, and 6; one dropped out after the initial visit. Divalproex initiated at 250 milligrams (mg) twice daily, and could be increased by 250 to 500 mg at weekly visits if in not seen. At their last visit (whenever it occurred), mean dose of responders was 1125 mg/day compared for non-responders. Six of nine evaluable subjects were rated as "much improved" or better on the Clinic Impression Scale (CGI) at their last weekly visit. Scores on the Mania Rating Scale (MRS) declined, but extent. In 3 responders, serum valproic acid concentrations ranged from 51 to 113 nanograms/milliliter. F studies were suggested by the investigators (Townsend et al, 2001).

2) A pilot study suggests that a 10-week course of divalproex sodium may provide symptomatic improve with borderline personality disorders (DSM-IV axis II); however, the validity of these results are limited du out rate and small sample size. In a double- blind, randomized (2:1 ratio) manner, 16 patients were assig sodium or placebo. Six patients completed the study and 10 dropped out. Overall, 100% of those assigne withdrew, while 50% allocated to divalproex sodium withdrew. No one withdrew due to side effects. Com baseline, divalproex sodium-treated patients had significantly improved scores on the Clinical Global Imp Improvement scale (CGI-I) (p=0.006). Of the 6 patients, 5 were considered to be responders, ie, were m very much improved, based on the CGI-I. On the Global Assessment Scale (assessment of overall funct treated with divalproex sodium had significantly improved scores compared with baseline (p=0.003). Son

among those in the divalproex sodium group was shown on the Beck Depression Inventory (BDI) and sli
occurred on the Aggression Questionnaire (AQ), related to aggressive feelings and actions. Divalproex s
as 250 milligrams at bedtime and gradually titrated to doses sufficient to maintain serum levels of 80 mic
the highest tolerated dose. The authors concluded that more study of divalproex sodium in this patient p
warranted (Hollander et al, 2001).

4.5.B.7 Brain injury - Seizure; Prophylaxis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Not effective prophylaxis (Glantz et al, 1996)

c) Adult:

1) Divalproex is not effective for the prophylaxis of seizures in patients with brain tumors. In a study of 7
newly-diagnosed brain tumors, divalproex or placebo was given within 14 days of diagnosis. Divalproex
adjusted to achieve trough levels in the range of 50 to 100 mcg/mL; the median duration of follow-up wa
five percent of patients treated with divalproex suffered seizures compared to 24% of patients treated wi
authors conclude that anticonvulsant therapy is not indicated in patients with brain tumors unless they su
(Glantz et al, 1996).

4.5.B.8 Cluster headache

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective in 2 cases of cluster headaches with migraine-like features (Wheeler, 1998)

c) Adult:

1) Two patients with cluster headache and prominent migraine-like features had their headaches remit v
use (Wheeler, 1998). Both patients had been unresponsive to multiple medications and one to surgical i
first, a 37-year-old man with a 15-year history of cluster headaches with an atypical visual aura, received
milligrams (mg) twice daily. Headache remission occurred within 2 months. Divalproex was tapered after
remained in remission. The second, a 55-year-old man with a 16-year history of cluster headaches alon
without aura, was given divalproex 250 mg 3 times daily with 750 mg nightly. Headache remission occur
months. He was then slowly tapered down to 375 mg daily.

4.5.B.9 Complex partial epileptic seizure

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (10 years and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated in adults and children age 10 years and older as monotherapy or adjunctive therapy for co
seizures occurring in isolation or in association with other types of seizures (Prod Info DEPAKOTE(R
release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Info DEPAK
release oral tablets, 2006)

c) Adult:

1) Monotherapy

a) In a dose-comparison study of divalproex sodium monotherapy in 265 patients converted from ot
there was either no change or a reduction in complex partial seizure rates in 54% and 64% of patien
and high-dose divalproex sodium monotherapy, respectively. Patients who experienced 2 or more C
despite adequate doses of carbamazepine, phenobarbital, primidone, or phenytoin monotherapy we
receive divalproex sodium with either low-dose (mean concentration, 71 micrograms/milliliter (mcg/m
high-dose (mean concentration, 123 mcg/mL; n=131) monotherapy. Following a 2-week transition p
to divalproex sodium, the results at 8 weeks demonstrated a greater reduction in seizures in the high
seizures at baseline to 10.7) compared to the low-dose group (14.2 seizures at baseline to 13.8) (p
should be noted that there was no control group in this study, and less than 50% of the patients ran
the study (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DEPAKOTE(
capsules, 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006).

2) Adjunctive Therapy

a) In a 16 week, placebo-controlled study of 144 patients with complex partial seizures (CPS), the u sodium as adjunctive therapy was more effective in reducing the incidence of seizure compared with who experienced 8 or more CPS per 8 weeks despite therapeutic levels of carbamazepine or pheny were randomized to add-on therapy with either divalproex sodium (n=75) or placebo (n=69). The res demonstrated a reduction from baseline of 16 seizures to 8.9 for divalproex sodium, compared with seizures at baseline to 11.5 (p less than or equal to 0.05). Comparing divalproex sodium to placebo, vs 23% of patients who had at least a 50% reduction in CPS rate, respectively (Prod Info DEPAKOT extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) sprinkle oral capsules, 2008; Prod Inf delayed-release oral tablets, 2006).

b) Add-on therapy with divalproex was effective in reducing seizure frequency in a group of 137 pat partial seizures. Patients taking either carbamazepine or phenytoin, whose seizures were inadequat monotherapy, were randomized to either divalproex sodium or placebo after optimization of their mo regimen. The dose of divalproex was slowly adjusted to a maximum of 90 milligrams/kilogram/day. T divalproex resulted in a median seizure reduction of 7.9 seizures in eight weeks compared to 2.5 in treated with placebo. Six of the divalproex-treated patients became seizure-free during the study pe al, 1996).

4.5.B.10 Headache disorder, chronic

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Divalproex sodium demonstrated effectiveness in the treatment of adult patients with chronic daily h retrospective study (Freitag et al, 2001).

c) Adult:

1) Results from a retrospective study (n=138) indicated that divalproex sodium was effective in the treat patients with chronic daily headache. In this study, 67% (93 of 138) of the patients had at least a 50% re headache frequency (Freitag et al, 2001).

4.5.B.11 Manic bipolar I disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes (tablets, delayed-release tablets, extended-release tablets); Pediatric, no
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated for the treatment of acute manic or mixed episodes associated with bipolar disorder (with psychotic features) (Prod Info DEPAKOTE(R) ER extended-release oral tablets, 2008; Prod Info DE delayed-release oral tablets, 2006)

Ineffective in the treatment of manic symptoms in elderly patients with dementia (Tariot et al, 2001)

Efficacy of divalproex sodium extended-release tablets was not established in a single 4-week outpa placebo controlled trial (n=150; 76 on divalproex sodium) for the treatment of pediatric bipolar disorc DEPAKOTE(R) ER extended-release oral tablets, 2008).

c) Adult:

1) In two 3-week, placebo-controlled, parallel-group studies, divalproex sodium had significantly superio measures of assessed outcomes for acute mania compared with placebo. In both studies, patients were divalproex sodium delayed-release 250 milligrams (mg) orally three times a day and adjusted to achieve levels in the range of 50 to 100 micrograms/milliliter (mcg/mL) in study 1, and 40 to 150 mcg/mL in study completion of the study, patients were receiving a mean dose of 2402 mg/day in study 1 and a mean dos in study 2. The percentage of patients who achieved a 30% or greater reduction from baseline in sympto divalproex sodium group compared with placebo was 60% vs 26% in study 1, and 58% vs 29% in study for each divalproex group compared to placebo) (Prod Info DEPAKOTE(R) delayed-release oral tablets,

2) In a 3-week, randomized, double-blind, parallel-group study, adult patients diagnosed with bipolar I di mixed type, hospitalized with acute mania treated with divalproex sodium extended-release had significa Mania Rating Scale (MRS) scores compared with placebo. Patients received an initial dose of divalproex release 25 milligrams/kilogram (mg/dg) orally once a day, increased by 500 mg/day on day 3, and then a a plasma valproate level of 85 to 125 microgram/milliliter (mcg/mL). At the end of the study, the mean da mg (range, 1500 to 5500 mg), and mean valproate plasma levels were 89.5 mcg/mL (Prod Info DEPAKC extended-release oral tablets, 2008).

3) Divalproex sodium (target dosage of 20 milligrams/kilogram/day) did not improve signs and symptom associated with dementia in elderly patients during a double-blind, placebo-controlled study (n=172), but symptoms of agitation. In this 6-week trial, there was no significant difference between drug and placebo from the Brief Psychiatric Rating Scale (BPRS), but scores on the Cohen-Mansfield Agitation (CMAI) Inv

significant improvement in the divalproex sodium-treated group. Twenty-two percent of divalproex sodiur and 4% of patients who received placebo withdrew from the study because of adverse effects, primarily s et al, 2001).

d) Pediatric:

1) Efficacy of divalproex sodium extended-release tablets was not established in a single 4-week outpat placebo controlled trial (n=150; 76 on divalproex sodium) for the treatment of pediatric bipolar disorder. C years of age, with pediatric bipolar disorder received an initial daily dose of divalproex sodium of 15 milli (mg/kg)(max 750 mg) with flexible dosing used to achieve a clinical response and/or target serum valpro 125 mcg/mL with a maximum dose of 35 mg/kg. Change from baseline on the YMRS scale at final evalu primary efficacy endpoint. A mean maximum daily dose of 1457 mg (27.1 mg/kg) and mean final serum v concentration of 80 mcg/mL were attained during the study (Prod Info DEPAKOTE(R) ER extended-relea 2008).

2) Oral loading doses of divalproex sodium 15 milligrams/kilogram/day (in divided doses) produced troug concentrations in the therapeutic range by day 5 of dosing in male pediatric psychiatry inpatients (n=16; years). All subjects in this retrospective study received concomitant atypical neuroleptics. Divalproex the defined as 50 to 120 micrograms/milliliter (mcg/mL). These doses were well tolerated by the normal-weig more side effects seen at plasma concentrations above 90 mcg/mL. Overweight subjects benefited from the formula: ideal body weight (IBW) plus 40% multiplied by actual weight minus IBW (Good et al, 2001).

4.5.B.12 Migraine; Prophylaxis

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes (tablets, delayed-release tablets, extended-release tablets); Pediatric, no
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Divalproex sodium is indicated for the prophylaxis of migraine headache in adults (Prod Info DEPAK extended-release oral tablets, 2008; Prod Info DEPAKOTE(R) delayed-release oral tablets, 2006).
Efficacy of divalproex sodium extended-release tablets for migraine prophylaxis was not established double-blind, placebo-controlled, parallel-group, four equal armed (placebo, 250 milligrams (mg), 50 mg) study (n=304; 231 on divalproex sodium) in pediatric patients ages 12 to 17 years old (Prod Info ER extended-release oral tablets, 2008).
In an open-label, retrospective study in 42 adolescents and children, divalproex sodium provided a 5 reduction in migraine frequency (Caruso et al, 2000).

c) Adult:

1) The average incidence of migraine headache attacks was reduced following once-daily prophylactic t divalproex sodium extended-release (ER) tablets. In a randomized, controlled, double- blind, multicenter at least a 6-month history of migraine headache attacks and experiencing an average of 2 or more migra the previous 3 months entered a 4-week baseline phase during which they maintained a headache diary reported at least 2 migraine attacks during the baseline period received either divalproex sodium-ER (n= milligrams (mg)/day for 1 week titrated to 1000 mg/day; mean dose, 871 mg/day) or placebo (n=115) for Following 12 weeks of treatment, a significantly greater reduction in the mean baseline migraine headacl in patients who took divalproex sodium-ER as compared with placebo (mean reduction, 1.2 vs 0.6, respe This reduction from baseline reached significance during the first 4 weeks of treatment (p=0.035) and rer throughout the second and third 4-week periods (p=0.006 and p=0.045, respectively). Adverse events w between treatment groups (Freitag et al, 2002).

2) A case report describes how divalproex brought dramatic relief of migraine headaches induced by se serotonin reuptake inhibitor (SSRI), in a 44-year-old woman with a history of refractory major depression 2000). Divalproex 750 milligrams (mg)/day immediately reduced the frequency, severity, and duration of (valproate serum level was 240 micromoles/liter). After 3 months, the patient was headache-free most of months, the dose of divalproex was increased to 1500 mg/day as the migraines had become more frequ patient was successfully maintained on a daily regimen of sertraline 100 mg, divalproex 1500 mg, and ox needed. The authors suggest that valproate be considered for patients who have a history of migraine or experience migraine while being treated with a selective serotonin reuptake inhibitor.

d) Pediatric:

1) Efficacy of divalproex sodium extended-release tablets for migraine prophylaxis was not established i blind, placebo-controlled, parallel-group, four equal armed (placebo, 250 milligrams (mg), 500 mg, and 1 (n=304; 231 on divalproex sodium) in pediatric patients ages 12 to 17 years old. The study consisted of a period followed by a 12 week experimental period (including an initial 2 week titration period) with placeb each dose. Reduction from baseline in the 4 week migraine headache rate was the primary efficacy endp DEPAKOTE(R) ER extended-release oral tablets, 2008).

2) In an open-label, retrospective study (n=42), divalproex sodium was shown to be safe and effective fo treatment of migraine headache in adolescents and children (aged 7 to 16 years, mean 11.3 years) (Car Study subjects had a history of 1 to 4 headaches per month. After a 4-month course of divalproex treatm in headache frequency occurred in 33 (78.5%), 75% reduction in headache frequency in 6 (14.2%), and were virtually headache-free (p less than 0.05). Initial doses of divalproex were 15 milligrams/kilogram (n

(divided into 2 doses) with titration upward over 6 weeks based on response. Daily doses over the 4-mor
period included 15 mg/kg (n=9), 25 mg/kg (n=16), 35 mg/kg (n=10), and 45 mg/kg (n=7). Most common
were gastrointestinal upset, weight gain, somnolence, dizziness, and tremor; mild transient elevation of li
occurred in 4 patients. Doses were decreased but no one discontinued divalproex due to side effects.

4.5.B.13 Panic disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Efficacy in small, open-label studies only (Baetz & Bowen, 1998)

c) Adult:

1) In an 8-week, open-label study, divalproex was shown to be effective in patients with previously unres
disorder and mood instability (Baetz & Bowen, 1998). Patients (18 to 65 years old) received divalproex 2
twice daily and increased by 250-mg increments to a target level of 300 to 600 micromoles/L (45 to 90 m
patients completed the study and 2 dropped out due to side effects. Panic attacks decreased significantly
2.6/week (p=0.0318). Also decreased were the Hamilton Anxiety Rating Scale (p=0.0001) and the Beck
(p=0.003).

4.5.B.14 Periodic limb movement disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Improvement in sleep occurred in a small study cohort receiving valproate (Ehrenberg et al, 2000)

c) Adult:

1) Sleep quality and duration were improved in 6 outpatients (aged 28 to 62 years, mean 41.5 years) giv
valproate for periodic limb movement disorder. After a mean 6 months of therapy, dosages of valproate r
600 milligrams taken at bedtime. Polysomnographic findings included a significant increase in sleep effic
significant decrease in stage 1 (light) sleep (p=0.04), significant increases in stages 3 and 4 (deep) sleep
change in stage 2 (rapid eye movement-REM) sleep. Mean total sleep time increased from 5.8 to 6.4 ho
trend toward a reduction in the number of periodic limb movements per hour of sleep and in the number
arousals (p=0.062). Daytime alertness was subjectively reported to be improved. No subject discontinue
the end of the study; subsequently 2 patients terminated the drug, 1 due to weight gain and the other du
side effects (Ehrenberg et al, 2000).

4.5.B.15 Pervasive developmental disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

A small cohort of patients with autism disorders showed some improvement with valproate treatmen
2001).

c) Adult:

1) Divalproex sodium therapy was associated with some improvement of social interaction skills, repetiti
impulsivity, and other traits related to autism in an open-label, retrospective study (n=14). Included in the
consecutive patients with autism (10; DSM-IV), Asperger's disorder (2), and pervasive developmental dis
otherwise specified (2). Ten were children/adolescents and 4 were adults (age range 5 to 40 years, mea
scores ranged from 20 to 105, mean 69.1). Three subjects had a history of seizures. Divalproex sodium
doses and adjusted to maintain concentrations within the therapeutic range (between 50 and 100 milligra
Mean final dose was 768 mg/day (range 125 to 2500 mg/day) and mean duration of valproate treatment
Concomitant medications were taken by 10 patients, and included antidepressants, atypical neuroleptics
and alpha-1 agonists. Based on the Clinical Global Impressions-Improvement scale (CGI-I), 10 of 14 sub
sustained responders, with ratings of much or very much improved. Four patients showed improvement i
interactions. Four showed improvement related to repetitive behavior (ie, reduced obsessive-compulsive

patients were discontinued in the first 2 weeks due to severe behavioral activation. Other adverse effects
(5), digestive disturbances (3), weight gain (3), hair loss (2), mood lability (1), and elevated liver enzymes
recommend that controlled studies be undertaken (Hollander et al, 2001).

4.5.B.16 Posttraumatic headache

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective in some patients based on a retrospective study (Packard, 2000)

c) Adult:

1) Of 100 patients with chronic daily posttraumatic headache, 60% showed mild (n=44) to moderate (n= (patient-rated) after at least 1 month of divalproex sodium, based on a retrospective chart review; the dru well tolerated, with no serious side effects. Mild improvement was defined as 25% to 50% better, and mo than 50% improvement. In all subjects, headache was the result of mild head injury and had persisted fo months. Six patients became headache-free for 1 month or more, and 35 patients reported that their dail became episodic, with headache-free days between episodes. Twenty-six patients had no improvement, discontinued therapy due to side effects (nausea, weight gain, hair loss, tremor). Divalproex dosing was generally started as 250 milligrams (mg) daily (sometimes as 125 mg twice daily), increased by 250 mg response, and peaked at a maximum of 500 mg 3 times a day (Packard, 2000).

4.5.B.17 Schizoaffective disorder, bipolar type

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Adjunctive use may produce improvements in bipolar type schizoaffective disorder (Bogan et al, 200 Standard preparations and extended-release formulations of divalproex sodium are equally efficacio schizoaffective disorders; however, higher daily doses of extended-release formulations are require 2003).

c) Adult:

1) In a retrospective study (n=20), add-on divalproex therapy appeared to be well-tolerated and efficacic with schizoaffective disorder, bipolar type (aged 23 to 52 years, mean 38 years). Improvement in the Clir Impression (CGI) Scale scores occurred in 15 of 20 (75%) patients (p=0.0001); no change in CGI scores patients. None of the cohort showed worsening of their disorder; and no one discontinued divalproex due effects. Most common side effects were anxiety (n=2) and agitation (n=2); 1 person experienced extrapy symptoms/tremors. Other concurrent medications were most frequently antipsychotics (n=19), antidepre lithium (n=6). Mean daily dose of divalproex was 986 milligrams (mg) (range, 375 to 1750 mg); mean pe 61 micrograms/milliliter. Mean follow-up was 24 weeks (Bogan et al, 2000).

2) In a 6-week, open-label pilot study, dose-adjusted extended-release divalproex was equally efficaciou the standard preparation in bipolar and schizoaffective disorders. Twelve euthymic and clinically stable p enrolled into the study. Eight of these patients had been diagnosed with bipolar I or II disorder and 4 wer bipolar-type schizoaffective disorder. Each patient had received regular divalproex sodium twice daily for weeks and were maintained at serum valproic acid concentrations between 50 to 120 micrograms/millilit dose. Patients were switched to extended-release divalproex at doses rounded to the nearest 500 milligr Extended-release divalproex doses were administered once daily at bedtime. Doses were adjusted to at valproic acid levels achieved with the standard preparation. Average daily doses of the extended-release 20.7% higher than those of the standard preparation (1.19 grams versus 1.5 grams, p=0.0009). Clinical s evaluated using the Young Mania Rating Scale, the Hamilton Depression Rating Scale, Clinical Global Ir severity and improvement, the Global Assessment of Functioning Scale and the Brief Psychiatric Rating no significant differences between the baseline and endpoint ratings. Reported adverse effects were also an increase in polyuria-polydipsia (p=0.03) (Centorrino et al, 2003).

4.5.B.18 Sedative withdrawal delirium

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

May reduce symptoms associated with sedative-hypnotic withdrawal (Harris et al, 2000)

c) Adult:

1) Four controlled studies and several case reports and case series suggest that valproate may be effec withdrawal and benzodiazepine withdrawal. In contrast, one double-blind, controlled trial failed to suppor

valproate for benzodiazepine withdrawal. In an open-label study, there were no significant differences in withdrawal symptoms between valproate- and phenobarbital-treated patients, nor were there differences or pulse rate responses associated with the 2 agents. In another comparative study, valproate and chlor reported to have similar efficacy in ethanol withdrawal, but physiological effects were poorly documented controlled trial might have supported this use of valproate, but dismissed the treatment drug (valproate) b frequent association with GI distress (probably related to use of the valproic acid form of the drug). In a s valproate and lorazepam, valproate was found to be effective and well-tolerated in the treatment of ethar another report, two manic schizoaffective patients had successful withdrawal from ethanol when valproat milligrams/kilogram/day was combined with low-dose lorazepam. A patient with panic disorder failed to b clonazepam until valproate was added to therapy. Another report describes 4 cases of protracted withdra during tapering of benzodiazepines; the symptoms were notably eased after the addition of valproate. Tw reported in which valproate prevented alcohol or benzodiazepine relapse (Harris et al, 2000).

4.5.C Valproate Sodium

Absence seizure, Simple and complex

Behavioral syndrome - Dementia

Brain injury; Prophylaxis - Seizure

Catatonia

Complex partial epileptic seizure

West syndrome

4.5.C.1 Absence seizure, Simple and complex

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (10 years and older)
Efficacy: Adult, Effective; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIa; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Intravenous sodium valproate is indicated for simple and complex absence seizures when administr valproate products is not possible (Prod Info DEPACON(R) IV injection, 2006)

4.5.C.2 Behavioral syndrome - Dementia

a) Overview

FDA Approval: Adult, no; Pediatric, no

Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Conflicting results reported regarding the effectiveness of valproic acid in the treatment of dementia-
AGITATION (Sival et al, 2003) (Sival et al, 2002)

c) Adult:
1) Sodium valproate treatment offered no advantage over placebo in the treatment of dementia-related a
behavior in forty-two patients. In a randomized, double-blind, placebo-controlled, cross- over trial, patient
behavior and senile dementia received oral doses of either placebo or sodium valproate suspension 480
divided doses) for three weeks and then crossed over to the other treatment arm following a one-week w
Sodium valproate was no more effective than placebo in the treatment of aggression in this group of pati
2003).
2) In a randomized, placebo-controlled, double-blind study of 42 elderly patients (mean age=80.4 years)
had no effect versus placebo in the treatment of aggressive behavior in dementia. Sodium valproate was
three weeks at a fixed dose of 6 milliliters (mL) of a 40 milligram per milliliter (mg/mL) oral suspension tw
daily dose was 480 mg. Significant improvements in other measures, such as restlessness, melancholic,
behaviors, suggest that treatment duration was sufficient to produce therapeutic effects (Sival et al, 2002

4.5.C.3 Brain injury; Prophylaxis - Seizure

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Not effective prophylaxis

c) Adult:
1) Valproate sodium injection should not be used in patients with acute head trauma for the prophylaxis
seizures. In a study evaluating the effect of valproate sodium injection in the prevention of post-traumatic
patients with acute head injuries, patients were assigned to receive either valproate sodium injection for
by oral valproate for either one or six months, or phenytoin intravenous given for one week followed by p
incidence of death was found to be higher in the 2 groups assigned to the valproic acid treatment compa
those assigned to the phenytoin treatment group (13% versus 8.5%). Evaluation of the cause of death di
specific drug-related causation. Furthermore, without a placebo group it is difficult to determine the actua
these head trauma patients. Until further information is available, the manufacturer recommends not usir
sodium injection in patients with acute head trauma for the prophylaxis of post-traumatic seizures (Prod I
1999).

4.5.C.4 Catatonia

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Several cases of catatonia were improved with intravenous VALPROIC ACID

c) Adult:
1) A 38-year-old man with severe catatonic schizophrenia was markedly improved after receiving intrave
VALPROIC ACID (Kruger & Braunig, 2001). The patient required an average of 10 hospital admissions p
acute phases of his illness. In the acute phases, he would exhibit motor excitement, impulsive aggressio
iterations, screaming, negativism, gegenhalten, and impulsive behavior (such as binge eating, pica, and
masturbation). Between acute phases, he had severe negative symptoms, along with bizarre behaviors.
unsuccessfully treated with typical and atypical neuroleptics. On the index admission, he could not be giv
because he was unable to open his mouth due to extreme rigidity. He was started on high-dose IV valpro
milligrams (mg)/day, followed on the succeeding days by 3000 mg, 2500 mg, and 1800 mg. Each day his
symptoms were reduced from the previous day (90% symptom reduction over 4 days). After day 4, he w
valproate orally (900 mg/day for a plasma level of 60 micrograms/liter maintenance dosing). He required
admissions for the following 6 months. The authors noted that since this case, they have treated 3 more
successfully with a similar regimen.

4.5.C.5 Complex partial epileptic seizure

FDA Labeled Indication

a) Overview
FDA Approval: Adult, yes; Pediatric, yes (10 years and older)

Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Intravenous sodium valproate is indicated as monotherapy and adjunctive therapy for complex partia occurring in isolation or in association with other types of seizures when administration of oral valpro possible (Prod Info DEPACON(R) IV injection, 2006)
Carbamazepine is generally the first line agent for complex partial seizures

4.5.C.6 Febrile seizure

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

As effective as PHENOBARBITAL

c) Pediatric:

1) Recurrence rates of febrile convulsions during one year were not statistically different among 196 chil convulsions treated with either PHENOBARBITAL, PRIMIDONE or SODIUM VALPROATE (Minagawa & The children on SODIUM VALPROATE received either 20 to 25 milligrams/kilogram/day (mg/kg/day) twi mg/kg/day three times daily, or 30 mg/kg/day twice daily. However, the dosage regimen of VALPROATE mg/kg/day twice daily was relatively inferior to the other regimens of VALPROATE in the prophylactic eff regimens were of equal efficacy in the long-term prophylaxis of febrile convulsions in children.

4.5.C.7 Manic bipolar I disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproate has been used for mania secondary to bipolar disorder

c) Adult:

1) Four out of 5 acutely manic patients responded to intravenous valproate loading in an open study (Gr Five bipolar I patients received valproate 1200 or 1800 milligrams on day 1 followed by dosage individua side effects. Their mean baseline Bech-Rafaelson Mania Rating Scale score was 30.2 which improved t patient had actually been unresponsive to oral valproate. On day 5 most were switched to oral dosing. T that with the intravenous loading a quick saturation of plasma-binding proteins occurred which could hav beneficial action.

2) One uncontrolled study reported improvement in 5 of 7 patients with MANIA given VALPROIC ACID (milligrams daily) for 6 weeks. All patients had not responded to previous therapy with LITHIUM and neur 1984).

4.5.C.8 Migraine

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Valproate sodium has been used with mixed results for acute treatment of migraine headache (Math (Tanen, 2003)

c) Adult:

1) Results from an open-label, prospective study (n=61) indicate that intravenous valproate sodium (300 effective for the acute treatment of migraine headache. In this preliminary report, significant improvemen 0.001) (decreased headache severity) occurred in 73% of the migraine sufferers. Mean time to onset of r complete relief were 8 minutes and 25 minutes, respectively (Mathew et al, 2000).

2) In a randomized, double-blinded trial, intravenous prochlorperazine was more effective than intraven treating acute migraine headaches. Forty patients presented to emergency with a migraine headache wi and were recruited into the trial. Patients received either 500 milligrams (mg) of sodium valproate or 10 m prochlorperazine diluted to 10 milliliters in normal saline. After the 2 minute infusion, patients used visual grade their pain, nausea and sedation every 15 minutes for 60 minutes. Median pain scores improved 64 (mm) in the prochlorperazine group and 9 mm in the valproate group (p less than 0.001). Median nausea

35.5 mm in prochlorperazine patients and 2 mm in valproate patients (p less than 0.001). Median sedatic
4 mm in prochlorperazine patients and 0 mm in valproate patients (p=0.603). Over time, prochlorperazin
improvement in patient pain 30 minutes post dose (p less than 0.001) and in patient nausea 15 minutes
(p=0.002). Sodium valproate did not show significant improvement in symptoms over time. At the conclu
minute follow-up period, 79% of valproate patients and 25% of prochlorperazine patients required rescue
insufficient symptom relief (p=0.001). Extrapyramidal reactions were reported in 2 prochlorperazine patie

4.5.C.9 Myoclonus

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

In case reports, valproic acid was useful for myoclonus

c) Adult:

1) Sodium valproate diminished MYOCLONIC ASTATIC ATTACKS and sudden falls in 18 parkinsonian
(Henneberg et al, 1998). These patients also had polyspikes or polyspike-wave complexes on electroenc
(EEG). Sodium valproate 600 to 1800 milligrams/day was administered to achieve a level of at least 60 u
and EEG readings improved in 16 patients. The authors suspect that a generalized epilepsy may have c
myoclonus and falls.

4.5.C.10 Neuropathic pain

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Some pain reduction in patients with cancer-related neuropathic pain in a pilot study

c) Adult:

1) According to an open-label phase II study, a 2-week course of sodium valproate brought some pain r
with cancer-related neuropathic pain. Valproate was initiated at 200 milligrams (mg) twice a day with titra
not controlled and toxicity was not present) of 200 mg at intervals of 2 to 3 days to a maximum of 600 mg
Nineteen of 25 patients completed the study and the median valproate dose at day 15 was 600 mg twice
55.6% of those completing the study had a reduction in average pain by at least one category (eg, from s
moderate, or from moderate to mild), and 66.7% also had a decline in pain category for their worst pain.
timeframe, 66.7% had a decline in their absolute pain score (scale of 1 to 10 based on the Brief Pain Inv
average and worst pain. The proportion reporting a 50% reduction in pain score was 27.8% for both aver
pain. Most common side effects were drowsiness, unsteadiness, nausea, and decreased appetite; one p
due to toxicity. It was noted that after the study period ended, 89% of subjects continued on valproate as
the patient or doctor to be of benefit (Hardy et al, 2001).

4.5.C.11 Seizure, Multiple seizure types; Adjunct

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (10 years and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Intravenous sodium valproate is indicated as adjunctive therapy for multiple seizure types when adm
valproate products is not possible (Prod Info DEPACON(R) IV injection, 2006)

c) Adult:

1) General Information

a) Results of several clinical trials indicate that SODIUM VALPROATE alone or in combination with
anticonvulsants is effective in GRAND MAL SEIZURES (Covanis et al, 1982a; Pinder et al, 1977e; F
1975a; Simon & Penry, 1975). Of 519 patients who received SODIUM VALPROATE, mostly as an a
anticonvulsant agents, 239 (46%) experienced a 75% or more reduction in seizure frequency. Howe
ineffective in about 33% of these patients (Pinder et al, 1977e). Other studies have reported respons
100% when used as single-agent therapy (Rimmer & Richens, 1985g; Fuerstein, 1983; Covanis et a

2) The efficacy of VALPROATE SODIUM in 10 patients (21 to 50 years of age) with INTRACTABLE SE
DISORDERS was evaluated (Adams et al, 1978a). VALPROATE was administered initially in doses of 3
every 8 hours and increased weekly over a period of 12 weeks. All patients received concomitant anticor
responses were observed in general seizure disorders including tonic, tonic-clonic, atonic-akinetic and si

types. The most impressive results were observed in ATONIC-AKINETIC SPELLS. Considerable variatic
partial seizures, with 0% to 75% decrease in seizure frequency. EEG reading revealed the degree of epi
roughly correlated with the decrease in seizure frequency. Plasma levels of VALPROATE SODIUM of ap
mcg/mL in 5 patients was associated with a 50% decrease in seizure frequency.

d) Pediatric:

1) Successful results were reported in 22 of 27 children with grand mal seizures given SODIUM VALPR
600 and 2000 milligrams daily (dose depended upon age), for 4 to 5 weeks (Forster, 1972).

2) Good results were reported in one 17-year-old female with status epilepticus administered initial dose
milligrams 4 times daily followed by an increase to 600 mg 4 times daily for greater than 6 weeks (Manhi
The patient responded well to gradually increasing doses of sodium valproate and made a rapid recover
discharged and a follow-up 6 weeks later revealed the patient was much improved with relatively few sei

4.5.C.12 Status epilepticus

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category C; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Oral, rectal and intravenous VALPROIC ACID have been effective treating status epilepticus refract
anticonvulsants

c) Adult:

1) Two female patients were successfully treated with 500 milligrams of intravenous valproate for myocl
epilepticus. Each girl presented with a history of epilepsy treatment and chief complaints of 24 hours or r
spells, jerking, shuddering, and confusion. Mental status returned to normal and jerking and shuddering s
approximately 5 minutes after the infusion was completed in each girl (Sheth et al, 2000).

2) A 25-year-old woman with generalized nonconvulsive status epilepticus was successfully treated with
valproate (Kaplan, 1999). She had been receiving oral valproate and required levels greater than 125 mi
(mg)/milliliter to control her seizures. During a previous episode, she had been treated with intravenous l
lethargy had led to a hospital admission. Intravenous valproate 500 mg was administered at 20 mg/minu
minutes. There were no adverse effects locally or on pulse or blood pressure. The patient was able to re
afterwards.

3) Two mentally retarded patients with intractable status epilepticus were treated with SODIUM VALPRO
1977). The first patient was given SODIUM VALPROATE via nasogastric tube and then 400 mg by recta
days. The second patient was given 600 mg every 6 hours as a rectal suppository for 5 days. Prior to ad
patients were receiving DIAZEPAM, PHENYTOIN, SODIUM AMOBARBITAL, and 1 patient was also rec
clonazepam. Seizures were controlled in both patients and AMOBARBITAL was subsequently withdrawn
in seizure activity. The authors suggest that rectal administration may be a practical and effective metho
epilepticus when the oral route is not available.

4) One adult patient in focal spike-and-wave status epilepticus responded to valproic acid 30 milligrams/
intravenously (Chez et al, 1999).

d) Pediatric:

1) Three pediatric patients in slow spike-and-wave status epilepticus responded to valproic acid 30 milli
intravenously (Chez et al, 1999).

2) Good results were reported in one 17-year-old female with status epilepticus administered initial dose
milligrams 4 times daily by an increase to 600 mg 4 times daily for greater than 6 weeks. (Manhire & Esp
patients responded well to gradually increasing doses of SODIUM VALPROATE and made a rapid recov
was discharged and a follow-up 6 weeks later revealed the patients was much improved with relatively fe

4.5.C.13 Tardive dyskinesia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Mixed results have occurred

c) Adult:

1) Tardive dyskinesia improved in some patients receiving VALPROATE SODIUM at 300 milligrams 3 ti
over a period of 2 weeks in a controlled study. All patients received concomitant neuroleptic therapy. Res
VALPROATE SODIUM produced improvement in 14 of 32 patients with oro-facial dyskinesia, with impro
in akinesia, rigidity, akathisia and dystonic spasms (Linnoila & Viukari, 1979). Further data are required t
efficacy of VALPROATE in tardive dyskinesia.

4.5.C.14 Trigeminal neuralgia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Produces mixed results

c) Adult:
1) Mixed outcomes occurred when SODIUM VALPROATE was tried in 20 patients with trigeminal neura patients had no attacks for 6 to 18 months, while in 3 patients the frequency and severity of attacks were least 50%. Four patients responded well when SODIUM VALPROATE was used in combination with oth patients showed little or no response while one patient showed poor tolerance to SODIUM VALPROATE 1980).

4.5.C.15 West syndrome

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Effective in INFANTILE SPASMS (40% of patients) (Siemes et al, 1988a)

c) Pediatric:
1) Monotherapy with VALPROIC ACID was effective in the treatment of infantile spasms in a prospectiv 22 children aged 4 to 11 months (Siemes et al, 1988a). VALPROIC ACID (as SODIUM VALPROATE) w oral doses of 15 milligrams/kilogram/day; this was increased every second day by 10 milligrams/kilogram ceased or a maximum dose of 100 milligrams/kilogram/day was achieved. If seizures were not controlled to 6 weeks of treatment, oral DEXAMETHASONE 0.4 to 0.5 mg/kg/day was added to the regimen. The d VALPROATE ranged from 40 to 100 milligrams/kilogram/day (mean, 74). Total seizure control was achie patients within 3 months of starting VALPROATE; after 6 to 12 months, 73% of patients were free of seiz monotherapy, and at 18 to 24 months, 88% of children remained seizure free. Developmental status afte treatment demonstrated severe and very severe retardation in approximately 40% of children, with mode 25% and no or slight retardation in approximately 35%.

4.6 Comparative Efficacy / Evaluation With Other Therapies

Biperiden

Bromocriptine

Carbamazepine

Cyproheptadine

Ethosuximide

Haloperidol

Lithium

Olanzapine

Phenobarbital

Phenytoin

Primidone

Prochlorperazine

Progabide

Propranolol

Topiramate

4.6.A Biperiden

4.6.A.1 Extrapyramidal disease

a) A double-blind crossover comparison of valproic acid, biperiden, and placebo was conducted in 15 psychi neuroleptic-induced extrapyramidal symptoms (Friis et al, 1983). Biperiden therapy was superior to valproic a decreasing symptoms. Valproic acid had no significant effects on akathisia, a slight beneficial effect on hyper movements, and aggravated parkinsonism-like symptoms.

4.6.B Bromocriptine

4.6.B.1 Nelson syndrome

a) Bromocriptine significantly suppressed plasma adrenocorticotropin hormone (ACTH) secretion in 6 wome Syndrome. ACTH was measured after receiving therapy with each of the following: placebo, cyproheptadine, bromocriptine. Also they received each of the following combinations: cyproheptadine and valproic acid; and cyproheptadine and valproic acid. Only bromocriptine caused a significant decrease in plasma ACTH (P less the combination of the 3 drugs (P less than 0.05). However, the combined effect of the 3 drugs did not signifi effect of bromocriptine alone (Mercado-Asis et al, 1997a).

4.6.C Carbamazepine

Epilepsy

Epilepsy, Children

Rheumatic chorea

4.6.C.1 Epilepsy

a) One hundred eighty-one patients with previously untreated epilepsy were randomized to valproic acid, phe carbamazepine as monotherapy and followed for 14 to 24 months. All 3 drugs were highly effective in the cor seizures but less effective for partial seizures. There was no significant difference between the overall incider between the 3 drugs (Callaghan et al, 1985a).

b) Carbamazepine and sodium valproate were shown to be equally effective in controlling seizures in patient diagnosed primary generalized or partial seizures (Richens et al, 1994). In this large multicenter study patient randomized to either carbamazepine or valproate and followed for a period of three years. Although long-term similar in the two groups, significantly more patients in the carbamazepine group (15% vs 5%) discontinued t first six months due to adverse reactions (predominantly rash). Headache and dizziness were also reported n the carbamazepine group; weight gain was reported more often in patients receiving sodium valproate.

c) Results from a large multicenter trial comparing valproate with carbamazepine in the treatment of complex secondarily generalized tonic-clonic seizures indicate similar effectiveness of both drugs for control of seconc tonic-clonic seizures. However, for complex partial seizures, carbamazepine was more effective and was ass adverse reactions (Mattson et al, 1992). Long-term side effects associated with valproate therapy included w loss or change in texture, and tremor. Hypersensitivity, characterized by rash, occurred more frequently in tho carbamazepine.

d) Patients switched to high dose valproic acid (target serum level 80 to 150 micrograms/milliliter) demonstra improved seizure control versus treatment with their baseline antiepileptic drug. Participating patients had pa history of at least 2 complex partial seizures per month with or without secondarily generalized tonic-clonic se maintained on therapeutic levels of either carbamazepine, phenytoin, phenobarbital or primidone. A 30% me complex partial seizures and a 70% median reduction for secondarily generalized tonic-clonic seizures over p occurred. The authors conclude that valproic acid is efficacious as monotherapy for partial-onset seizures an considered as first-line therapy (Beydoun et al, 1997).

e) In a double-blinded, randomized study, topiramate, carbamazepine and valproate monotherapy demonstr to study exit, times to first seizure and proportions of patients who were seizure-free during the final 6 months Newly diagnosed epilepsy patients were randomized to receive topiramate 100 milligrams (mg) daily (n=210) mg daily (n=199), or traditional therapy (n=204). Patients in the traditional therapy arm were prescribed either 600 mg/day or valproate 1250 mg/day depending on the prescribing physician's treatment choice. Patients w months after the final patient was enrolled. Of the total 285 patients, 46% completed the study. Adverse even 19% and 23% of discontinuations in the topiramate and traditional therapy arms, respectively. Ineffective trea for 11% and 12% of discontinuations in the topiramate and traditional therapy arms, respectively. The time to to first seizure between the arms did not differ (p=0.53 and 0.35, respectively). The proportion of patients who

experience a seizure during the last 6 months of the study was 49% of topiramate-100 mg patients and 44% other arms. Dose related paresthesia (25 to 33%), difficulty with concentration or attention (4 to 11%), langua 7%), confusion (3 to 6%), nausea (7 to 14%) and abdominal pain (3 to 7%) were reported with topiramate. Ca valproate were associated with concentration and attention difficulty (4% and 1%), and language problems (6 Carbamazepine was also associated with confusion (3%) (Privitera et al, 2003a).

4.6.C.2 Epilepsy, Children

a) The efficacy and tolerability of phenobarbital, phenytoin, carbamazepine, and sodium valproate in the trea epilepsy were compared in a long-term, prospective, randomized trial (de Silva et al, 1996a). Children aged 3 (n=167) with at least two previously untreated tonic-clonic or partial seizures were eligible for participation in t drugs were equally efficacious with 20% of the patients remaining seizure free and 73% achieving 1-year rem However, randomization to phenobarbital was discontinued early in the study period due to unacceptable sid Carbamazepine and sodium valproate were the best tolerated with only 4% of children discontinuing treatmer 9% of children treated with phenytoin.

4.6.C.3 Rheumatic chorea

a) Carbamazepine and valproic acid were found to be safe and equally effective in the treatment of choreic r of clinical improvement, time to complete remission, duration of treatment, and recurrence rates in a group of patients with Sydenham's chorea. In this open-label trial, 7 children received 20 to 25 milligrams per kilogram sodium valproate and a matched group of 17 children received 15 mg/kg/day of carbamazepine. No adverse reported by either group.

Demographics and Response to Treatment			
	Sodium valproate	Carbamazepine	P

(Genel et al, 2002)			

4.6.D Cyproheptadine

4.6.D.1 Nelson syndrome

a) Bromocriptine significantly suppressed plasma adrenocorticotropin hormone (ACTH) secretion in Nelson's women with Nelson's Syndrome had their ACTH measured after receiving therapy with each of the following: cyproheptadine, valproic acid, and bromocriptine. Also they received each of the following combinations: cypr valproic acid; and bromocriptine, cyproheptadine and valproic acid. Only bromocriptine caused a significant d ACTH (P less than 0.05), as did the combination of the 3 drugs (P less than 0.05). However, the combined ef did not significantly exceed the effect of bromocriptine alone (Mercado-Asis et al, 1997).

4.6.E Ethosuximide

4.6.E.1 Absence seizure

a) SUMMARY: Sodium valproate has been as effective as ethosuximide in children with petit mal seizures (P Suzuki et al, 1972; Sato et al, 1982; Callaghan et al, 1982). Sodium valproate 500 to 2400 mg daily (mean, 8 been as effective as ethosuximide 200 to 1200 mg daily (mean, 438 mg daily) (Pinder et al, 1977b).

b) Valproic acid and ethosuximide were compared in a double-blind, response-conditional crossover study o in 16 previously untreated patients and 29 refractory patients (18 male and 27 female; 4 to 18 years of age) (In the previously untreated patients, valproic acid was as effective as ethosuximide in reducing generalized s discharges on the telemetered EEG. Adverse reactions to valproic acid or ethosuximide were generally mild a

withdrawal or dosage reduction.

4.6.F Haloperidol

4.6.F.1 Mania

a) Divalproex and haloperidol were found to be equally efficacious in the management of acute psychotic ma bipolar disorder. In this study, patients (n=36) were randomized to therapy with divalproex (20 mg/kg/day) or mg/kg/day) for a period of six days. Divalproex was given at a dosage considered to be a loading dose to pro concentrations of approximately 80 mg/L after one day of treatment. Improvement was greatest during the fir treatment; extrapyramidal side effects were observed much more often in patients treated with haloperidol (M 1996).

4.6.G Lithium

4.6.G.1 Bipolar disorder - Mania

a) SUMMARY: Valproic acid may be superior to lithium in managing patients with higher numbers of depress episodes; therapeutic serum levels of either drug may help predict clinical response and outcome. Limited ev that suicide risk may be lower with lithium than with divalproex.

b) A review of 3 randomized, double-blinded, placebo-controlled studies concluded that a more rapid antima achieved with olanzapine or oral loading of divalproex than with standard titration divalproex, lithium or placel term studies, oral-loaded divalproex (n=80) was either initiated at 30 milligrams/kilogram/day (mg/kg/day) for and maintained at 20 mg/kg/day or it was initiated at 20 mg/kg/day for the first 2 days and gradually increase 20 mg/kg/day plus 1000 mg by day 6. This regimen was compared to divalproex (n=87) initiated at 250 mg 3 titrated to serum levels of 40 to 150 micrograms/milliliter (mcg/mL), lithium (n=54) initiated at 300 mg 3 times to 0.4 to 1.5 milliequivalents per liter, and olanzapine (n=55) initiated at 10 mg/day and titrated to a maximum placebo (n=72). Patients were followed for 10 days and efficacy was assessed using the change from baselir the Mania Rating Scale (MRS), the Manic Syndrome Scale (MSS) and the Behavior and Ideation Scale (BIS) analyses showed that MRS measurements from oral-loaded divalproex patients were not significantly differer patients. However, it showed significant differences from standard titration divalproex and placebo by day 5 a days 7 to 8 (p less than 0.02). Similar results were found for MSS and BIS measurements. Dry mouth and inc was more commonly reported with divalproex load compared to standard titration (p less than 0.05). Howeve divalproex was associated with an increased incidence of dizziness, general pain and back pain (p less than overall was associated with greater decreases in platelet counts than other groups (p less than 0.05). Lithium with greater reports of headache and fever (p less than 0.05) and olanzapine was associated with greater ad as dry mouth, weight gain, edema, speech disorder, rhinitis, increases in total cholesterol and increases in se aminotransferase) overall (p less than 0.05) (Hirschfeld et al, 2003a).

c) In a large-scale retrospective review of claims data, lithium treatment was associated with a lower risk of s death compared to the same risks while on divalproex. Health plan data from two managed care organizatior identify 20638 health plan members with type 1 or type 2 bipolar disorder, who had received 1 or more presc divalproex, or carbamazepine. Over an 8-year follow-up period and using lithium as a referent, patients on di hazard ratios of 2.7 for suicide death (event rate per 1000 person-years 1.7, versus 0.7 for lithium); 1.7 for att hospitalization (event rate per 1000 person-years 10.5, versus 4.2 for lithium); and 1.8 for attempts ascertaine emergency department (event rates not reported for both study sites). Comparisons of lithium to carbamazep drug therapy, or no drug treatment were less consistent or stable (Goodwin et al, 2003). Confounding factors interpretation of these results include underrepresentation of certain patient populations in managed care mo diagnoses that might influence drug choice, and reliance on diagnostic coding rather than evaluative researcl outcomes.

d) Response to lithium, but not to valproic acid, worsened with increased numbers of depressive or manic ep hospitalized for the treatment of manic episodes had their records reviewed for their illness histories. Using a fitting equation for change in Manic Syndrome Score of the Schedule of Affective Disorders and Schizophren conducted of the relationship between treatment response and the number of previous episodes. It was note episodes, the response to lithium dropped for subjects having at least 11 or more episodes. For subjects with manic episodes, response to lithium and divalproex was identical. However, in subjects with more than 11 ma response to lithium decreased and differed significantly from that to divalproex (p=0.007). Similarly, in patient depressive episodes, patients were less likely to respond to lithium as compared to divalproex (p=0.004)(Swa

e) In a retrospective review, lithium appeared to be more effective than valproic acid in the treatment of mani however, when only patients with therapeutic levels were reviewed, results were similar (Chen et al, 1999). C patients (55-years-old or older) were reviewed to assess the efficacy of lithium (n=30) and valproic acid (n=2 Global Impression rating scale was used to assess outcomes on day 5 and at discharge. Overall more patien with lithium than valproic acid at day 5 (p=0.033) and at discharge (p=0.011). However, patients with a lithium millimoles/liter or greater, or with valproic acid levels of 65 to 90 micrograms/milliliter had similar outcomes. T suggest that there may be no difference in outcome if appropriate drug serum levels are achieved in elderly p

f) In a 3-week parallel, double-blind study, a history of multiple (greater than 10) pervious episodes of mania with a poor response to lithium but not to valproic acid (Swann et al, 1999). Patients with acute mania (n=154 to lithium, valproic acid or placebo. The primary efficacy measure was the manic syndrome score from the Sc Disorder and Schizophrenia scale. A relationship between response to medication and number of previous m apparent at approximately greater than or less than 10 episodes. For a low number of previous episodes (les lithium and valproic acid were significantly more effective than placebo (p less than 0.005 for both). For patie

episodes (greater than 10) only the response to valproic acid was significantly better than placebo (p less tha
g) Pretreatment depression-related symptoms were a strong predictor of a better response to valproic acid tl
179 patients hospitalized with an acute manic episode, patients were randomized to receive a 3 week treatm
valproic acid, lithium, or placebo. Patients had comprehensive evaluations of behavior and symptoms with th
measure being the change in mania factor scores on the Schedule for Affective Disorders and Schizophrenia
This study also noted that: lithium was substantially more effective in classic mania than in depressive mania
valproic acid did not differ between classic and depressive mania; and lithium resistance in depressive mania
gender, age, substance abuse, or overall severity of illness (Swann et al, 1997).
h) The efficacy of lithium carbonate was compared with that of valproate in 27 patients with DSM-III-R acute
(Freeman et al, 1992). The study was a 3-week, randomized, double-blind, parallel groups design in which se
symptoms was measured with the Schedule for Affective Disorders and Schizophrenia, change version (SAD
Assessment Scale (GAS), and the Brief Psychiatric Rating Scale (BPRS). Nine of 14 patients treated with val
13 treated with lithium responded favorably at the end of the study. Elevated pre-treatment SADS-C depressi
associated with good response to valproate but not to lithium. Lithium and valproate were both effective in im
symptoms, and lithium was slightly more efficacious overall. Treatment with valproate alone may be particula
manic patients with mixed affective states.
i) In a decision analysis model, divalproex was found to be less costly than lithium for the acute and prophyla
patients with bipolar disorder over a one-year time period. Four attributes of overall patient management were
model: the response rate to initial therapy; the mean length of hospital stay; the rates of adverse effects; and
treatment costs. In the overall analysis, initial therapy with divalproex resulted in costs that were 9% lower tha
treatment with lithium, most likely due to a more rapid response with divalproex and shorter length of hospital
were most significant in patients with mixed mania and rapid cycling; however, cost savings with lithium thera
recognized in patients with classic mania (Keck et al, 1996a).

4.6.H Olanzapine

4.6.H.1 Mania

a) A review of 3 randomized, double-blinded, placebo-controlled studies concluded that a more rapid antima
achieved with olanzapine and oral loading of divalproex than with standard titration divalproex, lithium or plac
short-term studies, oral-loaded divalproex (n=80) was either initiated at 30 milligrams/kilogram/day (mg/kg/da
days and maintained at 20 mg/kg/day or it was initiated at 20 mg/kg/day for the first 2 days and gradually incr
maximum of 20 mg/kg/day plus 1000 mg by day 6. This regimen was compared to divalproex (n=87) initiated
daily and titrated to serum levels of 40 to 150 micrograms/milliliter (mcg/mL), lithium (n=54) initiated at 300 m
and titrated to 0.4 to 1.5 milliequivalents per liter, and olanzapine (n=55) initiated at 10 mg/day and titrated to
mg/day and placebo (n=72). Patients were followed for 10 days and efficacy was assessed using the change
measurement of the Mania Rating Scale (MRS), the Manic Syndrome Scale (MSS) and the Behavior and Ide

with greater adverse events (such as dry mouth, weight gain, edema, speech disorder, rhinitis, increases in t
and increases in serum alanine aminotransferase) overall (p less than 0.05) (Hirschfeld et al, 2003).
b) Olanzapine was superior to divalproex for the treatment of acute mania in a 3-week, randomized, double-
hundred fifty one patients with bipolar I disorder, manic or mixed episode, and with or without psychotic featu
flexibly dosed olanzapine (5 to 20 milligrams (mg) per day) or divalproex (500 to 2500 mg/day). Modal doses
for olanzapine and 1401 mg/day for divalproex. A divalproex blood level of 50 microgram/liter (mcg/L) or grea
therapeutic range) was attained by approximately 87% of divalproex-treated patients. The mean improvemen
Mania Rating Scale total score was 13.4 points for the olanzapine group and 10.4 points for the divalproex gr
0.03). In subgroup analysis, the difference was significant (in favor of olanzapine) among patients without psy
(p=0.06), but there was no difference between treatments among patients with psychotic features. Clinical res
greater improvement in they Young Mania Rating Scale score) was achieved by 54% of olanzapine-treated p
divalproex-treated patients (p=0.058). Time-to- remission was significantly shorter with olanzapine (3 days vs
than 0.04). There were more adverse events with olanzapine, mainly somnolence, dry mouth, and weight gai
occurred more frequently in the divalproex group (Tohen et al, 2002).

4.6.I Phenobarbital

Epilepsy

Febrile seizure

4.6.I.1 Epilepsy

a) The efficacy and tolerability of phenobarbital, phenytoin, carbamazepine, and sodium valproate in the trea epilepsy were compared in a long-term, prospective, randomized trial (de Silva et al, 1996b). Children aged 3 (n=167) with at least two previously untreated tonic-clonic or partial seizures were eligible for participation in t drugs were equally efficacious with 20% of the patients remaining seizure free and 73% achieving 1-year rem
b) Patients switched to high concentration valproic acid (target level 80 to 150 micrograms/mililiter) demonst or improved seizure control versus treatment with their baseline antiepileptic drug. Participating patients had and a history of at least 2 complex partial seizures per month with or without secondarily generalized tonic-cl while being maintained on therapeutic levels of either carbamazepine, phenytoin, phenobarbital or primidone reduction in complex partial seizures and a 70% median reduction for secondarily generalized tonic-clonic se baseline therapy occurred. The authors conclude that valproic acid is efficacious as monotherapy for partial-c that it should be considered as first-line therapy (Beydoun et al, 1997a).

4.6.I.2 Febrile seizure

a) Phenobarbital in doses of 3 to 5 milligrams/kilogram/day was reported as effective as valproic acid 20 to 3 milligrams/kilogram/day in preventing febrile seizures (Wallas et al, 1980; Cavazzuti, 1975), whereas a more indicated that, in these doses, valproic acid was superior to phenobarbital with a lower order of toxicity (Lee &
b) Phenobarbital in doses of approximately 5 milligrams/kilogram/day was as effective as valproic acid in dos approximately 35 milligrams/kilogram/day in prevention of febrile convulsions (Herranz et al, 1984). These do plasma levels of approximately 16 mcg/mL for phenobarbital and 57 mcg/mL for valproic acid, resulting in effi 91% of children, respectively. Side effects occurred in 77% of phenobarbital-treated children as opposed to 4 acid-treated children; phenobarbital toxicity was primarily irritability, hyperactivity and sleep disorders, wherea produced gastrointestinal symptoms. In this study, primidone in doses of approximately 18 mg/kg/day (serum phenobarbital, 14 mcg/mL) was effective in 88% of patients. These data suggest that both valproic acid and p effective as phenobarbital in the prophylaxis of febrile convulsions. Although side effects were higher with phe therapy, valproic acid required dosage change and withdrawal of treatment in 10% and 4% of patients, respe no withdrawal of therapy was required in phenobarbital-treated patients. Changes in dose were required in 1 phenobarbital-treated patients.
c) Although valproic acid may be as effective as phenobarbital in prevention of febrile convulsions, the poten of the drug would preclude its routine initial use (Lott, 1982).

4.6.J Phenytoin

Epilepsy

Epilepsy, Children

Seizure; Prophylaxis

4.6.J.1 Epilepsy

a) SUMMARY: Valproic acid is as effective as phenytoin in the treatment of newly diagnosed generalized tor (Rimmer & Richens, 1985e; Wilder et al, 1983; Turnbull et al, 1983).
b) One hundred eighty-one patients with previously untreated epilepsy were randomized to valproic acid, phe carbamazepine as monotherapy and followed for 14 to 24 months (Callaghan et al, 1985). The oral drug dose phenytoin 300 mg/day (adults) and 5 to 10 mg/kg/day (children), carbamazepine 600 mg/day (adults) and 5 t (children), and valproic acid 600 mg/day (adults) and 5 to 10 mg/kg/day (children). All 3 drugs were highly eff control of generalized seizures but less effective for partial seizures. There was no significant difference betw incidence of side effects between the 3 drugs.
c) No difference was reported in efficacy between valproic acid and phenytoin therapy in previously untreate or partial seizures (Turnbull et al, 1985).
d) One study reported the similar efficacy of phenytoin and valproate in newly diagnosed complex partial sei al, 1983).
e) Patients switched to high concentration valproic acid (target level 80 to 150 micrograms/milliliter) demonst or improved seizure control versus treatment with their baseline antiepileptic drug. Participating patients had and a history of at least 2 complex partial seizures per month with or without secondarily generalized tonic-cl while being maintained on therapeutic levels of either carbamazepine, phenytoin, phenobarbital or primidone reduction in complex partial seizures and a 70% median reduction for secondarily generalized tonic-clonic se baseline therapy occurred. The authors conclude that valproic acid is efficacious as monotherapy for partial-c that it should be considered as first-line therapy (Beydoun et al, 1997).

4.6.J.2 Epilepsy, Children

a) The efficacy and tolerability of phenobarbital, phenytoin, carbamazepine, and sodium valproate in the trea epilepsy were compared in a long-term, prospective, randomized trial (de Silva et al, 1996). Children aged 3 t (n=167) with at least two previously untreated tonic-clonic or partial seizures were eligible for participation in t drugs were equally efficacious with 20% of the patients remaining seizure free and 73% achieving 1-year rem

4.6.J.3 Seizure; Prophylaxis

a) In a double-blind, 1-year study, phenytoin and valproate were equally effective in preventing seizures afte (Beenen, 1999). Patients undergoing surgery for brain tumor, trauma, or vascular lesions were randomized p receive either phenytoin 100 milligrams (mg) 3 times daily (n=50) or valproate 500 mg 3 times daily (n=50). A started intravenously after surgery and switched to oral dosing (or via nasogastric tube) as soon as possible. each group experienced a seizure. There was no difference found in the 2 groups in time to first seizure or se There was also no significant difference in the number of patients having to discontinue therapy due to adver phenytoin group, 2 in the valproate group). Neuropsychological testing also showed no significant differences phenytoin and valproate groups on cognitive functioning. This study verifies that either drug may be used for prophylaxis. Since 4 patients experienced their first seizure on the day of surgery, the authors recommend st the week before surgery or giving a loading dose after surgery.

b) Valproic acid was as effective as phenytoin for the prophylaxis of short- and long-term seizures following t injury, however there was a trend seen towards increased mortality in the valproic acid groups (Temkin et al, hours of injury, patients (ages 14-years and older) were randomized to receive either phenytoin for 1 week (n acid for 1 month (n=120), or valproic acid for 6 months (n=127). A phenytoin loading dose was administered a milligrams/kilogram (mg/kg) intravenously (IV) followed by maintenance dosing at 5 mg/kg/day divided into 2 acid loading dose was given at 20 mg/kg intravenously followed by a maintenance dose of 15 mg/kg/day divi Plasma concentrations of each drug were followed and adjusted to therapeutic levels. Early seizures occurre phenytoin treated patients and in 4.5% of the combined valproic acid groups (p not significant). There was als difference in the occurrence of late seizures. The death rate after 2 years was 13.4% for the combined valpro 7.2% for the phenytoin group (p=0.07). The authors conclude that the lack of any additional benefit from valp phenytoin, and the possibly higher mortality rate, suggest that valproic acid should not be routinely used for p posttraumatic seizures.

c) The incidence of death was higher in patients receiving valproate sodium injection followed by oral valproa receiving phenytoin intravenous followed by placebo for the prophylaxis of post-traumatic seizures in patients trauma. In a study evaluating the effect of valproate sodium injection in the prevention of post- traumatic seizu assigned to receive either valproate sodium injection for one week followed by oral valproate for either one or phenytoin intravenous given for one week followed by placebo. The incidence of death was found to be highe assigned to the valproate treatment compared to the rate in those assigned to the phenytoin treatment group 8.5%). Evaluation of the cause of death did not reveal any specific drug-related causation. Furthermore, witho group, it is difficult to determine the actual mortality rate of these head trauma patients. Until further informatio manufacturer recommends not using valproate sodium injection in patients with acute head trauma for the pr traumatic seizures (Prod Info Depacon(R), 1999).

4.6.K Primidone

Epilepsy

Febrile seizure

4.6.K.1 Epilepsy

a) Patients switched to high concentration valproic acid (target level 80 to 150 micrograms/milliliter) demonst or improved seizure control versus treatment with their baseline antiepileptic drug. Participating patients had and a history of at least 2 complex partial seizures per month with or without secondarily generalized tonic-cl while being maintained on therapeutic levels of either carbamazepine, phenytoin, phenobarbital or primidone reduction in complex partial seizures and a 70% median reduction for secondarily generalized tonic-clonic se baseline therapy occurred. The authors conclude that valproic acid is efficacious as monotherapy for partial-o that it should be considered as first-line therapy (Beydoun et al, 1997b).

4.6.K.2 Febrile seizure

a) Primidone, phenobarbital and valproic acid were equally effective over a 1-year period in the prophylaxis o convulsions in 95 children (Herranz et al, 1984a). Inclusion criteria included complicated febrile convulsions (than 15 minutes, focal or followed by transient or permanent neurological changes) or simple febrile convulsi factors (convulsions before 12-months-old, 3 or more seizures, history of neurological disorder, delay in move deficiency, microcephaly, or a history of febrile convulsions in parents or siblings). Patients were not randomi disclosed if therapy was blinded. All groups of patients presented with similar clinical characteristics and risk significantly difference between the groups was that the primidone group contained patients who all had expe seizure attacks while the other 2 groups only had approximately 70% of patients experience that many attack distribution was also uneven with 30 phenobarbital patients, 17 primidone patients and 48 valproic acid patie phenobarbital were dosed to achieve phenobarbital levels of 15 mcg/mL and valproic acid was dosed to achi plasma levels of 50 mcg/mL. Successful therapy was determined if there was no recurrence of febrile convul first year. The percentages of patients without recurrence of febrile convulsions were 80%, 88%, and 92% of with phenobarbital, primidone, and valproic acid, respectively. The differences between the groups were not s Adverse effects were experienced by 77%, 53%, and 45% of the patients treated with phenobarbital, primido acid, respectively. The adverse effects experienced with primidone were relatively less severe than with pher

valproic acid. None of the children on primidone had to change doses or withdraw from the study because of while 10% and 4% of the children on valproic acid and phenobarbital, respectively, did so. The most common with primidone and phenobarbital included hyperactivity, irritability, and disturbances of sleep, while with valp gastrointestinal effects (nausea, vomiting, and anorexia) were most common.

b) The recurrence rate of febrile convulsions over a one year period in 196 children under 3-years-old were r different between phenobarbital, primidone, or valproic acid prophylaxis therapy (Minagawa & Miura, 1981). F 5 mg/kg/day in 2 doses, primidone 15 to 20 mg/kg/day in 2 doses, valproic acid 20 to 25 mg/kg/day in 2 or 3 acid 30 mg/kg/day in 2 doses were administered to 196 children who had experienced at least 2 febrile convu method for dividing the patients into the drug therapy groups and any differences between them were not dis dosage regimen of valproic acid 20 to25 mg/kg/day in 2 doses was noted to be relatively inferior to the other dosing regimens for prophylactic effect. The remaining regimens appeared to be of equal efficacy in the long- of febrile convulsions.

4.6.L Prochlorperazine

4.6.L.1 Migraine, acute

a) In a randomized, double-blinded trial, intravenous prochlorperazine was more effective than intravenous v acute migraine headaches. Forty patients presented to emergency with a migraine headache with or without recruited into the trial. Patients received either 500 milligrams (mg) of sodium valproate or 10 mg of prochlorp 10 milliliters in normal saline. After the 2 minute infusion, patients used visual analog scales to grade their pa sedation every 15 minutes for 60 minutes. Median pain scores improved 64.5 millimeters (mm) in the prochlo and 9 mm in the valproate group (p less than 0.001). Median nausea scores improved 35.5 mm in prochlorpe and 2 mm in valproate patients (p less than 0.001). Median sedation scores improved 4 mm in prochlorperaz mm in valproate patients (p=0.603). Over time, prochlorperazine led to marked improvement in patient pain 3 dose (p less than 0.001) and in patient nausea 15 minutes post dose (p=0.002). Sodium valproate did not sh improvement in symptoms over time. At the conclusion of the 60 minute follow-up period, 79% of valproate p prochlorperazine patients required rescue therapy due to insufficient symptom relief (p=0.001). Extrapyramid reported in 2 prochlorperazine patients (Tanen et al, 2003).

4.6.M Progabide

4.6.M.1 Epilepsy

a) In a single-blind, cross-over study, progabide (median maximal dose of 2.4 grams (g) daily) was reported acid (median maximal dose of 1.8 g daily) as add-on therapy in patients with refractory epilepsy. In addition, associated with increases in serum glutamic-oxaloacetic transaminase (SGOT) levels (more than twice the u 62 patients treated; an adverse interaction with phenytoin and progabide resulted in phenytoin intoxication ar phenytoin dosage in 9 patients (Crawford & Chadwick, 1986).

4.6.N Propranolol

4.6.N.1 Migraine; Prophylaxis

a) Valproic acid exhibited equivalent efficacy to propranolol in the prophylaxis of migraine without aura in a s crossover study (n=37). Each 12-week treatment phase, separated by a 4-week placebo washout, consisted divalproex sodium 125 milligrams (mg) twice daily titrated to a goal 1500 mg/day, or propranolol sustained-re titrated to a goal 180 mg/day. Significant (at least 50%) reductions in migraine frequency occurred in 19%, 63 placebo, valproic acid and propranolol groups, respectively. Active treatments were well-tolerated and signific efficacious than placebo, but did not differ statistically from each other (Kaniecki, 1997).

4.6.O Topiramate

4.6.O.1 Epilepsy

a) In a double-blinded, randomized study, topiramate, carbamazepine and valproate monotherapy demonstr to study exit, times to first seizure and proportions of patients who were seizure-free during the final 6 months Newly diagnosed epilepsy patients were randomized to receive topiramate 100 milligrams (mg) daily (n=210) mg daily (n=199), or traditional therapy (n=204). Patients in the traditional therapy arm were prescribed either 600 mg/day or valproate 1250 mg/day depending on the prescribing physician's treatment choice. Patients w months after the final patient was enrolled. Of the total 285 patients, 46% completed the study. Adverse even 19% and 23% of discontinuations in the topiramate and traditional therapy arms, respectively. Ineffective trea for 11% and 12% of discontinuations in the topiramate and traditional therapy arms, respectively. The time to to first seizure between the arms did not differ (p=0.53 and 0.35, respectively). The proportion of patients who experience a seizure during the last 6 months of the study was 49% of topiramate-100 mg patients and 44% other arms. Dose related paresthesia (25 to 33%), difficulty with concentration or attention (4 to 11%), langua 7%), confusion (3 to 6%), nausea (7 to 14%) and abdominal pain (3 to 7%) were reported with topiramate. Ca valproate were associated with concentration and attention difficulty (4% and 1%), and language problems (6 Carbamazepine was also associated with confusion (3%) (Privitera et al, 2003).

TRAZODONE

0.0 Overview

1) Class
- **a)** This drug is a member of the following class(es):
  - Antidepressant
  - Triazolopyridine

2) Dosing Information
- **a)** Trazodone Hydrochloride
  - **1)** Adult
    - **a)** Depression
      - **1)** outpatients, 150 mg/day ORALLY in divided doses; may increase
      days; MAX dosage 400 mg/day (Prod Info trazodone hcl tablets, 200
      - **2)** inpatients, 150 mg/day ORALLY in divided doses; may increase d
      days; MAX dosage 600 mg/day (Prod Info trazodone hcl tablets, 200
  - **2)** Pediatric
    - **a)** Safety and effectiveness in pediatric patients have not been establishe

3) Contraindications
- **a)** Trazodone Hydrochloride
  - **1)** Hypersensitivity to trazodone

4) Serious Adverse Effects
- **a)** Trazodone Hydrochloride
  - **1)** Cardiac dysrhythmia
  - **2)** Depression, worsening
  - **3)** Hemolytic anemia
  - **4)** Hypertension
  - **5)** Hypotension
  - **6)** Leukocytosis
  - **7)** Methemoglobinemia
  - **8)** Priapism
  - **9)** Seizure
  - **10)** Suicidal thoughts
  - **11)** Suicide

5) Clinical Applications
- **a)** Trazodone Hydrochloride
  - **1)** FDA Approved Indications
    - **a)** Depression

(generic), 86) (Prod Info Trazodone Hydrochloride (generic), 86a).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Geriatric Patients

1.3.1 Normal Dosage

Trazodone

Trazodone Hydrochloride

1.3.1.A Trazodone

1.3.1.A.1 Electroconvulsive therapy
See Drug Consult reference: DRUGS FOR SEIZURE PROLONGATI

1.3.1.B Trazodone Hydrochloride

1.3.1.B.1 Oral route
a) The therapeutic dose ranges from 50 to 600 milligrams daily. Mos
100 to 300 milligrams/day in single or divided daily doses (Anon, 197
200 milligrams/day have been well tolerated (Rawls, 1982c).
b) The manufacturer recommends that therapy be initiated with 150
and increased gradually, as needed, every 3 to 4 days in increments
doses should not exceed 400 milligrams/day in divided doses. Inpatie
milligrams/day in divided doses, but this dose should not be exceede
on the lowest effective dose (Prod Info Desyrel(R), 1998c).
c) Gradual increases in dosage by 25 to 50 milligrams every 2 week
reduce drowsiness and dizziness with large doses on initiation of ther

1.3.1.B.2 DEPENDENCE
a) After a 60-day study of 50 patients, no drug dependence was obs
25 milligrams three times daily therapy (Piccione & Laguardia, 1975).

1.3.1.B.3 OBESITY
a) The clearance of trazodone appeared unchanged in obese individ
kilograms). It was suggested that the dose of the drug during chronic
rather than total body weight in this patient population (Greenblatt et

1.3.2 Dosage in Renal Failure
A) Trazodone Hydrochloride
1) Dosage adjustments are not required in renal insufficiency (Catanese

1.3.4 Dosage in Geriatric Patients
A) Trazodone Hydrochloride
1) Geriatric patients may not tolerate a single daily dose of trazodone and
considered (Anon, 1979). In one controlled study involving 20 geriatric inp
optimal dose of trazodone was reported to be 150 milligrams daily, in divi
1986).
2) A reduction in clearance and an increase in the half-life of trazodone w
following single intravenous and oral doses (25 and 50 milligrams, respec
The clearance of the drug in elderly females was not significantly affected
patients. Based upon these data, it is suggested that dose reductions of t

chronic therapy in elderly males.

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Initial Response

a) 1 week (Prod Info Desyrel(R), 1998b).

1) Symptomatic relief may be seen during the first week, with optima evident within 2 weeks. Twenty-five percent of those who respond to weeks (up to 4 weeks) of drug administration (Prod Info Desyrel(R), 1

2.2 Drug Concentration Levels

A) Time to Peak Concentration

1) 0.5 to 2 hours (Rawls, 1982a; Georgotas et al, 1982a).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Bioavailability

1) 65% (Nilsen & Dale, 1992a).

B) Effects of Food

1) increased absorption (Prod Info Desyrel(R), 1998b).

a) Total drug absorption may be up to 20% higher when the drug is t empty stomach; hence, trazodone should be given shortly after a me side effects may increase under fasting conditions (Prod Info Desyrel

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding

a) 89% to 95% (Rawls, 1982a; Georgotas et al, 1982a).

2) OTHER DISTRIBUTION SITES

a) PLASMA

1) Trazodone does not appear to selectively localize in any one in the plasma (Prod Info Desyrel(R), 1998b).

B) Distribution Kinetics

1) Volume of Distribution

a) 0.47 to 0.84 L/kg (Nilsen et al, 1993; Nilsen & Dale, 1992a).

1) The volume of distribution following a single 100-mg oral traz following multiple oral trazodone doses, the Vd ranges from 0.47 (Nilsen et al, 1993; Nilsen & Dale, 1992a).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) Liver, extensive (Rawls, 1982a; Georgotas et al, 1982a).

a) Trazodone is extensively metabolized in the liver by oxidation and
Georgotas et al, 1982a). Cytochrome P450 3A4 metabolizes trazodo
chlorophenylpiperazine (Prod Info Desyrel(R), 2003b). It appears tha
involved in its metabolism (Otani et al, 1998). Only 0.13% of a dose i
unchanged trazodone (Brogden et al, 1981).

B) Metabolites
1) meta-Chlorophenylpiperazine, active (Otani et al, 1998).
2) Conjugated compounds, inactive (Baiocchi et al, 1974).
3) Diol derivative, inactive (Baiocchi et al, 1974).
4) Hydroxy derivative, inactive (Baiocchi et al, 1974).
5) N-oxide, inactive (Baiocchi et al, 1974).

2.3.4 Excretion
A) Kidney
1) Renal Clearance (rate)
a) 3 to 5.3 L/hr (Nilsen & Dale, 1992a; Nilsen et al, 1993).
2) Renal Excretion (%)
a) 70% to 75% (Al-Yassiri et al, 1981; Brogden et al, 1981).
B) Other
1) OTHER EXCRETION
a) FECES
1) 21% (Jauch et al, 1976).

2.3.5 Elimination Half-life
A) Parent Compound
1) ELIMINATION HALF-LIFE
a) 7.1 hours (Nilsen & Dale, 1992a; Nilsen et al, 1993).
1) The manufacturer reports a biphasic elimination pattern with
followed by a slower phase half-life of 5 to 9 hours (Prod Info De

3.0 Cautions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING
1) Trazodone Hydrochloride
a) Oral (Tablet)
1) Antidepressants increased the risk of suicidal thinking and behavior (s
children and adolescents with Major Depressive Disorder (MDD) and othe
considering the use of trazodone hydrochloride or any other antidepressa
balance this risk with the clinical need. Patients who are started on therap
clinical worsening, suicidality, or unusual changes in behavior. Families a
of the need for close observation and communication with the prescriber.
approved for use in pediatric patients.
2) Pooled analyses of short-term (4 weeks to 16 weeks) placebo-controll
(SSRIs and others) in children and adolescents with major depressive dis
compulsive disorder (OCD), or other psychiatric disorders (a total of 24 tri
have revealed a greater risk of adverse events representing suicidal think
the first few months of treatment in those receiving antidepressants. The
patients receiving antidepressants was 4%, twice the placebo risk of 2%.
trials (Prod Info trazodone hydrochloride oral tablet, 2005).

3.1 Contraindications
A) Trazodone Hydrochloride
1) Hypersensitivity to trazodone

3.2 Precautions

A) Trazodone Hydrochloride
1) Suicidal ideation and behavior or worsening depression; increased risk, pa
adolescents, during the first few months of therapy (Anon, 2004)
2) Bipolar disorder; the possibility that a major depressive episode may be the
disorder should be ruled out prior to initiating antidepressant therapy (Anon, 2
3) Cardiac disease; trazodone is potentially arrhythmogenic
4) Concomitant administration of antihypertensive drugs may require decreas
antihypertensive drug
5) Concomitant treatment with electroconvulsive therapy
6) Discontinue use of trazodone for as long as clinically feasible prior to electi
7) During the acute recovery period after myocardial infarction
8) In suicidal or seriously depressed patients, prescribe in limited quantities u
9) May increase or decrease prothrombin time (PT) in patients taking warfari
10) Pregnancy or lactation
11) Priapism may occur, possibly requiring surgical intervention

Bradyarrhythmia

Cardiac dysrhythmia

Cardiovascular finding

Edema

Heart block

Hypotension

Prolonged QT interval

Tachyarrhythmia

3.3.1.A.1 Bradyarrhythmia

a) Summary

1) Occasional sinus BRADYCARDIA has occurred in long-term
1998a).

3.3.1.A.2 Cardiac dysrhythmia

a) Summary

1) Recent clinical studies in patients with pre-existing cardiac dis
may be arrhythmogenic in some patients in that population. Arrh
premature ventricular contractions, ventricular couplets, and in tv
beats) of ventricular tachycardia. There have also been several p
arrhythmias in trazodone- treated patients who had pre-existing
of prospective studies are available, patients with pre- existing ca
monitored, particularly for cardiac arrhythmias (Prod Info Desyre
Janowsky et al, 1983a; Aronson & Hafez, 1986; Pellettier & Bart
1983).

b) Incidence: rare

c) LITERATURE REPORTS

1) Trazodone administration has been associated with aggravat
patients with pre-existing cardiac disease (Janowsky et al, 1983;
patient had a mitral valve prolapse and the other had hypertensio
atherosclerosis. Administration of trazodone 50 to 300 milligrams
the frequency of ventricular arrhythmias within 1 to 2 weeks. The
with cardiac arrhythmias and/or mitral valve prolapse should be
trazodone administration. Although trazodone presumably lacks
manufacturer warns that close monitoring is recommended for pa
(Prod Info Desyrel(R), 1998a).

2) Trazodone was associated with the occurrence of premature
angina in a 45-year-old male when the dose of the drug was incr
daily, following an approximate one month course of 50 to 150 m
After withdrawal from trazodone, the chest pain and arrhythmias
previous history of cardiovascular disease.

3) In a hospitalized patient who developed ventricular fibrillation
of trazodone 75 milligrams for three days was associated with si
bradycardia and sinus arrest, hypotension, and premature ventri
Bartolucci, 1984).

4) In three patients, aged 26, 61 and 41 years with preexisting c
trazodone appears to have exacerbated premature ventricular co
ventricular tachycardia in one case (Janowsky et al, 1983; Vlay &

3.3.1.A.3 Cardiovascular finding

a) Summary

1) In clinical trials, cardiovascular effects of trazodone reported i
HYPERTENSION, hypotension, SYNCOPE, tachycardia or PALI
breath (Prod Info Desyrel(R), 1998a). Additional cardiovascular e
voluntarily reported to the manufacturer include CARDIOSPASM
ACCIDENT OR STROKE, CONGESTIVE HEART FAILURE, ede
CONDUCTION BLOCK, ATRIAL FIBRILLATION, MYOCARDIAL
ARREST, arrhythmia, and ventricular ectopic activity, including v
Desyrel(R), 1998a).

b) Arrhythmia, bradycardia, edema, heart block, hypotension, tachyc
have been reported with the administration of trazodone.

3.3.1.A.4 Edema

a) Summary

1) Peripheral edema was described in 10 of 100 patients admini

to 600 milligrams (mg) daily for depression (Barrnett et al, 1985). was 56 years, with 9 being women. The mean dose of the drug t daily and was associated with a weight gain of 4.5 kilogram (kg) authors failed to provide information on the time of onset of eden Withdrawal of the drug or reduction in dose resulted in edema re edema, with an onset within 24 hours of initiation of trazodone th allergic response in one case, but no immunologic evidence was 1987).

3.3.1.A.5 Heart block

a) Summary

1) Trazodone has been reported to produce minimal to no effect not produced the cardiotoxicity observed with tricyclic antidepres 1981). However, other data have described ventricular arrhythmi in heart patients (Janowsky et al, 1983; Rausch et al, 1984), sug pre-existing cardiac disease (Prod Info Desyrel(R), 1998a; Raus

b) LITERATURE REPORTS

1) Complete heart block occurred in 77-year-old alcoholic with d single dose of trazodone (50 milligrams). The patient had a histo cardiovascular disease, hypertension and mitral regurgitation; a attacks was also present (Rausch et al, 1984). These data sugge trazodone may produce cardiac conduction defects in patients at

3.3.1.A.6 Hypotension

a) Summary

1) The most frequent cardiovascular side effect during therapy is may be accompanied by syncope, especially in patients taking c therapy (Rakel, 1984)(Spivak et al, 1987). The mild hypotension trazodone therapy is usually transient and not requiring discontin 1980a; Rawls, 1982b; Georgotas et al, 1982b). However, adjustr medication may be necessary if administered concurrently (Prod

b) Incidence: rare

3.3.1.A.7 Prolonged QT interval

a) Summary

1) Trazodone 150 milligrams, administered in a single dose to e to significantly prolong the QTc interval and decrease T wave he (Burgess et al, 1982).

3.3.1.A.8 Tachyarrhythmia

a) Summary

1) Trazodone may be associated with the exacerbation of ventri 1990; Himmelhoch et al, 1984; Vlay & Friedling, 1983).

b) LITERATURE REPORTS

1) Exercise-induced nonsustained ventricular tachycardia was d with no underlying heart disease receiving trazodone 50 milligrar trazodone was confirmed by treadmill testing initially, following di rechallenge with trazodone (Vitullo et al, 1990).

2) Trazodone does not appear to produce tachycardia, even in p consistently lowers baseline heart rate in therapeutic doses (Him

3) Exacerbation of ventricular tachycardia was associated with a 41-year-old female patient. The patient had a history of complex symptomatic only with palpitations. On one occasion, while not r started on trazodone 50 milligrams daily for depression. Two wee patient experienced dizzy spells and a Holter recording demonst rate of 160 beats per minute. Trazodone was discontinued and v returned to baseline. Due to potential hazards, the patient was n 1983). Administration of trazodone to patients with ventricular ec cardiac monitoring.

3.3.2 Dermatologic Effects

3.3.2.A Trazodone Hydrochloride

Dermatological finding

Diaphoresis

Erythema multiforme

Rash

3.3.2.A.1 Dermatological finding

a) Summary

1) Dermatologic effects of trazodone therapy voluntarily reporte ALOPECIA, LEUKONYCHIA or white patches under the nails, P URTICARIA (Prod Info Desyrel(R), 1998a).

b) Trazodone has been reported to cause alopecia, pruritus, diaphor rash.

3.3.2.A.2 Diaphoresis

a) Summary

1) Allergic and edematous skin reactions and SWEATING or CL of patients or more treated with trazodone in clinical trials (Prod I

3.3.2.A.3 Erythema multiforme

a) Summary

1) Erythema multiforme was described in a 63-year-old woman days of oral trazodone 300 to 400 milligrams. The patient presen papular eruption and erythematous scaly plaques on both the ha carbonate had also been prescribed and both drugs were discon symptomatic treatment with betamethasone ointment. The patie heel and erosions on the tongue and buccal mucosa two days af foot soaks and Chloraseptic(R) mouthwash were begun. The pat sequelae. Lithium has not been associated with erythema multif patient for two weeks without incident. The first symptoms of a ra trazodone was begun; this led the authors to suggest that trazod (Ford & Jenike, 1985).

3.3.2.A.4 Rash

a) Summary

1) Skin rashes, which respond to drug withdrawal and/or antihis during trazodone therapy (Trapp et al, 1979); (Al- Yassiri & Bridg

3.3.3 Endocrine/Metabolic Effects

3.3.3.A Trazodone Hydrochloride

Body temperature finding

Endocrine finding

Isolated prolactin deficiency

Metabolic finding

Shivering

Weight change finding

3.3.3.A.1 Body temperature finding

a) Trazodone has been reported to cause chills.

3.3.3.A.2 Endocrine finding

a) Summary

1) Endocrine effects of trazodone therapy voluntarily reported to HYPERAMYLASEMIA and syndrome of inappropriate antidiureti

(Prod Info Desyrel(R), 1998a). Additional endocrine effects of tra
reported to the manufacturer include BREAST ENLARGEMENT
HIRSUTISM (Prod Info Desyrel(R), 1998a).

b) Hyperamylasemia, syndrome of inappropriate antidiuretic hormon
prolactin levels have been reported with the administration of trazodo

3.3.3.A.3 Isolated prolactin deficiency

a) Summary

1) Several studies have demonstrated no change (Nair, 1979) o
prolactin levels (Roccatagliata et al, 1979; Rolandi et al, 1981a)
reports of BREAST TENDERNESS were found in the literature (
manufacturer received 8 incident reports, although none had sub
Comm, 1985).

3.3.3.A.4 Metabolic finding

a) Trazodone has been reported to cause both weight gain and weig

3.3.3.A.5 Shivering

a) Summary

1) Chills has been reported voluntarily to the manufacturer as ar
therapy (Prod Info Desyrel(R), 1998a).

3.3.3.A.6 Weight change finding

a) Summary

1) WEIGHT GAIN and WEIGHT LOSS were both reported in ov
(Prod Info Desyrel(R), 1998a).

3.3.4 Gastrointestinal Effects

3.3.4.A Trazodone Hydrochloride

Constipation

Gastrointestinal tract finding

Loss of appetite

Nausea and vomiting

Xerostomia

3.3.4.A.1 Constipation

a) Summary

1) Constipation has been reported as an adverse effect of trazo
study with imipramine, the incidence of constipation was less in t
imipramine treated patients (20%) (Gershon & Newton, 1980a).

3.3.4.A.2 Gastrointestinal tract finding

a) Summary

1) Other gastrointestinal effects reported in 1% of patients or mo
abdominal or GASTRIC DISORDERS, TASTE DISORDERS, DI
reduced appetite. Increased SALIVATION has also been reporte
Desyrel(R), 1998a).

b) Anorexia, constipation, dry mouth, nausea, vomiting, and diarrhea
administration of trazodone.

3.3.4.A.3 Loss of appetite

a) Summary

1) CASE REPORT - Anorexia and hypomania were reported in
(mg) trazodone and 500 mg of tryptophan three times a week. A
was discontinued (Patterson & Srisopark, 1989).

3.3.4.A.4 Nausea and vomiting

a) Summary

1) Nausea and vomiting are the most frequently reported advers
1998a).

3.3.4.A.5 Xerostomia

a) Summary

1) XEROSTOMIA has been reported with trazodone therapy, bu
than in imipramine-treated patients (45%) (Gershon & Newton, 1

3.3.5 Hematologic Effects

3.3.5.A Trazodone Hydrochloride

Agranulocytosis

Hematology finding

3.3.5.A.1 Agranulocytosis

a) Summary

1) CASE REPORT - A 40-year-old male had been using trazodo
admission, with no history of any other concurrent drug or chemi
perianal furuncles. Hematology laboratory values were normal w
erythrocyte sedimentation rate (ESR) and decreased leukocyte c
of 4.0 - 10.0 x 10(9)). Differential cell count was reported to be 7
and 1% eosinophils (absolute neutrophil count 0). Pus from his f
aureus. Treatment was begun with flucloxacillin. Trazodone thera
later, his leukocyte count had increased and ESR had decreased
laboratory values had returned to normal (Van der Klauw et al, 1

3.3.5.A.2 Hematology finding

a) Summary

1) Hematologic effects of trazodone therapy voluntarily reported
HEMOLYTIC ANEMIA, LEUKOCYTOSIS, and METHEMOGLOE
1998a).

b) Agranulocytosis, hemolytic anemia, leukocytosis, and methemogl
trazodone therapy.

3.3.6 Hepatic Effects

3.3.6.A Trazodone Hydrochloride

Cholestasis

Hepatitis

Increased liver enzymes

Liver finding

3.3.6.A.1 Cholestasis

a) Summary

1) Cholestasis has resulted from the use of trazodone (Rettman
Nies, 1983).

b) LITERATURE REPORTS

2001).

2) A 75-year-old Asian woman, who had experienced chronic na
trazodone, presented with dark urine, pale stools, and jaundice f
months of trazodone treatment, 150 milligrams/day, for depressi
elevated prothrombin time (PT), partial thromboplastin time (PTT
Negative immunostains on liver biopsy and serologic tests for he
remote past exposure to hepatitis B but not of ongoing viral infec
discontinuing trazodone, the nausea and anorexia resolved. Ami
and PPT normalized within 2 weeks, while bilirubin and gamma g
gradually returned to normal in 6 months (Beck et al, 1993).

3.3.6.A.3 Increased liver enzymes

a) Summary

1) Trazodone has been reported to cause elevated liver enzyme
normalize after discontinuing the drug (Fernandes et al, 2000; Cl

b) LITERATURE REPORTS

1) Jaundice and elevated liver function tests occurred in a 38-ye
taking trazodone for 18 months and while she was also using lov
arthritis. She presented with itching, nausea, and an episode of v
withdrawn, and her liver tests started to improve. Approximately
own took trazodone for two days. Her bilirubin, aspartate aminotr
transaminase levels promptly rose. Normalization occurred with
(Fernandes et al, 2000).

2) Hepatotoxicity was reported in a 63-year-old male treated for
disorder with trazodone, following three weeks of therapy (doses
that time, liver function tests were mildly elevated. Eight days lat
elevated and biopsy revealed mild portal expansion with modera
several mononuclear and polymorphonuclear leukocytes, scatter
acidophil bodies. Hepatic enzymes returned to normal four week
(Chu et al, 1983). A cause and effect relationship is difficult to es
enzymes did not peak until eight days after discontinuing the dru

Dystonia

Myoclonus

Neurological finding

Parkinsonism

Seizure

Somnolence

3.3.9.B.1 Dystonia

a) Summary

1) Dystonic reactions have been reported only in case reports. A effect is impairment of nigrostriatal dopamine activity by serotoni 1997).

b) LITERATURE REPORTS

1) In one case report, a 14-year-old boy was initially treated with (mg)/day (given in the morning) with gradual increases to 150 mg mg/day (given at night) was added to the regimen on day seven. treatment), the boy developed acute DYSTONIA, manifested as which was controlled with three intramuscular doses of 2 mg ber Trazodone was discontinued and the symptoms did not recur (Te

2) In a case report, dystonia was reported in a 24-year-old man disorder. The patient started on trazodone 25 milligrams (mg) at this dose was increased to 50 mg. Three days after starting the h

the emergency department with his mouth immobile in an open p stiffness and feeling as if his face was "frozen." The symptoms w a single 50 mg dose of intravenous diphenhydramine. Because t noted over a year later in the patient's treatment after he began t authors hypothesized that the mechanism causing the dystonia v possibly associated with enhancement of serotonergic neurotran dopamine activity (Lewis et al, 1997).

3.3.9.B.2 Myoclonus

a) Summary

1) Myoclonus has been reported in patients receiving trazodone upon withdrawal of trazodone (Patel et al, 1988; Garvey & Tollef

b) LITERATURE REPORTS

1) Myoclonus was reported in a 38-year-old woman receiving 30 1988). This may be related to serotonergic activity.

2) A high incidence of myoclonus was reported with cyclic antide imipramine, desipramine, amitriptyline, doxepin, trazodone, nortr Tollefson, 1987). Ninety-eight patients (93%) with major depress with these agents in initial doses of 50 milligrams (mg) daily of im increasing to a maximum of 300 mg daily after several weeks. O developed myoclonus after initiation of therapy, with the myoclor nine (9%) and resulting in withdrawal of the antidepressant or a r occurred within one month of therapy in 81% of the 39 patients, v myoclonus within two weeks; the mean dose of antidepressant b myoclonus was 169 mg daily in imipramine equivalents, which w utilized by the patients not developing myoclonus (164 mg daily) withdrawal of the antidepressant but persisted if medication char spontaneous remission of myoclonus was observed in nine patie development of myoclonus were observed.

3.3.9.B.3 Neurological finding

a) Summary

1) Central nervous system effects reported in over 1% of patient DISORIENTATION, HEADACHE, INSOMNIA, MEMORY IMPAIR COORDINATION, PARESTHESIA, and TREMORS (Prod Info D effects of trazodone therapy voluntarily reported to the manufact EXTRAPYRAMIDAL SYMPTOMS, GRAND MAL SEIZURES, IN DYSKINESIA, VERTIGO, and WEAKNESS (Prod Info Desyrel(F FATIGUE have also been reported in relatively high incidence.

b) Delirium, drowsiness, dystonia, myoclonus, headache, ataxia, sei dizziness, and fatigue have been reported with administration of trazo

3.3.9.B.4 Parkinsonism

a) Summary

1) CASE REPORT: A 57-year-old man who had undergone hem stage renal disease was given oral trazodone 100 milligrams/day depressive symptoms disappeared, but over 18 months he gradu symptoms, including cogwheel rigidity, akinesia, and gait disturb within 1 week of discontinuing trazodone. No serum concentratio were obtained, but the clinical course strongly suggested that the induced by trazodone (Fukunishi et al, 2002).

3.3.9.B.5 Seizure

a) Summary

1) Based on reports to the manufacturer, over 30 cases of seizu administration. Sixteen reported cases had previous documente al, 1985; Pers Comm, 1983; Tasini, 1986).

b) Incidence: rare

c) LITERATURE REPORTS

1) Another report described a 47-year-old man who developed c treatment with trazodone 150 mg/day for three weeks. Electroen abnormal after discontinuation of trazodone and it was speculate underlying seizure disorder (Tasini, 1986).

2) Multiple tonic-clonic seizures occurred in a 50-year-old woma following 18 days of trazodone therapy (50 milligrams daily) (Lefl also had fever on admission; it was unclear if this contributed to

3.3.9.B.6 Somnolence

a) Summary

1) The most commonly reported adverse effects of trazodone th LETHARGY. In a study of nine patients who received trazodone days, three were lethargic and two were drowsy (Kellams et al, 1 1982b).

b) LITERATURE REPORTS

1) Twelve of 50 patients who were receiving 200 to 600 milligrar dizzy during a four week treatment period (Feighner, 1980a). Dr patients in another report (Rawls, 1982b).

3.3.10 Ophthalmic Effects

3.3.10.A Trazodone Hydrochloride

Blurred vision

Eye / vision finding

Intraocular pressure finding

3.3.10.A.1 Blurred vision

a) Summary

1) Blurred vision has been reported as an adverse effect of traz patients in clinical trials (Prod Info Desyrel(R), 1998a). However, imipramine, the incidence of blurred vision was less in trazodone patients (20%) (Gershon & Newton, 1980a).

3.3.10.A.2 Eye / vision finding

a) Summary

1) Tired, red, or ITCHING EYES were reported in approximately trazodone in clinical trials. DIPLOPIA, in association with trazodc reported to the manufacturer (Prod Info Desyrel(R), 1998a).

2) The reappearance or persistence of an image has been asso patients receiving trazodone therapeutically (Hughes & Lessell,

b) Trazodone has been reported to cause blurred vision, intraocular and itchy eyes, and vision changes.

3.3.10.A.3 Intraocular pressure finding

a) Summary

1) Trazodone produces a slight decrease in intraocular pressure glaucoma by increasing outflow and decreasing production of aq reduction occurs in 180 minutes. However, after three hours intra level slightly below pretreatment values (Daniel & Fiore, 1972). T beneficial in patients with open-angle glaucoma and concomitan associated trazodone use with increased IOP (Pae et al, 2003).

b) LITERATURE REPORTS

1) A 61-year-old woman, with a 6-year history of angle-closure g increase in intraocular pressure (IOP) following the administratio maintained an IOP of 13 to 19 millimeters of mercury (mmHg) in regimen of daily drops of timolol 0.5% and pilocarpine 5%. Three milligrams (mg) per day for depressive symptoms, she develope eye pain and intermittent headache. Her IOP, 6 days after startin left eye and 40 mmHg in the right eye. Trazodone was discontinu acetazolamide 500 mg/day. Two days later her IOP returned to b

3.3.12 Psychiatric Effects

Abnormal ejaculation

Increased libido

Priapism

Reduced libido

3.3.14.B.1 Abnormal ejaculation

a) Summary

1) INHIBITION OF EJACULATION was reported in a 51-year-ol
50 milligrams (mg) at bedtime for 3 days, then 100 mg at bedtim
trazodone and substitution with doxepin 50 mg at bedtime result
EJACULATORY INHIBITION (Jones, 1984).

3.3.14.B.2 Increased libido

a) Summary

1) Trazodone administration produced an increase in libido in th
cases, trazodone was given in gradually increasing doses up to
sexual drive were observed when this dose was achieved. Two p

drug due to this effect (Gartrell, 1986).

3.3.14.B.3 Priapism

a) Summary

1) Trazodone therapy has been associated with the occurrence surgical intervention (Prod Info Desyrel(R), 1998a; Pecknold & L Pescatori et al, 1993); (Scher et al, 1983)(Hanno et al, 1988); (C

b) Incidence: rare

c) LITERATURE REPORTS

1) In a case report, a patient treated first with nefazodone and th priapism after beginning trazodone therapy. A 51- year-old man, depressive disorder, participated in a trial of nefazodone at a dos day for a period of 6 weeks. After completion of the experimental therapy with trazodone 300 mg/day. After 17 days of therapy witl allopurinol for gout contracted during this period) the patient repo was discontinued. The patient subsequently was treated with net of priapism were reported (Pecknold & Langer, 1996).

2) A 34-year-old woman who had received fluoxetine 40 milligra treatment of depression was started on trazodone to combat fluo fluoxetine was decreased to 20 mg per day and trazodone 25 mg 50 mg at bedtime was added. Five days after starting trazodone onset irritation in the clitoral region that four days later developed PRIAPISM. Both drugs were discontinued and she received oral hydrochloride/guaifenesin twice daily for 2 days. The clitoral disc within 24 hours and there was no further clitoral dysfunction repo

3) Priapism has been seen as an adverse effect from therapeuti (Hanno et al, 1988); (Carson & Mino, 1988). Surgery was require the manufacturer and permanent impotence has been a sequela

4) In 57 cases reported to the United States Food and Drug Adr be mostly likely to occur during the first 28 days of therapy, with (mg) daily (median, 150 mg daily) (Warner et al, 1987). The med developed priapism was 40 years; however, all age groups appe adverse effect. It is suggested that patients be well informed of th given trazodone and to discontinue the drug if any unusual erect

3.3.14.B.4 Reduced libido

a) Summary

1) Decreased libido was reported in 1% of patients in clinical tria trazodone therapy voluntarily reported to the manufacturer incluc incontinence and urinary retention (Prod Info Desyrel(R), 1998a)

3.3.15 Respiratory Effects

3.3.15.A Trazodone Hydrochloride

3.3.15.A.1 Respiratory finding

a) Summary

1) Sinus or NASAL CONGESTION was reported in approximate trials. APNEA, in association with trazodone therapy, was volunt (Prod Info Desyrel(R), 1998a).

b) Nasal congestion and apnea have been reported with the adminis

3.3.16 Other

3.3.16.A Trazodone Hydrochloride

Summary

Anticholinergic adverse reaction

Died without sign of disease

Drug withdrawal

3.3.16.A.1 Summary

a) OTHER EFFECTS

1) Although trazodone produces fewer anticholinergic effects tha these effects have been reported with trazodone use. Unexplain with the administration of trazodone.

3.3.16.A.2 Anticholinergic adverse reaction

a) Summary

1) Trazodone produces significantly fewer anticholinergic effects (Taylor et al, 1980; Georgotas et al, 1982b; Gershon & Newton, one study, the incidence of anticholinergic effects with trazodone similar to placebo, but imipramine, in comparison, produced sign (Gershon & Newton, 1980a). Trazodone's lower degree of antich drug useful in glaucoma patients with depression (Rawls, 1982b) of increased intraocular pressure associated with trazodone use

3.3.16.A.3 Died without sign of disease

a) Summary

1) Unexplained death has been reported voluntarily to the manu trazodone therapy (Prod Info Desyrel(R), 1998a).

3.3.16.A.4 Drug withdrawal

a) Summary

1) Although uncommon, a withdrawal syndrome has been repor discontinuation of trazodone.

b) LITERATURE REPORTS

1) A trazodone withdrawal syndrome has been reported followin therapeutic doses of traxodone. It has been suggested that deve due to serotonergic effects and short half-lives of trazodone and chlorophenylpiperazine, which may result in noradrenergic rebou Withdrawal signs/symptoms have consisted of insomnia, vivid dr abdominal pain. anxiety, palpitations, hypomania, headache. my formication (Otani et al, 1994; Peabody, 1987; Menza, 1986); (TI Rapid withdrawal has been reported to result in predominantly ga respond to administration of atropine. It has been suggested that following rapid withdrawal (Montalbetti & Zis, 1988).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Pro Trimesters)

3) Clinical Management

a) There is insufficient clinical experience with trazodone to confirm its sa data are available, caution should be exercised with the use of trazodone

4) Literature Reports

a) One report describes the outcomes of 12 pregnancies exposed to traz electively terminated, and the remaining ten resulted in children without m 1996). One hundred newborns (out of 229,101 births in a surveillance stu recipients) had been exposed to trazodone during the first trimester of pre exposures, one major birth defect was observed; no details are available (Rosa & Baum, 1995).

b) Animal studies indicate that high doses in rats and rabbits (15 to 50 tin contributed to increased fetal resorption and congenital anomalies. Early a lower birth weights for offspring in animals receiving high doses (Rivett & These studies were designed with trazodone dosing of 10 to 300 mg/kg d to and during mating, throughout pregnancy and lactation, and in a separa days of pregnancy and throughout lactation. Additionally, rats and rabbits during the middle portion of pregnancy developed no anomalies in offsprin Suzuki, 1973).

B) Breastfeeding

1) American Academy of Pediatrics Rating: Drugs for which the effect on nurs be of concern. (Anon, 2001)

2) Thomson Lactation Rating: Infant risk cannot be ruled out.
a) Available evidence and/or expert consensus is inconclusive or is inade when used during breastfeeding. Weigh the potential benefits of drug trea before prescribing this drug during breastfeeding.
3) Clinical Management
a) Trazodone is excreted into human milk in small amounts. Despite the effects in breast-fed infants, the American Academy of Pediatrics classifie effect on nursing infants is unknown, but may be of concern (Anon, 2001)
4) Literature Reports
a) Trazodone is excreted in low concentrations in breast milk following si were administered single oral doses of 50 mg, with a resultant milk-plasm that newborn infants would ingest less than 0.005 mg/kg of trazodone foll mother and subsequent breast feeding for a 12-hour period (Verbeeck et

3.5.1.A Acetophenazine

1) Interaction Effect: hypotension

2) Summary: Concomitant administration of trazodone with chlorpromazi

additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986f).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.B Amiodarone
1) Interaction Effect: increased risk of QT interval prolongation and torsac
2) Summary: Both amiodarone and trazodone are metabolized by CYP3A amiodarone is also a CYP3A4 inhibitor (Prod Info CORDARONE(R) oral t prolongation and torsades de pointes has been reported with the coadmir trazodone in 2 cases (Antonelli et al, 2005; Mazur et al, 1995). Caution is coadministered. Cardiac function may need to be closely monitored.
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: QT interval prolongation and torsades de pointe amiodarone and trazodone has been reported (Prod Info CORDARONE(R al, 2005; Mazur et al, 1995). Use caution if these agents are coadminister be monitored.
7) Probable Mechanism: unknown
8) Literature Reports
a) A case report described QT interval prolongation and polymorpho (torsades de pointes) in a 74-year-old woman receiving amiodarone a woman, who had a history of hypertension, stable angina, diastolic he pacemaker for sick sinus syndrome, and depression, presented with medications included nifedipine, furosemide, and aspirin. Amiodarone mg/day, and was later reduced to 100 mg/day 6 months prior to curre been initiated 2 months prior to current presentation at an initial dose increased over 2 weeks to 150 mg/day. While neurological exam and normal, cardiac examination revealed a II/VI systolic ejection murmur prolonged QT, QTc, and JTc intervals (0.72, 0.777, and 0.561 second to an ECG obtained prior to initiation of trazodone (baseline). Subsec trazodone were discontinued. However, recurrent episodes of polymo developed. Although treatment with intravenous lidocaine and magne episodes were managed by increasing the ventricular pacing rate to 9 episodes did not recur following gradual reduction of the ventricular p minutes over 48 hours, and the ECG pattern was similar to baseline, shortening to 0.52, 0.561, and 0.324 seconds, respectively (Mazur et
b) A chart review of 6 patients revealed a case of syncope and TdP i addition of amiodarone (50 mg/day) for paroxysmal atrial fibrillation to mg/day). The patient, who had a history of coronary artery disease, d hyperlipidemia, presented with syncope 2 months following the initiat proposed that in addition to the amiodarone-trazodone combination, p have contributed to the occurrence of torsades in this patient (Antone

3.5.1.C Amprenavir
1) Interaction Effect: an increase in trazodone plasma levels and may inc
2) Summary: Concomitant use of amprenavir and trazodone may result in concentrations due to amprenavir inhibition of CYP3A4-mediated trazodo when using these medications together and consider a reduction of trazoc trazodone side effects such as nausea, dizziness, hypotension, and syncc Capsules, 2005).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Consider a lower dose of trazodone if it is used amprenavir. Monitor patients receiving trazodone and amprenavir for adve nausea, dizziness, hypotension, and syncope.
7) Probable Mechanism: inhibition of CYP3A4-mediated trazodone metab
8) Literature Reports
a) Coadministration of trazodone with ritonavir, a potent CYP3A4 inh amprenavir, resulted in significant trazodone pharmacokinetic change concurrent administration of a total of 4 doses ritonavir 200 mg twice

trazodone increased the peak plasma trazodone concentration (Cma

3.5.1.D Atazanavir

1) Interaction Effect: an increase in trazodone plasma levels and increase (nausea, dizziness, hypotension)

2) Summary: Atazanavir may inhibit the CYPA-mediated metabolism of tr atazanavir (with or without ritonavir) and trazodone may elevate plasma le should be monitored for increased trazodone side effects including nause hypotension. A reduction in trazodone dosing may be warranted (Prod Inf 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Caution is advised for the concomitant use of at and trazodone. Patients receiving atazanavir and trazodone should be mo effects and hypotension. Consider a reduction in trazodone dosing (Prod 2005).

7) Probable Mechanism: inhibition of CYP3A4-mediated trazodone metab

3.5.1.E Carbamazepine

1) Interaction Effect: decreased trazodone plasma concentrations

2) Summary: An increase in carbamazepine concentration/dose ratio was added to therapy, although the patient did not exhibit any signs of carbam 1999a). Trazodone serum concentrations have been decreased during co carbamazepine. Patients should be closely monitored to see if there is a r trazodone when taking both drugs (Prod Info Desyrel(R), 2003a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: When given concurrently with carbamazepine, t should be closely monitored and trazodone dose adjustments made as ne

7) Probable Mechanism: induction of trazodone CYP3A4-mediated metal

8) Literature Reports

a) A 53-year-old male diagnosed with generalized partial epilepsy wa mg daily with a corresponding serum concentration of 7.9 mg/L. The calculated by dividing the serum concentration (mg/L) by the dose (m therapy was initiated for depression, and two months later the carban had increased to 10.0 mg/L with a corresponding concentration/dose concentration of the main pharmacologically active metabolite of carb 10,11-epoxide, was not measured. Although this patient did not show carbamazepine toxicity, this drug interaction may be clinically signific higher carbamazepine steady-state concentration (Romero et al, 199

3.5.1.F Chlorpromazine

1) Interaction Effect: hypotension

2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986o).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.

7) Probable Mechanism: additive hypotensive effects

3.5.1.G Clarithromycin

1) Interaction Effect: an increase in trazodone plasma levels

2) Summary: Patients receiving trazodone therapy concurrently with clari exposure to trazodone due to clarithromycin-mediated inhibition of CYP3A 2009).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: established

6) Clinical Management: Consider a lower dose of trazodone if it is used

clarithromycin. Monitor patients receiving trazodone and clarithromycin fo
sedation, memory impairment, or impaired psychomotor performance.
7) Probable Mechanism: inhibition of CYP3A-mediated trazodone metabo
8) Literature Reports
a) Increased plasma concentrations and pharmacodynamic effects c
with clarithromycin was demonstrated in a randomized, double-blind,
healthy volunteers. The study involved five treatment protocols: (a) pl
(5 mg) plus placebo, (c) zolpidem (5 mg) plus clarithromycin (500 mg
placebo, and (e) trazodone (50 mg) plus clarithromycin (500 mg). Blo
intermittently throughout the study to determine plasma concentratior
clarithromycin. Coadministration of trazodone with clarithromycin con
increase in trazodone Cmax (922 +/- 161 nanogram/mL versus 681 +
trazodone AUC (9,275 +/- 3,216 nanogram/mL per hour versus 4,668
Trazodone elimination half-life increased with coadministration of clar
(13.9 +/- 8.1 hr versus 7.1 +/- 1.6 hr), and oral clearance was reduce
+/- 27 mL/min). The sedative effects of trazodone were also enhance
no significant changes in pharmacokinetics or pharmacodynamics of
clarithromycin treatment groups (Farkas et al, 2009).

3.5.1.H Darunavir
1) Interaction Effect: increased trazodone plasma concentrations
2) Summary: Coadministration of ritonavir-boosted darunavir and trazodo
plasma concentrations of trazodone, possibly due to inhibition of CYP3A-
by darunavir/ritonavir. As this may result in trazodone adverse effects (na
syncope), caution is advised when darunavir/ritonavir and trazodone are a
lower dose of trazodone should be considered (Prod Info PREZISTA(R) fi
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concurrent administration of ritonavir-boosted d
increase trazodone plasma concentrations. Use caution when these agen
patients for signs of increased trazodone adverse effects (nausea, dizzine
consider using a lower trazodone dose (Prod Info PREZISTA(R) film coat
7) Probable Mechanism: inhibition of CYP3A-mediated trazodone metabo

3.5.1.I Delavirdine
1) Interaction Effect: increased plasma concentrations of trazodone and i
adverse effects (nausea, dizziness, hypotension, syncope)
2) Summary: Trazodone is metabolized in the liver by CYP3A4 enzymes.
inhibitors, such as delavirdine, may decrease the metabolism of trazodon
plasma concentrations. Although, the drug interaction between delavirdine
studied, adverse effects such as nausea, dizziness, hypotension and sync
coadministration of trazodone and ritonavir. Therefore, caution is advised
are administered concomitantly and a reduction in trazodone dosage shou
RESCRIPTOR(R) oral tablets, 2006).
3) Severity: moderate
4) Onset: delayed

6) Clinical Management: Use caution with the coadministration of delavirc
patients for signs of increased trazodone adverse effects (nausea, dizzine
Consider reducing trazodone dosage when administering concomitantly w
7) Probable Mechanism: inhibition of cytochrome P450 3A4-mediated tra

3.5.1.J Digoxin
1) Interaction Effect: increased digoxin serum concentrations and an incr
(nausea, vomiting, arrhythmias)
2) Summary: Digoxin maximum serum concentrations were increased ne
after nefazodone (an antidepressant structurally related to trazodone) wa
randomized, crossover interaction study (Dockens et al, 1996a). Digoxin t
woman after trazodone was added to a stable treatment regimen that incl
had remained within a stable therapeutic range for many months prior to t
(Rauch & Jenike, 1984c). Increased serum digoxin serum concentrations
patients treated concurrently with trazodone and digoxin (Prod Info Desyr
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor digoxin concentrations when trazodone

discontinued from concomitant treatment with digoxin. Also, monitor patie
digoxin toxicity. Adjust digoxin dose accordingly.
7) Probable Mechanism: unknown
8) Literature Reports
a) Digoxin serum concentrations were increased nearly 30% compar
(a phenylpiperazine antidepressant structurally related to trazodone)
digoxin. In an open, randomized, triple-crossover interaction study, h
an 8-day oral regimen of digoxin 0.2 milligrams (mg) daily, nefazodor
drugs administered concomitantly during each 8-day trial period; all s
alternate study regimen after a 10-day wash-out period. Steady-state
time curve (AUC) and peak (Cmax) and trough (Cmin) serum concen
by 15%, 29% and 27%, respectively (p less than 0.05, each paramet
observed in vital signs, heart rate, or PR, QRS, and QT intervals. The
adverse events did not differ between treatment groups (Dockens et
b) Digoxin toxicity occurred in a 68-year-old woman after trazodone
regimen that included digoxin. Prior to beginning trazodone therapy,
remained within therapeutic range for many months (at a dose of digo
and on admission was 0.8 nanograms/milliliter (ng/mL). She was hos
trazodone was initiated at a dose of 50 milligrams (mg) on day 1, and
by day 11. On treatment day 14, the patient complained of nausea ar
measured at 2.8 ng/mL. Trazodone 300 mg daily was continued and
therapeutic digoxin serum levels were restored. The patient's digoxin
therapeutic range after conversion to an every-other-day regimen of
continued to receive trazodone 300 mg daily (Rauch & Jenike, 1984b
c) Increased serum concentrations of digoxin have been observed ir
treatment with trazodone (Prod Info Desyrel(R), 2003b).

3.5.1.K Droperidol
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation,
arrest)
2) Summary: Any drug known to have the potential to prolong the QT inte
with droperidol. Possible pharmacodynamic interactions can occur betwee
arrhythmogenic agents such as antidepressants that prolong the QT inter
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Droperidol should be administered with extreme
factors for development of prolonged QT syndrome, such as treatment wi
7) Probable Mechanism: additive cardiac effects

3.5.1.L Ethopropazine
1) Interaction Effect: hypotension
2) Summary: Concomitant administration of trazodone with chlorpromazi
additive hypotensive effects in two case reports. Withdrawal of trazodone
hypotension (Asayesh, 1986a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v
effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.M Fluoxetine
1) Interaction Effect: trazodone toxicity (sedation, dry mouth, urinary rete
(hypertension, hyperthermia, myoclonus, mental status changes)
2) Summary: When given concurrently, trazodone and fluoxetine have be
effective with and without side effects (Metz & Shader, 1990; Swerdlow &
1992; Maes et al, 1997a). Coadministration of trazodone and fluoxetine ha
speech dysfunction in a 43-year old man following traumatic brain injury (
have also been several reports of serotonin syndrome due to interactions
reuptake inhibitors and antidepressants (George & Godleski, 1996a; Reev
Lee, 1996). Serotonin syndrome is a rare but potentially fatal condition of
characterized by hypertension, hyperthermia, myoclonus and changes in
Further clinical studies are necessary to determine the incidence and impl
associated with this drug combination.
3) Severity: major
4) Onset: delayed

5) Substantiation: probable
6) Clinical Management: Due to the potential for impairment in trazodone monitored for any signs of trazodone toxicity. Occasional dosage reductio Serotonin syndrome, characterized by hypertension, hyperthermia, myocl may also occur during concomitant therapy.
7) Probable Mechanism: decreased trazodone clearance
8) Literature Reports
a) Five cases of elevated antidepressant levels, four involving tricycli imipramine, desipramine) and one involving trazodone, have been re fluoxetine, the ratio of antidepressant level to dose increased by 109 tricyclics and by 31% in the patient on trazodone. The trazodone-trea and unstable gait (Aranow et al, 1989).
b) A 44-year-old man developed symptoms characteristic of serotoni interaction between fluoxetine and trazodone. The patient had been t trazodone 100 mg daily for approximately two months before sympto experienced disorientation, tremor, diaphoresis, and anxiety, followec loss of consciousness. After the patient was treated with cyproheptac resolved over the next 30 minutes. Trazodone was discontinued and fluoxetine 40 mg daily without further complications (George & Godle
c) Serotonin syndrome was also reported in a 29-year-old woman ta The patient was treated with trazodone 200 mg daily at bedtime for a depression and insomnia. The patient's depressive symptoms were u trazodone was subsequently decreased to 50 mg daily at bedtime for mg every morning was added. Within 24 hours after the first dose of agitated, confused, shaky, and diaphoretic. Upon examination, the pa intermittent myoclonus in all extremities, hyperreflexia, tremor, and di antidepressant medications, the patient's symptoms resolved (Reeve
d) A 43-year-old male with traumatic brain injury developed speech fluoxetine and trazodone. The patient was being treated with trazodo pain as a result of a fall. After undergoing a comprehensive psychiatr rehabilitation, fluoxetine 20 mg every morning was added to the patie symptoms of depression. Within one week of starting therapy with flu his speech and later exhibited a slow rate of speech, increased paus phonemes, and word-finding difficulties. After discontinuation of fluox therapy, the patient had marked improvement in speech difficulty and week (Patterson et al, 1997).
e) The pharmacokinetic effect of trazodone and fluoxetine cotherapy a major depressive episode. All were treated with trazodone 100 mg the addition of fluoxetine 20 mg daily, pindolol 7.5 mg daily, or placeb placebo had no significant effect on the plasma concentrations of traz meta-chlorophenylpiperazine (mCPP). However, when fluoxetine was of mCPP increased from a mean baseline value of 11.3 ng/mL to 38. increase was also associated with an improvement in the clinical resp (Maes et al, 1997).

3.5.1.N Fluphenazine

1) Interaction Effect: hypotension
2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986n).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.O Fosamprenavir

1) Interaction Effect: an increase in trazodone plasma levels
2) Summary: Concomitant use of amprenavir, the active metabolite of fos result in increased trazodone plasma concentrations due to amprenavir in trazodone metabolism. Exercise caution when using these medications to of trazodone dosing. Monitor for trazodone side effects such as nausea, d syncope (Prod Info LEXIVA(R) oral solution, oral tablets, 2009; Prod Info 2005).
3) Severity: moderate
4) Onset: unspecified

5) Substantiation: theoretical
6) Clinical Management: Concomitant use of fosamprenavir (with or witho
cause increased trazodone plasma concentrations, and should be used w
dose of trazodone if it is used with a CYP3A4 inhibitor such as fosampren
fosamprenavir and trazodone for adverse effects, including sedation, naus
syncope (Prod Info LEXIVA(R) oral solution, oral tablets, 2009).
7) Probable Mechanism: inhibition of CYP3A4-mediated trazodone metal
metabolite of fosamprenavir
8) Literature Reports
a) Coadministration of trazodone with ritonavir, a potent CYP3A4 inh
fosamprenavir, resulted in significant trazodone pharmacokinetic cha
concurrent administration of a total of 4 doses ritonavir 200 mg twice
trazodone increased the peak plasma trazodone concentration (Cma
fold, increased the half-life 2.2-fold, and decreased trazodone clearar
of trazodone and ritonavir, adverse effects reported included nausea,
Info Desyrel(R) Oral Tablet, 2005).

3.5.1.P Foxglove

1) Interaction Effect: increased risk of digitalis toxicity
2) Summary: A single case report documents digoxin toxicity resulting fro
(Rauch & Jenike, 1984a). Theoretically, foxglove may be similarly affected
to digoxin.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Avoid concomitant use of foxglove and trazodor
intermittent trazodone doses will affect foxglove clearance (i.e., delayed e
to digitalis toxicity). Patients who choose to combine foxglove with trazodo
closely for signs and symptoms of toxicity (e.g., nausea, vomiting, drowsir
muscle weakness, hallucinations).
7) Probable Mechanism: not specified
8) Literature Reports
a) Trazodone added to a previously stable dose of digoxin resulted i
days. A 68-year-old woman with a 30-year history of unipolar affectiv
inpatient psychiatric service. Medical history was significant for conge
atrial tachyarrhythmias, and impaired renal function presumed secon

nausea and vomiting resolved within 3 days. She continued trazodon
resumed at 125 mcg every other day resulting in therapeutic levels (F

3.5.1.Q Ginkgo

1) Interaction Effect: excessive sedation and potential coma
2) Summary: A single case report has described a semicomatose state fo
trazodone. Since no rechallenge of either agent alone or together was per
reaction was due to the combination or an unusual reaction to either agen
agonist activity at GABA receptors (Sasaki et al, 1999; Cott, 1995), as we
cytochrome P450 3A4 (CYP3A4) activity, producing more of the active me
which further enhances the release of GABA (Galluzzi et al, 2000a). In co
in vitro (Budzinski et al, 2000a). However, in vitro findings may not transla
therefore the clinical significance of this in vitro finding is unknown.
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: A single case report has described a semicomat
with trazodone. Since no rechallenge of either agent alone or together wa
the reaction was due to the combination or an unusual adverse reaction to
known about this potential interaction, avoid concomitant use of ginkgo ar
cannot be avoided, use a low dose of trazodone and monitor the patient c
sedation.
7) Probable Mechanism: induction of cytochrome P450 3A4 by ginkgo to
metabolite mCPP of trazodone
8) Literature Reports

a) An 80-year-old female diagnosed with probable Alzheimer's disea
80 mg twice daily and trazodone 20 mg twice daily following treatmer
bromazepam 3.5 mg daily, donepizil 5 mg at bedtime, and vitamin E
donepezil, and vitamin E were discontinued. On the third day of treat
the patient developed gait instability and drowsiness, fell asleep one
awakened. Blood pressure was 120/55, Glasgow coma scale was 6/
and the patient woke immediately. Trazodone and ginkgo were disco
bromazepam. At evaluation 2 months later, cognitive function and be
mechanism of the interaction between gingko and trazodone was hyp
combination of weak GABA agonist activity of ginkgo, and induction
increased production of the active metabolite of trazodone, mCPP wh
release (Galluzzi et al, 2000).
b) Ginkgo biloba inhibited CYP3A4 in vitro with an IC50 of 4.75 mmo
CYP3A4 inhibitor, was compared with ginkgo and other phytochemic
mmol, making it 23.3 times more inhibitory than the most inhibitory pl
with an IC50 of 0.03 mmol. Ginkgo was a much weaker inhibitor of C
significant drug interactions may occur with the inhibitory phytochemi
metabolized by CYP3A4 (Budzinski et al, 2000).

3.5.1.R Indinavir
1) Interaction Effect: an increase in trazodone plasma levels
2) Summary: Coadministration of trazodone with ritonavir (an indinavir-re
potent CYP3A4 inhibition) produced increases in peak plasma trazodone
elimination half-life, increased area under the concentration-time curve, a
clearance. During concomitant use of trazodone and ritonavir, adverse eff
hypotension, and syncope. Other signs and symptoms associated with ex
included priapism, respiratory arrest, seizures, and EKG changes (Prod Ir
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Consider a lower dose of trazodone if it is used
indinavir. Monitor patients receiving trazodone and indinavir for adverse e
hypotension, syncope, and/or priapism.
7) Probable Mechanism: inhibition of CYP3A-mediated trazodone metabo

3.5.1.S Itraconazole
1) Interaction Effect: increased trazodone serum concentrations
2) Summary: Substantial elevations are expected in trazodone serum co
concomitantly with itraconazole, a potent CYP3A4 inhibitor (Prod Info Des
3) Severity: moderate
4) Onset: unspecified

4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: If linezolid and trazodone are used concomitantl of serotonin syndrome such as neuromuscular abnormalities (including hy rigidity, clonus, peripheral hypertonicity, and shivering), autonomic hypera mydriasis, diaphoresis, and diarrhea), and mental status changes (includi Serotonin syndrome can be life-threatening. If serotonin syndrome develo agents and provide supportive care and other therapy as necessary (Boye
7) Probable Mechanism: inhibition of serotonin metabolism by monoamin
8) Literature Reports
a) In one case report, a 37-year-old male experienced symptoms of s concomitant treatment with citalopram and linezolid. He was admitted right leg. His medical history consisted of hypertension, multiple myel passive-aggressive behavior, and adaptation trouble. The patient was resistant staphylococcus aureus (MRSA) with intravenous vancomyci was receiving oral citalopram 40 mg daily, olanzapine 2.5 mg daily, tr clonazepam 2 mg three times daily, hydromorphone 125 mg subcuta medications. On day five, the patient's infection improved and vancor discharged two days later on a regimen of oral linezolid 600 mg twice days of linezolid therapy, the patient reported having panic attacks ar linezolid, he was readmitted to the hospital for these symptoms, when tremors, excessive sweating, palpitations, and peribuccal numbness. mmHg) and heart rate (112 bpm) were elevated. On day two, his bloc he was still anxious and experiencing multiple panic attacks. Methotri bisoprolol 5 mg daily, and ondansetron 8 mg as needed were introdu increased to 12.5 mg/day. One day four, linezolid was suspected as a syndrome and was discontinued. Only one dose of linezolid remained five, the patient's level of anxiety decreased and blood pressure varie his symptoms subsided and blood pressure (140/80 mmHg) and hea normal (Bergeron et al, 2005).

3.5.1.V Mesoridazine
1) Interaction Effect: hypotension
2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986h).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.W Methotrimeprazine
1) Interaction Effect: hypotension
2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986d).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.X Nefazodone

1) Interaction Effect: increased trazodone serum concentrations
2) Summary: Substantial elevations are expected in trazodone serum cor concomitantly with nefazodone, a CYP3A4 inhibitor (Prod Info Desyrel(R)
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Consider a lower dose of trazodone if it is used inhibitor such as nefazodone. Monitor patients receiving trazodone and ne including sedation, nausea, hypotension, syncope, and/or priapism.
7) Probable Mechanism: inhibition of CYP3A4-mediated trazodone metal

3.5.1.Y Nelfinavir

1) Interaction Effect: increased plasma concentrations of trazodone and i adverse effects (nausea, dizziness, hypotension, syncope)
2) Summary: Trazodone is metabolized by cytochrome P450 3A4 (CYP3 nelfinavir, which are cytochrome P450 3A substrates and inhibitors, may c trazodone, causing increased trazodone plasma concentrations. Although nelfinavir and trazodone has not been studied, adverse effects such as na syncope have occurred following coadministration of trazodone and ritona when nelfinavir and trazodone are administered concomitantly. Reduction considered (Prod Info VIRACEPT(R) oral tablets, oral powder, 2005).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Use caution with the coadministration of nelfinav patients for signs of increased trazodone adverse effects (nausea, dizzine Consider reducing trazodone dosage when administering concomitantly w VIRACEPT(R) oral tablets, oral powder, 2005).
7) Probable Mechanism: inhibition of cytochrome P450 3A4-mediated tra

3.5.1.Z Paroxetine

1) Interaction Effect: serotonin syndrome (hypertension, hyperthermia, m
2) Summary: There have been several reports of serotonin syndrome du selective serotonin reuptake inhibitors and antidepressants, including one and trazodone coadministration (George & Godleski, 1996c; Reeves & Bu 1996a). Serotonin syndrome is a rare but potentially fatal condition of sero characterized by hypertension, hyperthermia, myoclonus and changes in Further clinical studies or case reports are necessary to determine the inc serotonin syndrome associated with this drug combination.
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Concurrent use of paroxetine and trazodone sho Monitor patients for signs and symptoms of serotonin syndrome (hyperter mental status changes).
7) Probable Mechanism: additive serotonergic effects
8) Literature Reports
a) Serotonin syndrome was reported in a 29-year old woman taking patient was treated with trazodone 200 mg daily at bedtime for appro depression and insomnia. The patient's depressive symptoms were u trazodone was subsequently decreased to 50 mg daily at bedtime for mg every morning was added. Within 24 hours after the first dose of p agitated, confused, shaky, and diaphoretic. Upon examination, the pa intermittent myoclonus in all extremities, hyperreflexia, tremor, and di antidepressant medications, the patient's symptoms resolved (Reeve
b) A 44-year old man developed symptoms characteristic of serotoni interaction between fluoxetine and trazodone. The patient had been t trazodone 100 mg daily for approximately two months before sympto experienced disorientation, tremor, diaphoresis, and anxiety, followed loss of consciousness. After the patient was treated with cyproheptac resolved over the next 30 minutes. Trazodone was discontinued and fluoxetine 40 mg daily without further complications (George & Godle

3.5.1.AA Perphenazine

1) Interaction Effect: hypotension

2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986l).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.AB Phenytoin
1) Interaction Effect: increased phenytoin serum concentrations and an ir (ataxia, hyperreflexia, nystagmus, tremor)
2) Summary: Increased phenytoin serum concentrations have occurred i treatment with trazodone and phenytoin (Prod Info Desyrel(R), 2003d). Ph patient receiving concurrent treatment with the 2 drugs (Dorn, 1986).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Measure serum levels of phenytoin after initiatio discontinuation of trazodone; adjust dosage accordingly.
7) Probable Mechanism: unknown
8) Literature Reports
a) In 1 case concomitant administration of phenytoin and trazodone increases in phenytoin serum concentrations and phenytoin toxicity. I may competitively inhibit the metabolism of phenytoin, binding of phe phenytoin excretion. It may be prudent to monitor phenytoin serum cc the combination until further data is available (Dorn, 1986).

3.5.1.AC Pipotiazine
1) Interaction Effect: hypotension
2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.AD Prochlorperazine
1) Interaction Effect: hypotension
2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986e).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.AE Promazine
1) Interaction Effect: hypotension
2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986b).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.AF Promethazine
1) Interaction Effect: hypotension

2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986j).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.AG Propiomazine
1) Interaction Effect: hypotension
2) Summary: Concomitant administration of trazodone with chlorpromazi additive hypotensive effects in two case reports. Withdrawal of trazodone hypotension (Asayesh, 1986i).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor blood pressure, particularly in patients v effect. Advise patient to rise slowly from laying or sitting position.
7) Probable Mechanism: additive hypotensive effects

3.5.1.AH Ritonavir
1) Interaction Effect: an increase in trazodone plasma levels and increase
2) Summary: Ritonavir inhibits the CYPA-mediated metabolism of trazod with trazodone produced a 34% (95% CI) increase in peak plasma trazod (95%CI) increase in total area under the concentration-time curve, and a life. Patients should be monitored for increased trazodone side effects inc syncope and hypotension. A reduction in trazodone dosing may be warra liquid-filled capsule, oral solution, 2005; Greenblatt et al, 2003a).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Patients receiving trazodone and ritonavir shoul sedative effects and hypotension. Consider a reduction in trazodone dosi
7) Probable Mechanism: inhibition of CYP3A-mediated trazodone metab
8) Literature Reports
a) Coadministration of ritonavir and trazodone produces a significant trazodone concentration (Cmax), prolongation of elimination half-life, reduction in oral clearance. Ten subjects participated in a randomize study with 7 days elapsing between treatments. The four treatment c placebo to match trazodone, plus placebo to match ritonavir; Treatme ritonavir placebo; Treatment C: placebo to match trazodone plus ritor Treatment D: trazodone 50 mg plus ritonavir 200 mg X 4 doses. Rito coadministration produced a significant increase in trazodone Cmax 842 +/- 64 ng/mL (treatment B) and 1125 +/- 111 ng/mL (treatment D SE elimination half-life in treatment B was 6.7 +/- 0.7 h and in treatme 0.05). The mean +/- SE total AUC for treatment B was 5.86 +/- 0.83 r was 13.88 +/- 2.89 (p less than 0.01). The mean +/- SE apparent ora B was 155 +/- 23 and for treatment D was 75 +/- 12 (p less than 0.00 psychomotor performance (the DSST), and a quantitatively small incr EEG caused by trazodone were all enhanced by coadministration of

3.5.1.AI St John's Wort
1) Interaction Effect: an increased risk of serotonin syndrome (hypertensi mental status changes)
2) Summary: One pooly defined case of a patient developing serotonin s therapy with St. John's Wort has been reported (DeMott, 1998a). Four ca serotonin syndrome-like symptoms following the addition of St. John's Wo case with nefazodone therapy (Lantz et al, 1999). A patient exhibited a s sedative/hypnotic intoxication after adding St. John's Wort to paroxetine t Wort is thought to inhibit serotonin reuptake and may have mild monoami (Singer et al, 1999; Thiede & Walper, 1994), which when added to selecti may result in serotonin syndrome. This interaction may be extended to tra SSRI, inhibits serotonin uptake. Serotonin syndrome is a condition of ser manifests as restlessness, myoclonus, changes in mental status, hyperre tremor. If the syndrome is not recognized and correctly treated, death can

3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Avoid concomitant use of St. John's Wort and tr
trazodone of up to 15 hours, St. John's Wort should be avoided for at leas
trazodone discontinuation.
7) Probable Mechanism: additive pharmacologic effects resulting in exce

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling
chest tightness, trouble breathing.
Painful, prolonged erection of your penis.
Skin rash.
Unexplained fever or sore throat.

If you notice these less serious side effects, talk with your doctor:
Changes in vision, such as trouble focusing.
Constipation or diarrhea.
Drowsiness or dizziness.
Dry mouth.
Headache.
Nausea, vomiting, upset stomach.

Nervousness, trouble sleeping.

If you notice other side effects that you think are caused by this medicine, tell y

4.3 Place In Therapy

A) Depression is a complicated disorder and consequently this disease's treatmer most prevalent diagnostic syndromes among affective disorders are major depress tricyclic antidepressants (TCAs), selective serotonin reuptake inhibitors (SSRIs), ar inhibitors (MAOIs) are considered the most effective agents for treating major depr disorders, lithium is the preferred therapy; carbamazepine and valproic acid are co

B) Trazodone is equally effective for treating mild typical or endogenous depressic questions remain as to the effectiveness of trazodone for treating moderate-to-sev patients seem to have difficulty tolerating adequate doses. Trazodone possesses t without anticholinergic effects. Other advantageous characteristics of this agent inc anxiety disorders, agitation, obsessive compulsive behavior, and a comparatively s following overdoses. Trazodone may also be safely combined with MAOIs for refra of trazodone include a high incidence of priapism, orthostatic hypotension, and indi and ventricular arrhythmias. However, compared with the TCAs, trazodone is still c

C) Trazodone does have a place in therapy for treating endogenous or typical dep secondary to the TCAs, the SSRIs, and the MAOIs in most circumstances. Trazod without anticholinergic effects may be useful in elderly patients refractory to standa patients with an unusually high potential for suicide, trazodone may be considered that commonly treat elderly depressed patients, refractory depressed patients, or o threatening suicide should consider trazodone for formulary inclusion.

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) Trazodone, which was first synthesized in 1966, represents a different clas triazolopyridines. Structurally, it does not bear any similarity to tricyclic antidep antidepressants, or MAO inhibitors. The antidepressant activity of trazodone a selectively inhibit serotonin reuptake. At low doses, trazodone appears to act a higher doses as an agonist (Maj et al, 1979; Stefanini et al, 1976).

2) Unlike other antidepressants, trazodone does not potentiate catecholamine It does appear to have a sedative effect and slight muscle relaxant properties, (Silvestrini et al, 1968). Trazodone does not have any significant effect on prol 1979)(Rolandi et al, 1981).

3) Trazodone appears to be equally effective in bipolar and unipolar depressic antidepressant therapy is its short onset of action and low incidence of anticho effects. However, some studies have indicated the onset of action of trazodon (Rawls, 1982a; Brogden et al, 1981; Rickels, 1981). Some data has suggested which may be less than or equal to other benzodiazepines; however, sufficient determine that these effects are related directly to properties of the drug or sec existing depression.

B) REVIEW ARTICLES

1) A comprehensive review of the second-generation antidepressant agents (trazodone, nomifensine) has been presented (Caccaro & Siever, 1985).

2) Other uses of antidepressant agents, including enuresis, bulimia, anorexia pain, migraine headache, and peptic ulcer disease have been reviewed (Orsul

3) A review of clinical guidelines for utilizing antidepressants in the treatment is available (Salzman, 1985).

4) Drug-interactions of antidepressants are reviewed in German language (Za

b) Summary:

Effective for treatment of INSOMNIA induced by monoamine oxidase

c) Adult:

1) In a small double-blind, placebo-controlled, crossover trial (n=7), a TRAZODONE 50 milligrams each evening improved sleep disturbanc who had responded to brofaromine, but who had experienced insomr oxidase inhibitor (MAO-I). Mean number of nightly awakenings and n lower after trazodone therapy compared with baseline (p=0.019 and Subjectively, some patients felt they had better and deeper sleep with mild. Larger controlled trials are needed (Haffmans & Vos, 1999).

2) The benefits of trazodone in the treatment of insomnia secondary (MAOI) therapy were demonstrated in a small, open study (Nierenbe patients with depression were treated with either tranylcypromine, ph developed insomnia after receiving MAOI therapy for 5 to 60 days. Tr 200 milligrams daily (mean, 85 milligrams daily) was reported to prod 12 patients (92%) within 1 week of treatment; 9 of the 13 patients we

inhibitors with trazodone without the occurrence of intolerable advers
are required to further evaluate the efficacy of trazodone in this clinic

4.5.B.2 Agoraphobia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:

Effective for symptomatic improvement

c) Adult:

1) Trazodone 300 milligrams daily was effective in reducing anxiety,
symptoms in outpatients with PANIC DISORDER or agoraphobia wit
study involving 11 patients (Mavissakalian et al, 1987).

4.5.B.3 Alcohol withdrawal syndrome

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:

Appears to be beneficial in the treatment of acute alcohol withdrawal

c) Adult:

1) Total abstinence was reported after 90 days of trazodone treatme
patient open study. After completing acute detoxification (mean perio
(50 to 100 milligrams (mg) per day) and tiapride (300 to 600 mg/day),
detoxification program and began trazodone therapy with daily doses
(mean 135 mg). Baseline and 90-day Discan scale scores for anxiety
exhibited a significant reduction in mean score at the end of the trial (
abstinence combined with the rate of controlled drinking patterns was
drugs used in this indication, as was the recidivism rate (Janiri et al, 1
2) Seventeen chronic alcoholics abruptly stopped drinking ethanol a
trazodone 100 milligrams/day. Based on the Hamilton anxiety rating s
significant global improvements and regression of pre-treatment clinic
depression, fear, and insomnia. After 3 to 5 days of trazodone therap
completely. It is thought that trazodone is beneficial due to the dopam
activity (Roccatogliata et al, 1980).

4.5.B.4 Benzodiazepine withdrawal

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:

Effective as an aid to discontinuing benzodiazepine in a small study

c) Adult:

1) Ten patients experienced generally mild and transitory benzodiaz
receiving trazodone (100 mg three times a day) during a 2- to 4-week
benzodiazepine dependence. After their benzodiazepines were progr
discontinued, the patients were discharged on trazodone 300 milligra
benzodiazepine-free during a 1-year follow-up and showed significan
(300 to 185 milligrams/day) and in Hamilton Rating Scales scores for
screens were not performed; benzodiazepine abstinence was determ
general practitioner assessments (Ansseau & De Roeck, 1993).

4.5.B.5 Chronic pain

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Ineffective
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:
NOT effective for relief of BURNING MOUTH SYNDROME in a small

c) Adult:
1) An 8-week course of oral TRAZODONE 200 milligrams every eve analgesic efficacy for CHRONIC MOUTH PAIN than did placebo in a weeks, patient-rated visual analog pain scores dropped by 13.9 and trazodone and control groups (NS). Overall, 8 of 11 (73%) trazodone (76%) placebo-treated patients rated themselves as 'improved' (NS). more dizziness (p less than 0.001) and drowsiness (p less than 0.05) 1999).

4.5.B.6 Dementia

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:
May offer some benefit to patients with aggressive behavior or repetit dementia

c) Adult:
1) A pilot open-label study found that oral TRAZODONE produced s behavior of 14 consecutive patients (mean age 70.5 years) with FRO diagnosed according to criteria of the Lund and Manchester Groups (received trazodone 50 milligrams (mg) 3 times a day, followed by a 2 day. Ratings on the Neuropsychiatric Inventory (NPI) showed signific aggression, anxiety, and irritability, comparing scores after 4 weeks c than 0.05). After completion of the 300-mg dosing period, significant disinhibition, and aberrant motor behavior were also noted (p less tha 1999).
2) Trazodone was effective in the treatment of PALILALIA, a conditic involuntary repetition (two or more times) of a phrase or word, in an 8 dementia. Within three weeks of treatment, an oral dose level of 300 and the palilalia was no longer evident. The patient had also exhibite and aggressiveness. These conditions disappeared as well and the p sedation. The patient died 9 months later but had no further episodes that time (Serra-Mestres et al, 1996).
3) Trazodone, gradually increased to 300 milligrams/day, effectively SCREAMING (10 to 12 hours per day) of a 84-year-old psychiatric pa episodes stopped 2 weeks after receiving trazodone, and no serious Her repetitive screaming was previously unaltered by trials of either h hydroxyzine (Pasion & Kirby, 1993).
4) Combined therapy with trazodone and tryptophan was effective in dementia (Wilcock et al, 1987). Trazodone 50 milligrams two times a milligrams two times a day, with dosing adjustments to achieve thera effects, was reported effective in improving aggressiveness in 4 of 6 dementia.
5) One case report described benefits of a combination of trazodone L-tryptophan (up to 2.5 grams daily) in the treatment of disordered be in an 82-year-old woman with moderately advanced dementia (Greer

4.5.B.7 Depression

FDA Labeled Indication

a) Overview
FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:
Effective for depression with or without prominent anxiety (Prod Info I

c) Adult:
1) In a randomized trial of 379 patients from 16 centers, patients rec milligrams/day, imipramine 100 to 300 milligrams/day, or placebo for Hamilton scores were reduced by 25% in the placebo-treated patient

imipramine-treated patients. Anticholinergic effects were much more
imipramine than in patients treated with trazodone or placebo. Fifteer
44% of the imipramine patients had dry mouth. Blurred vision occurre
imipramine-treated patients. Bowel disturbances occurred in 8% and
urine flow in 1% and 4%, respectively (Gershon & Newton, 1980b).
2) A year-long study was conducted in 79 subjects to evaluate the lo
trazodone compared to imipramine in the treatment of primary depres
(36%) and 7 (24%) patients remained on either trazodone or imipram
found to be more effective in HAM-D illness rating and clinical global
statistical significance not presented). Anticholinergic side effects wer
imipramine group but drowsiness was more frequent in the trazodone
3) In a double-blind study of 60 geriatric patients receiving trazodone
milligrams/day) or imipramine (average dose 145 milligrams/day) for
treatment of unipolar depression, both trazodone and imipramine sho
significant improvement in the Hamilton depression scale for both dru
difference in the Beck depression scale between trazodone and imipr
efffects seen with the trazodone-treated patients (Gerner et al, 1980b
4) Several reports have suggested efficacy of trazodone in the treatr
suggesting the drug has anxiolytic effects separate from its antidepre
One study has reported that trazodone 75 mg daily and diazepam 15
effective than placebo in the treatment of anxiety. In the treatment of
was reported superior to diazepam. Another report indicated that traz
daily had definite anxiolytic properties, but it was not superior to chlor
(Rawls, 1982c).
5) Many clinical trials have compared the effectiveness of trazodone
studies found trazodone to be as effective as imipramine in treating d
than placebo, with trazodone causing more sedation but fewer antich
(Davis & Vogel, 1981; Mann et al, 1980; Gershon et al, 1981; Kellam
Feighner, 1980b; Escobar et al, 1980a).

4.5.B.8 Diabetic neuropathy

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:

61.3% rate of symptomatic improvement; 22.6% complete relief
Controlled studies needed
Trazodone has been used to treat painful diabetic neuropathy (P
of chronic pain (Manufacturer comment., 5/88.; Panel comment.,

c) Adult:

1) In a prospective, open-label study, 19 of 31 adult patients (61.3%)
diabetic neuropathy with use of oral TRAZODONE 50 or 100 milligra
patients (22.6%) obtained complete relief. Therapeutic failures includ
no relief (100-mg doses) and 8 patients (25.8%) who discontinued th
doses), which included dizziness (5), headache (2), and insomnia (1)
50 mg/day at bedtime; after 2 weeks, doses were raised to 100 mg/d
and had not experienced complete relief (Wilson, 1999).

4.5.B.9 Erectile dysfunction; Diagnosis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Ineffective
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:

No efficacy shown in the treatment of ERECTILE DYSFUNCTION

c) Adult:

1) Oral trazodone in a total daily dose of 150 milligrams (mg) was no
the treatment of erectile dysfunction in a double-blind, placebo-contro
run-in period, patients randomized to the trazodone treatment group t
morning and two 50-mg capsules in the evening for 4 weeks; patients
identical capsules on the same schedule. To avoid selection bias, the
impotence was not identified until after completion of the treatment re

results demonstrated no significant difference (p=0.98) between the t group treated with placebo. Patients with psychogenic impotence res other patients, 23% versus 15%, respectively, but the difference was (p=0.45) (Meinhardt et al, 1997a).
2) A 3-month course of TRAZODONE 50 milligrams orally at bedtime placebo for treatment of erectile dysfunction, according to a randomiz the group receiving trazodone, 19% reported improved erections com placebo (p less than 0.5) (Costabile & Spevak, 1999).

4.5.B.10 Essential tremor

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:
Efficacy suggested in early case report, but not supported in subsequ

c) Adult:
1) Trazodone 150 milligrams orally per day was ineffective in the trea in a small, controlled study (Koller, 1989). This study suggests that al neurotransmission are most likely not involved in the pathophysiology
2) Trazodone 100 to 150 milligrams daily, in divided doses, appeared of essential tremor in 2 patients (McLeod & White, 1986). Improveme after 3 weeks of treatment; both patients had not responded to propra milligrams daily).

4.5.B.11 Insomnia

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:
Improved sleep latency and duration in primary insomnia, although d placebo diminished over time

c) Adult:
1) Single-dose TRAZODONE orally at bedtime improved insomnia ir accompanied by a depressive state (concomitant hypnotics were pro study). Patients received bedtime trazodone 50 milligrams (mg)/day f of either 50-mg (n=16), 75-mg (n=6), or 100-mg doses (n=11). Score (HAS) (related to sleep disorders) and the Hamilton Rating Scale for morning awakening, lack of sound sleep, difficulty in initiating sleep) v weeks of trazodone therapy (p values not reported) and showed furth (p=0.01, HAS scores for 50- and 100-mg groups). After 6 weeks, tota prolonged for patients receiving 50-mg (p less than 0.05) or 100-mg c Depressive state symptoms also improved. No one dropped out due considered the 100-mg nightly dose to be the most effective (Mashiko
2) Trazodone 50 milligrams (mg) before bedtime was somewhat effe insomnia in a parallel-group, double-blind, 2-week randomized study zolpidem 10 mg and placebo (n=278). At the end of the first week, th lower in trazodone-treated patients (p=0.01), relative to placebo. How week, sleep latency in trazodone-treated patients (54.5 minutes) did patients treated with placebo (64.7 minutes). Sleep duration was sign with trazodone therapy (366.4 minutes) than with placebo (344.6 min difference in these 2 treatment groups was no longer significant at th clinical significance in both parameters was primarily due to improver over time while the level of improvement with both drugs was essenti week of treatment. Zolpidem was slightly superior to both trazodone a (Walsh et al, 1998a).

4.5.B.12 Migraine, Pediatric; Prophylaxis

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive
Recommendation: Pediatric, Class III

Strength of Evidence: Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:
May be effective in decreasing frequency and duration of headaches
See Drug Consult reference: MIGRAINE - RECOMMENDATIONS FO AND ADOLESCENTS

c) Pediatric:
1) The effectiveness of trazodone in the prophylaxis of PEDIATRIC M measured in a double-blind, placebo-controlled study. Thirty-five pedi subjects received either trazodone (1 milligram/kilogram/day) or place week washout period, the groups were switched to the opposite treat There was no difference in frequency or duration of migraine attacks either the first 12 weeks or during the 4-week washout period. During the trazodone group was significantly improved in relation to both freq compared to the placebo group. The strong placebo effect demonstra not unusual in migraine studies, and the authors concluded that trazo antidepressants in the prophylaxis of pediatric migraine headaches (E

4.5.B.13 Neuroleptic-induced acute akathisia

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:
Improved symptoms of neuroleptic-induced akathisia in pilot study

c) Adult:
1) Symptoms of neuroleptic-induced akathisia improved following tra schizophrenia. In an open-label, pilot study, schizophrenic patients (n received trazodone (50 milligrams (mg)/day for 1 day, then increased addition to their current, stable, neuroleptic medication for 5 days. Me scores improved significantly from baseline to endpoint (p less than 0 anxiety, and psychosis were also improved from baseline to endpoint of insomnia during treatment. All patients withdrawn from treatment a reemergence of neuroleptic-induced akathisia within 1 day after the n when therapy was re- initiated in one patient, relief was reported with (Stryjer et al, 2003).

4.5.B.14 Schizophrenia

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE

b) Summary:
Appears to have no effect on psychotic episodes, but may improve so depression

c) Adult:
1) Trazodone has been evaluated in the treatment of schizophrenia, drug has any effect on psychotic episodes (Deutsch et al, 1977; Sing reports trazodone did appear to improve depression associated with s prove useful in these types of patients. Trazodone apparently does n as opposed to other tricyclic antidepressants (Rawls, 1982c).

4.6 Comparative Efficacy / Evaluation With Other Therapies

Amitriptyline

Chlordiazepoxide

Clorazepate

Desipramine

Dothiepin

Doxepin

Fluoxetine

Imipramine

Mianserin

Triazolam

Venlafaxine

Zolpidem

4.6.A Amitriptyline

Depression

Impaired cognition

Rheumatoid arthritis

4.6.A.1 Depression

a) SUMMARY: Many comparative studies have reported that trazodone i
the treatment of endogenous depression (Rickels & Case, 1982; Goldberg
Finnerty, 1980; Goldberg et al, 1981).

b) In a study of 40 depressed patients (20 agitated, 20 retarded), patients
milligrams (mg) three times a day or trazodone 50 mg three times a day a
washout period (LaPierre et al, 1980). The agitated, depressed patients w
and the retarded, depressed patients who were treated with trazodone we
than the agitated, depressed patients on trazodone and the retarded, dep
Based on multivarient analysis of the clinical global impression, amitriptyli
agitated depressed patients and trazodone was more effective in retarded

c) The efficacy of trazodone was compared with amitriptyline and placebo
depression in 202 outpatients (Rickels & Case, 1982). Patients were rand
milligrams (mg), amitriptyline 25 mg, or lactose placebo. Initial dose of all
for 7 days followed by adjustment to the maximum of eight capsules daily
effective than placebo with clinical efficacy of each agent being similar. Th
toxicity was lower in trazodone-treated patients. This study suggests that
as effective as amitriptyline 75 to 200 mg in treating depression in outpati
less anticholinergic toxicity.

d) No significant difference between trazodone 150 to 300 milligrams (mg
150 mg/day in antidepressant effect or onset was seen in a study of 50 pa
depression (Carney et al, 1984). Trazodone demonstrated an early superi
caused dry mouth more commonly; other side effects were comparable.

4.6.A.2 Impaired cognition

a) The effects of trazodone 100 milligrams (mg), amitriptyline 50 mg, and
healthy, geriatric patients in a double-blind, cross-over study (Burns et al,
tracking multiple stimuli to perform simultaneous tasks (DA), rapidly coord
output (CTT), processing information gathered in short-term memory (VBI
task (vigilance). Amitriptyline impaired DA, CTT, and vigilance, while trazo
authors concluded that trazodone caused less impairment of the central n
amitriptyline.

4.6.A.3 Rheumatoid arthritis

a) Amitriptyline 1 milligram/kilogram (mg/kg) per day for 3 days, followed
reported superior to both desipramine 1 mg/kg/day for 3 days, followed by

trazodone 1.5 mg/kg/day for 3 days, followed by 3 mg/kg/day thereafter, i
depressed and nondepressed patients with rheumatoid arthritis (Frank et
regimens produced significant decreases in pain relative to baseline, only
better than placebo; amitriptyline was associated with a significant reducti
tender joints.

4.6.B Chlordiazepoxide

4.6.B.1 Anxiety

a) No significant difference in improvement of anxiety in patients treated
chlordiazepoxide has been reported (Wheatley, 1976). A double-blind stu
mg/day and chlordiazepoxide for a 4-week period using the Hamilton Anx
from each treatment group were very much improved. Ten trazodone and
were much improved and 10 trazodone and 11 chlordiazepoxide patients
worse. Three patients were not evaluable. For both treatment groups drov
adverse effect with 22 patients experiencing the effect.

4.6.C Clorazepate

Adjustment disorder - Cancer

Adjustment disorder - HIV infection

4.6.C.1 Adjustment disorder - Cancer

a) SUMMARY: TRAZODONE may have equal or greater efficacy compa
treatment of adjustment disorders in breast-cancer patients; trazodone an
and tolerability.

b) A small, double-blind pilot study (n=23; efficacy analysis=18) found tha
TRAZODONE had equal or greater benefit compared with CLORAZEPAT
adjustment disorders (DSM-III-R) accompanied by anxiety or depressed r
emotion and conduct (Razavi et al, 1999). Included were women with a 1
Hospital Anxiety and Depression Scale (HADS). Enrollees were randomiz
milligrams (mg)/day (n=13) or oral clorazepate 10 mg/day (n=10), with up
days. Trazodone mean daily dose was 111.5 mg, and clorazepate, mean
investigator ratings on the Clinical Global Impression (CGI) scale showed
group (10 of 11) and 57.1% of the clorazepate group (4 of 7) were 'very m
'minimally improved' (p=0.14). Improvement on the Global Severity Index
trazodone-treated patients (-0.68) compared with clorazepate-treated pati
adverse events rated as severe occurred in the trazodone and 5 severe a
clorazepate group. One patient receiving trazodone withdrew due to adve

4.6.C.2 Adjustment disorder - HIV infection

a) SUMMARY: TRAZODONE may be more efficacious than CLORAZEP
adjustment disorders in patients with HIV; trazodone appeared to have gr

b) A small, double-blind trial (n=21) found a 28-day course of TRAZODO
treatment than CLORAZEPATE for HIV-positive patients with adjustment
accompanied by anxiety or depressed mood and/or mixed disturbance of

clorazepate group were 'very much improved', 'improved', or 'minimally im
appeared to be more marked in the trazodone group for depressive symp
slightly more pronounced in the clorazepate group for anxiety symptoms (
adverse event occurred in 8 clorazepate-treated patients and 6 trazodone
treatment, doses were reduced in 1 patient treated with trazodone and 2 t
adverse effects. More adverse events and a higher number of severe adv
clorazepate treatment. One patient in each group withdrew due to adverse
to lack of efficacy (De Wit et al, 1999).

4.6.D Desipramine

4.6.D.1 Depression

a) A double-blind study of 30 patients with endogenous, endoreactive, re
compared the effects of trazodone 200 to 400 mg/day to desipramine. Aft

similar results for both drugs for the parameters of depression, suicide, ins agitation as measured by the Hamilton Rating scale. Trazodone-treated p anxiety than did desipramine treated patients (Piccione et al, 1975).

4.6.E Dothiepin

4.6.E.1 Depression

a) No significant differences in efficacy or type of adverse effects were se with trazodone in 196 patients with mixed anxiety/depression (Moon et al, preferable to dothiepin because of lesser severity of side effects. In a 6-w study, either trazodone 150 mg (n=97) or dothiepin 75 mg (n=99) were ac included the 17- item and 21-item Hamilton Depression Rating Scales (HI Scale (HARS), and the investigator's judgement of global severity and imp improvement in depression scores (P=0.0001) and anxiety scores (P=0.0 Global severity significantly improved in both groups; at week 6, improven improved for 54 patients (71%) in the trazodone group and 52 patients (69 Although types of adverse effects were similar for both groups, the trazod proportion of mild symptoms compared with the dothiepin group; at weeks reported a lower percentage of symptoms as severe.

b) Dothiepin (75 to 150 mg/d) and trazodone (150 to 300 mg/d) were equ depression in a single-blind, 24-week study of 35 depressed patients (Pie were not matched for severity of depression which varied greatly among t completed the 6-month trial. Both treatment groups showed significant rec ratings from 4 weeks onward, and there was significant improvement in th first week onward. There were no significant differences between the 2 gr Drowsiness was the most frequent side effect in the trazodone-treated gro were more common in the dothiepin-treated group.

c) In a 6-week, double-blind study, lofepramine and dothiepin had similar depression in elderly patients (range 65 to 88 years); lofepramine had an incidence of dry mouth, blurred vision, and drowsiness (Fairbairn et al, 19 dothiepin-treated group and 6 in the lofepramine-treated group did not co patients in each group. Many of the participants were receiving other med phenothiazines, benzodiazepines, and chlormethiazole, throughout the tri lofepramine 70 mg/d were given for 1 week, then doses were doubled for measured on the Montgomery-Asberg Depression Scale (MADRS) at wee improvement occurred in both treatment groups. There were not significar Compared with dothiepin-treated patients, the lofepramine-treated patient and day-time drowsiness; only 1 patient in each group withdrew from the

4.6.F Doxepin

4.6.F.1 Depression

a) No significant difference in safety or efficacy was seen in a comparison during weeks 1, 3, and 6 was 125 milligrams (mg), 221 mg, and 246 mg) during weeks 1, 3, and 6 was 58 mg, 105 mg, and 127 mg) in 30 outpatie in a 6-week, double-blind, parallel study (Himmelhoch, 1986).

b) No significant difference was reported in a double-blind study of 101 p trazodone and doxepin in the treatment of depression (Murphy & Ankier,

4.6.G Fluoxetine

Depression

Mania

4.6.G.1 Depression

a) Fluoxetine was as effective as trazodone in the treatment of major dep outpatient study involving 43 patients (Debus et al, 1988). The mean final fluoxetine in the responding patients were 284 and 29 mg daily, respectiv corresponding doses were 327 and 33 mg, respectively. HAM-D scores w fluoxetine when compared to trazodone and sleep was improved to a grea Adverse effects occurred to a similar degree with each agent with the exc frequent with fluoxetine) and dizziness (more frequent with trazodone).

b) A six-week, double-blind trial compared fluoxetine (21 patients) with tra treatment of major depression (Perry et al, 1989). Although trazodone app

greater improvement in HAM-D and Clinical Global Impressions scores at
not statistically significant at 4, 5, and 6 weeks. The authors surmise that
been due to: an insufficient fluoxetine dose early in the trial (mean daily d
during week 3 were 21 mg and 241 mg, respectively), which was mitigate
in fluoxetine doses compared to trazodone doses; a slower onset of antid
compared to trazodone; or a higher incidence of depressive illness lasting
fluoxetine group (67%) than in the trazodone group (37%, reported incorre
authors cite the statistically significant fluoxetine-associated weight loss s
lb/patient) as a clinically significant advantage for this agent, trazodone wa
loss in this study (mean 0.13 lb/patient), and the weight losses exhibited b
significantly different.

4.6.G.2 Mania

a) In literature reports of drug-induced mania caused by fluoxetine or traz
manifested symptoms of mania more slowly than trazodone-treated patien
onset of mania in fluoxetine-treated patients was significantly longer than
days (range = 10 to 154 days) versus 16 days (range =4 to 70 days) resp

4.6.H Imipramine

4.6.H.1 Depression

a) Trazodone is not therapeutically superior to imipramine, but its side eff
et al, 1979; Feighner, 1980; Gerner et al, 1980; Escobar et al, 1980; Work
1984). Anticholinergic side effects occurred more frequently in patients tre
treated with trazodone in a multi-centre trial (Gershon & Newton, 1980).

b) A multicenter trial involving 379 patients treated with trazodone 200 to
imipramine 100 to 300 mg/day or placebo for 21 to 24 days demonstrated
of equal efficacy (Gershon & Newton, 1980). Another study involving 28 p
depression receiving an average trazodone dose of 287 mg/day or an ave
mg/day for 28 days also demonstrated equal effectiveness between the 2
results of a double-blind study involving 45 patients suggested that trazod
a more rapid and prolonged improvement than did imipramine 100 to 300
double-blind controlled study of 40 patients with endogenous depression,
300 mg) produced more improvement of Hamilton depression scale score
trazodone (maximum daily dose 600 mg) (Escobar et al, 1980).

c) Seventy-four patients were enrolled in a nonrandomized study with pla
evaluate the efficacy of imipramine, alprazolam, and trazodone in the trea
al, 1986). Twenty-nine patients were assigned to imipramine, 28 to trazod
treatment. All patients were treated with placebo for 3 weeks and then blir
for clinical response and side effects. Both imipramine and alprazolam we
agoraphobia, however, alprazolam had a faster onset of action. Clinical re
one week with alprazolam therapy and were generally not observed in imi
third or fourth week of therapy. Trazodone therapy was considered not eff
agoraphobia.

d) In a double-blind controlled study, imipramine and placebo were comp
treatment of 45 hostile patients with primary depression. The mean doses
6.26 capsules/day of 50 milligrams (mg) trazodone, 6.37 capsules/day of
capsules/day of placebo. Three of 17 patients in the trazodone groups ex
Hamilton total score on or before day 7 of therapy. On day 14, 8 patients
achieved this level of improvement. Of the imipramine- treated patients, n
improvement at day 7. However, by day 14, eight patients in the group ha
reduction in total Hamilton differences in the subjects tested through the s
Clinical global impressions showed a highly significant difference betweer
proportion of improved patients at the end of 28 days of treatment. Global
trazodone was significantly (p less than 0.01) better than placebo for tens
behavior and difficulty in sleeping. It was significantly (p less than 0.05) be
lacking energy behavior and anxious, worried, afraid behavior and concer
was slightly better (p less than 0.10) for irritable, annoyed, impatient or an
most frequent side effect experienced by trazodone treated patients. Antic
common effects in the imipramine group (Feighner, 1980).

e) Ten institutions participated in a multi-center, double-blind, placebo-co
trazodone or imipramine in 263 in-patients. Inclusion criteria included prim
endogenous type, minimum score of 18 on the Hamilton Rating Scale for
7 of 21 symptoms in 3 of 5 categories of the symptom profile for depressic
100 mg daily for trazodone or imipramine. At the end of 28 days, 113 patic
efficacy or side effects. Drop out rates were 37% each for imipramine and
Both drugs were statistically superior to placebo in improvement of HAM-

There was no significant difference between trazodone and imipramine. B
caused statistically significantly fewer anticholinergic side effects, 19% an
imipramine 52% (Gershon, 1981).

4.6.I Mianserin

Depression

Erectile dysfunction

4.6.I.1 Depression

a) SUMMARY: Several clinical trials have shown mianserin to be equally
treatment of depression (Altamura et al, 1989; Bucknall et al, 1988; Beaur
double-blind trial, 100 to 200 milligrams (mg) trazodone was compared wi
(Beaumont et al, 1984) . Although there were significant dropouts in the m
equally effective. Due to side-effects associated with mianserin, trazodone
(30 to 80 mg) was compared with trazodone (150 to 400 mg) and placebo
study involving 16 cardiac patients (Bucknall et al, 1988) . Both drugs wer
significant cardiovascular effects detected. A trend toward hypotension wa
b) Oral mianserin 30 to 120 milligrams (mg) daily was reported as effectiv
mg daily in the treatment of mild-to-moderate depression (endogenous or
(Bennie et al, 1984).
c) Trazodone in doses of 100 to 200 milligrams (mg) daily was reported s
(60 to 120 mg daily) and diazepam (15 to 30 mg daily) in reducing sympto
study over 3 to 6 weeks compared the antidepressant and anxiolytic effec
diazepam in patients with mild to moderate depression (with or without an
superior to diazepam in improving the patients ability to concentrate and r
Significantly more patients developed side effects with mianserin than eith
(Richards et al, 1982).
d) Clinical outcomes were equal in all 3 groups of patients in a double-bli
trazodone, mianserin, and amitriptyline in the treatment of 106 elderly dep
associated with fewer overall side effects (Altamura et al, 1989).

4.6.I.2 Erectile dysfunction

a) Trazodone was more effective than mianserin, ketanserin, or placebo i
double-blind, randomized, placebo-controlled trial. One hundred patients v
trazodone 50 milligrams (mg) three times a day, ketanserin 20 mg twice a
times a day, or placebo. Patients were evaluated after 30 days. Positive re
of trazodone-treated patients, 19.1% of ketanserin-treated patients, 31.6%
and 13.6% with placebo. Response to trazodone was significantly greater

4.6.J Triazolam

1) Adverse Effects
a) In a comparison of adverse effects of triazolam in doses of 0.125, 0.25
trazodone in doses of 50, 100, and 200 mg and placebo, trazodone did no
of study tasks. Triazolam, in the highest dose, significantly impaired learni
Subjective ratings of drug effect and sedation demonstrated comparable d
drugs, indicating some equivalence on a behavioral basis. Test subjects v
0.5, 1, 1.5, 2, 2.5, 3, 4, 5, and 6 hours after drug administration. Testing o
rated by subjects and/or observers, including: Profile of Mood States (POI
Inventory (ARCI); drug effect questionnaire; end-of-day questionnaire; obs
learning, recall, and performance measures; repeated acquisition procedu
Symbol-Substitution Test (DSST); circular lights test; balance task; and pi
did not investigate the relative abuse potential of the drugs, but the author
in this area would be useful because of the high incidence of anxiety and
histories of drug abuse (Rush et al, 1997).

4.6.K Venlafaxine

4.6.K.1 Depression

a) Venlafaxine produced antidepressant efficacy comparable to trazodon
controlled trial. In this outpatient study, 225 patients were randomized to v
(mg) per day, trazodone (mean = 300 mg/day) or placebo. Response rate
respectively. Venlafaxine appeared to be more effective than trazodone ir
disturbance and retardation factor as evidenced on the Hamilton Rating S

was noted that this effect may have been due to the sedating nature of tra common in the venlafaxine group compared to dizziness and somnolence (Cunningham et al, 1994).

4.6.L Zolpidem

4.6.L.1 Insomnia

a) Zolpidem 10 milligrams (mg) was slightly superior to trazodone 50 mg increasing sleep duration in a 2-week, randomized, parallel-group, double The periods of sleep latency at the end of week 1 were 48.2 minutes and treated with zolpidem or trazodone, respectively (p less than 0.037), but d end of week 2 (64.7 minutes versus 54.5 minutes, respectively). The slee in both groups compared to the group treated with placebo (p=0.001). Pat reported longer sleep durations at week 1 than those treated with trazodo minutes, respectively) with a trend toward significance (p less than 0.060) between drugs at week 2. The reduction in clinical significance in both pa compared with placebo, was primarily due to improvement in the placebo level of improvement with both drugs was essentially unchanged in the se of the slightly shorter period of sleep latency, zolpidem may have some ac treatment of primary insomnia (Walsh et al, 1998).

DRUGDEX® Evaluations

DEXTROAMPHETAMINE

0.0 Overview

1) Class
- **a)** This drug is a member of the following class(es):
  Amphetamine (class)
  CNS Stimulant

2) Dosing Information
- **a)** Dextroamphetamine Sulfate
  - **1)** Adult
    - **a)** Narcolepsy
      - **1)** immediate-release, 5 to 60 mg ORALLY in 2 to 3 divided doses daily (Prod Info dextroamphetamine s
      - **2)** sustained-release, 5 to 60 mg ORALLY as single daily dose (Prod Info DEXEDRINE(R) oral tablets, s
  - **2)** Pediatric
    - **a)** (immediate-release) not FDA approved for children under 3 yr of age with attention deficit hyperactivity dis
    - **b)** (sustained-release) not FDA approved for children under 6 yr of age with attention deficit hyperactivity dis
    sustained-release oral capsules, 2007)
      - **1)** Attention deficit hyperactivity disorder
        - **a)** (immediate-release, age 3 to 5 yr) initial, 2.5 mg ORALLY once daily, increase by 2.5 mg/day at
        mg/day (Prod Info dextroamphetamine sulfate oral tablets, 2007)
        - **b)** (immediate-release, age 6 yr and older) initial, 5 mg ORALLY once or twice daily, increase by 5 r
        40 mg/day (Prod Info dextroamphetamine sulfate oral tablets, 2007)
        - **c)** (sustained-release, age 6 yr and older) initial, 5 mg ORALLY once or twice daily, increase by 5-m
        response; MAX 40 mg/day (Prod Info DEXEDRINE(R) oral tablets, sustained-release oral capsules,
      - **2)** Narcolepsy
        - **a)** (age 6 to 12 yr) 5 mg/day ORALLY, increase by 5 mg/day at 1 wk intervals to optimum response
        should be dosed once daily, immediate-release doses may be given at intervals of 4 to 6 hours (Pro
        2007; Prod Info DEXEDRINE(R) oral tablets, sustained-release oral capsules, 2007)
        - **b)** (age 12 yr and older) 10 mg/day ORALLY, increase by 10 mg/day at 1 wk intervals to optimum re
        tablets should be dosed once daily, immediate-release doses may be given at intervals of 4 to 6 hou
        tablets, 2007; Prod Info DEXEDRINE(R) oral tablets, sustained-release oral capsules, 2007)

3) Contraindications
- **a)** Dextroamphetamine Sulfate
  - **1)** advanced arteriosclerosis (Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006)
  - **2)** agitated states; may aggravate symptoms (Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab
  - **3)** cardiovascular disease, symptomatic (Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets,
  - **4)** concomitant use of monoamine oxidase inhibitors (MAOI), or within 14 days of MAOI use; hypertensive crisis r
  release oral capsules, oral tablets, 2006)
  - **5)** drug dependence, history of; potential for abuse (Prod Info DEXEDRINE(R) sustained-release oral capsules, c
  - **6)** glaucoma (Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006)
  - **7)** hypersensitivity/idiosyncrasy to sympathomimetic amines (Prod Info DEXEDRINE(R) sustained-release oral ca
  - **8)** hypertension, moderate to severe (Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 20
  - **9)** hyperthyroidism (Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006)

4) Serious Adverse Effects
- **a)** Dextroamphetamine Sulfate
  - **1)** Body temperature above normal
  - **2)** Central nervous system stimulation (Severe)
  - **3)** Dead - sudden death
  - **4)** Hypersensitivity disorder
  - **5)** Psychotic disorder
  - **6)** Tachyarrhythmia

5) Clinical Applications
- **a)** Dextroamphetamine Sulfate
  - **1)** FDA Approved Indications
    - **a)** Attention deficit hyperactivity disorder
    - **b)** Narcolepsy

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms

D-Amphetamine
Dexamfetamine
Dexamphetamine
Dextroamphetamine
Dextroamphetamine Sulf
Dextroamphetamine Sulfate

1.2 Storage and Stability

A) Dextroamphetamine Sulfate

1) Preparation

a) Oral route

1) Avoid late evening doses due to resulting insomnia (Prod Info DEXEDRINE(R) oral tablets, sustained Dexedrine(R), 2002)

2) Give first dose of immediate-release tablet on awakening, and additional doses at intervals of 4 to 6 h

B) Oral route

1) Dextroamphetamine tablets should be stored in well-closed containers, and the elixir in tight, light-resistant cor degrees Centigrade, preferably at 15 to 30 degrees Centigrade (59 to 86 degrees F); freezing of the elixir should should be stored at temperature, between 20 and 25 degrees C (68 and 77 degrees F) (Prod Info Dexedrine(R), (R) capsules, 1999; Prod Info Dextrostat(R), 1998).

1.3 Adult Dosage

1.3.1 Normal Dosage

1.3.1.A Cataplexy - Narcolepsy

See Drug Consult reference: NARCOLEPSY AND CATAPLEXY - DRUG THERAPY

1.4 Pediatric Dosage

1.4.1 Normal Dosage

1.4.1.A Dextroamphetamine Sulfate

1.4.1.A.1 Oral route

Attention deficit hyperactivity disorder

Narcolepsy

1.4.1.A.1.a Attention deficit hyperactivity disorder

1) Immediate-Release

a) For children 3 to 5 years of age with attention deficit disorder, the recommended initial oral d milligrams/day. The daily dosage is increased by 2.5 milligrams at weekly intervals until the opti should rarely exceed 40 milligrams. The first dose should be given on awakening if tablets or lic intervals of 4 to 6 hours (Prod Info dextroamphetamine sulfate oral tablets, 2007).

b) For children 6 years of age and older with attention deficit disorder, the recommended initial once or twice daily. The daily dosage is increased by 5 milligrams at weekly intervals until the o total daily dose exceed 40 milligrams . The first dose should be given on awakening, with subse (Prod Info dextroamphetamine sulfate oral tablets, 2007).

2) Extended-Release

a) For children aged 6 years and older with attention deficit disorder, the recommended initial d release is 5 milligrams (mg) once or twice daily, with 5-mg increases at weekly intervals until the daily dose of 40 mg is rarely necessary (Prod Info DEXEDRINE(R) oral tablets, sustained-relea

1.4.1.A.1.b Narcolepsy

1) Immediate-release

a) For children 6 to 12 years of age with narcolepsy, the recommended initial dose of oral dextı milligrams (mg) daily, with 5-mg increases at weekly intervals until the optimum dose is attainec tablets, 2007).
b) For children 12 years of age and older with narcolepsy, the initial dose of oral dextroamphet 10-mg increases at weekly intervals until the optimum dose is attained. The first dose should be or 2) spaced at intervals of 4 to 6 hours. Exceeding a total dose of 40 mg/day is rarely necessai recommended to determine if there is a recurrence of behavioral symptoms sufficient to require dextroamphetamine sulfate oral tablets, 2007).

2) Sustained-release
a) For children 6 to 12 years of age with narcolepsy, the recommended initial dose of oral dextı (mg) once daily, with 5-mg increases at weekly intervals until the optimum dose is attained (Pro release oral capsules, 2007).
b) For children 12 years of age and older with narcolepsy, the recommended initial dose of ora once daily, with 10-mg increases at weekly intervals until the optimum dose is attained (Prod In release oral capsules, 2007).
c) Dosage should be reduced if adverse reactions become intolerable (Prod Info DEXEDRINE(2007).

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset
1) Initial Response
a) 2 to 3 hours (Angrist et al, 1987).
B) Duration
1) Single Dose
a) 4 to 24 hours (Johnson et al, 1971).
1) The duration of the effects may be prolonged by alkalinization or shortened by acidification of the urin
2) Each dextroamphetamine sustained-release capsule is prepared such that an initial dose is promptly released gradually over a prolonged period of time. Dextroamphetamine's therapeutic effects may persis

2.2 Drug Concentration Levels

A) Time to Peak Concentration
1) Oral, tablets: 60 to 180 minutes (Prod Info Dexedrine(R), dextroamphetamine sulfate tablets and Spansule(R) 1998a).
2) Oral, extended-release capsules: approximately 8 hours (Prod Info Dexedrine(R), dextroamphetamine sulfate
3) Oral, extended-release capsules: approximately 7 hours (Prod Info Adderall XR(TM), 2002);(Tulloch et al, 200
B) URINE ASSAY
1) A semiquantitative EMIT(R) homogenous enzyme immunoassay is available for measurement of the commonl limit (sensitivity) is 2 mcg/mL for amphetamine or methamphetamine. The assay also detects phenylethylamines a to eliminate interference from over-the-counter cold medications that contain ephedrine, pseudoephedrine, or phe assay is also available that detects as little as 0.7 mcg/mL of amphetamine; this method correlated well with GLC studies (Prod Info EMIT(R) urine amphetamine assay, 1983).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

Extracorporeal Elimination

2.3.1 Absorption
A) Bioavailability
1) well-absorbed (Becket & Tucker, 1968; Becket et al, 1968).
a) The bioavailability of the extended-release capsule is similar to that of the immediate-release tablet (F sulfate tablets and Spansule(R) capsules, 1999a).
B) Effects of Food
1) none (Angrist et al, 1987).
a) Absorption of the extended-release capsule is similar in either the fed or fasted state (Prod Info Dexe Spansule(R) capsules, 1999a).
b) Food does not affect absorption, but it prolongs time to reach maximal plasma concentration by 2.5 h high-fat meal) (Prod Info Adderall XR(TM), 2002);(Tulloch et al, 2002).

2.3.2 Distribution
A) Distribution Sites
1) Tissues and Fluids
a) CEREBROSPINAL FLUID
1) Cerebrospinal fluid levels of dextroamphetamine are approximately 80% of plasma levels (Angga
B) Distribution Kinetics
1) Volume of Distribution
a) 6.11 L/kg (Anggard, 1970a).

2.3.3 Metabolism
A) Metabolism Sites and Kinetics
1) Liver, extensive
a) Amphetamine is hepatically metabolized to both acidic and basic metabolites primarily by deaminatio et al, 1972; Anggard et al, 1973b; Beckett & Shenoy, 1973). Dextroamphetamine is the dextrorotatory isc behave in a similar fashion.
B) Metabolites
1) Hippuric acid (Davies et al, 1971)(Caldwell et al, 1972; Anggard et al, 1973b; Sever et al, 1973).
2) Benzoic acid (Davies et al, 1971)(Caldwell et al, 1972; Anggard et al, 1973b; Sever et al, 1973).
3) Norephedrine (Davies et al, 1971)(Caldwell et al, 1972; Anggard et al, 1973b; Sever et al, 1973).
4) 4-hydroxynorephedrine (Davies et al, 1971)(Caldwell et al, 1972; Anggard et al, 1973b; Sever et al, 1973)
5) Benzyl methyl ketone (Davies et al, 1971)(Caldwell et al, 1972; Anggard et al, 1973b; Sever et al, 1973).

2.3.4 Excretion
A) Kidney
1) Renal Excretion (%)
a) 17% to 73% (Anggard et al, 1973b).
1) The urinary excretion of dextroamphetamine is dependent on pH; at a pH of less than 6.6, 67% t urine (Olin, 1990; Anggard et al, 1973b; Caldwell et al, 1972; Beckett & Shenoy, 1973). At a urine pH unchanged in the urine (Anggard et al, 1973b).

2.3.5 Elimination Half-life
A) Parent Compound
1) ELIMINATION HALF-LIFE
a) 7 to 34 hours (Prod Info Dextrostat(R), 1998a; Anggard et al, 1973b).
1) The half-life of dextroamphetamine is dependent on urine pH. In patients with a urine pH of less t in patients with a urine pH of greater than 6.7, the half-life ranges from 17 to 34 hours (Anggard et a
2) Average half-life of dextroamphetamine tablets is 10 to 12 hours (Prod Info Dexedrine(R), dextro capsules, 1999a; Prod Info Dextrostat(R), 1998a). Half-life of the extended-release capsules is appr

2.3.6 Extracorporeal Elimination
A) Hemodialysis
1) Dialyzable: Yes (Zalis & Parmley, 1963).
a) Hemodialysis has been demonstrated to enhance the elimination of amphetamine in animals (Zalis & procedure in human overdoses has not been proven. Dextroamphetamine is the dextrorotatory isomer o behave in a similar fashion.
B) Peritoneal
1) Dialyzable: Yes (Zalis & Parmley, 1963).
a) Peritoneal dialysis has been demonstrated to enhance the elimination of amphetamine is animals (Za procedure in human overdoses has not been proven. Dextroamphetamine is the dextrorotatory isomer o behave in a similar fashion.

3.3.3.A.1 Hyperthyroidism

a) One group of clinicians reports 4 cases of amphetamine abuse that resulted in an elevated free thyro
and symptoms of hyperthyroidism (Morely et al, 1980). The levels of T4 appeared to be inappropriately e
HYPERTHYROXINEMIA appeared to be secondary to an increase in circulating TSH. All levels returned
amphetamine in 2 of the 4 cases; the remaining 2 patients refused further follow-up after the initial levels
dextrorotatory isomer of amphetamine and would be expected to behave in a similar fashion.

b) The signs and symptoms of amphetamine abuse are similar to those of THYROTOXICOSIS; it is unc
secondary to hyperthyroxinemia (Morely et al, 1980).

3.3.4 Gastrointestinal Effects

3.3.4.A Dextroamphetamine Sulfate

3.3.4.A.1 Gastrointestinal tract finding

a) A variety of gastrointestinal effects including DRY MOUTH, UNPLEASANT TASTE, DIARRHEA, CON
have been reported during dextroamphetamine therapy (Prod Info Dexedrine(R), dextroamphetamine su
Prod Info Dextrostat(R), 1998).

3.3.5 Hematologic Effects

3.3.5.A Dextroamphetamine Sulfate

3.3.5.A.1 Leukemia

a) One report describes a case of a 24-year-old white male who ingested 8 to 16 tablets/day of amphet
myeloblastic leukemia that was heralded by weakness, sweating, calf pain, and fever (Berry, 1966). Des
rapidly deteriorated into coma, apnea, and death. A possible cause and effect relationship with chronic a
drug possesses a benzene ring that has been known to cause hematologic effects. Dextroamphetamine
and would be expected to behave in a similar fashion.

3.3.7 Immunologic Effects

3.3.7.A Dextroamphetamine Sulfate

3.3.7.A.1 Hypersensitivity disorder

a) Hypersensitivity reactions, including angioedema and anaphylaxis, have been associated with amphe
extended-release oral capsules, 2006).

3.3.9 Neurologic Effects

3.3.9.A Dextroamphetamine Sulfate

Central nervous system finding

Cerebrovascular disease

Disturbance in speech

Extrapyramidal sign

Gilles de la Tourette's syndrome

3.3.9.A.1 Central nervous system finding

a) Children with attention deficit hyperactive disorder (ADHD) who have normal electroencephalograms they receive stimulant therapy for ADHD (METHYLPHENIDATE, DEXTROAMPHETAMINE, or combinat DEXTROAMPHETAMINE (Adderall(R)). However, children with epileptiform EEGs may have considerab occurrence of seizure may or may not be attributable to use of the stimulant. These conclusions were ba epilepsy who were diagnosed with ADHD. All had EEGs prior to parental choosing of stimulant treatmen children's ADHD. Overall, 36 children (15.4%) demonstrated epileptiform abnormalities compared with 1 abnormalities, 30 received stimulant treatment for ADHD. Three of the 30 who received stimulant therap including a 9-year-old female, a 7-year-old male, and a 6-year- old male. The girl was treated uneventful months after withdrawal of methylphenidate experienced a 4-minute generalized tonic-clonic seizure. He abnormality. Of the 2 boys, the first experienced a 2-minute generalized tonic clonic seizure with focal or second boy had an episode at 10 months after initiation of methylphenidate; he was heard to fall and wa minutes. EEGs of both boys had shown rolandic spikes, a focal epileptiform abnormality. One child who beginning methylphenidate (Hemmer et al, 2001).

b) Dextroamphetamine 0.15 mg/kg intravenously induced a dysphoric reaction, with DROWSINESS, an postmenopausal women (Halbreich et al, 1981). Young healthy men, who received the same dose, expe patients were screened to rule out physical and mental disorders.

c) One author reports 3 cases of OBSESSIVE-COMPULSIVE BEHAVIOR as a result of dextroampheta diagnosed as suffering from attention deficit disorder. The duration of stimulant therapy before the devel and 7 years, and the duration of symptoms was 4 to 7 months. A case of amphetamine-induced COMPU responsive to pyridoxine (B6) therapy (Frye & Arnold, 1981).

d) Due to its mechanism of action, dextroamphetamine may cause central nervous system (CNS) stimu DIZZINESS, INSOMNIA, EUPHORIA, dysphoria, TREMOR, and HEADACHE (Prod Info Dexedrine(R),

3.3.9.A.2 Cerebrovascular disease

a) Investigators reported 4 cases of INTRACRANIAL HEMORRHAGE following oral or nasal use of amp al, 1983). Two of these patients had abnormal appearing cerebral blood vessels on angiography. Availab hemorrhage may also occur in patients who use these drugs for the first time and nonrecreationally.

b) One article reports a case of intracranial hemorrhage that occurred 3 hours after the ingestion of amp (D'Souza & Shraberg, 1981). The admitting blood pressure was 210/120 (systolic/diastolic). No evidence was found on CT Scan. Others report INTRACRANIAL HYPERTENSION in a chronic amphetamine abu prednisone without a residual neurologic deficit. Dextroamphetamine is the dextrorotatory isomer of amp similar fashion (Delaney & Estes, 1981).

c) Four cases of STROKE were reported in patients (29 to 45 years of age) thought to have abused me hemorrhaging and 2 had cerebral ischemic infarctions (Perez et al, 1999).

3.3.9.A.3 Disturbance in speech

a) Central nervous system (CNS) stimulants can increase the rate of speech and reduce the fine coordi DYSPHONIA and VOICE TREMORS (Damste, 1978).

3.3.9.A.4 Extrapyramidal sign

a) Chronic amphetamine abuse may induce extrapyramidal effects such as choreiform or ATHETOID M that resemble the gait seen in Huntington's chorea. The syndrome generally develops during amphetami abstinence; however, the symptoms may persist for long periods of time. Dopamine receptor-blocking ag (Lundh & Lunving, 1981)(Rundell et al, 1988). Dextroamphetamine is the dextrorotatory isomer of amphe similar fashion.

3.3.9.A.5 Gilles de la Tourette's syndrome

a) The incidence of TICS emergence was 7.8% in children treated with stimulant medication (METHYLF PEMOLINE) for attention deficit hyperactivity disorder, based on a retrospective chart review (n=555). Th children if they were free of tics and without a history of tics according to the practice of the settings in wh 8.3% of subjects treated with methylphenidate, 6.3% treated with dextroamphetamine, and 7.7% treated dose or duration of stimulant therapy. Mean age of subjects was 11 years. A significant correlation occur tics. As the authors noted, these children may have developed tics, regardless of treatment with the med

studies in women and animals are not available. Drugs should be given only if the potential benefit justifies th
See Drug Consult reference: PREGNANCY RISK CATEGORIES
2) Crosses Placenta: Unknown
3) Clinical Management

a) Amphetamines are not recommended for use during pregnancy except possibly in the case of narcolepsy drug is indicated and according to established regimens, amphetamines are not expected to create a significa abuse of amphetamines does increase the potential risk of maternal, fetal, and neonatal morbidity. Although evidence suggests an increased incidence of cardiac defects and cleft palate in neonates born to mothers tak et al, 1981).

4) Literature Reports

a) Eleven infants were born with biliary atresia to mothers who had taken amphetamines in various doses du development of a biliary tree) (Levin, 1971). In a controlled group of 50 normal infants, it was noted that 3 of 5

b) A large prospective, observational study of pregnancy and child development was undertaken related to a phenmetrazine) prescribed to gravid women during different stages of pregnancy and evaluated for their tera The severe congenital anomaly rate (SCA) per 100 live-born children at age 5 years did not differ from the SC did not use these drugs. There was, however, an excess of oral clefts in the offspring of mothers who had am the last menstrual period. A rough test of efficacy of anorectic drugs was made by comparing mean weight ga prescription; it showed only short-term and limited reduction of weight gain.

c) In a further report, clinicians evaluated the outcome of pregnancy in 52 women who had abused intravenc pregnancy, with results being compared to a control group of 52 nonabusing women (Little et al, 1988). Body was decreased significantly in neonates born to mothers abusing methamphetamine during pregnancy. Howe not increased significantly compared to the control group.

d) A statistically significant correlation between aggressive behavior and amphetamine exposure during fetal 1994).

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk has been demonstrated.

a) Evidence and/or expert consensus has demonstrated harmful infant effects when used during breastfeedi prescribed or patients should be advised to discontinue breastfeeding.

2) Clinical Management

a) Amphetamines are concentrated in human breast milk. Adverse effects reported in exposed infants includ 2001). The manufacturer of Adderal(R) suggests that breastfeeding women taking amphetamines be counse 2003).

3) Literature Reports

a) One study reported that concentrations of amphetamine were 3 and 7 times higher in breast milk than pla respectively, following administration of dextroamphetamine 20 mg daily to a nursing mother with narcolepsy occurred in the infant. Although only a small fraction of the maternal dose is expected to be transferred to the patients abstain from long-term nursing during amphetamine treatment.

4) Drug Levels in Breastmilk

a) Parent Drug

1) Milk to Maternal Plasma Ratio

a) One study reported that concentrations of amphetamine were 3 and 7 times higher in breast milk delivery, respectively, following administration of dextroamphetamine 20 mg daily to a nursing moth untoward effects occurred in the infant. Although only a small fraction of the maternal dose is expect the authors suggest that patients abstain from long-term nursing during amphetamine treatment.

imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i
effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb
methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th
pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g
fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical
doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc
1969). However, a systemic review of stimulants in the treatment of depression concluded that although

ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt
appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.D Calamus

1) Interaction Effect: reduced effect of amphetamines
2) Summary: Calamus antagonized spontaneous motor activity and amphetamine-induced hyperactivity in m
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Use caution with concomitant use of calamus and amphetamines.
7) Probable Mechanism: not specified
8) Literature Reports

a) Calamus antagonized spontaneous motor activity and amphetamine-induced hyperactivity in mice. C
(0.2 milliliters of 10, 25, 50 milligrams/kilogram (mg/kg)). One group of mice received 4 mg/kg chlorproma
spontaneous motor activity was compared to untreated mice. In another test, mice were injected IP with
calamus followed by amphetamine. Calamus significantly reduced spontaneous motor activity in a mann
and 25 mg/kg and significantly reduced amphetamine-induced hyperactivity at 25 mg/kg (Panchal et al,

3.5.1.E Citalopram

1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: Concurrent use of citalopram and dextroamphetamine resulted in symptoms of serotonin syndr
citalopram and dextroamphetamine are used concomitantly, monitor closely for symptoms of serotonin syndr
threatening. If serotonin syndrome develops, discontinue the offending agents and provide supportive care ar
Shannon, 2005).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: A case of serotonin syndrome was reported with coadministration of citalopram and
citalopram and dextroamphetamine are used concomitantly, monitor closely for symptoms of serotonin syndr
(including hyper-reflexia, tremor, muscle rigidity, clonus, peripheral hypertonicity, and shivering), autonomic h
diaphoresis, the presence of bowel sounds, and diarrhea), and mental status changes (including agitation an
threatening. If serotonin syndrome develops, discontinue the offending agents and provide supportive care ar
Shannon, 2005).
7) Probable Mechanism: additive pharmacologic effects
8) Literature Reports

a) A 32-year-old male on dextroamphetamine experienced serotonin syndrome approximately 1 week a
dextroamphetamine 5 mg three times daily for attention deficit hyperactivity disorder. He started 75 mg a
was increased to 150 mg daily. Approximately 2 weeks after starting venlafaxine he experienced markec
admission he was alert and oriented. He experienced diaphoresis, shivering, and fine motor tremor. His
pressure was 142/93 mmHg, and temperature was 37.3 degrees Celsius. No nystagmus or ocular clonus
reactive. He had generalized hypertonia, hyperreflexia, inducible ankle clonus, frequent myoclonic jerking
oris muscle. No abnormality was shown on ECG, except sinus tachycardia with a baseline tremor. Dextr
discontinued and cyproheptadine (up to a total of 32 mg over 3 hours) was administered. Symptoms reso
morning. Dextroamphetamine was restarted 3 days later. Four days later citalopram was started. Approx
symptoms as he did with dextroamphetamine and venlafaxine. Agitation, nausea, diarrhea, and teeth cle
was discontinued. Two doses of cyproheptadine were given and within 2 days he was asymptomatic (Pri

3.5.1.F Clomipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte
from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with
Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m
most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
& Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs
monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf
capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if
closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen
amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet
VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab

2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c
imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i
effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb
methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th
pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g
fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical
doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc
1969). However, a systemic review of stimulants in the treatment of depression concluded that although
ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt
appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.G Clorgyline

1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of dextroamphetamine concomitantly or within 14 days following the administration of a mo
(Prod Info Dexedrine(R), 1995c). Amphetamines stimulate the release of norepinephrine, and the use of mon
more norepinephrine being made available at nerve receptor sites through inhibition of catecholamine degrad
of norepinephrine, which increases sympathetic activity (Gilman et al, 1990d). Coadministration of indirect-ac
in severe hypertension and hyperpyrexia (Krisko et al, 1969d; Lloyd & Walker, 1965d; Mason, 1962d; Dally, 1
dextroamphetamine or pemoline in addition to a MAOI was observed during a study of patients with treatmen
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a m
7) Probable Mechanism: increased norepinephrine availability
8) Literature Reports
a) Severe headaches and hypertensive crises are well-documented in the literature as being associated
include cardiac arrhythmias, chest pain, hyperpyrexia, and death (Goldberg, 1964b).
b) In a study of 32 patients with treatment-refractory depression, efficacy of combination therapy with a c
(pemoline or dextroamphetamine) with a monoamine oxidase inhibitor (MAOI) was studied. Some of the
tricyclic antidepressants and lithium, in addition to the study medications. Most of the patients (78%) exp
months during coadministration, and 31% of the patients continued treatment after the study. Four of the
discontinued the medications due to impotence, orthostatic hypotension, elevated blood pressure, or sha
dextroamphetamine and a MAOI discontinued the medications due to memory problems, parkinsonian s
patients experienced mood cycling, five to hypomania and one to mania. No patients developed symptor
(Fawcett et al, 1991h).

3.5.1.H Desipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte
from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with
Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m
most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
& Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs
monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf
capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if
closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen
amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet
VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab
2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c
imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i
effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb
methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th
pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.I Dothiepin

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in
effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb

methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.P Moclobemide

1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)

2) Summary: Use of dextroamphetamine concomitantly or within 14 days following the administration of a mo (Prod Info Dexedrine(R), 1995). Amphetamines stimulate the release of norepinephrine, and the use of monc more norepinephrine being made available at nerve receptor sites through inhibition of catecholamine degrac of norepinephrine, which increases sympathetic activity (Gilman et al, 1990). Coadministration of indirect-acti in severe hypertension and hyperpyrexia (Krisko et al, 1969; Lloyd & Walker, 1965; Mason, 1962; Dally, 1962 dextroamphetamine or pemoline in addition to a MAOI was observed during a study of patients with treatmen

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a r

7) Probable Mechanism: increased norepinephrine availability

8) Literature Reports

a) In a study of 32 patients with treatment-refractory depression, efficacy of combination therapy with a ((pemoline or dextroamphetamine) with a monoamine oxidase inhibitor (MAOI) was studied. Some of the tricyclic antidepressants and lithium, in addition to the study medications. Most of the patients (78%) exp months during coadministration, and 31% of the patients continued treatment after the study. Four of the discontinued the medications due to impotence, orthostatic hypotension, elevated blood pressure, or sha dextroamphetamine and a MAOI discontinued the medications due to memory problems, parkinsonian s patients experienced mood cycling, five to hypomania and one to mania. No patients developed symptor (Fawcett et al, 1991).

3.5.1.Q Nialamide

1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)

2) Summary: Use of dextroamphetamine concomitantly or within 14 days following the administration of a mo (Prod Info Dexedrine(R), 1995j). Amphetamines stimulate the release of norepinephrine, and the use of monc more norepinephrine being made available at nerve receptor sites through inhibition of catecholamine degrac of norepinephrine, which increases sympathetic activity (Gilman et al, 1990k). Coadministration of indirect-ac in severe hypertension and hyperpyrexia (Krisko et al, 1969j; Lloyd & Walker, 1965j; Mason, 1962j; Dally, 19(dextroamphetamine or pemoline in addition to a MAOI was observed during a study of patients with treatmen

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a r

7) Probable Mechanism: increased norepinephrine availability

8) Literature Reports

a) In a study of 32 patients with treatment-refractory depression, efficacy of combination therapy with a ((pemoline or dextroamphetamine) with a monoamine oxidase inhibitor (MAOI) was studied. Some of the tricyclic antidepressants and lithium, in addition to the study medications. Most of the patients (78%) exp months during coadministration, and 31% of the patients continued treatment after the study. Four of the discontinued the medications due to impotence, orthostatic hypotension, elevated blood pressure, or sha dextroamphetamine and a MAOI discontinued the medications due to memory problems, parkinsonian s patients experienced mood cycling, five to hypomania and one to mania. No patients developed symptor (Fawcett et al, 1991p).

3.5.1.R Nortriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.S Opipramol

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCA monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.T Pargyline

1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of dextroamphetamine concomitantly or within 14 days following the administration of a m (Prod Info Dexedrine(R), 1995i). Amphetamines cause the release of norepinephrine, and the use of MAOIs available at nerve receptor sites through inhibition of catecholamine degradation; concurrent use leads to gre sympathetic activity (Gilman et al, 1990j). Coadministration of indirect-acting sympathomimetics and MAOIs h hyperpyrexia (Krisko et al, 1969i; Lloyd & Walker, 1965i; Mason, 1962i; Dally, 1962i).
3) Severity: contraindicated

4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a r
7) Probable Mechanism: increased norepinephrine availability

3.5.1.U Phenelzine

1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Amphetamines cause the release of norepinephrine, and the use of monoamine oxidase inhibit being made available at nerve receptor sites through inhibition of catecholamine degradation. Concurrent use which increases sympathetic activity (Gilman et al, 1990a). Coadministration of indirect-acting sympathomime hypertension and hyperpyrexia (Krisko et al, 1969a; Lloyd & Walker, 1965a; Mason, 1962a; Dally, 1962a). So dextroamphetamine or pemoline in addition to a MAOI was observed during a study of patients with treatmen However, the concurrent use of dextroamphetamine and phenelzine is contraindicated (Prod Info Nardil(R), 1
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a r
7) Probable Mechanism: increased norepinephrine availability
8) Literature Reports
a) Severe headaches and hypertensive crises are well-documented in the literature with this combinatio arrhythmias, chest pain, hyperpyrexia, and death (Goldberg, 1964).
b) In a study of 32 patients with treatment-refractory depression, efficacy of combination therapy with a (pemoline or dextroamphetamine) with a monoamine oxidase inhibitor (MAOI) was studied. Some of the tricyclic antidepressants and lithium, in addition to the study medications. Most of the patients (78%) exp months during coadministration, and 31% of the patients continued treatment after the study. Four of the discontinued the medications due to impotence, orthostatic hypotension, elevated blood pressure, or sha dextroamphetamine and a MAOI discontinued the medications due to memory problems, parkinsonian s patients experienced mood cycling, five to hypomania and one to mania. No patients developed symptor (Fawcett et al, 1991b).

3.5.1.V Procarbazine

1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of dextroamphetamine concomitantly or within 14 days following the administration of a mo (Prod Info Dexedrine(R), 1995f). Amphetamines stimulate the release of norepinephrine, and the use of mon more norepinephrine being made available at nerve receptor sites through inhibition of catecholamine degrad of norepinephrine, which increases sympathetic activity (Gilman et al, 1990g). Coadministration of indirect-ac in severe hypertension and hyperpyrexia (Krisko et al, 1969f; Lloyd & Walker, 1965f; Mason, 1962f; Dally, 19 dextroamphetamine or pemoline in addition to a MAOI was observed during a study of patients with treatmen
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a r
7) Probable Mechanism: increased norepinephrine availability
8) Literature Reports
a) In a study of 32 patients with treatment-refractory depression, efficacy of combination therapy with a (pemoline or dextroamphetamine) with a monoamine oxidase inhibitor (MAOI) was studied. Some of the tricyclic antidepressants and lithium, in addition to the study medications. Most of the patients (78%) exp months during coadministration, and 31% of the patients continued treatment after the study. Four of the discontinued the medications due to impotence, orthostatic hypotension, elevated blood pressure, or sha dextroamphetamine and a MAOI discontinued the medications due to memory problems, parkinsonian s patients experienced mood cycling, five to hypomania and one to mania. No patients developed symptor (Fawcett et al, 1991l).

3.5.1.W Protriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if

closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.X Selegiline
1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of dextroamphetamine concomitantly or within 14 days following the administration of a m (Prod Info Dexedrine(R), 1995g). Amphetamines cause the release of norepinephrine, and the use of MAOIs available at nerve receptor sites through inhibition of catecholamine degradation; concurrent use leads to gre sympathetic activity (Gilman et al, 1990h). Coadministration of indirect-acting sympathomimetics and MAOIs hyperpyrexia (Krisko et al, 1969g; Lloyd & Walker, 1965g; Mason, 1962g; Dally, 1962g).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a r
7) Probable Mechanism: increased norepinephrine availability
8) Literature Reports
a) Severe headaches and hypertensive crises are well-documented in the literature as being associated include cardiac arrhythmias, chest pain, hyperpyrexia, and death (Goldberg, 1964d).

3.5.1.Y Sibutramine
1) Interaction Effect: an increased risk of hypertension and tachycardia
2) Summary: Sibutramine has been associated with substantial increases in blood pressure and heart rate ir administration of sibutramine and other centrally acting appetite suppressants has not been systematically ev and tachycardia may result. Therefore, the concurrent administration of sibutramine with another centrally act (Prod Info Meridia(R), 1997).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concomitant administration of sibutramine with other centrally active appetite s
7) Probable Mechanism: additive pharmacologic effects

3.5.1.Z Sodium Bicarbonate
1) Interaction Effect: amphetamine toxicity (hypertension, hyperpyrexia, seizures)
2) Summary: Sodium bicarbonate (ie, greater than 2 grams daily) may alkalinize the urine, increasing the un allowing for increased renal tubular reabsorption. Enhanced effects of amphetamine may occur due to increa al, 1973a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Lower doses of dextroamphetamine may be required with urinary alkalinizers. Moni
7) Probable Mechanism: decreased dextroamphetamine clearance

3.5.1.AA Toloxatone
1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of dextroamphetamine concomitantly or within 14 days following the administration of a m (Prod Info Dexedrine(R), 1995b). Amphetamines stimulate the release of norepinephrine, and the use of mor more norepinephrine being made available at nerve receptor sites through inhibition of catecholamine degrac of norepinephrine, which increases sympathetic activity (Gilman et al, 1990c). Coadministration of indirect-ac in severe hypertension and hyperpyrexia (Krisko et al, 1969c; Lloyd & Walker, 1965c; Mason, 1962c; Dally, 1 dextroamphetamine or pemoline in addition to a MAOI was observed during a study of patients with treatmen

3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a n
7) Probable Mechanism: increased norepinephrine availability
8) Literature Reports
a) In a study of 32 patients with treatment-refractory depression, efficacy of combination therapy with a c (pemoline or dextroamphetamine) with a monoamine oxidase inhibitor (MAOI) was studied. Some of the tricyclic antidepressants and lithium, in addition to the study medications. Most of the patients (78%) exp months during coadministration, and 31% of the patients continued treatment after the study. Four of the discontinued the medications due to impotence, orthostatic hypotension, elevated blood pressure, or sha dextroamphetamine and a MAOI discontinued the medications due to memory problems, parkinsonian s patients experienced mood cycling, five to hypomania and one to mania. No patients developed symptor (Fawcett et al, 1991f).

3.5.1.AB Tranylcypromine

1) Interaction Effect: a hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of dextroamphetamine concomitantly or within 14 days following the administration of a mo (Prod Info Dexedrine(R), 1995e). Amphetamines cause the release of norepinephrine, and the use of monoa norepinephrine being made available at nerve receptor sites through inhibition of catecholamine degradation. norepinephrine, which increases sympathetic activity (Gilman et al, 1990f). Coadministration of indirect-acting severe hypertension and hyperpyrexia (Krisko et al, 1969e; Lloyd & Walker, 1965e; Mason, 1962e; Dally, 196 dextroamphetamine or pemoline in addition to a MAOI was observed during a study of patients with treatmen
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Dextroamphetamine use during or within 14 days following the administration of a n
7) Probable Mechanism: increased norepinephrine availability
8) Literature Reports
a) Severe headaches and hypertensive crises are well-documented in the literature with this combinatio arrhythmias, chest pain, hyperpyrexia, and death (Goldberg, 1964c).
b) In a study of 32 patients with treatment-refractory depression, efficacy of combination therapy with a c (pemoline or dextroamphetamine) with a monoamine oxidase inhibitor (MAOI) was studied. Some of the tricyclic antidepressants and lithium, in addition to the study medications. Most of the patients (78%) exp months during coadministration, and 31% of the patients continued treatment after the study. Four of the discontinued the medications due to impotence, orthostatic hypotension, elevated blood pressure, or sha dextroamphetamine and a MAOI discontinued the medications due to memory problems, parkinsonian s patients experienced mood cycling, five to hypomania and one to mania. No patients developed symptor (Fawcett et al, 1991j).

3.5.1.AC Trimipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sho moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.AD Venlafaxine

1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: Two weeks of concurrent use of dextroamphetamine and venlafaxine resulted in symptoms of s et al, 2002). If dextroamphetamine and venlafaxine are used concomitantly, monitor closely for symptoms of life-threatening. If serotonin syndrome develops, discontinue the offending agents and provide supportive car Shannon, 2005).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: A case of serotonin syndrome was reported with coadministration of dextroampheta dextroamphetamine and venlafaxine are used concomitantly, monitor closely for symptoms of serotonin synd (including hyper-reflexia, tremor, muscle rigidity, clonus, peripheral hypertonicity, and shivering), autonomic h diaphoresis, the presence of bowel sounds, and diarrhea), and mental status changes (including agitation an threatening. If serotonin syndrome develops, discontinue the offending agents and provide supportive care a Shannon, 2005).
7) Probable Mechanism: additive pharmacologic effects
8) Literature Reports
a) A 32-year-old male on dextroamphetamine experienced serotonin syndrome approximately 2 weeks dextroamphetamine 5 mg three times daily for attention deficit hyperactivity disorder. He started 75 mg a was increased to 150 mg daily. Approximately 2 weeks after starting venlafaxine he experienced markec admission he was alert and oriented. He experienced diaphoresis, shivering, and fine motor tremor. His pressure was 142/93 mmHg, and temperature was 37.3 degrees Celsius. No nystagmus or ocular clonus reactive. He had generalized hypertonia, hyperreflexia, inducible ankle clonus, frequent myoclonic jerkin oris muscle. No abnormality was shown on ECG, except sinus tachycardia with a baseline tremor. Dextr discontinued and cyproheptadine (up to a total of 32 mg over 3 hours) was administered. Symptoms res morning. Dextroamphetamine was restarted 3 days later. Four days later citalopram was started. Approx symptoms as he did with dextroamphetamine and venlafaxine. Agitation, nausea, diarrhea, and teeth cle was discontinued. Two doses of cyproheptadine were given and within 2 days he was asymptomatic (Pri

3.5.2 Drug-Food Combinations

3.5.2.A Acidic Food

1) Interaction Effect: altered serum concentrations
2) Summary: Maximal absorption of amphetamines occurs in the alkaline environment of the small intestine taken with amphetamines may impair gastrointestinal absorption. Foods that increase urinary pH may decrea reabsorption of the amphetamine and increased serum levels. Foods that acidify urine increase renal clearan levels (Prod Info Dexedrine(R), 1998; Beckett & Rowland, 1965).
3) Severity: minor
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Dextroamphetamine should not be administered with acidic foods, such as citric fru
7) Probable Mechanism: pH-dependent absorption and clearance

4.0 Clinical Applications

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters

A) Dextroamphetamine Sulfate

1) Therapeutic

a) Physical Findings

1) Attention Deficit Hyperactivity Disorder (ADHD)

a) Improvement in mental and behavioral symptoms of ADHD, including inappropriate inattention, i performance.

2) Narcolepsy

a) Decreased frequency of narcoleptic attacks.

2) Toxic

a) Physical Findings

1) Attention Deficit Hyperactivity Disorder (ADHD)

a) The American Academy of Pediatrics (AAP) does not recommend the routine use of electrocardi cardiology evaluations (which were previously recommended by the American Heart Association (AI conditions that might place the child at risk for sudden cardiac death) before initiating stimulant thera ADHD in most children. The APA cited specific reasons for changing the recommendation including between stimulant drugs used to treat ADHD and sudden cardiac death (SCD), the frequency of suc stimulant drugs is not higher than that in the general population of children, and lack of cost-effective evaluation by pediatric cardiologist (Perrin et al, 2008).

b) Based on the American Academy of Pediatrics (AAP) and the American Heart Association (AHA monitoring recommendations have been established to assist clinicians in the evaluation of children dextroamphetamine, for ADHD (Perrin et al, 2008; Vetter et al, 2008):

- Conduct a thorough examination prior to initiating dextroamphetamine therapy for a diagnosis symptoms indicative of a cardiac condition, including palpitations, near syncope, or syncope.
- Obtain a complete family and patient history for conditions associated with SCD, and determir the-counter medications.
- Conduct a complete physical evaluation of the patient for hypertension, cardiac murmurs, phys and signs of irregular cardiac rhythms.
- Perform further evaluation if family history, patient history or physical exam is suggestive of ca visits, and if indicated, consult pediatric cardiologist (Perrin et al, 2008).
- Continue to assess the patient for cardiac symptoms and any changes in family history at follo
- Blood pressure and heart rate should be evaluated at baseline, during routine follow-up within 12 months. Increases in blood pressure and heart rate have been reported with stimulant use.

c) It is not conclusive whether chronic use of stimulants in children may be associated with suppres monitored during treatment (Prod Info DEXEDRINE(R) oral tablets, sustained-release oral capsules

4.2 Patient Instructions

A) Dextroamphetamine (By mouth)

Dextroamphetamine

Treats attention deficit hyperactivity disorder (ADHD). Also treats narcolepsy (a sleep problem). This medicine is a

When This Medicine Should Not Be Used:
You should not use this medicine if you or your child have had an allergic reaction to dextroamphetamine. You sh glaucoma, heart disease, blood vessel problems, an overactive thyroid, or high blood pressure. Do not use this m you are very nervous, tense, or agitated most of the time. You should not use this medicine if you have used a dru (MAOI), such as Eldepryl®, Marplan®, Nardil®, or Parnate®, in the past 14 days. Do not give the tablet and oral s the extended-release capsule to a child younger than 6 years old.

How to Use This Medicine:
Tablet, Liquid, Long Acting Capsule

Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed best for you. Do not use more medicine or use it more often than your doctor tells you to.
This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your d Ask your pharmacist for the Medication Guide if you do not have one. Your doctor might ask you to sign some information.
It is best to take the extended-release capsule form in the morning. Taking this medicine in the afternoon or e asleep.
If you use the short-acting tablet form of this medicine, take your last dose for the day about 6 hours before b instructions.
Swallow the extended-release capsule whole. Do not crush, break, or chew it.
This medicine is part of an ADHD treatment program that may also include counseling or special education. C all treatment measures.

If a Dose is Missed:

If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next d the missed dose. Do not use extra medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:
Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after need to throw away old medicine after the expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a
Make sure your doctor knows if you are using ammonium chloride, sodium acid phosphate, acetazolamide (D furazolidone (Furoxone®), glutamic acid, guanethidine (Ismelin®), norepinephrine (Levophed®), reserpine (H blood pressure medicines (such as atenolol, lisinopril, metoprolol, Cozaar®, or Diovan®), or certain pain mec Demerol®, or Darvon®).
Tell your doctor if you are also using cold or allergy medicines, ethosuximide (Zarontin®), haloperidol (Haldol medicines for depression (such as amitriptyline, doxepin, nortriptyline, Pamelor®, or Sinequan®), methenami or phenytoin (Dilantin®).
Do not eat citrus fruits (oranges, lemons, limes, grapefruit) or drink citrus juice when you take this medicine. D medicine.

Warnings While Using This Medicine:
Make sure your doctor knows if you are pregnant or breastfeeding, or if you or your child have heart problems
Tell your doctor if you or your child have muscle tics or Tourette's syndrome, a condition that causes you to h not able to control.
Your doctor should know if you or your child have epilepsy, or a history of seizures, depression, or mental illn problems. Also tell your doctor if you or anyone in your family has tried to commit suicide.
This medicine may be habit-forming. If you feel that the medicine is not working as well, do not use more thar instructions.
Do not stop using this medicine suddenly without asking your doctor. You may need to slowly decrease your

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, o
Blurred vision.
Changes in your mood or behavior.
Chest pain, shortness of breath, or fainting.
Fast, pounding, or uneven heartbeat.
Feeling very excited, fearless, restless, or happy.
Seeing, hearing, or feeling things that are not there.
Seizures.
Tremors or shaking.
Uncontrollable muscle movements or twitching.

If you notice these less serious side effects, talk with your doctor:
Constipation, diarrhea, or upset stomach.
Dry mouth or bad taste in your mouth.
Feeling restless or nervous.
Headache or dizziness.
Loss of appetite or weight loss.
Mild skin rash or itching.
Problems having sex.
Trouble sleeping.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) The primary indication for the use of amphetamines is the clinical condition of narcolepsy which relies on the centra stimulant properties of the drugs. In children with hyperkinesia and other abnormal behavioral problems, the amphetar remedial measures to reduce observed motor activity from baseline levels (Green & Warshauer, 1981). This reduced o hyperactive children given dextroamphetamine) accompanied by improved behavior and improved attention seems to (classroom situations) but also physically active tasks (structured sports situations).

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) Dextroamphetamine is a non-catechol sympathetic amine with pharmacologic actions that are similar to ephec
Dextroamphetamine produces central nervous system (CNS) and respiratory stimulation, a pressor response, my
urinary sphincter. The drug is felt to have a direct effect on both alpha- and beta-receptor sites in the peripheral sy
nerve terminals. The central nervous system action is thought to occur in the cerebral cortex and reticular activati
dextroamphetamine is probably secondary to the CNS stimulating effect in the hypothalamic feeding center (Weir
2) Dextroamphetamine sulfate is used to treat narcolepsy because of its CNS and respiratory stimulant properties
abnormal behavioral problems, dextroamphetamine appears to be of value in combination with other remedial me
baseline levels (Green & Warshauer, 1981a). This reduced observed motor activity from baseline values (in hyper
accompanied by improved behavior and improved attention seems to occur not only in physically inactive tasks (c
tasks (structured sports situations) (Rapoport et al, 1980).

b) Fenfluramine and dextroamphetamine were comparable in the treatment of obesity. In a study with fenflu
were randomly assigned to 1 of 3 groups: fenfluramine 20 mg, dextroamphetamine 5 mg, or placebo. Patient
three times a day at least one hour before meals. The patients who tolerated the drugs were allowed to incre
and were given advice on eating habits, but no specific diet was prescribed. Fenfluramine was clearly more e
dextroamphetamine in producing weight loss. At 7 weeks, fenfluramine patients lost 6.6 pounds compared to
The frequency of adverse effects with fenfluramine was significantly higher than with dextroamphetamine (St

4.6.C Mazindol

Narcolepsy

Obesity

4.6.C.1 Narcolepsy

a) Mazindol and dextroamphetamine were comparable for narcolepsy therapy. Mazindol was retrospectively
treatment of narcolepsy in 34 patients (Parkes & Schachter, 1979). Thirty-two patients had previously receive
daily (mean dose 47 milligrams). Oral mazindol was given as an initial dose of 2 milligrams twice a day 7 day
The dose of mazindol was adjusted by clinical response. After 1 year of treatment, the daily mazindol doses r
mazindol, 25 patients received clomipramine and 6 received clonazepam for cataplexy. Mazindol produced s
day-sleep attacks by 50%. This response was similar to that seen with dextroamphetamine, and both treatme
some patients responded to one drug and not the other. Mazindol had no effect on cataplexy or sleep paralys
with mazindol compared to dextroamphetamine. Mazindol produced less euphoria, sweating, and palpitations
considered as effective as dextroamphetamine 50 milligrams/day in preventing narcolepsy.

4.6.C.2 Obesity

a) Mazindol is as effective or more effective than dextroamphetamine in the treatment of exogenous obesity 1980a). Comparable doses are mazindol 1 milligram three times a day and dextroamphetamine 5 milligrams 1980a). Mazindol is indicated over dextroamphetamine and all amphetamines for the treatment of obesity. In treatment of obesity due to the high probability for dependence and the lack of significant advantages over ot

b) Mazindol is chemically unrelated to amphetamine derivatives; however, the anorectic effects are mediatec not serotoninergic mechanisms) (Garratini et al, 1974). Mazindol has some advantages over amphetamine d dependence potential (Craddock, 1976). Mazindol does produce stimulation to the central nervous system, b less severe than with amphetamines (Craddock, 1976). In addition, mazindol appears to be relatively safe for diabetes mellitus, mild-to-moderate hypertension, and rheumatoid arthritis are present (Weintraub & Lasagna used in patients with hypertension or diabetes.

4.6.D Methylphenidate

4.6.D.1 Attention deficit hyperactivity disorder

a) SUMMARY: In comparative studies, Adderall(R) (combination AMPHETAMINE/DEXTROAMPHETAMINE efficacy in the treatment of attention deficit hyperactive disorder in children. METHYLPHENIDATE requires tv daily doses.

b) The racemic mixture of L- and D-amphetamine (ADDERALL (R)) was at least as effective as methylpheni deficit hyperactivity disorder (ADHD), and was more effective at 4 to 5 hours post-administration (beyond met this within-subject, double-blind, placebo-controlled, crossover study, 25 children with ADHD (mean age 9.6 y (mg), 17.5 mg, Adderall (R) 7.5 mg, 12.5 mg, and placebo twice a day (at 7:45 a.m. and 12:15 p.m.) in a ranc Teachers and counselors rated their behavior throughout the day and at times beyond methylphenidate's exp Parents rated them at the end of the day and in the evening for possible rebound effects. When compared to significantly improved in-school behaviors (p less than 0.0001 and 0.001, respectively), classroom measures than 0.0001), and after-school behaviors (p less than 0.0001). Drug effects were significantly affected by time resulted in higher effect size (ES) than methylphenidate and higher doses consistently resulted in higher ES t significantly more effective than methylphenidate at midday and end of day (p less than 0.05). The ES of both increased in the afternoon, implicating the possibility of reducing the afternoon dose. Side effects were report preclude the use of both medications. Only 1 patient was eliminated from the study due to exacerbation of his to evaluate the possibility of once daily dosing of Adderall(R), and to compare the efficacy of methylphenidate

c) Once-daily Adderall(R) (combination AMPHETAMINE/DEXTROAMPHETAMINE) appeared to be as effec treatment of attention deficit hyperactive disorder in children aged 6 to 12 years, according to a double-blind, Also, a mid-afternoon dose of either Adderall or methylphenidate (MPH) produced better evening behavior th although either active treatment tended to induce loss of appetite and sleep difficulties. In a randomized mani received each day 1 of 7 treatment protocols: (1)MPH 0.3 milligram/kilogram (mg/kg) at 7:30, 11:30, and 15:3 MPH 0.15 mg/kg at 15:30; (3)MPH 0.3 mg/kg at 7:30; (4)Adderall 0.3 mg/kg at 7:30 and 15:30; (5)Adderall 0. 15:30; (6)Adderall 0.3 mg/kg at 7:30; or (7)placebo. While twice-daily MPH 0.3 mg/kg did not differ significant single morning-dose MPH 0.3 mg/kg produced less significant effects than either once-daily Adderall 0.3 mg/ MPH began to lose its effectiveness approximately 6.5 hours later. Evening behavior was rated better after M no evening differences were seen after mid-afternoon doses of either 0.3 or 0.15 mg/kg. Children showed dif responded more positively to MPH, 37% responded more positively to Adderall, and 38% responded equally responding more positively to MPH, one dose of MPH was sufficient to carry them all day and into the evenin positively to Adderall needed only once-daily dosing of the drug (Pelham et al, 1999a).

d) In a direct, double-blind, cross-over comparison of adverse effect profiles, both DEXTROAMPHETAMINE METHYLPHENIDATE 0.3 mg/kg twice daily were well-tolerated in 125 children with attention deficit disorder reported more frequently during drug therapy than at baseline were appetite suppression (both drugs) and ins severity of adverse effects was significantly higher in the dextroamphetamine group. However, only 1.6% of c because of adverse effects (Efron et al, 1997).

4.6.E Modafinil

Attention deficit hyperactivity disorder, Adult

Sleep disorder

4.6.E.1 Attention deficit hyperactivity disorder, Adult

a) Both modafinil and dextroamphetamine demonstrated efficacy and were well tolerated in the treatment of adults. During a double-blind, three-phase crossover study, 22 adults (mean age 40.8 years) who met DSM-I modafinil, dextroamphetamine, and placebo. The study design included three, 2-week drug treatment phases periods. At the beginning of each drug phase, patients received one capsule twice daily containing 50 milligra lactose. The dose was increased by an additional capsule twice daily every 1 to 2 days as tolerated up to a m dextroamphetamine, or 8 capsules of lactose. The mean optimum doses of modafinil and dextroamphetamin respectively. Rating scales and cognitive testing were completed at baseline and on the last day of each drug

When compared to placebo, modafinil and dextroamphetamine were associated with a significant reduction c (p less than 0.001). Although not statistically significant, less severe ADHD symptoms were associated with r Cognitive performance as measured by the Controlled Oral Word Association Test (COWAT) reached trend l compared to placebo (p less than 0.05). Both modafinil and dextroamphetamine were well-tolerated with insc suppression being the most commonly reported adverse effects (Taylor & Russo, 2000).

4.6.E.2 Sleep disorder

a) In studies involving healthy young and elderly subjects, oral modafinil 100 to 200 milligrams (mg) modafin of normal sleep than with dextroamphetamine 10 to 20 mg. Specifically, dextroamphetamine produced greate architecture, and deterioration of subjective sleep quality. The authors suggest the importance of differentiatir from "vigilance-increasing" properties of amphetamines (Saletu et al, 1989a; Saletu et al, 1989). However, dif significant in these studies. Total sleep time and sleep efficiency were also reduced significantly by modafinil with dextroamphetamine.

4.6.F Pemoline

4.6.F.1 Attention deficit hyperactivity disorder

a) Dextroamphetamine and pemoline are comparable for the treatment of attention deficit disorder. Magnesi dextroamphetamine in a double-blind, randomized, placebo-controlled study of 81 children with minimal brair received a maximum dose of 125 milligrams magnesium pemoline (mean 82 milligrams) and 40 milligrams of psychological tests were administered at baseline and at 8 weeks. At both 4 and 8 weeks, both drugs were s dextroamphetamine patients, 77% of the pemoline patients, and 30% of the placebo patients were improved. significant (p less than 0.003) changes for defiance, inattentiveness, and hyperactivity factors with both drugs showed a significant effect at 2 weeks (p=0.057) and at 4 weeks (p=0.022) compared to pemoline. Only after from placebo. After 8 weeks, however, the 2 treatments were indistinguishable for these factors. Anxiety and either drug. On the eight-factor parent symptom list, conduct disturbance, impulsivity, immaturity, and antisoc than 0.04). Factors not affected were anxiety, somatic complaints, obsessional traits, and hyperactivity. A res weeks and no difference between the 2 drugs was demonstrated at 8 weeks. The psychological test battery s placebo (p less than 0.004) in spelling, reading, Porteus Mazes, Frostig perceptual quotient, eye-motor coord drug-drug differences were noted. The major side effects with both drugs were insomnia and anorexia; insom therapy. Less than 5% of patients on dextroamphetamine experienced moderate or severe insomnia by the e psychological heterogenicity exists among children with minimal brain dysfunction. A child should receive dru probability that he will respond has been determined.

4.6.G Phentermine

4.6.G.1 Obesity

a) Despite differences in the pharmacologic effects and toxicity of the available anorexiant agents, all of the and no drug has been found superior to dextroamphetamine (AMA Department of Drugs, 1983). In addition, t of Drugs has indicated that amphetamines have no advantages over other anorectic agents that have a lowe Diethylpropion, mazindol, and phentermine are the preferred drugs for the management of obesity, based up central nervous system or cardiovascular toxicity (AMA Department of Drugs, 1983).

DRUGDEX® Evaluations

VENLAFAXINE

0.0 Overview

1) Class
- **a)** This drug is a member of the following class(es):
  - Antidepressant
  - Antidepressant, Bicyclic
  - Phenethylamine (class)
  - Serotonin/Norepinephrine Reuptake Inhibitor

2) Dosing Information
- **a)** Venlafaxine Hydrochloride
  - **1)** Adult
    - **a)** may convert to extended-release capsules or tablets based on nearest equivalent dose (mg/day) of stable
    2008; Prod Info venlafaxine extended release oral tablets, 2008)
    - **b)** taper dose prior to discontinuation to minimize risk of withdrawal symptoms (Prod Info EFFEXOR(R) oral
    venlafaxine extended release oral tablets, 2008)
      - **1)** Generalized anxiety disorder
        - **a)** (extended-release capsule) initial, 37.5 to 75 mg/day ORALLY (single dose); may increase dosa
        extended-release oral capsules, 2008)
      - **2)** Major depressive disorder
        - **a)** (immediate-release tablets) outpatients, 75 mg/day ORALLY (2-3 divided doses); may increase d
        oral tablets, 2008)
        - **b)** (immediate-release tablets) inpatients, 75 mg/day ORALLY (2-3 divided doses); may increase do
        Info EFFEXOR(R) oral tablets, 2008)
        - **c)** (extended-release capsules and tablets) 37.5 to 75 mg/day ORALLY (single dose); may increase
        XR(R) extended-release oral capsules, 2008; Prod Info venlafaxine extended release oral tablets, 2
      - **3)** Panic disorder, With or without agoraphobia
        - **a)** (extended-release capsule) starting dose, 37.5 mg/day ORALLY for 7 days; increase dose after
        intervals to a MAX dose of 225 mg/day (Prod Info EFFEXOR XR(R) extended-release oral capsules
      - **4)** Social phobia
        - **a)** (extended-release capsules and tablets) 75 mg/day ORALLY (single-dose) (Prod Info EFFEXOR
        tablets, 2008)
  - **2)** Pediatric
    - **a)** safety and efficacy not established in children (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFE
    release oral tablets, 2008)

3) Contraindications
- **a)** Venlafaxine Hydrochloride
  - **1)** concomitant use of monoamine oxidase inhibitors (MAOI) (Prod Info Effexor(R) oral tablets, 2009; Prod Info Ef
  release oral tablets, 2009)

4) Serious Adverse Effects
- **a)** Venlafaxine Hydrochloride
  - **1)** Bleeding, Abnormal
  - **2)** Depression, exacerbation
  - **3)** Gastrointestinal hemorrhage
  - **4)** Hepatitis
  - **5)** Hypomania
  - **6)** Hyponatremia
  - **7)** Mania
  - **8)** Neuroleptic malignant syndrome
  - **9)** Seizure
  - **10)** Serotonin syndrome
  - **11)** Suicidal thoughts

5) Clinical Applications
- **a)** Venlafaxine Hydrochloride
  - **1)** FDA Approved Indications
    - **a)** Generalized anxiety disorder
    - **b)** Major depressive disorder
    - **c)** Panic disorder, With or without agoraphobia
    - **d)** Social phobia

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms

Venlafaxine
Venlafaxine HCl
Venlafaxine Hydrochloride

C) Physicochemical Properties

1) Venlafaxine Hydrochloride

a) Molecular Weight

1) O-desmethylvenlafaxine (ODV): 263 (Howell et al, 1993); Venlafaxine: 277 (Howell et al, 1993); Venla EFFEXOR XR(R) extended-release oral capsules, 2008; Canada, 1997)

b) Partition Coefficient

1) Octanol/water: 0.43 (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extendec

c) pKa

1) 9.4 (Ellingrod & Perry, 1994)

d) Solubility

1) Venlafaxine hydrochloride has a solubility of 572 milligrams/milliliter in water adjusted to ionic strengtl Info EFFEXOR XR(R) extended-release oral capsules, 2008).

1.2 Storage and Stability

A) Venlafaxine Hydrochloride

1) Preparation

a) Oral route

1) Venlafaxine and venlafaxine extended-release should not be administered concurrently with a monoa and initiation of venlafaxine hydrochloride or at least 7 days between discontinuation of venlafaxine hydr EFFEXOR XR(R) extended-release oral capsules, 2008; Prod Info venlafaxine extended release oral tab

2) Administer venlafaxine and venlafaxine extended-release with food at approximately the same time e release oral capsules, 2008; Prod Info venlafaxine extended release oral tablets, 2008).

3) Swallow venlafaxine extended-release (XR) capsules and tablets whole with fluid. Do not divide, crus XR capsules may be administered by opening the capsule and sprinkling the contents on a spoonful of a (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008; Prod Info venlafaxine extended relea

B) Venlafaxine Hydrochloride

1) Oral route

a) Capsule, Extended Release/Tablet

1) Store at controlled room temperature, 20 to 25 degrees Celsius (68 to 77 degrees Fahrenheit) (Prod capsules, 2008).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Geriatric Patients

Dosage Adjustment During Dialysis

Dosage in Other Disease States

1.3.1 Normal Dosage

1.3.1.A Venlafaxine Hydrochloride

1.3.1.A.1 Oral route

Generalized anxiety disorder

Major depressive disorder

Panic disorder, With or without agoraphobia

Social phobia

1.3.1.A.1.a Generalized anxiety disorder

1) The initial recommended dosage for venlafaxine extended-release (XR) is 75 milligrams (mg)/da should be taken consistently at the same time each day. To allow new patients to adjust to therapy, made at intervals of at least 4 days. The maximum recommended dose is 225 mg/day. Although ver the need for continuing medication in patients with generalized anxiety disorder who improve with ve extended-release oral capsules, 2008).

1.3.1.A.1.b Major depressive disorder

1) The initial recommended dosage of regular-release venlafaxine is 75 milligrams (mg)/day, admin mg/day at intervals of at least 4 days. In the outpatient setting, doses above 225 mg/day demonstra inpatients responded to a mean dose of 350 mg/day. Therefore, the maximum recommended dose generally recommended that acute episodes of major depressive disorder be treated with sustained unknown whether the dose of venlafaxine required for maintenance treatment is the same as the do recommended in order to determine need for maintenance treatment and the appropriate maintenar
2) The initial recommended dosage for venlafaxine extended-release capsules and tablets is 75 mil may be taken in the morning or evening but should be taken consistently at the same time each day for 4 to 7 days. Dosage increases of 75 mg/day should be made at intervals of at least 4 days. The episodes of major depressive disorder be treated with sustained pharmacological therapy for severa required for maintenance treatment is the same as the dose needed to achieve an initial response. maintenance treatment and the appropriate maintenance dose (Prod Info EFFEXOR XR(R) extende
3) Administration of immediate-release venlafaxine once daily versus twice daily produced similar ir produced more rapid improvement (at 2 weeks) than once daily administration, but dose escalation once daily dosing, dose escalation proceeded as follows: (1) week 1 - 37.5 milligrams daily, (2) wee The twice daily regimen was similar except for the initial week where patients received 37.5 mg on c

1.3.1.A.1.c Panic disorder, With or without agoraphobia

1) The recommended starting dose of venlafaxine hydrochloride extended-release (XR) capsules fo day orally for 7 days. The dose may be increased to 75 mg per day after 1 week. For patients not re made at intervals of not less than 7 days. The maximum recommended dose is 225 mg per day (Pro
2) Patients may need to be evaluated periodically to determine the need for continuing medication. treatment with venlafaxine XR, patients who continued on venlafaxine XR experienced a significantl extended-release oral capsules, 2008).

1.3.1.A.1.d Social phobia

1) The initial recommended dosage for venlafaxine extended-release capsules and tablets is 75 mil evening but should be taken consistently at the same time each day. There is no evidence that high and efficacy in clinical trials lasting up to 6 months, the need for continuing medication in patients wi periodically reassessed (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008; Prod Inf

1.3.1.A.1.e Conversion To Venlafaxine XR

1) Depressed patients who are stabilized on immediate-release venlafaxine may be switched to the tablets. Further, individual dosage adjustments may be necessary (Prod Info EFFEXOR XR(R) exte 2008).

1.3.1.A.1.f Withdrawal Schedule

1) To minimize the risk of withdrawal symptoms, a gradual reduction in the dose rather than abrupt recommended. During clinical trials, the dose of venlafaxine XR was reduced by 75 milligrams per d EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008;

1.3.2 Dosage in Renal Failure

A) Venlafaxine Hydrochloride

1) During clinical trials, clearance was decreased while the elimination half-life was increased for venlafaxine filtration rate between 10 and 70 milliliters/minute). Therefore, the total daily dose should be reduced by 25% tablets, 2008; Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008; Prod Info venlafaxine exten

1.3.3 Dosage in Hepatic Insufficiency

A) Venlafaxine Hydrochloride
1) During clinical trials, clearance of venlafaxine was decreased while the elimination half-life was increased and mild to moderate hepatic impairment. Therefore, the total daily dose should be reduced by 50% in patien dose even more than 50%, and further individualization of dose may be necessary in some patients with cirrh EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008; Prod Info

1.3.4 Dosage in Geriatric Patients
A) Venlafaxine Hydrochloride
1) Clearance of venlafaxine is reduced by approximately 15% in the elderly, presumably because of the sligh adjustment based upon age of the patient is generally unnecessary. However, caution should be taken when EFFEXOR XR(R) extended-release oral capsules, 2008; Prod Info venlafaxine extended release oral tablets,

1.3.5 Dosage Adjustment During Dialysis
A) Venlafaxine Hydrochloride
1) Total daily dose should be reduced by 50% in hemodialysis patients (Prod Info EFFEXOR(R) oral tablets, venlafaxine extended release oral tablets, 2008).

1.3.6 Dosage in Other Disease States
A) Venlafaxine Hydrochloride
1) Pregnancy
a) Neonatal complications requiring prolonged hospitalization, respiratory support, and tube feeding hav reuptake inhibitors, and selective serotonin reuptake inhibitors late in the third trimester. The physician m tablets, 2008; Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008; Prod Info venlafaxine e

1.4 Pediatric Dosage

1.4.1 Normal Dosage

1.4.1.A Venlafaxine Hydrochloride

1.4.1.A.1 Oral route
a) The safety and efficacy have not been established in children (Prod Info EFFEXOR(R) oral tablets, 2(venlafaxine extended release oral tablets, 2008).

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration
A) Onset
1) Venlafaxine Hydrochloride
a) Initial Response
1) Depression, oral: 2 weeks to several months (Cantu et al, 1994; Montgomery, 1993; Prod Info EFFE) 2008)
a) Although some symptoms of major depression may improve within about 2 weeks (Cantu et al, 1 longer (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-release ora

2.2 Drug Concentration Levels
A) Venlafaxine Hydrochloride
1) Peak Concentration
a) Venlafaxine hydrochloride, oral, regular-release tablets: 53 ng/mL (25-mg dose); 167 to 225 ng/mL (75-mg
1) Mean Cmax for venlafaxine regular-release when 75 milligrams was administered every 12 hours wa 2008)
2) Mean Cmax values following administration of 25, 75, or 150 mg of the regular-release dosage form c 167, and 393 nanograms/mL (0.19, 0.603, and 1.42 micromoles/L), respectively (Klamerus et al, 1992a). venlafaxine per day (Prod Info EFFEXOR(R) oral tablets, 2008; Schweizer et al, 1994).
b) Venlafaxine hydrochloride, oral, extended-release capsules: 150 ng/mL (Prod Info EFFEXOR XR(R) exte
1) The mean Cmax value of venlafaxine following administration of 150 milligrams extended-release cap between the regular- and extended-release formulations when equal daily doses were administered. The capsules. Venlafaxine exhibits linear pharmacokinetics over the dose range of 75 to 450 mg of venlafaxi
2) Time to Peak Concentration

a) Venlafaxine hydrochloride, oral, regular-release tablets: 1 to 2 hours (Prod Info EFFEXOR XR(R) extende
1) Mean Tmax for venlafaxine regular-release when 75 milligrams was administered every 12 hours was maximum concentration was not significantly different when venlafaxine was administered as a tablet or
b) Venlafaxine hydrochloride, oral, extended-release capsules: 5.5 hours (Prod Info EFFEXOR XR(R) exten
1) The mean Tmax value of venlafaxine following administration of 150 milligrams extended-release cap regular- and extended-release formulations when equal daily doses were administered. The fluctuation i Venlafaxine exhibits linear pharmacokinetics over the dose range of 75 to 450 mg of venlafaxine per day

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

Extracorporeal Elimination

2.3.1 Absorption

A) Venlafaxine Hydrochloride
1) Bioavailability
a) Oral, regular-release: 12.6% (Ellingrod & Perry, 1994d).
1) About 92% of an oral dose is absorbed. Due to extensive first pass metabolism, only 12.6% is av Perry, 1994d).
2) The relative bioavailability was 100% in tablet form when compared to an oral solution (Prod Info
3) Compared to healthy subjects, venlafaxine oral bioavailability increased 2- to 3-fold when admini Info EFFEXOR(R) oral tablets, 2008).
b) Oral, extended release: 45% (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008).
1) At least 92% of a single oral dose of venlafaxine is absorbed. The absolute bioavailability of venl capsules, 2008).
2) Compared to healthy subjects, venlafaxine oral bioavailability increased 2- to 3-fold when admini Info EFFEXOR XR(R) extended-release oral capsules, 2008).
2) Effects of Food
a) No effect on systemic bioavailability (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR
1) Food had no effect on the absorption or bioavailability of venlafaxine or its active metabolite, O-d EFFEXOR XR(R) extended-release oral capsules, 2008).

2.3.2 Distribution

A) Distribution Sites
1) Venlafaxine Hydrochloride
a) Protein Binding
1) 27% to 30% (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-re
a) Venlafaxine and O-desmethylvenlafaxine, the major active metabolite, are approximately 27 Info EFFEXOR XR(R) extended-release oral capsules, 2008; Klamerus et al, 1992).
B) Distribution Kinetics
1) Venlafaxine Hydrochloride
a) Volume of Distribution
1) 7.5 L/kg (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-releas
a) The steady state volume of distribution is 7.5 and 5.7 L/kg for venlafaxine and O-desmethyl XR(R) extended-release oral capsules, 2008).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics
1) Venlafaxine Hydrochloride
a) Liver, extensive (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-rel
1) Venlafaxine is metabolized via the CYP2D6 isoenzyme (Prod Info EFFEXOR XR(R) extended-re
2) Following absorption, venlafaxine undergoes extensive first-pass metabolism in the liver, primaril desmethylvenlafaxine, N,O-didesmethylvenlafaxine, and other minor metabolites. The formation of release oral capsules, 2008; Troy et al, 1997b; Klamerus et al, 1992).
B) Metabolites

1) Venlafaxine Hydrochloride
a) O-desmethylvenlafaxine, active (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(
1) O-desmethylvenlafaxine is the only major active metabolite of venlafaxine hydrochloride (Prod In capsules, 2008).
b) N-desmethylvenlafaxine, active (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008; K
1) This metabolite is less active than O-desmethylvenlafaxine (Prod Info EFFEXOR XR(R) extende

3.3.1 Cardiovascular Effects

3.3.1.A Venlafaxine Hydrochloride

Heart failure

Hypertension

Increased heart rate

Palpitations

Prolonged QT interval

Summary

Vasodilatation

3.3.1.A.1 Heart failure

a) Two cases of interstitial pneumonia with heart failure have been reported following the use of venlafa month) in combination with steroid treatment led to a complete recovery in a 21- year-old woman. Howev multiple-organ failure and died despite attempts at treatment (Drent et al, 2003).

3.3.1.A.2 Hypertension

a) Incidence: 3% to 13%(Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extende

b) Immediate-release

1) In a dose comparison study of venlafaxine, a mean increase in supine diastolic blood pressure (S venlafaxine daily. There were essentially no changes observed in patients receiving 75 and 225 mg (Prod Info EFFEXOR(R) oral tablets, 2008).

2) Sustained increases in blood pressure have been reported in patients receiving therapeutic dose sustained increased supine diastolic blood pressure of 3% for venlafaxine doses less than 100 mg/c mg/day, and 13% for doses greater than 300 mg/day. Most of the blood pressure increases were be consequences. There have also been cases of elevated blood pressure during postmarketing use th controlled before treatment with venlafaxine and that blood pressure is routinely monitored during tr patients who experience a sustained increase in blood pressure while receiving venlafaxine (Prod In capsules, 2008).

3) Meta-analysis of controlled clinical studies revealed a crude incidence of sustained elevation in s imipramine, and 2.1% for placebo; this information was obtained during controlled clinical trials. Duri (p=0.0503) (Thase, 1998).

c) Extended-release

1) In premarketing studies, sustained hypertension occurred with the following frequency in patients capsules, 2008):

Studies #	Dose Range	Percent of patients with sustained HTN
Major depressive disorder	75 to 375 mg/day	3% (19/705)
Generalized anxiety disorder	37.5 to 225 mg/day	0.5% (5/101)
Social anxiety disorder	75 to 225 mg/day	0.6% (5/771)
Panic disorder	75 to 225 mg/day	0.9% (9/973)

Key: # = patients were on extended-release venlafaxine; * sustained hypertension (HTN) = defi mmHg or greater above baseline for 3 consecutive on-therapy visits; mg/day = milligrams/day; respectively; ** = up to 12 weeks and up to 6 months, respectively

Studies #	Discontinuation Rate due to sustained HTN ##	Range of SDBP increase
Major depressive disorder	0.7% (5/705)	12 to 16 mmHg
Generalized anxiety disorder	0.7% (10/1381) *	12 to 25 mmHg *
	1.3% (7/535) **	8 to 28 mmHg **
Social anxiety disorder	0.6% (5/771) ***	1 to 24 mmHg ***
Panic disorder	0.5% (5/1001) ***	7 to 19 mmHg ***

Key: # = patients were on extended-release venlafaxine; ## sustained hypertension (HTN) = defined as treatment-emergent supine diastolic blood pressure 90 mmHg or greater and 10 mmHg or greater above baseline for 3 consecutive on-therapy visits; * = up to 8 weeks; ** = up to 6 months;
*** = up to 12 weeks

Across all clinical trials in major depressive disorder, generalized anxiety disorder, social anxiet experienced an increase in supine diastolic blood pressure of 15 mmHg or more compared to 0 release venlafaxine experienced an increase in supine diastolic blood pressure of 20 mmHg or extended-release oral capsules, 2008).

3.3.1.A.3 Increased heart rate

a) Immediate-release

1) During clinical trials, venlafaxine hydrochloride treatment (averaged over all dose groups) was as no change for placebo. In a study with venlafaxine doses ranging from 200 to 375 milligrams (mg)/d approximately 2 beats per minute compared with a mean decrease of approximately 1 beat per minu

2) When electrocardiograms from 769 patients treated with venlafaxine and 450 patients with place baseline was 4 beats per minute in the venlafaxine group. In a flexible-dose study, the mean heart r

from 200 to 375 mg/day (mean dose greater than 300 mg/day) compared with 1.7 beats per minute heart rate include hyperthyroidism, heart failure, or recent myocardial infarction, particularly with dos

b) Extended-release

1) Treatment with extended-release venlafaxine was associated with a mean increase in pulse rate disorder, and panic disorder clinical trials (Prod Info EFFEXOR XR(R) extended-release oral capsul

Trial	Duration	Mean Change In Pulse Venlafaxine Extended-Release	Mean Char Plac
Major Depressive Disorder	up to 12 weeks	+ 2 beats/minute	+ 1 bea
Generalized Anxiety Disorder	up to 8 weeks	+ 2 beats/minute	+ less than 1
Social Anxiety Disorder	up to 12 weeks	+ 3 beats/minute	+ 1 bea
Panic Disorder	up to 12 weeks	+ 1 beat/minute	decrease of less t

2) When electrocardiograms were analyzed, extended-release venlafaxine was associated with an oral capsules, 2008). Results are summarized below:

Trial	Number of Patients With Analyzed Electrocardiograms (venlafaxine extended-release/placebo)	Mean Change In Hear Venlafaxine Exte
Major Depressive Disorder	495 (275/220)	+ 4 beats
Generalized Anxiety Disorder	908 (610/298)	+ 3 beats
Social Anxiety Disorder	1127 (593/534)	+ 5 beats
Panic Disorder	1056 (661/395)	+ 3 beat

3.3.1.A.4 Palpitations

a) Incidence: 3% (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008)

b) Palpitations have been reported in 3% of venlafaxine extended-release treated patients (n=819) com trials involving patients with social anxiety disorder (Prod Info EFFEXOR XR(R) extended-release oral ca

c) Palpitations were reported in 3 of 66 patients receiving venlafaxine 75 to 375 milligrams/day in one st

3.3.1.A.5 Prolonged QT interval

a) The corrected QT interval increased from baseline for venlafaxine extended-release treated patients recent history of myocardial infarction or unstable heart disease. The duration of the studies range from interval in venlafaxine extended-release relative to placebo treated patients (Prod Info EFFEXOR XR(R)

Studies	Mean change from baseline in QTc interval	
	Venlafaxine ER	Placebo
Major depressive disorder (n=495)	+ 4.7 msec	- 1.9 msec
Generalized anxiety disorder (n=908)	no difference from placebo	---
Social anxiety disorder (n=1127)	+ 3.4 msec	- 1.6 msec
Panic disorder (n=1056)	+ 1.5 msec	- 0.7 msec
Key: ER = extended-release; msec = millisecond		

b) A 60-year-old woman receiving 150 mg of venlafaxine daily for depression developed QT interval pro mmHg in both arms and mild dyspnea. An ECG showed sinus rhythm and a corrected QT (QTc) interval venlafaxine administration was stopped, and she was hospitalized for further evaluation. Her CBC, electr was not on any other medications besides venlafaxine and she denied consumption of grapefruit juice or death. A 24-hour ECG recorded multifocal premature ventricular complexes and couplets and a transtho the next several days, the QTc interval gradually decreased before stabilizing at 430 milliseconds (Letsa

3.3.1.A.6 Summary

a) Hypertension, palpitations, and vasodilation, primarily hot flashes have been experienced in patients EFFEXOR XR(R) extended-release oral capsules, 2008). The corrected QT interval increased from base placebo-treated patients. The mean heart rate increase was 8.5 beats per minute in patients receiving ve compared with 1.7 beats per minute for placebo (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EF prolongation has been reported in a 60-year-old woman receiving venlafaxine for depression (Letsas et a following the use of venlafaxine (Drent et al, 2003).

3.3.1.A.7 Vasodilatation

a) Incidence: 2% to 5.6% (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR(R) XR oral ex

b) During a dose comparison trial involving 358 patients, the incidence of vasodilatation was 0% for plac 375 milligrams/day, respectively (Prod Info EFFEXOR(R) oral tablets, 2008).

c) Vasodilation, primarily hot flashes, occurred in 3% to 4% of patients on extended-release venlafaxine extended-release oral capsules, 2008).

3.3.2 Dermatologic Effects

3.3.2.A Venlafaxine Hydrochloride

Acquired keratoderma palmaris et plantaris

Alopecia

Subungual hyperkeratosis

Sweating symptom

3.3.2.A.1 Acquired keratoderma palmaris et plantaris

a) A 57-year-old male smoker acquired palmoplantar keratoderma (psoriasiform) and subungual hyperk soles showed evidence of severe hyperkeratosis with an inflammatory red border. The epidermis had ps infiltrate on histopathological specimens. Massive subungual hyperkeratosis with paronychia was noted was noted after topical treatment with 10% urea, salicylic acid, caryolysin and oral retinoids. Within 4 to 5 improvement of the nails occurred (Dalle et al, 2006).

3.3.2.A.2 Alopecia

a) A 50-year-old woman experienced hair loss while being treated for depression with venlafaxine. The of 75 milligrams (mg) per day was raised to 150 mg/day after two weeks. Two weeks later she began to venlafaxine after three months, and her hair loss stopped completely one month later. In another episode days after achieving the dose of 150 mg/day. She discontinued venlafaxine and attained complete remis

3.3.2.A.3 Subungual hyperkeratosis

a) A 57-year-old male smoker acquired palmoplantar keratoderma (psoriasiform) and subungual hyperk soles showed evidence of severe hyperkeratosis with an inflammatory red border. The epidermis had ps infiltrate on histopathological specimens. Massive subungual hyperkeratosis with paronychia was noted was noted after topical treatment with 10% urea, salicylic acid, caryolysin and oral retinoids. Within 4 to 5 improvement of the nails occurred (Dalle et al, 2006).

3.3.2.A.4 Sweating symptom

a) Incidence: 6.7% to 25% (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) exter
b) During 4- to 8-week placebo-controlled trials of venlafaxine hydrochloride (dose ranging from 75 to 37 was 12% compared to 3% in patients receiving placebo (n=609) (Prod Info EFFEXOR(R) oral tablets, 20
c) During a dose comparison trial involving 358 patients, the incidence of sweating was 5.4% for placeb 375 milligrams/day, respectively (Prod Info EFFEXOR(R) oral tablets, 2008).
d) During clinical trials, sweating occurred in 10% to 14% of patients on extended-release venlafaxine c release capsules, 2006).

The table below provides the incidence rates of anorexia during clinical trials of extended-release ve

Studies	Incidence of Sweating	
	Venlafaxine ER	Placebo
Major depressive disorder (n=642)	14%	3%
Generalized anxiety disorder (n=1936)	10%	3%
Social anxiety disorder (n=1514)	13%	4%
Panic disorder (n=1663)	10%	2%
Key: ER = extended-release		

e) At 9 and 14 weeks, diaphoresis and pruritus occurred in 2 elderly women who were receiving venlafa (mg)/day and noted profuse night sweats, increased daytime sweating, and generalized itching without r without addition of allergy medications. The second patient noted profuse, generalized sweating and itch venlafaxine XR was effective in resolving her symptoms. The medication history, physical examination, a symptoms (Schwartz, 1999).
f) Profuse sweating has been reported in two patients following oral venlafaxine therapy for the treatmer (Adesanya & Varma, 1997; Garber & Gregory, 1997). The patient was restarted on venlafaxine therapy, diaphoresis did not recur, and the venlafaxine was increased to 75 mg three times daily with no subsequ
g) A study reported a 25% incidence of increased sweating in patients receiving venlafaxine 75 to 375 n (Schweizer et al, 1991).

3.3.3 Endocrine/Metabolic Effects

3.3.3.A Venlafaxine Hydrochloride

Height / growth finding

Hot sweats

Hyponatremia

Serum cholesterol raised

Serum triglycerides raised

Syndrome of inappropriate antidiuretic hormone secretion

Weight loss

3.3.3.A.1 Height / growth finding

a) Pediatric patients, especially patients younger than 12 years of age, on venlafaxine grew less than pe extended-release (n=122), on average, grew 0.3 centimeters (cm) compared with 1 cm for placebo treat disorder study. Pediatric patients on venlafaxine extended-release (n=146), on average, grew 0.8 centim major depressive disorder study. Height increases were less than expected based on data from age-and extended-release capsules, 2006).

3.3.3.A.2 Hot sweats

a) A 52-year-old menopausal woman experienced hot flashes while being treated for depression with ve total hysterectomy and bilateral salpingo-oophorectomy. Although she experienced hot flashes immediat After two weeks of therapy with extended- release venlafaxine 75 mg per day, the woman reported trans flashes were occurring daily and were rated moderate to severe. After seven weeks, the severity and fre was then increased to 150 mg/day to increase the antidepressant response. The woman had five days o Venlafaxine has been used to treat hot flashes (Grady-Weliky & Hartmann, 2001).

3.3.3.A.3 Hyponatremia

a) Summary

1) Hyponatremia has been reported with the use of selective serotonin reuptake inhibitors (SSRIs) a the syndrome of inappropriate antidiuretic hormone secretion (SIADH). Serum sodium levels lower t hyponatremia with SSRIs and SNRIs include the elderly and patients receiving diuretics or who are memory impairment, confusion, weakness, and unsteadiness which may or may not lead to falls. Sig respiratory arrest, and death. Discontinuation of venlafaxine therapy should be considered and appr (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-release oral capsu

b) LITERATURE REPORTS

1) Hyponatremia was reported in 15 patients following therapeutic use of venlafaxine. The average sodium concentrations ranged from 116 to 130 milliequivalents/liter (mEq/L) (normal 135 to 145 mE

2) A 70-year-old woman developed hyponatremia (125 millimoles per liter (mmol/L)) while taking ve She had previously developed SIADH while taking mirtazapine (Blass & Pearson, 2000).

3) A 76-year-old female developed hyponatremia (serum sodium level of 118 milliequivalents/liter) f and the patient's serum sodium level returned to baseline three days later following fluid restriction,

3.3.3.A.4 Serum cholesterol raised

a) Incidence: 5.3% (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-rel

b) Clinically relevant increases in serum cholesterol occur in 5.3% of venlafaxine immediate-release trea Clinically relevant was defined as a final or an average on-therapy increase in serum cholesterol of 50 m greater. Significant increases in mean serum cholesterol have been reported in patients receiving venlaf capsules (1 to 11.4 mg/dL) during multiple clinical trials. Periodic monitoring is recommended during long extended-release oral capsules, 2008; Anon, 1993).

c) Treatment with extended-release venlafaxine was associated with increases in serum cholesterol cor extended-release oral capsules, 2008). Results are summarized below:

Trial	Duration	Mean Change in Serum Cholesterol Venlafaxine Extended-Release	Mean Change
Major Depressive Disorder	up to 12 weeks	+ 1.5 mg/dL	-
Generalized Anxiety Disorder	up to 8 weeks up to 6 months	+1.0 mg/dL + 2.3 mg/dL	- -
Social Anxiety Disorder	up to 12 weeks up to 6 months	+ 7.9 mg/dL + 5.6 mg/dL	- -

Panic Disorder	up to 12 weeks	+ 5.8 mg/dL	- 3
mg/dL = milligrams/deciliter			

3.3.3.A.5 Serum triglycerides raised

a) Treatment with extended-release venlafaxine was associated with increases in fasting serum triglyce
(R) extended-release oral capsules, 2008). Results are summarized below:

Trials	Duration	Mean Change in Serum Triglycerides Venlafaxine Extended-Release	Mean Change in S Place
Social Anxiety Disorder	up to 12 weeks up to 6 months	+ 8.2 mg/dL + 11.8 mg/dL	+ 0.4 n + 1.8 n
Panic Disorder	up to 12 weeks up to 6 months	+ 5.9 mg/dL + 9.3 mg/dL	+ 0.9 n - 0.3 n
mg/dL = milligrams/deciliter			

3.3.3.A.6 Syndrome of inappropriate antidiuretic hormone secretion

a) Summary

1) Syndrome of inappropriate secretion of antidiuretic hormone has occurred in patients on venlafax
Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-release oral capsules, 2

b) LITERATURE REPORTS

1) About 8 months after starting venlafaxine, a 92-year-old woman developed the syndrome of inap
the serum sodium gradually fell from 133 to 124 milliequivalents/liter; the antidiuretic hormone conce
milliosmole/kilogram (mOsm/kg) was high compared to a low serum osmolality of 255 mOsm/kg. Ve
month. Due to the temporal relationship and similar reports to other selective serotonin reuptake inh

2) A 65-year-old man developed the syndrome of inappropriate antidiuretic hormone (SIADH) possi
he complained of dizziness; abnormal laboratory values included a serum sodium of 114 millimole/li
239 millimole/24 hours, and urine osmolality of 640 mOsm/L. Venlafaxine was stopped, and the pati
restriction was stopped, the serum sodium concentration and osmolality remained normal. Medical c
is recommended that patients treated with a selective serotonin reuptake inhibitor who develop sym
have a serum sodium measured (Meynaar et al, 1997).

3.3.3.A.7 Weight loss

b) Adult and pediatric patients being treated with antidepressants for major depressive disorder who exp aggressiveness, impulsivity, akathisia (psychomotor restlessness), hypomania, mania, or other unusual l antidepressant treatment and when the dose is adjusted. Symptoms such as these indicate the need for to treating patients with other psychiatric and nonpsychiatric disorders. If these symptoms are observed, symptoms are severe, sudden in onset, or were not part of the patient's initial symptoms. Patients and th (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-release oral capsules,

3.3.12.A.3 Feeling nervous

a) Incidence: 4% to 21.3% (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) exter

b) During 4- to 8-week placebo-controlled trials of venlafaxine hydrochloride (dose ranging from 75 to 37 (n=1033) was 13% compared to 6% in patients receiving placebo (n=609). Nervousness led to drug disc depression studies (Prod Info EFFEXOR(R) oral tablets, 2008).

c) During a dose comparison trial involving 358 patients, the incidence of anxiety was 4.3% for placebo 375 milligrams/day, respectively (Prod Info EFFEXOR(R) oral tablets, 2008).

d) The table below provides the incidence rates of nervousness during clinical trials of extended-release

Studies	Percent of patients with nervousness	
	Venlafaxine ER	Placebo
Major depressive disorder (n=642)	10%	5%
Generalized anxiety disorder (n=1936)	6%	4%
Social anxiety disorder (n=1514)	10%	5%
Panic Disorder (n=1663)	4%	6%
Key: ER = extended-release		

The discontinuation rates due to nervousness were 0.1% to 3% of patients on extended-release ver 2008).

3.3.12.A.4 Hallucinations

a) In a case report, a 17-year-old male exhibited visual and tactile hallucinations following a dose increa headaches. The patient had a family history of anxiety (maternal) and a personal history of DSM-IV mod disorder. He also had a history of drug reactions which included delirium following anesthesia, and visua psychiatric systems were normal. Upon presentation, he had a 6- to 7-month escalation of depression ar anxiety. Concomitant drugs included lamotrigine, eletriptan (once a week), hydrocodone/acetaminophen treatment with venlafaxine immediate release 37.5 mg once daily, the patient's symptoms persisted and dose he experienced visual and tactile hallucinations of crawling bugs and became disoriented 1 hour la delirium. Venlafaxine treatment was suspended until the next morning. On the second day, the patient w morning dose, the patient again experienced visual and tactile hallucinations and within 30 to 60 minutes to the emergency department the patient's symptoms resolved overnight 16 to 20 hours following his las and his anxiety has begun to improve with cognitive-behavioral therapy (Jacob & Ash, 2009).

3.3.12.A.5 Hypomania

a) During Phase 2 and Phase 3 trials with immediate-release venlafaxine, mania or hypomania occurred hypomania occurred in 0.3% of patients receiving venlafaxine extended-release compared with 0% of pla anxiety disorder studies was 0% and 0.2% for venlafaxine extended-release and placebo, respectively, v respectively. During panic disorder trials, the incidence of mania or hypomania was 0.1% and 0% in patie be used cautiously in patients with a history of mania (Prod Info EFFEXOR(R) oral tablets, 2008; Prod In

b) Two women with bipolar affective disorder developed hypomania after starting venlafaxine (Wilson & antidepressants during a two year period of depression. Venlafaxine 75 mg titrated to 225 mg daily resul of venlafaxine. After beginning venlafaxine 75 mg titrated to 150 mg, the second patient became hypoma 5 cases of mania associated with venlafaxine were reported to the United Kingdom's Committee on Safe venlafaxine in patients with bipolar disorder (Wilson & Jenkins, 1997).

3.3.12.A.6 Mania

a) During Phase 2 and Phase 3 trials with immediate-release venlafaxine, mania or hypomania occurred hypomania occurred in 0.3% of patients receiving venlafaxine extended-release compared with 0% of pla anxiety disorder studies was 0% and 0.2% for venlafaxine extended-release and placebo, respectively, v respectively. During panic disorder trials, the incidence of mania or hypomania was 0.1% and 0% in patie be used cautiously in patients with a history of mania (Prod Info EFFEXOR(R) oral tablets, 2008; Prod In

b) A 17-year-old female diagnosed with severe major depressive disorder per DSM-IV criteria experienc She started venlafaxine 37.5 mg/day, which was then gradually increased to 150 mg/day over a 2-week elated moods, increased energy levels, increased speech output, decreased need for sleep, increased g behavior which warranted hospital admission; and she met DSM-IV criteria for mania. Venlafaxine was d and valproate 750 mg/day (subsequently increased to 1500 mg/day) were initiated. The patient reached weeks and the patient remained euthymic during the last 6 month of valproate treatment. Since the patie venlafaxine treatment, the authors suspected venlafaxine-induced mania (Raman et al, 2007).

c) Three patients with no history of mania or hypomania developed mania when they were treated for de months (Shulman et al, 2001)

d) A 63-year-old man with bipolar disorder developed mania six days after venlafaxine was increased to daily and nefazodone but depressive symptoms had not improved after eight months of treatment with n Behavioral symptoms included verbal agitation, hyperactivity, grandiose ideas, thoughts of persecution, i fluphenazine 10 mg at bedtime and an increase in the divalproex sodium dose. Two weeks after stoppin weeks. This patient had been hospitalized several times for manic behavior, and this episode may have temporal relationship to initiation and discontinuation of venlafaxine suggests that venlafaxine may have

3.3.12.A.7 Paranoid delusion

a) Paranoid delusion developed in an 85-year-old Caucasian man following administration of venlafaxin dose from 75 milligrams (mg) daily to 150 mg daily for increasing depression, he began having paranoid the dose to 75 mg/day. Venlafaxine was withdrawn and symptoms resolved within 48 hours. Treatment v symptoms resolved again with the withdrawal of the drug. Sertraline therapy was initiated and no further

3.3.12.A.8 Suicidal thoughts

a) Incidence: rare (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-rele
b) Adult and pediatric patients being treated with antidepressants for major depressive disorder who exp aggressiveness, impulsivity, akathisia (psychomotor restlessness), hypomania, mania, or other unusual during early antidepressant treatment and when the dose is adjusted. Symptoms such as these indicate concern applies to treating patients with other psychiatric and nonpsychiatric disorders. If these symptom medications when symptoms are severe, sudden in onset, or were not part of the patient's initial symptor available for this drug (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-
c) A causal role for antidepressants in inducing suicidality has been established in pediatric patients. An with the clinical need. In pooled analyses of 24 short-term, placebo-controlled trials of nine antidepressar nefazodone, and venlafaxine extended-release) including over 4400 pediatric patients with major depres greater risk of suicidal behavior or ideation during the first few months of therapy was demonstrated in pa risk of suicidality was most consistently observed in the trials that included patients with major depressiv such as obsessive compulsive disorder and social anxiety disorder. No suicides occurred in these trials. patients is not known. It is also unknown whether this risk extends to adult patients (Anon, 2004). :
d) Pooled analyses of short-term placebo-controlled trials of antidepressants indicated that treatment wi adolescents and young adults with major depressive disorder and other psychiatric disorders. The poole (citalopram, fluoxetine, fluvoxamine, paroxetine, sertraline, bupropion, mirtazapine, nefazodone, and ver disorder (MDD), obsessive compulsive disorder, or other psychiatric disorders, as well as 295 trials (with MDD or other psychiatric disorders. There was a tendency toward an increase in the risk of suicidality in was highest in patients with MDD. The risk differences between drug versus placebo are provided below oral capsules, 2008):

Age Range	Drug-Placebo Difference in Number of Cases of Suicidality per 100 Patients Treated
Less than 18 years	14 Additional Cases
18 to 24 years	5 Additional Cases
25 to 64 years	1 Fewer Case
65 years and older	6 Fewer Cases

3.3.12.A.9 Summary

a) Anxiety, mania/hypomania, nervousness, and suicidal ideation/worsening of depression (rare) have b discontinuation of venlafaxine during clinical trials. Adult and pediatric patients being treated with antidep panic attacks, insomnia, irritability, hostility, aggressiveness, impulsivity, akathisia (psychomotor restless of their depression and/or suicidality, especially during early antidepressant treatment and when the dos possible changes in the medication (Prod Info EFFEXOR(R) oral tablets, 2008). Two women with bipolar 1997).

Neuroleptic malignant syndrome

Serotonin syndrome

Withdrawal sign or symptom

3.3.16.B.1 Neuroleptic malignant syndrome

a) Neuroleptic malignant syndrome developed 12 hours after adding venlafaxine 75 mg daily to trifluope effects. The patient presented with profound anxiety, malaise, rigidity, tremor, and severe diaphoresis. O pulse was 163 beats per minute, temperature 38.3 degrees C, and respiratory rate 25 breaths/minute. Al concentration (11,320 international units/L)) and white blood cell count 23.5 x 10(9)/L. Treatment consist hours. Vital signs were normal 24 hours after admission, and trifluoperazine was restarted without proble

3.3.16.B.2 Serotonin syndrome

a) Serotonin syndrome, including life-threatening cases, or neuroleptic malignant syndrome (NMS)-like r serotonin syndrome include mental status changes (eg, agitation, hallucination, coma), autonomic instab hyperreflexia, incoordination) and/or gastrointestinal symptoms (eg, nausea, vomiting, diarrhea). Severe rigidity, autonomic instability with possible rapid fluctuation of vital signs, and mental status changes. Se including triptans, with drugs that impair metabolism of serotonin, including MAOIs, or with antipsychotics 2009; Prod Info Effexor(R) oral tablets, 2009).

b) Despite compliance with the recommended two week washout period, three patients were diagnosed after stopping treatment with phenelzine, a 25-year-old woman started venlafaxine 37.5 mg/day. Followi legs, shakiness, sweating, tachycardia, tachypnea, fever, and increased blood pressure. The woman wa hours later with no residual problems. A 49-year-old woman also started venlafaxine 14 days after disco The woman's symptoms subsided 3 hours later without treatment. Fourteen days after terminating phene tightness, anxiety, and emesis. Symptoms subsided without medical treatment. Finally, a 29-year-old fer

after ingestion of venlafaxine, the woman experienced shakiness, stomach pain, facial flushing, crying, d successfully treated with cyproheptadine and lorazepam and had no residual problems. A longer waiting (Diamond et al, 1998b).

c) A 44-year-old woman experienced serotonin syndrome after accidentally ingesting two 15 mg phenel anxious 30 minutes after ingesting the medications. Forty-five minutes later she experienced lower extre arrival had an elevated blood pressure, heart rate, respiratory rate, and temperature. The patient also ex was given 50 grams of charcoal with sorbitol, hydration therapy, benzodiazepines for muscle rigidity, anc woman showed improvements and an additional six days later was discharged from the hospital with no

d) A 60-year-old female presented to the emergency department obtunded, tachycardic, hyperthermic, h dose of venlafaxine while on maintenance tranylcypromine therapy. The patient recovered following supp

3.3.16.B.3 Withdrawal sign or symptom

a) Withdrawal symptoms such as agitation, anorexia, anxiety, confusion, impaired coordination and bala hypomania, insomnia, nausea, nervousness, nightmares, sensory disturbances (including shock-like ele with abrupt discontinuation or dose reduction of venlafaxine at various doses. The frequency of these eff EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008).

b) A 45-year-old man and a 36-year-old woman reported electric shock-like sensations of the head shor experienced severe sensations of shock in his head and radiating to his back and arms on two occasions daily to 75 mg at bedtime and 150 mg at bedtime, respectively. The female patient was taking venlafaxin when trying to stop the medication on several occasions. Her dose was tapered to 37.5 mg three times a objects in her field of vision) when the medicine was withdrawn. For both patients, the sensations resolve

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info Effexor XR(R) extended-rele

a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other) available. Drugs should be given only if the potential benefit justifies the potential risk to the fetus.

2) Australian Drug Evaluation Committee's (ADEC) Category: B2(Australian Drug Evaluation Committee, 1999)

a) Drugs which have been taken by only a limited number of pregnant women and women of childbearing ag effects on the human fetus having been observed. Studies in animals are inadequate or may be lacking, but a

See Drug Consult reference: PREGNANCY RISK CATEGORIES

3) Crosses Placenta: Unknown

4) Clinical Management

a) Due to the lack of adequate, well-controlled studies in pregnant women, it is recommended that venlafaxir release oral capsules, 2009; Prod Info Effexor(R) oral tablets, 2009; Ferreira et al, 2007). Because adverse s the third trimester, the potential risks and benefits of venlafaxine therapy during this time should be taken into trimester (Prod Info Effexor XR(R) extended-release oral capsules, 2009; Prod Info Effexor(R) oral tablets, 20

5) Literature Reports

a) Neonates exposed to venlafaxine or other serotonin and norepinephrine reuptake inhibitors (SNRIs) or SS hospitalizations, respiratory support and tube feeding. These complications can occur immediately upon deliv difficulty, vomiting, hypoglycemia, hypotonia, hyperreflexia, tremor, jitteriness, irritability, and constant crying or a drug discontinuation syndrome. In some cases, clinical findings have been consistent with serotonin syn (R) oral tablets, 2009).

b) A multicenter, prospective, controlled study comparing the results of pregnant women who called into the trimester and who were being treated with venlafaxine (n=150), an SSRI (n=150), or a nonteratogenic drug (r patients taking venlafaxine. Of the 150 patients in the venlafaxine group, all were treated with venlafaxine in t pregnancy. Of the patients treated with venlafaxine, 105 patients took 75 mg/day of the immediate-release fo (hypospadias and neural tube defect with club foot) reported in the venlafaxine group (1.6%), compared with not a significant difference in pregnancy outcomes among the three groups. An increase in spontaneous abo and the nonteratogenic drugs group (7.3%), but it did not reach statistical significance (Einarson et al, 2001).

c) Seventy-nine neonates of mothers treated with SSRIs or venlafaxine (n=76) during the third trimester exhi mothers (n=90). Treatment included paroxetine 5 to 40 mg (n=46), fluoxetine 10 to 40 mg (n=10), venlafaxine fluvoxamine 50 to 150 mg (n=2) with a mean duration of 32 months for SSRI use. In the treated group, 1 pati gestational age was reported in exposed infants (38.3 weeks) compared with 39.7 weeks; p less than 0.001). spasms, hypotonia, irritability, sleep disturbances, apnea/bradycardia and tachypnea. Respiratory effects, inc neonates. Exposed neonates also had a longer median length of hospitalization compared with unexposed in were hospitalized nearly 4 times longer than unexposed infants (14.5 days vs 3.7 days; p less than 0.001). Et potential risks and benefits in continuing SSRI or venlafaxine treatment during pregnancy on an individual ba

d) A study of prospectively collected data suggests antenatal use of SSRI antidepressants is associated with 2005, researchers compared 52 neonates exposed to SSRI antidepressants (paroxetine (n=25), citalopram (antenatal period to 52 matched neonates with no exposure. Prolonged QTc is defined as an interval of greate pediatric cardiology and neonatology). A pediatric cardiologist, blinded to drug exposure, interpreted all electr markedly prolonged mean QTc intervals in exposed neonates compared to unexposed neonates (mean; 409 longer among exposed neonates (mean; 280 +/- 31 msec vs 261 +/- 25 msec, p less than 0.001). Ten percer than 460 msec) compared to none of the unexposed neonates. The longest QTc interval observed was 543 r

e) Two cases of seizures were reported in neonates born to mothers using venlafaxine during pregnancy. Se found in either case. Both children had subsequently normal growth and development at one year follow-up (

f) A case report described development of necrotizing enterocolitis in dichorial, diamniotic, twin infants on the

throughout pregnancy until delivery. The mother, who experienced uneventful first and second trimesters, wa
was diagnosed for which she received azithromycin for 4 days. She received betamethasone 12 g twice in 24
section at 33+2 weeks. Twin A and B weighed 1700 g and 1980 g, respectively, with Apgar scores of 6, 7, an
intubated on day 1 of life. Twin A was successfully extubated on day 2. On day 6, signs of necrotizing enteroc
observed in the infants. Subsequently, oral feeding was withheld and IV amikacin and amoxicillin were given
continued to deteriorate and underwent surgery on day 10. Bowel necrosis was observed. Therefore, termina
was performed. He underwent a second surgery for stomal stenosis on day 22 of life. At 5 months of age, the

2009).

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk wh
potential risks before prescribing this drug during breastfeeding.

2) Clinical Management

a) Venlafaxine is excreted in human breast milk. Because of the potential for serious adverse effects in nursi
nursing, taking into consideration the importance of the drug to the mother (Prod Info Effexor XR(R) extended
administered to a nursing woman, the nursing infant should be monitored closely for adverse effects (Ilett et a

3) Literature Reports

a) A study of 78 breast-feeding mothers treated with antidepressants (3 took venlafaxine at a dose of 162.5 r
venlafaxine. The mean weights of all infants exposed to antidepressants in the study were 7.26 +/- 0.71 kg fo
normative growth data and remained similar in separate analyses of each antidepressant. However, infants o
months or more) despite antidepressant treatment weighed significantly less at 6 months (p=0.002) when cor
infants born to mothers who did not relapse to depression. The small venlafaxine sample size, maternal use
took psychotropics such as benzodiazepines or tricyclic antidepressants during the study), and absence of a

b) A study describing 3 lactating women treated with venlafaxine and their nursing infants found infant mean
concentrations for the sum of venlafaxine plus O-desmethylvenlafaxine (ODV). The maternal drug dose was
the mothers. The authors suggest that breast-feeding should generally not be discouraged in mothers treatec

c) Venlafaxine and its metabolite, O-desmethylvenlafaxine (ODV) were detected in six infant blood samples
venlafaxine dose of 255 mg/day in a study of 6 women taking venlafaxine and their 7 nursing infants (mean a
concentration of 5 mcg/L, while ODV was present in four infants in concentrations ranging from 3 to 38 mcg/r
2.74 (range 2.3 to 3.2), respectively. Although no adverse effects were noted in the infants, the authors recor
the potential risks and benefits of breast-feeding during venlafaxine therapy (Ilett et al, 2002).

d) Detectable levels of the metabolite O-desmethylvenlafaxine (ODV) were reported in three infants exposec
milk (milk-to-plasma concentration ratio of 4:1 and 3:1, respectively). Total infant exposure was 7.6% of the w
(Ilett et al, 1998).

3.5.1.H Amoxicillin

1) Interaction Effect: an increased risk of serotonin syndrome

2) Summary: A 56-year-old male on venlafaxine experienced serotonin syndrome within 3 hours of taking an amoxicillin/clavulanate and venlafaxine are used concomitantly, monitor closely for symptoms of serotonin sy supportive care and other therapy as necessary (Boyer & Shannon, 2005).

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: A case of serotonin syndrome was reported with coadministration of amoxicillin/clav amoxicillin/clavulanate and venlafaxine are used concomitantly, monitor closely for symptoms of serotonin sy rigidity, clonus, peripheral hypertonicity, and shivering), autonomic hyperactivity (including tachycardia, mydri changes (including agitation and delirium). Serotonin syndrome can be life-threatening. If serotonin syndrome therapy as necessary (Boyer & Shannon, 2005).

7) Probable Mechanism: unknown

8) Literature Reports

a) A 56-year-old male on venlafaxine experienced serotonin syndrome within 3 hours of taking amoxicill mg twice daily for 10 months for depression. He experienced tingling in the tip of his tongue, intense para uncontrollable shivering and tremor, agitation, and he was frightened but not confused 2 hours after takir symptoms resolved after 6 hours and then he slept a further 8 hours. No further amoxicillin/clavulanate d same symptoms after the first dose. The patient continued on venlafaxine without further episodes. His r without any events (Connor, 2003).

3.5.1.I Anagrelide

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case reports and (SSRIs) and serotonin-norephinephrine reuptake inhibitors (SNRIs), including venlafaxine, is associated with ecchymoses, hematomas, epistaxis, and petechiae; life-threatening hemorrhages have also occurred. Coadr the risk of bleeding (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008a).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Use caution when venlafaxine is used concomitantly with antiplatelet agents. Close patients receiving antiplatelet agents concomitantly (Prod Info EFFEXOR XR(R) extended-release oral capsu

7) Probable Mechanism: unknown

3.5.1.J Ancrod

1) Interaction Effect: an increased risk of bleeding

2) Summary: Case reports and epidemiological studies have shown that use of selective serotonin reuptake venlafaxine, is associated with gastrointestinal bleeding. Bleeding events with SSRIs and SNRIs included cas have also occurred. Coadministration with warfarin or other anticoagulants may potentiate the risk of bleeding phenprocoumon) with concomitant selective serotonin reuptake inhibitors (SSRIs) resulted in an increased ris Increases in prothrombin time, partial thromboplastin time, or INR have been reported when venlafaxine was with warfarin or other drugs affecting coagulation should be undertaken with caution. symptoms could have resulted from the fluoxetine or marijuana alone. Caution is advised for patients using m
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Caution patients taking selective serotonin reuptake inhibitors to avoid concomitant
7) Probable Mechanism: additive serotonergic stimulation
8) Literature Reports
a) A 21-year-old female presented with mania, agitation, and grandiose delusions following use of mariju
reported smoking 2 "joints" during a 36-hour period. Over the next 24 hours, she developed increased en
perphenazine were given for agitation and excitement which gradually resolved over 4 days. She remain
prior to discharge. One week after discharge, she discontinued fluoxetine due to insomnia and feeling "h
rapid switch to mania after smoking marijuana with fluoxetine, the manic symptoms were associated with
from either fluoxetine or marijuana alone (Stoll et al, 1991).

3.5.1.T Carprofen

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.U Celecoxib

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.V Cilostazol

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case reports anc (SSRIs) and serotonin-norephinephrine reuptake inhibitors (SNRIs), including venlafaxine, is associated with ecchymoses, hematomas, epistaxis, and petechiae; life-threatening hemorrhages have also occurred. Coadr the risk of bleeding (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008a).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Use caution when venlafaxine is used concomitantly with antiplatelet agents. Close patients receiving antiplatelet agents concomitantly (Prod Info EFFEXOR XR(R) extended-release oral capsu
7) Probable Mechanism: unknown

3.5.1.W Cimetidine

1) Interaction Effect: an increased risk of venlafaxine toxicity (nausea, drowsiness, dizziness, ejaculatory dis
2) Summary: Concurrent administration of cimetidine and venlafaxine (both at steady state) resulted in a 43 concentration of venlafaxine (Prod Info venlafaxine extended release oral tablets, 2008). The major metabolit amounts in the circulation than the parent drug. Because of this, it is unlikely that a clinically significant intera in patients with preexisting hepatic or renal dysfunction (Troy et al, 1998a). Therefore, caution is advised whe hepatic or renal function (Prod Info venlafaxine extended release oral tablets, 2008).
3) Severity: minor
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concomitant use of cimetidine and venlafaxine may result in decreased venlafaxine as nausea, drowsiness, and dizziness; a decrease in dosage may be required with concomitant therapy. An a such as ranitidine or famotidine, may be an alternative.
7) Probable Mechanism: decreased venlafaxine clearance
8) Literature Reports
a) Eighteen healthy volunteers received venlafaxine 50 mg three times daily for five days alone and in c pharmacokinetics of venlafaxine. Venlafaxine has pharmacologic activity, and the metabolite O-desmeth cimetidine was coadministered, the average steady-state concentration of venlafaxine increased from a desmethylvenlafaxine did not change in the presence of cimetidine (388 ng/mL vs. 387 ng/mL). Therefor increased by an average of 13%. This increase is not expected to produce clinically significant alteration (Troy et al, 1998).

3.5.1.X Clarithromycin

1) Interaction Effect: increased plasma concentrations of venlafaxine
2) Summary: Caution is advised if a CYP3A4 inhibitor is administered with venlafaxine, due to the possible i (Prod Info venlafaxine extended release oral tablets, 2008). Patients should be monitored for venlafaxine toxi
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Patients should be monitored for signs of venlafaxine toxicity such as nausea, drow

7) Probable Mechanism: decreased venlafaxine clearance
8) Literature Reports
a) Caution is warranted with the concurrent use of CYP3A4 inhibitors, such as clarithromycin, and venla desvenlafaxine (ODV) (Prod Info venlafaxine extended release oral tablets, 2008).

3.5.1.Y Clomipramine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Tricyclic antidepressants (TCAs) and venlafaxine have been shown to prolong the QTc interval 1982). Even though no formal drug interaction studies have been done, the coadministration of tricyclic antide recommended (Prod Info Elavil(R), 1999). In addition, venlafaxine and tricyclic antidepressants (TCAs) may c (Perry, 2000; Prod Info Effexor(R) XR, 2003; Ellingrod & Perry, 1994a). Venlafaxine increased the AUC, Cma increased by 2.5 and 4.5 fold when administered with venlafaxine 37.5 mg and 75 mg every 12 hours, respec affected (Prod Info venlafaxine extended release oral tablets, 2008).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive effects on the QT interval, the concurrent administra
7) Probable Mechanism: decreased TCA and venlafaxine metabolism; additive effects on QT prolongation
8) Literature Reports
a) When administered with imipramine, the pharmacokinetics of imipramine and the 2-hydroxy metaboli (AUC), maximum concentration (Cmax), and minimum concentration (Cmin) of desipramine by approxim 12 hours) and by 4.5-fold (venlafaxine 75 mg every 12 hours). The clinical significance of this finding is u

3.5.1.Z Clonixin
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrently 2008).
7) Probable Mechanism: unknown

3.5.1.AA Clopidogrel
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case reports and (SSRIs) and serotonin-norephinephrine reuptake inhibitors (SNRIs), including venlafaxine, is associated with ecchymoses, hematomas, epistaxis, and petechiae; life-threatening hemorrhages have also occurred. Coadr the risk of bleeding (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008a).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Use caution when venlafaxine is used concomitantly with antiplatelet agents. Close patients receiving antiplatelet agents concomitantly (Prod Info EFFEXOR XR(R) extended-release oral capsu
7) Probable Mechanism: unknown

3.5.1.AB Clozapine
1) Interaction Effect: increased serum concentrations of clozapine and venlafaxine
2) Summary: Coadministration of clozapine with other drugs that are metabolized by cytochrome P450 2D6, The hepatic P450IID6 isoenzyme is apparently involved with clozapine metabolism. Venlafaxine is a weak inl (Prod Info Effexor(R) XR, 1999c; Ellingrod & Perry, 1994b). With clozapine-venlafaxine coadministration, botl concentrations of both. Controlled studies are needed to validate these expectations and to document the cli
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Monitor patients receiving concurrent clozapine and venlafaxine for signs of clozapi venlafaxine toxicity (somnolence). Doses of either or both medications may need to be reduced.
7) Probable Mechanism: decreased clozapine and venlafaxine metabolism

3.5.1.AC Danaparoid
1) Interaction Effect: an increased risk of bleeding
2) Summary: Case reports and epidemiological studies have shown that use of selective serotonin reuptake venlafaxine, is associated with gastrointestinal bleeding. Bleeding events with SSRIs and SNRIs included cas have also occurred. Coadministration with warfarin or other anticoagulants may potentiate the risk of bleeding phenprocoumon) with concomitant selective serotonin reuptake inhibitors (SSRIs) resulted in an increased ris Increases in prothrombin time, partial thromboplastin time, or INR have been reported when venlafaxine was

with warfarin or other drugs affecting coagulation should be undertaken with caution. Whenever venlafaxine i
coagulation parameters is recommended (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008a
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Use caution when venlafaxine is used concomitantly with warfarin or other drugs af
or discontinued in patients receiving anticoagulants, such as warfarin (Prod Info EFFEXOR XR(R) extended-
7) Probable Mechanism: additive adverse events
8) Literature Reports
a) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum
increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit
abnormal bleeding and compared them with 5818 control subjects also taking coumarins. Median duratic
showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95
(adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).

3.5.1.AD Defibrotide

1) Interaction Effect: an increased risk of bleeding
2) Summary: Case reports and epidemiological studies have shown that use of selective serotonin reuptake
venlafaxine, is associated with gastrointestinal bleeding. Bleeding events with SSRIs and SNRIs included cas
have also occurred. Coadministration with warfarin or other anticoagulants may potentiate the risk of bleedin

(adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).

3.5.1.AH Desvenlafaxine
1) Interaction Effect: increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, mental s
2) Summary: Desvenlafaxine is the major active metabolite of venlafaxine, and these agents should not be u
norepinephrine reuptake inhibitors, and their concomitant use may result in serotonin syndrome, which may b
hallucinations, loss of coordination, fast heart beat, rapid changes in blood pressure, increased body tempera
extended-release tablets, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of of desvenlafaxine and venlafaxine should be avoided, as desve
and norepinephrine reuptake inhibitors, and concomitant use increases the risk of serotonin syndrome (Prod
7) Probable Mechanism: additive serotonergic effect

3.5.1.AI Dexfenfluramine
1) Interaction Effect: serotonin syndrome (hypertension, hyperthermia, myoclonus, mental status changes)
2) Summary: Dexfenfluramine is a nonspecific serotonin agonist that both enhances the release of serotonin
selective serotonin reuptake inhibitor, such as venlafaxine, has the potential to cause serotonin syndrome (S
characterized by symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, diaph
(Sternbach, 1991k). Dexfenfluramine should not be used in combination with venlafaxine (Prod Info Redux(R
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of dexfenfluramine and venlafaxine may result in an additive increa
syndrome (hypertension, hyperthermia, myoclonus, mental status changes). Dexfenfluramine should not be u
7) Probable Mechanism: additive serotonergic effects

3.5.1.AJ Dexketoprofen
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc
NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec
(R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl
2008).
7) Probable Mechanism: unknown

3.5.1.AK Dextroamphetamine

1) Interaction Effect: an increased risk of serotonin syndrome

2) Summary: Two weeks of concurrent use of dextroamphetamine and venlafaxine resulted in symptoms of s venlafaxine are used concomitantly, monitor closely for symptoms of serotonin syndrome. Serotonin syndrom agents and provide supportive care and other therapy as necessary (Boyer & Shannon, 2005).

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: A case of serotonin syndrome was reported with coadministration of dextroamphetа concomitantly, monitor closely for symptoms of serotonin syndrome such as neuromuscular abnormalities (in shivering), autonomic hyperactivity (including tachycardia, mydriasis, diaphoresis, the presence of bowel sou Serotonin syndrome can be life-threatening. If serotonin syndrome develops, discontinue the offending agent

7) Probable Mechanism: additive pharmacologic effects

8) Literature Reports

a) A 32-year-old male on dextroamphetamine experienced serotonin syndrome approximately 2 weeks attention deficit hyperactivity disorder. He started 75 mg a day of venlafaxine for 1 week then the dose w experienced marked agitation, anxiety, shivering, and tremor. On admission he was alert and oriented. H per minute, blood pressure was 142/93 mmHg, and temperature was 37.3 degrees Celsius. No nystagm generalized hypertonia, hyperreflexia, inducible ankle clonus, frequent myoclonic jerking, and unilateral-t sinus tachycardia with a baseline tremor. Dextroamphetamine and venlafaxine were discontinued and cy and he was discharged the following morning. Dextroamphetamine was restarted 3 days later. Four days symptoms as he did with dextroamphetamine and venlafaxine. Agitation, nausea, diarrhea, and teeth cle cyproheptadine were given and within 2 days he was asymptomatic (Prior et al, 2002).

3.5.1.AL Dibenzepin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest

2) Summary: Tricyclic antidepressants (TCAs) and venlafaxine have been shown to prolong the QTc interval 1982). Even though no formal drug interaction studies have been done, the coadministration of tricyclic antid recommended (Prod Info Elavil(R), 1999). 6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.BC Fenbufen
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.BD Fenfluramine

1) Interaction Effect: serotonin syndrome (hypertension, hyperthermia, myoclonus, mental status changes)
2) Summary: Fenfluramine is a nonspecific serotonin agonist that both enhances the release of serotonin an serotonin reuptake inhibitor, such as venlafaxine, has the potential to cause serotonin syndrome (Schenck & symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, diaphoresis, shivering, more data are available, fenfluramine should not be used in combination with venlafaxine.
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of fenfluramine and venlafaxine may result in an additive increase i (hypertension, hyperthermia, myoclonus, mental status changes). Fenfluramine should not be used in combi
7) Probable Mechanism: additive serotonergic effects

3.5.1.BE Fenoprofen
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.BF Fentiazac
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.BG Floctafenine
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.BH Flufenamic Acid
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.BI Fluoxetine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest mental status changes)
2) Summary: Venlafaxine and fluoxetine have been shown to prolong the QTc interval at the recommended though no formal drug interaction studies have been done, the coadministration of drugs known to prolong th fluoxetine may result in serotonin syndrome (Chan et al, 1998a).
3) Severity: major
4) Onset: rapid

5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of venlafaxine and fluoxetine is not recommended.
7) Probable Mechanism: additive effects on QT prolongation; additive serotonergic effect

3.5.1.BJ Flurbiprofen
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.BK Fondaparinux
1) Interaction Effect: an increased risk of bleeding
2) Summary: Case reports and epidemiological studies have shown that use of selective serotonin reuptake venlafaxine, is associated with gastrointestinal bleeding. Bleeding events with SSRIs and SNRIs included cas have also occurred. Coadministration with warfarin or other anticoagulants may potentiate the risk of bleedin phenprocoumon) with concomitant selective serotonin reuptake inhibitors (SSRIs) resulted in an increased ris Increases in prothrombin time, partial thromboplastin time, or INR have been reported when venlafaxine was with warfarin or other drugs affecting coagulation should be undertaken with caution. Whenever venlafaxine i coagulation parameters is recommended (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008a
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Use caution when venlafaxine is used concomitantly with warfarin or other drugs af or discontinued in patients receiving anticoagulants, such as warfarin (Prod Info EFFEXOR XR(R) extended-
7) Probable Mechanism: additive adverse events
8) Literature Reports
a) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit abnormal bleeding and compared them with 5818 control subjects also taking coumarins. Median duratic showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95 (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).

3.5.1.BL Frovatriptan
1) Interaction Effect: increased risk of serotonin syndrome
2) Summary: A life-threatening condition known as serotonin syndrome may occur when triptans, such as fro (SNRI), such as venlafaxine. Symptoms of serotonin syndrome may include restlessness, hallucinations, loss temperature, overreactive reflexes, nausea, vomiting, and diarrhea. Clinicians should be aware that triptans r prescribed by a different physician. Discuss the risks of serotonin syndrome with patients who are prescribed and Drug Administration, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of a triptan, such as frovatriptan, and an SNRI, such as venlafaxir triptans may be commonly used intermittently and that either the triptan or the SNRI may be prescribed by a syndrome with the patient and monitor closely for symptoms of serotonin syndrome (restlessness, hypertherr
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation

3.5.1.BM Furazolidone
1) Interaction Effect: weakness, hyperreflexia, and incoordination
2) Summary: Although not its primary mechanism of action, furazolidone has monoamine oxidase inhibitor a receiving selective serotonin reuptake inhibitors (SSRI) in combination with monoamine oxidase inhibitors (M fluctuations of vital signs, and mental status changes that include extreme agitation progressing to delirium a SSRI, or within a minimum of 14 days of discontinuing therapy with a MAOI (Prod Info Furoxone(R), 1999).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If concurrent therapy with furazolidone and a selective serotonin reuptake inhibitor excess (mental status changes, diaphoresis, fever, weakness, hyperreflexia, incoordination).
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation

3.5.1.BN Ginkgo
1) Interaction Effect: increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, mental s

2) Summary: The addition of Ginkgo biloba and/or St. John's Wort to therapy with buspirone and fluoxetine r
is unclear if Ginkgo or St. John's Wort, the combination of both, or other patient factors, contributed to the eff
selective serotonin reuptake inhibitors (SSRIs). Caution is advised, especially when ginkgo is taken to counte
(Sloley et al, 2000; White et al, 1996), and has demonstrated serotonergic activity in animals (Ramassamy et
with SSRIs. The potential MAO inhibitory activity of ginkgo is questionable. A human study did not show MAC
extract inhibited MAO-A/MAO-B in the rat brain in vitro (Sloley et al, 2000; White et al, 1996) and MAO-B in h
following oral consumption (Porsolt et al, 2000).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients closely for symptoms of serotonin syndrome if ginkgo is combined
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation
8) Literature Reports
a) A 42-year-old female experienced symptoms consistent with a mixed hypomanic episode following cc
symptoms resolved following discontinuation of Ginkgo and St. John's Wort. The patient was being treat
twice daily and buspirone 15 mg twice daily. Several weeks prior to presentation, buspirone was increas
melatonin, and St. John's Wort in unspecified doses. Melatonin was considered unlikely to have contribu
since they may potentiate antidepressants, and considering the temporal relationship between the use o
symptoms. However, the brain injury was considered a possible contributor (Spinella & Eaton, 2002).

3.5.1.BO Haloperidol
1) Interaction Effect: increased haloperidol serum concentrations and an increased risk of cardiotoxicity (QT
2) Summary: Venlafaxine may inhibit haloperidol metabolism (Prod Info Effexor(R) XR, 2003c). Haloperidol i
Prod Info Haldol(R), 2001). Venlafaxine has been shown to prolong the QTc interval at the recommended the
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: The concurrent administration of haloperidol and venlafaxine is not recommended.
7) Probable Mechanism: decreased haloperidol metabolism; theoretical additive effect on QT prolongation
8) Literature Reports
a) Under steady-state conditions, venlafaxine 150 mg daily decreased the total oral clearance of a singl
in the haloperidol area under the concentration-time curve (AUC). The haloperidol maximum concentrati
elimination half-life of haloperidol was not affected. The mechanism behind this interaction is not known
b) Numerous case reports have described significant QTc prolongation and torsades de pointes (TdP) a
ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater wit
increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated
haloperidol-induced TdP, screen patients for a history of dilated cardiomyopathy or alcohol abuse, testin
throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc
alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from base
2003).

3.5.1.BP Heparin
1) Interaction Effect: an increased risk of bleeding
2) Summary: Case reports and epidemiological studies have shown that use of selective serotonin reuptake
venlafaxine, is associated with gastrointestinal bleeding. Bleeding events with SSRIs and SNRIs included cas
have also occurred. Coadministration with warfarin or other anticoagulants may potentiate the risk of bleedin
phenprocoumon) with concomitant selective serotonin reuptake inhibitors (SSRIs) resulted in an increased ris
Increases in prothrombin time, partial thromboplastin time, or INR have been reported when venlafaxine was

3.5.1.BY Isoxicam

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).

7) Probable Mechanism: unknown

3.5.1.BZ Itraconazole

1) Interaction Effect: increased plasma concentrations of venlafaxine

2) Summary: Caution is advised if a CYP3A4 inhibitor, such as itraconazole, is administered with venlafaxine desvenlafaxine (ODV) (Prod Info venlafaxine extended release oral tablets, 2008). Patients should be monito

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Patients should be monitored for signs of venlafaxine toxicity such as nausea, drow

7) Probable Mechanism: decreased venlafaxine clearance

8) Literature Reports

a) Caution is warranted with the concurrent use of CYP3A4 inhibitors, such as itraconazole, and venlafa desvenlafaxine (ODV) (Prod Info venlafaxine extended release oral tablets, 2008).

3.5.1.CA Jujube

1) Interaction Effect: an increased risk of serotonin syndrome

2) Summary: Serotonin syndrome developed within one hour in a 40-year-old female, when venlafaxine was nut) (Stewart, 2004). If Ziziphus jujube and venlafaxine are used concomitantly, monitor closely for symptoms syndrome develops, discontinue the offending agents and provide supportive care and other therapy as nece

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: A case of serotonin syndrome was reported with coadministration of Ziziphus jujube therefore, concomitant use is discouraged (Stewart, 2004). If Ziziphus jujube and venlafaxine are used concc abnormalities (including hyper-reflexia, tremor, muscle rigidity, clonus, peripheral hypertonicity, and shivering bowel sounds, and diarrhea), and mental status changes (including agitation and delirium). Serotonin syndro agents and provide supportive care and other therapy as necessary (Boyer & Shannon, 2005).

7) Probable Mechanism: additive pharmacologic effects

8) Literature Reports

a) Serotonin syndrome developed in a 40-year-old female, when venlafaxine was added to Ziziphus juju jujube 500 mg/day for insomnia, fatigue, nervousness, and poor appetite. After several weeks of treatme venlafaxine she experienced restlessness, nausea, dizziness, and ataxia. She then collapsed. She was and shivering. Peripheral pulses were absent but she had a carotid pulse of 50 bpm. Vital signs were 60/ signs were 180/100 mmHg, 80 beats/minute, and 14 breaths/minute. Vital signs and mental status norm venlafaxine at 150 mg/day, but did not restart jujube, and 1 month later remained stable (Stewart, 2004).

3.5.1.CB Ketoconazole

1) Interaction Effect: an increased risk of venlafaxine toxicity (nausea, drowsiness, dizziness, ejaculatory dis

3.5.1.CL Metoclopramide
1) Interaction Effect: an increased risk of developing extrapyramidal symptoms
2) Summary: A risk of serotonin syndrome with serious extrapyramidal reactions may occur with concomitan
developed extrapyramidal symptoms after metoclopramide was added to a regimen of venlafaxine (Fisher &
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Clinicians should be alerted to the possibility that patients may have an increased ri
metoclopramide. Close patient monitoring is warranted.
7) Probable Mechanism: synergistic dopaminergic inhibition
8) Literature Reports
a) Metoclopramide interacts with venlafaxine resulting in serotonin syndrome with serious dystonic-dysk
hospital after falling. She had been treated with venlafaxine 150 mg am and 75 mg pm for 3 years. The p
and clenching of the teeth after receiving metoclopramide intravenously. She was unresponsive for less
later, the patient developed mycolonic jerks and muscle rigidity and she became diaphoretic, confused a
and dilated pupils. Her temperature rose to 37.9 degrees Celsius, heart rate was 115 beats/min, respirat
values were normal. There was improvement in symptoms after intravenous diazepam was administered
increased muscle rigidity with intermittent forceful extensions of her legs and jerking of her arms. Two or
resolution of symptoms occurred on hospital day 3. Venlafaxine was reinstated without problems. Accord
was considered a probable cause of serotonin syndrome (Fisher & David, 2002).

3.5.1.CM Metoprolol
1) Interaction Effect: increased metoprolol plasma concentrations, but decreased metoprolol efficacy in lowe
2) Summary: Concomitant use of metoprolol and venlafaxine extended-release tablets may reduce the effica
administration. Some patients treated with venlafaxine have experienced dose-related increases in blood pre
extended-release tablets concomitantly (Prod Info Effexor XR(R) extended-release oral capsules, 2009).
3) Severity: major
4) Onset: unspecified
5) Substantiation: established
6) Clinical Management: Concurrent administration of metoprolol and venlafaxine extended-release tablets c
should be controlled before treatment with venlafaxine. Regularly monitor blood pressure in patients receiving
capsules, 2009).
7) Probable Mechanism: unknown
8) Literature Reports
a) In an interaction study of 18 healthy males, concomitant administration of metoprolol (100 mg every 2

increase in metoprolol plasma concentrations by approximately 30 to 40% without altering the plasma cc pharmacokinetic profile of venlafaxine or its O-desmethylvenlafaxine metabolite. It appeared that venlafa finding for hypertensive patients is unknown (Prod Info Effexor XR(R) extended-release oral capsules, 2(

3.5.1.CN Mirtazapine

1) Interaction Effect: an increased risk of serotonin syndrome

2) Summary: Concurrent use of mirtazapine and venlafaxine resulted in symptoms of serotonin syndrome in limbs, diaphoresis, hyperreflexia, tachycardia (greater than 100 beats per minute), and increased blood press symptoms of serotonin syndrome. Serotonin syndrome can be life-threatening. If serotonin syndrome develop necessary (Boyer & Shannon, 2005).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: A case of serotonin syndrome was reported with concomitant use of mirtazapine ar mirtazapine and venlafaxine are used together, monitor closely for symptoms of serotonin syndrome such as peripheral hypertonicity, and shivering), autonomic hyperactivity (including tachycardia, mydriasis, diaphoresi agitation and delirium). Serotonin syndrome can be life-threatening. If serotonin syndrome develops, disconti (Boyer & Shannon, 2005).

7) Probable Mechanism: additive serotonergic pharmacologic effects

8) Literature Reports

a) A 31-year-old female on mirtazapine experienced serotonin syndrome after venlafaxine was added. S decided to slowly discontinue mirtazapine, with 30 mg/day, and start venlafaxine extended-release 75 m gross tremor of the upper limbs, diaphoresis, hyperreflexia, tachycardia (greater than 100 beats per minu tomography. Mirtazapine and venlafaxine were discontinued and she was administered oral lorazepam a resolved 24 hours later (Dimellis, 2002).

3.5.1.CO Moclobemide

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, hyperthermia, myoclonus, mental sta

2) Summary: Concurrent administration or overlapping therapy with venlafaxine and a monoamine oxidase (state characterized by symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, concomitant use of serotonin specific reuptake inhibitors and MAO inhibitors (Prod Info Effexor(R) XR, 2000b & de Vries, 1990i). Concomitant use is contraindicated.

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Concurrent use of venlafaxine and a MAO inhibitor is contraindicated. Wait at least at least seven days after discontinuing venlafaxine before initiating therapy with a MAO inhibitor.

7) Probable Mechanism: inhibition of serotonin metabolism by monoamine oxidase

8) Literature Reports

a) Concomitant use of selective serotonin reuptake inhibitors and monoamine oxidase inhibitors can pro syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness, myoclonus, cha not recognized and correctly treated, death can result.

b) Two cases suggestive of an interaction between fluoxetine and selegiline, a selective monoamine oxi involved a first episode of mania being observed approximately one month after adding selegiline to fluo no further details were provided. The second case involved diaphoresis, vasoconstriction, and cyanosis selegiline. Both drugs were discontinued, with relatively quick resolution of symptoms. Rechallenge with

c) Five fatal overdose cases due to serotonin syndrome have been reported (Neuvonen et al, 1993). In moclobemide, a selective monoamine oxidase inhibitor, and citalopram. Of the three patients, blood con therapeutic level, and citalopram concentrations ranged from normal therapeutic levels to five times the t

d) A 34-year-old man experienced serotonin syndrome after ingesting venlafaxine 2.625 g and moclobe beats/min), tachypnea (26 breaths/min), altered mental status, hypertonia, and had a creatine phosphoki may act like an irreversible MAOI with large doses, increasing the level of serotonin in the synaptic cleft

e) A 32-year-old man taking moclobemide 20 mg twice daily and diazepam 15 mg daily was given venla vomiting, diaphoresis, hallucination and agitation. He also demonstrated muscle rigidity and ocular oscill mg and chlorpromazine 12.5 mg and his condition improved significantly (Chan et al, 1998).

3.5.1.CP Morniflumate

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).

7) Probable Mechanism: unknown

3.5.1.CQ Nabumetone

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable

7) Probable Mechanism: additive adverse events
8) Literature Reports

a) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit abnormal bleeding and compared them with 5818 control subjects also taking coumarins. Median duratic showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95 (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).

3.5.1.DD Phenelzine

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, hyperthermia, myoclonus, mental st
2) Summary: Serious, sometimes fatal, reactions have been seen with the combination of venlafaxine and m Effexor(R) XR, 2000c). Reports of adverse effects have included hyperthermia, rigidity, myoclonus, instability MAOIs and venlafaxine has also been reported to result in a condition termed serotonin syndrome (Klysner e potentially fatal condition of serotonergic hyperstimulation characterized by changes in mental status, restless one case serotonin syndrome occurred with initiation of venlafaxine therapy 16 days after discontinuation of another report, two additional patients were started on venlafaxine at least 14 days after discontinuation of ph 1998a).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Concurrent use of venlafaxine and a MAO inhibitor is contraindicated. Wait at least at least seven days after discontinuing venlafaxine before initiating therapy with a MAO inhibitor. Even if initia for development of serotonin syndrome.
7) Probable Mechanism: inhibition of serotonin metabolism by monoamine oxidase
8) Literature Reports

a) Concomitant use of serotonin specific reuptake inhibitors and monoamine oxidase inhibitors can prod syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness, myoclonus, cha not recognized and correctly treated, death can result.

b) A 46-year old man with depression was taking a regimen of phenelzine 30 mg three times daily and c initiating therapy with venlafaxine. The exact tapering regimen was not available. One day after the patie 60 minutes, the patient was confused, twitching, and had a full body tremor. The patient was also having propranolol, diphenhydramine, and lorazepam in the emergency room, with subsequent improvement in the intensive care unit with resolution of symptoms over the next day without further complications (Heisl

c) A 39-year old woman developed symptoms similar to serotonin syndrome due to an interaction betwe phenelzine 45 mg daily seven days earlier, took a single 37.5 mg dose of venlafaxine. The patient then e creatinine kinase level. After treatment with lorazepam and other supportive therapy, the patient's sympt dose (Phillips & Ringo, 1995).

d) A case of serotonin syndrome was reported in a 34-year old man due to an interaction between venla discontinued 16 days before the initiation of therapy with venlafaxine. Shortly after the first venlafaxine d tachycardia, and muscular rigidity. The patient had a temperature of 98.1 degrees F, a pulse of 115, and rigidity, and myoclonus in both feet, the patient was diagnosed with serotonin syndrome. The patient's sy three times daily for two days upon discharge. This case may be of major importance since phenelzine h venlafaxine. A longer washout period may be necessary (Kolecki, 1997).

e) A 44-year-old female was stabilized on phenelzine 30 mg twice daily and alprazolam 0.5 mg three tim phenelzine and alprazolam. Within 45 minutes she began to experience extremity shaking and rapid resp increased muscle tone, and diminished verbal responsiveness. Vital signs included blood pressure of 13 degrees Celsius. The diagnosis of serotonin syndrome was made. Following intubation and seven days (Weiner et al, 1998).

f) In a case report on four patients, symptoms of serotonin syndrome were noted, even in two cases wh patients ranged in age from 25 to 49 years, and all had been on phenelzine for co-existing migraine and of the four patients had been advised to wait 14 days after stopping phenelzine to start taking venlafaxin experienced symptoms including agitation, shaking, diaphoresis, hyperthermia, slight hypertension, dizzi one hour of administration of venlafaxine, and all the patients were returned to baseline within 24 hours

3.5.1.DE Phenindione

1) Interaction Effect: an increased risk of bleeding
2) Summary: Case reports and epidemiological studies have shown that use of selective serotonin reuptake

venlafaxine, is associated with gastrointestinal bleeding. Bleeding events with SSRIs and SNRIs included cas
have also occurred. Coadministration with warfarin or other anticoagulants may potentiate the risk of bleedinç

a) When administered with imipramine, the pharmacokinetics of imipramine and the 2-hydroxy metaboli (AUC), maximum concentration (Cmax), and minimum concentration (Cmin) of desipramine by approxim 12 hours) and by 4.5-fold (venlafaxine 75 mg every 12 hours). The clinical significance of this finding is u

3.5.1.DO Rasagiline

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, hyperthermia, myoclonus, mental st
2) Summary: Concomitant use of rasagiline and venlafaxine, a serotonin-norepinephrine reuptake inhibitor (SSRIs and non-selective MAOIs has been reported to cause serious, sometimes fatal reactions. Signs and s sign fluctuations, and mental status changes progressing to extreme agitation, delirium, and coma. Similar re elapse after discontinuing rasagiline before initiating venlafaxine therapy (Prod Info AZILECT(R) oral tablets, therapy with rasagiline (Prod Info EFFEXOR(R) oral tablets, 2007).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of rasagiline and venlafaxine is not recommended. Wait at least 14 least 7 days after discontinuing venlafaxine before initiating therapy with rasagiline (Prod Info AZILECT(R) or
7) Probable Mechanism: inhibition of serotonin metabolism by monoamine oxidase

3.5.1.DP Ritonavir

1) Interaction Effect: increased plasma concentrations of venlafaxine
2) Summary: Caution is advised if a CYP3A4 inhibitor, such as ritonavir, is administered with venlafaxine, du desvenlafaxine (ODV) (Prod Info venlafaxine extended release oral tablets, 2008). Patients should be monito
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Patients should be monitored for signs of venlafaxine toxicity such as nausea, drow
7) Probable Mechanism: decreased venlafaxine clearance
8) Literature Reports
a) Caution is warranted with the concurrent use of CYP3A4 inhibitors, such as ritonavir, and venlafaxine desvenlafaxine (ODV) (Prod Info venlafaxine extended release oral tablets, 2008).

3.5.1.DQ Rizatriptan

1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: There have been case reports of weakness, hyperreflexia, and incoordination following concon specific reuptake inhibitor (SSRI) (Prod Info Imitrex(R), 1998). Because rizatriptan is a 5HT 1B/1D receptor a 1998a). Concurrent use of a triptan and an SSRI may result in serotonin syndrome which may be life-threate coordination, fast heart beat, rapid changes in blood pressure, increased body temperature, overreactive refl commonly used intermittently and that either the triptan or the SSRI may be prescribed by a different physicia combination and monitor them closely for symptoms of serotonin syndrome (US Food and Drug Administratic
3) Severity: major
4) Onset: delayed

5) Substantiation: probable
6) Clinical Management: Coadministration of a triptan, such as rizatriptan, and an SSRI may result in a life-th used intermittently and that either the triptan or the SSRI may be prescribed by a different physician. If these monitor closely for symptoms of serotonin syndrome (restlessness, hyperthermia, hyperreflexia, incoordinatic
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation
8) Literature Reports
a) Twelve healthy volunteers received paroxetine 20 mg daily for two weeks and a single dose of rizatrip paroxetine (Prod Info Maxalt(R), 1998).

3.5.1.DR Rofecoxib
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc NSAIDs has been associated with an increased risk of bleeding. Bleeding events have included epistaxis, ec (R) oral tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When venlafaxine and a nonsteroidal antiinflammatory agent are given concurrentl 2008).
7) Probable Mechanism: unknown

3.5.1.DS Saquinavir
1) Interaction Effect: increased plasma concentrations of venlafaxine
2) Summary: Caution is advised if a CYP3A4 inhibitor, such as saquinavir, is administered with venlafaxine. desvenlafaxine (ODV) (Prod Info venlafaxine extended release oral tablets, 2008). Patients should be monito
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Patients should be monitored for signs of venlafaxine toxicity such as nausea, drow
7) Probable Mechanism: decreased venlafaxine clearance
8) Literature Reports
a) Caution is warranted with the concurrent use of CYP3A4 inhibitors, such as saquinavir, and venlafaxi desvenlafaxine (ODV) (Prod Info venlafaxine extended release oral tablets, 2008).

3.5.1.DT Selegiline
1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, hyperthermia, myoclonus, mental sta
2) Summary: Concurrent administration or overlapping therapy with venlafaxine and a monoamine oxidase (state characterized by symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, concomitant use of serotonin specific reuptake inhibitors and MAO inhibitors (Prod Info Effexor(R) XR, 2000f Concomitant administration of venlafaxine and selegiline is contraindicated, and a minimum of 14 days shoul minimum of 7 days should elapse after discontinuing venlafaxine before initiating therapy with selegiline (Pro reported 15 days after discontinuation of selegiline therapy and initiation of venlafaxine therapy, indicating tha
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Concurrent use of venlafaxine and selegiline is contraindicated. Wait at least 14 da seven days after discontinuing venlafaxine before initiating therapy with selegiline.
7) Probable Mechanism: inhibition of serotonin metabolism by monoamine oxidase
8) Literature Reports
a) Concomitant use of serotonin specific reuptake inhibitors and monoamine oxidase inhibitors can prod syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness, myoclonus, cha not recognized and correctly treated, death can result.
b) A 26-year old woman who had been taking isocarboxazid for eight weeks stopped taking the drug for the patient became restless and developed leg twitches. The patient was later admitted to the emergenc disturbances. After treatment with diazepam and propranolol the patient did not improve. The patient wa symptoms after the second dose (Lappin & Auchincloss, 1994n).
c) A drug interaction was reported in a 61-year old woman in which sertraline 100 mg twice daily was ac taking the first sertraline dose, the patient was found in a semicomatose state, with elevated body tempe Hg. After transportation to the hospital, the patient was misdiagnosed as having neuroleptic malignant sy sertraline and phenelzine. The authors suggest that monoamine oxidase inhibitor (MAOI) therapy should serotonin reuptake inhibitor (SSRI) and that before starting a MAOI, SSRI therapy should be discontinue 1994o).
d) Two cases reports suggested a possible interaction between fluoxetine and selegiline (Suchowersky approximately one month after adding selegiline to fluoxetine therapy. The patient improved two months case involved diaphoresis, vasoconstriction, and cyanosis of the hands which occurred in close tempora relatively quick resolution of symptoms. Rechallenge with fluoxetine alone occurred without incident.
e) Although it has been suggested that MAOIs be discontinued for at least 14 days before the initiation c venlafaxine 15 days after cessation of selegiline. The patient had been treated previously with multiple a

50 mg. All medications were discontinued due to poor response and venlafaxine 37.5 mg was started 15 including profound anxiety, diarrhea, myoclonic jerks, shivering, tremor, and diaphoresis. These symptor further complications. The authors suggested that some patients may need a longer washout period betv

3.5.1.DU Sibrafiban

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case reports anc (SSRIs) and serotonin-norephinephrine reuptake inhibitors (SNRIs), including venlafaxine, is associated with ecchymoses, hematomas, epistaxis, and petechiae; life-threatening hemorrhages have also occurred. Coadr the risk of bleeding (Prod Info EFFEXOR XR(R) extended-release oral capsules, 2008a).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Use caution when venlafaxine is used concomitantly with antiplatelet agents. Close patients receiving antiplatelet agents concomitantly (Prod Info EFFEXOR XR(R) extended-release oral capsu
7) Probable Mechanism: unknown

3.5.1.DV Sibutramine

1) Interaction Effect: an increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, ment
2) Summary: Sibutramine inhibits the reuptake of norepinephrine, dopamine, and serotonin. In addition, the t neurotransmitters. A hyperserotonergic state, termed serotonin syndrome, may result if sibutramine is given c and selective serotonin reuptake inhibitors is not recommended (Prod Info Meridia(R), 1997).
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Sibutramine should not be administered with serotonergic agents, including selectiv
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation
8) Literature Reports
a) Serotonin syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness, m the syndrome is not recognized and correctly treated, death can result (Sternbach, 1991a).

3.5.1.DW St John's Wort

1) Interaction Effect: an increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, ment
2) Summary: One case of serotonin syndrome likely resulting from concomitant use of St. John's Wort and v of serotonin syndrome-like symptoms following the addition of St. John's Wort to sertraline or nefazodone the have mild monoamine oxidase inhibitory activity (Singer et al, 1999; Thiede & Walper, 1994), which when adc syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness, myoclonus, changes Wort was initially characterized as a monoamine oxidase inhibitor (MAOI), it is now believed that insufficient I (Muller et al, 1997). It remains possible that the mild MAOI property of St. John's Wort may contribute to an ir (Demisch et al, 1989). Concomitant administration of monoamine oxidase inhibitors (MAOIs) with SSRIs has manufacturers. This contraindication may be extended to venlafaxine which, though not an SSRI, inhibits ser discontinuing St. John's Wort before starting a SSRI (Gordon, 1998), and may be applied to venlafaxine as w

A) Venlafaxine (By mouth)

Venlafaxine

Treats depression. Effexor XR® also treats panic disorder, social anxiety disorder, and generalized anxiety disorc

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to venlafaxine, or if you have used an MAO
days.

How to Use This Medicine:
Long Acting Capsule, Long Acting Tablet, Tablet

Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed
use it more often than your doctor tells you to.
It is best to take this medicine with food or milk.
Swallow the extended-release capsule whole. Do not crush, break, or chew it.
If you cannot swallow the extended-release capsule, you may open it and pour the medicine into a small amo
it without chewing.
It is best to take this medicine at the same time each day.
This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your d
Guide if you do not have one. Your doctor might ask you to sign some forms to show that you understand this

If a Dose is Missed:

If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next d
medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:

Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after
expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a

Make sure your doctor knows if you are using an MAO inhibitor (such as isocarboxazid, phenelzine, selegilin
inhibitor within the last 14 days. Using these medicines with venlafaxine could cause serious health problems

Muscle spasms, twitching, or stiffness.
Seizures or tremors.
Severe nausea or diarrhea.
Unexplained fever, sweating, or shivering.
Unusual behavior or thoughts of hurting yourself or others.
Unusual bleeding or bruising.
Unusual tiredness or weakness.

If you notice these less serious side effects, talk with your doctor:
Anxiety, trouble sleeping, or unusual dreams.
Blurred vision.
Constipation or dry mouth.
Headache.
Mild nausea, vomiting, loss of appetite, or weight loss.
Problems with sex.
Sleepiness.
Warmth or redness in your face, neck, arms, or upper chest.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Venlafaxine Hydrochloride

1) Like the SSRIs, venlafaxine does not cause the anticholinergic, sedative, or cardiovascular adverse effects typ activating effect, at least with acute administration. Although its clinical significance is unclear, it inhibits synaptos patients with previous experience with tricyclic antidepressants indicate that venlafaxine has a different adverse e

2) Despite availability of newer antidepressants, 30% to 40% of patients with severe depression fail to achieve co limited clinical trials, venlafaxine was comparable to tricyclic antidepressants and superior to selective serotonin r response rates may result from the dual action of venlafaxine on the norepinephrine and serotonin system. Furthe Venlafaxine extended-release was superior to placebo in the prevention of recurrent episodes of depression in pa maintenance phase trials (Kocsis et al, 2007; Keller et al, 2007).

3) One potential advantage of venlafaxine is its apparent rapid onset of action; significant improvement of depres 2 weeks of therapy. However, it has not been established that venlafaxine clearly works faster than other antidepr trials, rather than a distinguishing characteristic of this drug. If additional research including comparative trials sup should be considered.

4) Preliminary data suggest that venlafaxine may be useful in the treatment of obsessive-compulsive disorder an these disorders.

4.4 Mechanism of Action / Pharmacology

A) Venlafaxine Hydrochloride

1) MECHANISM OF ACTION

a) Venlafaxine hydrochloride is an antidepressant agent that potentiates the neurotransmitter activity in the c norepinephrine and dopamine reuptake. Venlafaxine and its active metabolite, O-desmethylvenlafaxine (ODV slightly less potent inhibitors of neuronal norepinephrine reuptake, and weak inhibitors of neuronal dopamine serotonin reuptake inhibitors (Prod Info EFFEXOR(R) oral tablets, 2008; Prod Info EFFEXOR XR(R) extende Perry, 1994; Saletu et al, 1992; Muth et al, 1991; Fabre & Putmann, 1987).

b) Venlafaxine is a bicyclic antidepressant that has been referred to as an atypical or "second-generation" ar dopamine in order of decreasing potency. It does not inhibit monoamine oxidase, and does not show the deg antidepressants have been shown to exhibit. No affinity for central muscarinic-cholinergic, dopaminergic, hist demonstrated for venlafaxine or its major active metabolite, O-desmethylvenlafaxine. In animal studies, venla Other antidepressant properties include its ability to reverse reserpine hypothermia and to cause pineal beta- Saletu et al, 1992a; Yardley et al, 1990).

c) Venlafaxine is a racemic mixture; while the pharmacologic profile of the levo(-) isomer is similar to that of 1992).

2) ELECTROENCEPHALOGRAPHIC EFFECTS

a) Electroencephalographic (EEG) analysis in patients receiving venlafaxine has shown that it exerts signific compared with placebo, alpha power is decreased, relative delta/theta and beta powers are increased, and th antidepressants such as imipramine (Saletu et al, 1992a).

3) NEUROPSYCHIATRIC EFFECTS
- **a)** Administration of venlafaxine has been shown to cause significant improvement in attention, concentratio to placebo in healthy volunteers. This is thought to be due to activation of all 3 neurotransmitter systems (i.e., with higher doses, most likely due to the drug's serotonergic activity (Saletu et al, 1992a).

4) REVIEW ARTICLES
- **a)** Two reviews provide a discussion of the efficacy of selective serotonin reuptake inhibitors and other antid
- **b)** The efficacy of antidepressants in reducing panic attack frequency, symptoms of depression, social avoid
- **c)** A review article discussed the rational treatment of depression and included a discussion of each class of
- **d)** The pharmacology and therapeutic potential of venlafaxine has been reviewed (Holliday & Benfield, 1995
- **e)** Drug-interactions of antidepressants are reviewed in German language (Zapotoczky & Simhandl, 1995).

4.5 Therapeutic Uses

4.5.A Venlafaxine Hydrochloride

Antineoplastic adverse reaction - Neurotoxicity

Attention deficit hyperactivity disorder

Binging - Eating disorder

Bipolar disorder, depressed phase

Cancer pain

Cerebrovascular accident - Depression

Depression - Perimenopausal disorder

Diabetic neuropathy

Dysthymia

Generalized anxiety disorder

Hot sweats, Breast cancer-related

Major depressive disorder

Menopausal flushing

Obsessive-compulsive disorder

Panic disorder, With or without agoraphobia

Posttraumatic stress disorder

Premenstrual dysphoric disorder

Recurrent major depressive episodes; Prophylaxis

Severe major depression with psychotic features

Social phobia

Tension-type headache; Prophylaxis

4.5.A.1 Antineoplastic adverse reaction - Neurotoxicity

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Venlafaxine extended-release completely resolved paclitaxel-neurosensory toxicity in a 69-year-old

c) Adult:

1) In a single case report, venlafaxine hydrochloride extended-release (XR) completely resolved paclitax milligrams (mg)/m(2) and carboplatin for ovarian cancer. After failure of clonazepam 1.5 mg, venlafaxine resolved pin-pricks and parerethises in both her hands and wrists (Durand & Goldwasser, 2002).

4.5.A.2 Attention deficit hyperactivity disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Results of a prospective, 6-week, open-label trial (n=13) demonstrate that venlafaxine therapy impro Abali, 2004).

c) Pediatric:

1) Symptoms of attention deficit hyperactivity disorder (ADHD) improved following venlafaxine treatment 6 to 15 years of age (mean age, 9.9 years) with ADHD and without comorbid depression received venlaf dose, 40.38 mg/day) for 6 weeks. No other psychotropic medications were allowed during the study. Res Clinical Global Impression (CGI)-Improvement scale. The total mean score of the Connor Parent Index w including significant improvement in individual index items such as "short attention span", "easily distract CGI-Severity rating was also significantly improved from baseline to endpoint (p less than 0.05) and ther who did not respond to venlafaxine treatment had comorbid conditions, including tic disorder or oppositic complicated by venlafaxine therapy. Transient adverse effects included stomachache (n=2), somnolence (56.25 mg/day) and one patient, with a comorbid tic disorder, experienced behavioral activation and wors safety and efficacy of venlafaxine in the treatment of ADHD in pediatric patients (Mukaddes & Abali, 200

4.5.A.3 Binging - Eating disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Results of a retrospective study (n=35) indicate venlafaxine may be an effective treatment for binge-

c) Adult:

1) The results of a small, retrospective study indicate that venlafaxine may be an effective treatment for eating disorder (n=35) received venlafaxine alone (n=29) or as an adjunctive therapy (n=6) at a mean do (range, 28 to 300 days). Some patients also received behavioral dietary counseling (91%), formal psych amitriptyline, bupropion, paroxetine, or sertraline. Patients on single or combination venlafaxine therapy frequency, Clinical Global Impressions-Severity of Illness (CGI-S) scale scores for binge eating and depr 0.0001). Fifteen (43%) patients lost at least 5% of their baseline weight and 7 (20%) patients lost at least sexual dysfunction (14%), insomnia (14%), nausea (11%), and blood pressure changes (46%). A small i

4.5.A.4 Bipolar disorder, depressed phase

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

No significant difference between adjunctive bupropion, sertraline or venlafaxine was revealed amor risk of switching into (hypo)mania was significantly higher with venlafaxine in a randomized, double- Venlafaxine monotherapy was more effective than lithium for the initial treatment of bipolar II major d randomized, open-label, clinical trial (n=83) (Amsterdam & Shults, 2008).

Venlafaxine and paroxetine were both significantly effective adjunctive treatments for breakthrough observed with venlafaxine in a single-blind, randomized, comparative trial (n=60) (Vieta et al, 2002).

c) Adult:

1) General Information

a) The incidence of bipolar disorder is reported to occur in 1% to 3% of the population. Most importa comparison to (hypo)manic episodes and have a 10% to 20% lifetime risk of death by suicide (Post for reduction of morbidity and mortality in patients with bipolar affective disorder. However, practice inadequate. The American Psychiatric Association recommends that initial treatment of bipolar II ma stabilizer and the lowest-effective dose, short-term antidepressant therapy (Amsterdam & Shults, 20 antidepressant monotherapy may be considered in bipolar II major depressive episode in patients w mood stabilizer monotherapy for mild to moderate bipolar II depression and combination mood stabi treatment completely (Amsterdam & Shults, 2008). Historical studies have provided evidence that a (eg, venlafaxine, tricyclic antidepressants) may increase the risk of switch into a hypomanic or mani no significant differences between adjunctive bupropion, sertraline, or venlafaxine among response mania switch was significantly higher with venlafaxine compared with bupropion and sertraline (Pos treatment with venlafaxine or paroxetine were both significantly effective for the treatment of breakth or manic switch was observed with venlafaxine (Vieta et al, 2002). In contrast, venlafaxine monothe major depressive episode with low occurrence of hypomanic switch in a prospective, randomized tri sizes, distinguishing between inclusions of bipolar I or bipolar II patients, a clear definition of switch, would be beneficial for consistent and effective control of major depressive episode and minimizatio Shults, 2008; Vieta et al, 2002).

2) Clinical Trials

a) No significant difference between adjunctive bupropion, sertraline or venlafaxine was revealed a the risk of switching into (hypo)mania was significantly higher with venlafaxine compared with bupro (n=174). All patients were currently treated with at least 1 mood stabilizer or antimanic agent. Subje (n=51), sertraline 50 to 200 mg/day (n=58), or venlafaxine 37.5 to 375 mg/day (n=65) for 10 weeks. the study. Symptoms were assessed using the Inventory of Depression Symptomatology (IDS), the Disorder (CGI-BP). The outcome measures included antidepressant response (defined as either a 5 depression score), antidepressant remission (defined as an IDS score less than 12 and/or a CGI-BP hypomania (defined as either an increase of 2 points on the CGI-BP manic severity score during an at any time point). At week 10, the response rates for bupropion, sertraline and venlafaxine were 49 differences were not statistically significant between groups and controlling for lithium use did not alt venlafaxine. Based on at least a 2-point increase on the CGI-BP score, (hypo)manic switching occu respectively. When these data were analyzed using survival analysis in order to control for the effec treatment groups was significant (p=0.002), and controlling for lithium demonstrated similar results (the significant difference in the risk of switching-time between venlafaxine and sertraline (p=0.01, ac lithium), while there was no significant difference between sertraline and bupropion (p=0.9). The risk score (greater than 13) was analyzed. By study endpoint, 4%, 7%, and 15% of patients switched in for lithium did not change the results. The difference between venlafaxine, bupropion and sertraline mania of at least 3 or YMRS greater than 13 criteria were used (p=0.03 without controlling for lithium cycling was lower with bupropion when compared with venlafaxine (p less than 0.01) but there was venlafaxine. The percentages of patients who discontinued the study prematurely for any reason we Withdrawal for adverse events did not vary between the 3 groups. Limitations of the study include n

b) Venlafaxine monotherapy was more effective than lithium for the initial treatment of bipolar II ma randomized, open-label, clinical trial (n=83). DSM-IV bipolar II adult patients with an ongoing acute included in the trial. All patients had a baseline, 17-item Hamilton Depression Rating Scale (HAM-D psychosis in the preceding 3 months or if they were nonresponsive to venlafaxine or lithium during t neuroleptics, tranquilizers or over-the-counter antidepressant agents were not allowed. Any previous Concomitant zolpidem, zaleplon or trazodone was allowed for severe insomnia. Eligible patients age (n=40) for 12 weeks. Venlafaxine was initiated at 37.5 milligrams (mg)/day, increased to 75 mg/day mg/day by week 4. The highest tolerated dose was maintained for an additional 8 weeks. Lithium wa required serum lithium level of 0.5 millimoles (mmol)/L during week 2. Lithium dose was optimized t maintained for an additional 8 weeks. At baseline, study subjects had a history of bipolar II for 18.5 - 18.7 +/- 8.7 years and first hypomanic episode at age 20.7 +/- 8.2. The mean baseline HAM-D 28 sc group. At the end of the study, 79.1% of patients in the venlafaxine group and 37.5% of patients in t was a greater reduction in HAM-D 28 (primary endpoint) with venlafaxine monotherapy compared w (95% CI, -11.97 to -1.18; p=0.017). Venlafaxine monotherapy yielded a greater number of responde 20%; p less than 0.0005). The proportion of remitters (final HAM-D 28 score of 8 or less) was also s 0.0005). There was no significant difference between treatment groups in the mean Young Mania R each, experienced subsyndromal hypomanic and hypomanic symptoms (2.4% vs 2.6%; p=0.99). Or patient in the lithium group discontinued due to increasing suicidal ideation. Other common adverse mouth (32.6% vs 10%), somnolence (30.2% vs 22.5%) and difficulty thinking (16.3% vs 32.5%) in th of a placebo/control group, short treatment duration and small sample population size (Amsterdam &

c) Venlafaxine and paroxetine were both significantly effective adjunctive treatments for breakthrou manic switch was observed with venlafaxine in a single(rater)-blind, randomized, comparative trial (episode indicated by a score of greater than 17 on the 17-item Hamilton Rating Scale for Depressio carbamazepine, other) for at least 6 months prior to the current depressive episode, and required to throughout the study period. Recent treatment with antidepressant or antipsychotics during the prev attempt, currently abusing alcohol or other psychotropics, using concomitant anxiolytics, had previou Scale (YMRS). Eligible patients were randomly assigned to either venlafaxine (n=30; age 45.5 years

6 weeks. Based on response and tolerability, the venlafaxine group received 37.5 milligrams (mg) tv trial was 179.2 +/- 91 mg/day. The paroxetine group received 20 mg/day titrated by 10-mg/day incre modified intent-to-treat population, defined as all patients who took at least 1 dose of study medicati significant improvement in HAM-D 28 scores from baseline to endpoint (primary endpoint). The char to 13.8 +/- 6.7 for paroxetine (both p less than 0.0001). Venlafaxine was numerically superior to parc defined as a reduction in HAM-D 28 score by 50% or more from baseline, was 48% in the venlafaxir HAM-D score of less than 10 and a Clinical Global Impressions (CGI) severity score of 1 was 33% ir occurred in 4 patients (13%) in the venlafaxine group: 2 switched to hypomania (YMRS score = 12 a (3%) in the paroxetine group who switched to hypomania (YMRS score = 17) (p not significant). The treatment and antidepressant discontinuation. One manic episode required hospitalization. Commor vs 7%), headache (3% vs 10%) and insomnia (10% vs 0%) in the venlafaxine and paroxetine groups study design, small sample population size and short follow-up period (Vieta et al, 2002).

4.5.A.5 Cancer pain

See Drug Consult reference: MANAGEMENT OF CANCER-RELATED PAIN IN ADULT PATIENTS

4.5.A.6 Cerebrovascular accident - Depression

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

During an open study, 12 post-stroke patients benefited from venlafaxine treatment administered wi

c) Adult:

1) Twelve patients who received venlafaxine within 2 weeks of a stroke showed a decrease in depressiv (mg) daily with an increase to 150 mg daily after 2 days. Response was evaluated with the Hamilton Dep (MADRS). After 5 weeks of treatment, the HAM-D score decreased from 24.3 to 7.25, and the MADRS d dose was decreased in 1 patient due to agitation; 3 patients had nausea during initiation of treatment. Ba with depression secondary to stroke (Dahmen et al, 1999).

4.5.A.7 Depression - Perimenopausal disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

In a small, open-label trial, extended-release venlafaxine therapy reduced depressive symptoms and
