1) In a small, 8-week, open-label trial, treatment with extended-release venlafaxine reduced depressive perimenopausal if they reported one or more climacteric symptoms (hot flushes, sweating, vaginal dryne criteria comprised of presence of current depressive disorder confirmed by the DSM-IV Axis I disorders, non-hormonal method of contraception. The study was initiated on day 10, 11, or 12 of the menstrual cyc orally once daily during week 1 and 75 mg daily during week 2. Data collection instruments included the global impression severity (CGI-S), and a standard measure of 4 subscales: psychiatric, somatic, vasom When clinically necessary, dosage was increased in 75-mg increments after the week 2 and week 4 visit observed by week 2 and were sustained through week 8. Antidepressant response (greater than 50% Ha equal to 7) was achieved in 12 subjects (75%) after 8 weeks of venlafaxine therapy (75 to 225 mg/day). 71%, and anxiety subscores reduced by 63%. Vasomotor and sexual dysfunction subscores were not sig vasomotor subscores greater than 0, a 37.5% decline was observed at week 8 (p less than 0.05). Howev vasomotor symptoms observed in women who had baseline vasomotor symptoms and that further studie depression (Ladd et al, 2005).

4.5.A.8 Diabetic neuropathy

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Dose-related, clinically significant reductions in pain were demonstrated with venlafaxine extended-r (Rowbotham et al, 2004).
One case report demonstrated the effectiveness of venlafaxine depot combined with gabapentin for Venlafaxine relieved the unremitting pain of diabetic peripheral neuropathy in 8 patients who found r

In a series of 11 patients, venlafaxine relieved the pain associated with diabetic peripheral neuropat

c) Adult:

1) The efficacy of venlafaxine extended-release (XR) for the treatment of painful diabetic neuropathy wa outpatients with metabolically stable type 1 or 2 diabetes and bilateral distal peripheral neuropathy of at l XR at a dose of 75 milligrams (mg) or 150 to 225 mg daily or placebo orally for 6 weeks. Primary efficacy and Pain Relief (VAS-PR) scales. Of the 244 patients randomized, 242 made up the intent-to-treat (ITT) in the venlafaxine XR 75 mg group, 67.3 mm in the venlafaxine XR 150 to 225 mg group, and 68.8 in the reductions in mean adjusted pain intensity scores were 32%, 50%, and 27% for venlafaxine XR 75 mg, v significantly more effective than placebo (p less than 0.001) and venlafaxine XR 75 mg (p =0.006) at wee venlafaxine 150 to 225 mg was significantly more effective than placebo by week 6 (59.9 mm versus 43. placebo (51 mm versus 43.6 mm). The percentages of patients who were considered responders (at leas placebo groups at week 6 (LOCF) were 56% and 34%, respectively (p less than 0.01). The number neec was 4.5 at week 6. The most common treatment-emergent adverse events associated with both venlafax occurred in 6%, 5%, and 1% of the venlafaxine XR 75 mg, venlafaxine XR 150 to 225 mg, and placebo g changes during treatment. Adverse events leading to study withdrawal did not significantly differ betweer

2) The combination of venlafaxine depot (75 milligrams (mg) three times daily) and gabapentin relieved history of type 1 diabetes. The patient developed burning pain and tenderness of the arms and legs and pain was not relieved despite the following treatments: paracetamol and dextropropoxyphene for 7 mont buprenorphine for 3 months; then eight different analgesics. Placing her legs in buckets of cold water for developed orthostatism, preproliferative retinopathy and moderate signs of distal sensory, autonomic, an 75 mg three times daily), and after 7 months was greatly improved with controllable distal pains. Analges

3) Venlafaxine relieved the unremitting pain of diabetic peripheral neuropathy in 8 patients who found nc acetaminophen, carbamazepine, capsaicin, and amitriptyline were not successful, either due to lack of e patients responded to venlafaxine 37.5 milligrams twice daily with dramatic relief in symptoms associatec rapidly without interruption of treatment. No serious side effects were observed (Kiayias et al, 2000).

4) Eleven patients with type 2 diabetes mellitus and painful diabetic neuropathy had a 75% to 100% red patients had been treated unsuccessfully with other medications known to alleviate the pain associated v 75 milligrams/day, all patients noted a 75% to 100% reduction in pain. No adverse effects were reported pain 2 to 3 days later. When venlafaxine was restarted, the pain was relieved promptly. This series sugg

4.5.A.9 Dysthymia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

During 9-week, open study, venlafaxine was effective for treating dysthymic disorder in 14 patients (

c) Adult:

1) In a 9-week, open study, 10 and 4 patients showed a complete and modest response, respectively, tc determination of baseline Hamilton Rating Scale for Depression (HAM-D-17) and Beck Depression Inver was titrated to a maximum dose of 225 mg daily. Seven patients improved with venlafaxine 75 mg daily; weeks, and met proposed criteria for remission of dysthymic disorder. This study suggests that venlafaxi are needed.

4.5.A.10 Generalized anxiety disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes (extended-release capsule only); Pediatric, no
Efficacy: Adult, Effective; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIa; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Venlafaxine extended-release is approved for treating generalized anxiety disorder (GAD), as define 2008).

Extended-release venlafaxine was more effective than placebo for improving the symptoms of depre generalized anxiety disorder; however, time to response was greater in patients with comorbidity tha

Venlafaxine extended-release was safe and effective for long-term treatment (6 months) of generali (n=251) (Gelenberg et al, 2000).

Extended-release venlafaxine was superior to placebo for relieving generalized anxiety disorder in n blind trial (n=349) (Rickels et al, 2000).

In two randomized, placebo-controlled, 8-week studies enrolling children with generalized anxiety di one individual trial and the pooled analysis (Rynn et al, 2007).

c) Adult:

1) Extended release (XR) venlafaxine was more effective than placebo for improving the symptoms of d generalized anxiety disorder (GAD). However, time to response was greater in patients with comorbidity

meeting DSM-IV criteria for major depressive disorder in a double-blind, randomized trial (n=368), results and compared to results of the noncomorbid patients. Patients took once-daily doses of venlafaxine XR increased to a maximum of 225 mg. According to the criteria of more than 50% reduction (from baseline) improvement with venlafaxine was significantly greater (p less than 0.05) than with placebo by 12 weeks however, overall, there was no evident trend for a placebo-drug difference until after the eighth week of t evident as early as week 2. By week 12, response rate was 66% on HAM-D and 59% on HAM-A for thos 2001a).

2) Venlafaxine extended-release (XR) was safe and effective for the long-term treatment of generalized (n=251) who met DSM-IV criteria for GAD without a diagnosis of major depressive disorder were random age, 41 years) or placebo (n=127; mean age, 38 years) for 28 weeks. Primary outcome measures includ HAM-A psychic anxiety factor score, and the Clinical Global Impressions (CGI) scale Severity of Illness a evaluable for the efficacy analysis. The overall dropout rate was 59%, with 60 and 44 patients in the venl observation-carried-forward (LOCF) method, the adjusted mean changes from baseline to week 28 for H changes for HAM-A psychic anxiety score were -7.4 for venlafaxine XR and -4.2 for placebo (p less than 0.001). Significant (p less than 0.01) changes in the HAM-A scores were seen as early as week 1 with ve differences between venlafaxine XR and placebo were maintained throughout the final assessment at we where significant reductions were noted with venlafaxine XR compared with placebo at week 1 (p=0.02) Illness scores for venlafaxine XR compared to placebo became initially noted at week 2, but became mo superior to placebo on the CGI-Global Improvement item at all times assessed beyond week 1. Respons or a CGI-Global Improvement score of 1 or 2) during weeks 6 through 28 were at least 69% in the venlaf most common adverse events occurring with at least twice the frequency with venlafaxine XR were anor sweating. Over time (days 57 to 196), these events subsided with continued therapy (Gelenberg et al, 20

3) Extended-release (XR) venlafaxine was superior to placebo for relieving generalized anxiety disorder double- blind trial, patients were given placebo (n=96) or venlafaxine XR (n=253) at one of 3 dose levels for the first week; during the second week, those assigned to the 150 and 225 mg/day groups were raise the end of week 1 and throughout the 8 weeks of treatment, efficacy measures for all doses of venlafaxir were indistinguishable for the 2 highest doses of venlafaxine, although, according to the Anxiety Subscal mg/day. Most discontinuations (29% of patients) were caused by adverse reactions and occurred within nausea, insomnia, dry mouth, somnolence, dizziness, and asthenia (Rickels et al, 2000).

d) Pediatric:

1) Extended-release venlafaxine may improve generalized anxiety disorder in children as evaluated in tw identical in design and were analyzed separately and in a pooled analysis. Children with generalized anx once daily (n=157) or placebo (n=163) and were titrated up according to body weight for 8 weeks, follow dose was 225 mg/day for children weighing greater than or equal to 50 kilograms (kg). Patients were stra equal to 20 on the severity component of the generalized anxiety section of the Columbia Schedule for A Patients were excluded if they had major depressive disorder, acute suicidality, social anxiety, or other p in the composite score of nine delineated items from the Columbia K-SADS (primary endpoint) was grea 12.4; p less than or equal 0.001); however, there was not a significant difference between treatment grou patients responded (defined as at least a 50% decrease from baseline in the nine-item Columbia K-SAD group (38%) compared to the placebo group (17%; p-value not reported) in the first study, but not in the of nine delineated items from the Columbia K-SADS generalized anxiety disorder section was 17.4 point ($p < 0.001$). In both studies, patients treated with extended-release venlafaxine experienced greater impr most common adverse events in the extended-release venlafaxine group that were twice as frequent as

4.5.A.11 Hot sweats, Breast cancer-related

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

In two randomized, double-blind, crossover trials, treatment with oral extended-release venlafaxine reductions in hot flash frequency, severity, and bother compared to placebo in breast cancer survivo In a randomized, double-blind German study (n=80), treatment with oral venlafaxine was significantl women with primary breast cancer (Loibl et al, 2007).

c) Adult:

1) General Information

a) Practice guidelines and limited clinical trials support short-term efficacy of oral venlafaxine in bre 2007; Loibl et al, 2007; Hickey et al, 2008). In two, 14-week, randomized, double-blind, placebo-con venlafaxine, primarily in Caucasian breast cancer survivors, both doses administered demonstrated physiologically-assessed), severity, and bother compared to placebo (Carpenter et al, 2007). Furthe evident in this study. In another 4-week, randomized, double-blind, controlled study in adult women frequency to a greater extent compared to clonidine (Loibl et al, 2007). Treatment-emergent adverse (Carpenter et al, 2007; Loibl et al, 2007).

2) Clinical Trials

a) Treatment with oral extended-release (ER) venlafaxine 37.5 milligrams (mg; low-dose) or 75 mg flash frequency, severity, and bother compared to placebo in breast cancer survivors in two random

initiated 4 weeks prior to study entry and continued during the entire study duration. The primary endpoir
combined score of frequency and severity (range, 1=mild to 4=very severe). At baseline, study patients h
the modified intent-to-treat analysis of 191 evaluable patients at the end of the study, patients receiving v
activity scores at week 4 from baseline (37%, 61%, and 61% reduction in the venlafaxine 37.5 mg, 75 mg
than 0.001 vs placebo). A reduction of more than 50% in hot flash activity occurred in 45%, 63%, and 55
20% in the placebo group. No difference in efficacy was noted between the 75 mg and the 150 mg group
adverse events included dry mouth, nausea, decreased appetite, and constipation, which occurred more
2000).

a) An 8-week, open-label, longitudinal extension of this trial demonstrated that efficacy of venlafaxi
randomized, placebo-controlled trial that entered the open-label continuation phase, 102 patients we
37.5 to 150 milligrams (mg)/day. At 8 weeks, the venlafaxine doses used were 37.5 mg (n=26), 75 m
from baseline (week 1 of placebo-controlled phase) in hot flash frequency was reported at study enc
experienced an additional mean 26% reduction in hot flash scores, the approximate 60% reduction i

phase was maintained during the open-label extension. Common adverse events in the continuatior (Barton et al, 2002).

3) Low-dose venlafaxine decreased hot flash activity by 81% in men receiving androgen deprivation the 12.5 milligrams twice daily for 4 weeks. Using a diary, patients recorded the number and severity of daily daily hot flashes decreased from 10 at baseline to 6 after 4 weeks of treatment. This was accompanied b weeks, 52% of patients wished to continue venlafaxine treatment. Nausea was the primary adverse effec

4) Low-dose venlafaxine was effective in reducing the incidence and severity of hot flashes in women w therapy (n=5). Patients received venlafaxine 25 milligrams (mg) daily for 5 weeks. The average number (54%) patients reported a 50% or greater decrease in the incidence of hot flashes (P less than 0.0002). study were consistent with previous studies (Loprinzi et al, 1998).

4.5.A.14 Obsessive-compulsive disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Venlafaxine extended-release (XR) was as effective as paroxetine in the primary treatment of patier (Denys et al, 2003a).

During a double-blind study (n=150), venlafaxine was effective as a crossover therapy in patients wi al, 2004).

Venlafaxine was effective for the treatment of obsessive compulsive disorder in two separate case s Hollander, 1996; Zajecka et al, 1990).

c) Adult:

1) Primary Therapy

a) Venlafaxine extended-release (XR) was as effective as paroxetine in the treatment of patients wi study, patients (n=150) with OCD and a score of at least 18 (or at least 12, if only obsessions or onl received either venlafaxine XR (initial, 75 milligrams (mg)/day, titrated to 300 mg/day by week 7) or Both paroxetine and venlafaxine XR treatments were effective, producing mean reductions of 7.8 ar decrease in the total Y-BOCS score from baseline was seen at week 3 for venlafaxine XR-treated p no significant differences in responder rates between treatment groups. In the venlafaxine XR group Similarly, in the paroxetine group, 44% and 22% of patients were partial responders and full respon treatments with regard to reduction of anxious or depressive symptoms (as measured by the Hamilt treatments, most adverse effects were of mild or moderate severity and included somnolence, swea

2) Crossover Therapy

a) Patients with obsessive-compulsive disorder (OCD) refractory to initial treatment with a selective a double-blind switch study, patients (n=150) with primary OCD received venlafaxine (titrated to 300 responders (n=43) were switched to the opposite therapy (venlafaxine, n=16; paroxetine, n=27) for a was defined as a reduction in the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) below 25%. (week 16) to endpoint, however the score was significantly reduced in paroxetine-treated patients (p statistically superior as compared with venlafaxine (p=0.017). The response rate during phase II of t group and a 56% (15/27) response rate in the paroxetine group (p=0.01). At the end of both phases between treatment groups including somnolence, sweating, headache, constipation, insomnia, naus

b) Venlafaxine was effective in the treatment of obsessive-compulsive disorder in a 28-year-old ma resulted in sedation, nausea, and dry mouth. A 3-week course of paroxetine 20 mg/d was discontinu anxiety, and agitation. Venlafaxine 25 mg 3 times daily was initiated and titrated up to 75 mg 3 times 24 to 7. Ten months later the patient was still responding well.

c) Venlafaxine may be useful in the treatment of obsessive-compulsive disorder. In one case report compulsive disorder refractory to amitriptyline, fluoxetine, and clomipramine was treated with venlafa baseline NIMH Global Obsessive-Compulsive Scale score was 12. At 4 weeks, there was significan dose of venlafaxine was increased to 375 mg/day over the next week; continued improvement in ob weeks (NIMH score=4). At that time, the patient requested discontinuation of venlafaxine due to per NIMH score went back to 12 (Zajecka et al, 1990).

4.5.A.15 Panic disorder, With or without agoraphobia

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes (extended-release capsule only); Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Venlafaxine hydrochloride extended-release capsules are indicated for the treatment of panic disord extended-release oral capsules, 2008).

Results of a double-blind, randomized, controlled trial (n=664) comparing venlafaxine extended-rele

demonstrated greater improvement with venlafaxine XR and paroxetine than with placebo (Pollack e

c) Adult:

1) Results of a double-blind, randomized, controlled trial which compared venlafaxine extended-release greater improvement with venlafaxine XR and paroxetine than with placebo. Although paroxetine was inc placebo only. Nondepressed outpatients with a diagnosis of panic disorder with or without agoraphobia v median full-symptom panic attacks, 6), venlafaxine XR 150 mg/day (n=168; baseline median full-sympto attacks, 6), or placebo (n=163; baseline median full-symptom panic attacks, 6.1) orally for 12 weeks. The attacks in the last observation carried forward (LOCF) end point analysis, which was assessed using the Panic Disorder Severity Scale, Clinical Global Impressions-Severity (CGI-S) and -Improvement (CGI-I) s (no full-symptom panic attacks on the PAAS and CGI-S scores of 1 (not at all ill) or 2 (borderline ill). Res that patients who received venlafaxine XR or paroxetine experienced significantly greater improvement c groups had a significantly higher percentage of patients (p less than 0.001 for each active treatment grou study endpoint compared with the placebo group (venlafaxine XR 75 mg, 54.4%; venlafaxine XR 150 mg full-symptom panic attacks was also significantly greater in the three active treatment groups compared t venlafaxine XR 150 mg, (-6.5) p less than or equal to 0.001, paroxetine, (-6) p less than or equal to 0.01) in Panic Disorder Severity Scale total score compared with placebo at week 12 (p less than 0.001 for ea patients who responded to active treatments were 76.6% (venlafaxine XR 75 mg), 79.2% (venlafaxine X less than 0.001 for all three active treatment groups relative to placebo). The percentage of patients who mg), 43.4%% (venlafaxine XR 150 mg), and 44.4% (paroxetine) compared with 23.7% of patients receiv Adverse events were mild or moderate and similar between treatment groups. The most common advers tremor (Pollack et al, 2007).

2) In 2 double-blind, multicenter, placebo-controlled studies, venlafaxine hydrochloride extended-release patients with panic disorder. The 12-week studies included adult outpatients who met DSM-IV criteria for venlafaxine (75 or 150 milligrams (mg)/day in one study and 75 or 225 mg/day in the other study) or plac free of full-symptom panic attacks on the Panic and Anticipatory Anxiety Scale (PAAS); the mean change the percentage of patients who were much or very much improved (rated as responders) on the Clinical venlafaxine than with placebo. A dose-response relationship was not established in these fixed-dose stu phase study with venlafaxine extended-release capsules (75 to 225 mg/day) were randomly assigned to defined as having 2 or more full-symptom panic attacks per week for 2 consecutive weeks or discontinua average for 34 days. Results from the randomized phase indicated that patients who continued to receiv extended-release oral capsules, 2008).

4.5.A.16 Posttraumatic stress disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Venlafaxine extended-release was somewhat effective and well tolerated for the treatment of posttra controlled trial (n=538) (Davidson et al, 2006) and a 6-month, double-blind, randomized controlled tr

c) Adult:

The efficacy and safety of venlafaxine extended-release (XR) were demonstrated in a 6-month, double-b diagnosis of posttraumatic stress disorder (PTSD). Patients were included in the study if they had a scor symptoms of PTSD for at least the previous 6 months. Following a washout period of at least 1 week, pa (n=161; mean age, 42.2 years) or placebo (n=168; mean age, 40.5 years) for 24 weeks. The primary out Secondary measures included the frequency of remission (defined as 20 or less on the CAPS-SX-17), ti 224 (68%) completed the study. The mean maximum daily dose of venlafaxine XR was 221.5 mg/day. Ir 29.2 at week 24 in the venlafaxine-XR group compared with a decrease from 82.9 to 38.1 in the placebo week 24 in completers were -59.2 and -54, for venlafaxine XR and placebo, respectively, and were not s improvement from week 4 onward (last observation carried forward (LOCF). Mean LOCF change scores 0.001). Efficacy measures related to symptom cluster scores are outlined in the table:

Outcome Measure	Venlafaxine XR Baseline	Venlafaxine XR Week 24
CAPS-SX-17 cluster B (reexperiencing) score	24.6	8
CAPS-SX-17 cluster C (avoidance/numbing) score	31.8	11.5
CAPS-SX-17 cluster D (hyperarousal) score	24.6	9.8

LOCF remission rates for venlafaxine XR and placebo were 50.9% and 37.5% (p=0.01), respectively, at were 44.7% and 33.3%, respectively (p=0.04). The most commonly reported adverse effects associated weight change of at least 7% occurred more frequently in venlafaxine-treated patients (12%) than placeb

The efficacy and safety of venlafaxine extended-release (XR) were demonstrated in a 12-week, double-b diagnosis of posttraumatic stress disorder (PTSD). Patients were included in the study if they had a scor symptoms of PTSD for at least the previous 6 months. Following a washout period of at least 1 week, pa (n=179), flexible-dose sertraline (50 to 200 mg/day) (n=173), or placebo (n=179) for 12 weeks. The prim baseline in the CAPS-SX-17 score week 12. Secondary efficacy measures included changes in CAPS-S (defined as a CAPS-SX-17 score of 20 or less). Of the 538 patients randomized, 531 received treatment venlafaxine XR was 224.6 mg compared with 151.4 mg for sertraline. Change scores for the primary out (LOCF) for venlafaxine and placebo are summarized in the table below. The magnitude of the difference to both primary and secondary efficacy values was minimal and clinically insignificant.

	Mean Change From Baseline (95% Confidence Interval)	
CAPS-SX-17 Outcome Measure	Venlafaxine XR	Pla
Total Score	-41.51	-3
Reexperiencing Cluster Score	-12.54	-1
Avoidance Cluster Score	-16.99	-1
Hyperarousal Cluster Score	-11.57	-9

Remission rates at week 12 were 30.2% for venlafaxine XR and 19.6% for placebo (p less than 0.05). Ve adverse effects being headache (29%), nausea (24%), and dry mouth (18%) (Davidson et al, 2006).

4.5.A.17 Premenstrual dysphoric disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Venlafaxine was superior to placebo for alleviation of premenstrual dysphoric disorder symptoms du

c) Adult:

1) Venlafaxine was superior to placebo for alleviation of symptoms associated with premenstrual dysph dysphoric disorder (renamed PMDD in DSM-IV) after 3 levels of screening were randomly assigned to re cycles. The initial dose of venlafaxine was 25 milligrams (mg) twice daily. In the absence of response, th 200 mg daily. Data from 143 women were used in the efficacy analysis. The mean doses of venlafaxine cycle, venlafaxine was associated with a 42% decrease in symptoms, as assessed by the Daily Symptor the second cycle and thereafter, decrease from baseline was 57% for venlafaxine and 31% for placebo. symptoms. There was no difference between venlafaxine and placebo in effect on appetite. The rate of r venlafaxine group and 35% in the placebo group (p=0.003). There were no serious adverse effects. The from 36% in the first cycle to 15% in the second cycle; insomnia; dizziness; and decreased libido (Freem

4.5.A.18 Recurrent major depressive episodes; Prophylaxis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Results from the Prevention of Recurrent Episodes of Depression with Venlafaxine for Two Years (P (ER) was effective in preventing recurrence of depression in patients who had been successfully tre maintenance (1 or 2 years) therapy (Keller et al, 2007a; Kocsis et al, 2007; Keller et al, 2007).

c) Adult:

1) Results of the double-blind, randomized PREVENT (Prevention of Recurrent Episodes of Depression (ER) was effective for the prevention of recurrent depressive episodes when given as long-term mainten depressive symptoms for at least 1 month prior to the start of the study and a score of at least 18 on the randomized to venlafaxine ER 75 to 300 milligrams (mg) per day (n=821) or fluoxetine 20 to 60 mg per d 37.5 mg per day or fluoxetine 10 mg per day and titrated based on response and tolerability. Patients wh 50% or more) or remission (defined as HDRS score of 7 or less), remained on double-blind venlafaxine E responders after the continuation phase were then enrolled into 2 consecutive 12-month maintenance ph acute and continuation phases, while overall the study was powered for the primary endpoint of time to r reduction from acute phase baseline that was not more than 50% at 2 consecutive visits or at last valid v reduction in HDRS score from acute phase baseline) in the maintenance phase for venlafaxine ER comp fluoxetine-treated patients being more severely depressed in the acute phase than venlafaxine-treated p venlafaxine ER and fluoxetine was 79% while remission rates were 49% and 50%, respectively (p=0.719

differences between treatment groups at end point with regard to the proportion of patients who maintain response rates for venlafaxine ER and fluoxetine at the end of the continuation phase were 90% and 92% overall comparison). Venlafaxine ER responders after the 6-month continuation phase were then randon placebo, while fluoxetine responders continued taking fluoxetine during the first one-year maintenance p 129 patients receiving venlafaxine ER and 129 patients receiving placebo. At study endpoint, venlafaxine and secondary definitions of recurrence (p=0.005 and p less than 0.001, respectively). The probability of confidence interval (CI), 31.8 to 52.2%) and 23.1% for venlafaxine ER (95% CI, 15.3 to 30.9%) (p=0.005 enrolled in another 12-month maintenance phase, and venlafaxine responders were randomized to venla responders continued taking fluoxetine. Placebo responders continued to receive placebo in the second longer time to recurrence compared with placebo (p less than 0.001). The probability of recurrence at mo 0 to 16.8%) (p less than 0.001). The rate of response or remission at 12 months was also significantly hi respectively; p=0.002) (Keller et al, 2007a; Kocsis et al, 2007; Keller et al, 2007).

4.5.A.19 Severe major depression with psychotic features

See Drug Consult reference: PSYCHOTIC DEPRESSION - DRUG THERAPY

4.5.A.20 Social phobia

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes (extended-release capsule and tablet only); Pediatric, no
Efficacy: Adult, Effective; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIa; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Venlafaxine extended-release capsules and tablets are approved for treating adults with social anxie (R) extended-release oral capsules, 2008; Prod Info venlafaxine extended release oral tablets, 2008 Low-dose (75 milligram (mg)/day) and high-dose (150 to 225 mg/day) venlafaxine extended-release month, randomized, placebo-controlled trial (n=395) (Stein et al, 2005).
Results of a randomized, placebo-controlled trial (n=293) demonstrated the efficacy and safety of ve al, 2007).

c) Adult:

1) Venlafaxine extended-release (XR) was safe and effective for the treatment of generalized social anx outpatients (n=395; mean age, approximately 37 years) diagnosed with GSAD as defined by DSM-IV we flexible higher dose of venlafaxine XR 150 to 225 mg per day (n=129), or placebo (n=129) for 28 weeks. (LSAS). Some secondary efficacy measures included the proportion of responders (ie, Clinical Global Im (ie, LSAS score of 30 or less). The proportion of patients who withdrew from the study for any reason wa XR groups, respectively (p less than 0.05 for both). The final intent to treat population was 364, and the m 213.7 mg for the flexible-dose group. The adjusted mean change from baseline in the LSAS total score a 37.8 for the combined venlafaxine XR groups, and -23.5 for the placebo group (p less than 0.001 for all c placebo and venlafaxine XR-treated patients (combined and at low- and high-dose), respectively, were r venlafaxine XR-treated patients (combined and at low- and high-dose), respectively, were remitters (p le groups, the study did not find significant differences in response or remission rates between the low and associated with venlafaxine XR at a higher rate than placebo included abnormal ejaculation (12 to 18% v 12%), dry mouth (19 to 23% vs 6%), nausea (34 to 37% vs 10%), and somnolence (24 to 29% vs 14%). attempts committed suicide on day 86 of the study. There were 3 other reports of suicidal ideation or atte receiving placebo (Stein et al, 2005).

d) Pediatric:

1) Results of a randomized, placebo-controlled trial (n=293) demonstrated the efficacy and safety of ver children and adolescents. Pediatric outpatients (aged 8 to 17 years) diagnosed with SAD were randomiz milligrams (mg) orally daily and was titrated based on patient weight to a maximum dose of 225 mg daily Anxiety Scale (SAS-CA) and the Clinical Global Impression Improvement (CGI-I) score which identified r improved) or 2 (much improved) at week 16. Of the 293 patients randomized, 285 were included in the in receiving venlafaxine XR and in 27% of patients receiving placebo. The most common reason for discon mg/kilogram. The mean SAS-CA scores improved from a baseline of 64.8 +/- 10.1 to 40.6 +/- 1.25 at we group. The ITT random regression analyses indicated a statistically significant improvement associated v adjusted for baseline SAS-CA score were 56% (95% confidence interval (CI), 47% to 64%) for patients r The effect of baseline SAS-CA score was not significant (p=0.172), whereas effect of treatment was (p=0 g=0.46) and number needed to treat (n=5; 95% CI, 3 to 13) indicate a moderately clinically meaningful b were more common than with placebo included asthenia (20% vs 9%; p=0.012), anorexia (22% vs 3%; p mild to moderate and most often resolved with continued therapy. Discontinuation of treatment due to ad respectively. There were 3 cases of suicidal ideation in patients receiving venlafaxine (two during treatm no suicides or suicide attempts reported during the study period (March et al, 2007).

4.5.A.21 Tension-type headache; Prophylaxis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy

Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Treatment with venlafaxine extended-release resulted in less days with tension-type headache whe
et al, 2007).

c) Adult:
1) Results of a prospective, double-blind, randomized controlled trial demonstrated the efficacy and safe
(TTH) in outpatients (n=60) without a current diagnosis of depression or anxiety disorders or a history of
orally daily for 12 weeks. The dose of venlafaxine XR was 75 milligrams (mg) daily for 1 week and then
variable was the number of days with headache as assessed using patients' diaries. Diary completion ra

Bupropion

Buspirone

Clomipramine

Duloxetine

Fluoxetine

Imipramine

Medroxyprogesterone Acetate

Mirtazapine

Paroxetine

Pregabalin

Sertraline

Trazodone

4.6.A Bupropion

4.6.A.1 Bipolar disorder, depressed phase

a) There were no significant differences between bupropion, sertraline, and venlafaxine with regard to respo
switching into hypomania or mania was significantly higher with venlafaxine compared with bupropion and se
outpatients diagnosed with bipolar depression. All patients were receiving at least one mood stabilizer with in
bupropion 75 to 450 milligrams (mg)/day (n=51), sertraline 50 to 200 mg/day (n=58), or venlafaxine 37.5 to 3
Depression Symptomatology (IDS), the Young Mania Rating Scale (YMRS), and the Clinical Global Impressi
antidepressant response (defined as either a 50% or greater improvement in IDS score or a decrease of at le
IDS score less than 12 and/or a CGI-BP depression score of 1 at study endpoint), and antidepressant-relatec
score during any point of the trial or a CGI-BP manic severity score of 3 or more or a YMRS score above 13
were 49%, 53%, and 51%, respectively, while remission rates were 41%, 36%, and 34%, respectively. Differe
reported. Controlling for lithium use did not alter the results. Based on CGI-BP score, switching to mania or h
and sertraline (9%; p less than 0.01 overall). During post hoc analysis, it was demonstrated that the switch ef
venlafaxine and sertraline (p=0.01, adjusted for lithium) and bupropion (p less than 0.01, adjusted for lithium)

Based on YMRS score, switching occurred in 4%, 7%, and 15% of patients receiving bupropion, sertraline, a (31%) and bupropion (14%) and sertraline (16%) treatment groups remained significant when the combinatio for lithium; p=0.02 when controlled for lithium). Post hoc analysis results again showed that the difference wa history of rapid cycling was also higher with venlafaxine (43%) compared to bupropion (14%) and sertraline (for any reason were 31%, 41%, and 45% in the bupropion, sertraline and venlafaxine groups, respectively (P

4.6.B Buspirone

4.6.B.1 Generalized anxiety disorder

a) One small study suggests that venlafaxine could be an alternative to buspirone in patients with generalize of GAD received venlafaxine XR 75 milligrams (mg)/day (n=4), venlafaxine XR 150 mg/day (n=4), buspirone than 50% decline on the Hamilton Anxiety Scale. Improvement was seen in 2 venlafaxine 75 mg patients, 2 v size, no specific conclusions could be made (Rolland et al, 2000).

b) Venlafaxine XR was useful for treating generalized anxiety disorder (GAD); for many efficacy measures, i diagnosed by DSM-IV criteria were randomly assigned to blinded treatment with placebo, buspirone 30 millig treatment was titrated over 1 week. At study conclusion, the Hamilton Rating Scale for Anxiety (HAM-A) scor the HAM-A psychic anxiety, HAM-A anxious mood, and HAM-A tension scores were significantly lower for ve placebo and buspirone for selected weeks on the Clinical Global Impressions-Severity of Illness scale (CGI-S 10%, 22%, 28%, and 15% of patients treated with placebo, venlafaxine XR 75 mg, venlafaxine XR 150 mg, a

4.6.C Clomipramine

4.6.C.1 Depression

a) Venlafaxine 105 milligrams/day (average dose) tended to be more effective than clomipramine 105 milligr patients; however, the difference was not statistically significant (Holliday & Benfield, 1995b). Patients were a Rating Scale, and the Clinical Global Impressions scale. Venlafaxine was associated with fewer anticholinerg

4.6.D Duloxetine

4.6.D.1 Major depressive disorder

a) A meta-analysis of published, peer-reviewed, randomized, placebo-controlled, double-blind trials found th to placebo in remission and response rates for major depressive disorder and although there was a trend in f compared to duloxetine. A systematic literature search of Cochrane, EMBASE, and MEDLINE (1996 to Janua evaluate efficacy (n=1754) and discontinuation/safety (n=1791). Patients had a one week placebo lead-in per to 225 mg per day for a minimum of 8 weeks. The primary outcomes were remission and response rates. Re (HAM-D) score to less than or equal to 7 or to a Montgomery-Asberg Depression Rating Scale (MADRS) sco baseline in either the HAM-D or MADRS scores. The secondary outcomes evaluated were dropout rates and venlafaxine XR and were statistically significant compared to placebo (both p less than 0.001). No significant XR were compared. Patients receiving placebo had a higher dropout rate due to lack of efficacy compared to patients in the active drug treatment groups dropped out due to adverse effects compared to placebo (duloxe XR were compared, no statistically significant differences were found for dropout rates due to lack of efficacy A sensitivity analysis was also performed and included 2 additional studies, one study for venlafaxine XR dea with comorbid pain. Adding the 2 studies demonstrated similar results with both drugs having a statistically si

Outcome	Active Drug	Active Drug vs Placebo

	venlafaxine XR	-0.107	-0.151 to -0.064	<0.001
ADRs = adverse drug reactions; XR = extended release; CI = confidence interval				
(a) The rate when meta-analytic rate of placebo is subtracted from the active drug rate.				
(b) Corresponding p value of the difference rate calculated with a Z-test.				
(c) Negative difference rates indicate a larger effect for placebo.				

4.6.E Fluoxetine

Depression

Mixed anxiety and depressive disorder

4.6.E.1 Depression

a) Analysis of pooled data from 8 randomized, double-blind studies (n=2045) showed a remission rate of dep (SSRIs), and 25% with placebo. Remission was defined as a total score of 7 or less on the 17-item Hamilton effective than SSRIs from 2 weeks onward and from placebo from 3 weeks onward. The end-of-therapy remi ratio for remission was 1.5, in favor of venlafaxine over SSRIs (Thase et al, 2001).

b) Venlafaxine and fluoxetine had similar efficacy in the treatment of major depression in an 8 week, double- 37.5 milligrams (mg) twice daily, and 186 patients were randomized to receive fluoxetine 20 mg daily. If patie 75 mg twice daily and fluoxetine to 20 mg twice daily. Primary outcome measures were scores on the Hamilt Scale (MADRS), the Clinical Global Impressions Severity of Illness Score (CGI-S), and the Clinical Global Im scores improved significantly after 8 weeks of therapy. CGI-I scores were also improved, 80.6% of patients s fluoxetine. Remission rates were equivalent in both groups, 60.2%, as determined by scores of 8 or less on t number of patients that required a dosage increase, fluoxetine (n=54) and venlafaxine (n=43). After treatmen greater in the venlafaxine group than the fluoxetine group. The frequency of adverse events associated with and tolerability between venlafaxine and fluoxetine (Cost e Silva, 1998).

c) Venlafaxine was effective in the treatment of major depression in an 8-week, open-label, comparative trial milligrams (mg) twice daily; 55 received fluoxetine 20 mg daily. If after 15 days of treatment response was ina daily. Both medications were significantly effective in treating major depression, as determined by improveme Asberg Depression Rating Scale (MADRS), and the Clinical Global Impressions Scale (CGI). There were no existed in patients requiring higher doses of venlafaxine than fluoxetine. Patients treated with venlafaxine we (Diaz-Martinez et al, 1998).

d) Venlafaxine 200 mg/day for 4 weeks tended to be more effective than fluoxetine 40 mg/day in the treatme significant by the end of the 6-week study period (Holliday & Benfield, 1995c). Patients were assessed using and the Clinical Global Impressions scale. The incidence of adverse effects was similar for both groups.

4.6.E.2 Mixed anxiety and depressive disorder

a) Extended release (XR) venlafaxine was more effective than placebo for improving the symptoms of depre anxiety disorder (GAD). However, time to response was greater in patients with comorbidity than in patients v better than placebo in patients with comorbidity. From the data of all the patients meeting DSM-IV criteria for subset of patients who had comorbid GAD (n=92) were analyzed separately and compared to results of the r (mg), fluoxetine 20 mg, or placebo for 12 weeks. Doses could be increased to a maximum of 225 mg for venl (from baseline) in the Hamilton-Depression (HAM-D) and Hamilton- Anxiety (HAM-A) scores, improvement w of treatment. There was a similar trend with fluoxetine, but at no time was fluoxetine statistically superior to pl however, overall, there was no evident trend for a placebo- drug difference until after the eighth week of treat as early as week 2. By week 12, response rate was 66% on HAM-D and 59% on HAM-A for those taking ven placebo (Silverstone & Salinas, 2001).

4.6.E.3 Adverse Effects

a) During a randomized, double-blind trial of elderly patients with major depression, the rate of study disconti venlafaxine (27%) compared with patients receiving placebo (9%; p=0.0017) but there were no significant diff (p=0.0666) or when fluoxetine was compared to venlafaxine (p=0.1838). Elderly patients (mean age, 71 year fluoxetine (n=100), or placebo (n=96) for 8 weeks. The dose of venlafaxine was titrated from 37.5 to 225 milli 29-day period. The most frequently reported adverse events in the venlafaxine and fluoxetine groups were na adverse events most frequently reported in the placebo group were headache (22%) and dry mouth (15%) (S

4.6.F Imipramine

4.6.F.1 Depression

a) Venlafaxine and imipramine resulted in similar improvement in depression with melancholia in hospitalize on 1 test (Benkert et al, 1996). Over 5 days, the dose of venlafaxine was rapidly increased from 75 to 375 mi mg/day. The dose of imipramine was increased from 50 to 200 mg/day over 5 days and was continued at this Montgomery-Asberg Depression Rating Scale (MADRS), but for the 21-item Hamilton Rating Scale for Depre (p=0.036). Adverse effects were reported in 69% and 76% of patients treated with venlafaxine and imipramin for imipramine (p less than 0.05) and nausea for venlafaxine (p=0.011). While this study enrolled 167 patients Additional studies are needed to provide conclusive evidence for a more rapid onset of effect with venlafaxine

b) Venlafaxine was found to have antidepressant efficacy comparable to imipramine in outpatients with mod double-blind placebo controlled study in 224 outpatients with depression of moderate to marked severity. Bas Rating Scale for Depression (HAM-D), the Montgomery-Asberg Depression Rating Scale (MADRS), the Clini daily dose of venlafaxine was 182 mg +/- 48 milligrams and the mean maximal total daily dose of imipramine times a day schedule after meals. Venlafaxine showed a significant clinical advantage over imipramine at the to the higher attrition rate for imipramine as compared to venlafaxine. Attrition rates due to adverse effects we mouth, and dizziness were the most prominently reported adverse effects for venlafazine (Schweizer et al, 19

4.6.G Medroxyprogesterone Acetate

4.6.G.1 Hot sweats

a) Single dose medroxyprogesterone acetate (MPA) significantly reduces hot flashes compared to venlafaxi old versus those older than 50), current tamoxifen and raloxifene use, duration of hot flash symptoms (less th flashes per day (two to three versus four to nine or more). Patients were then randomized to receive either ve

MPA 400 mg intramuscularly (IM) for one dose or MPA 500 mg IM at 2 week intervals for three total doses. T
this arm due to unexpectedly slow accrual rate. The completed study analysis refers mainly to the two major
and severity at 1 week of baseline and throughout the 6 week treatment period. After 6 weeks, if patients wer
randomized to MPA). Nurses contacted patients monthly for the next 5 months and then every other month fo
about the average number of mild, moderate, or severe hot flashes they were experiencing per day. At the er
baseline with MPA compared with 53% (n=94) in the venlafaxine group (p<0.0001). No hot flashes were repo
treatment week (p=<0.0001). During the first treatment week, venlafaxine group had significantly more nause
dryness (p=.01) and sleepiness (p=.02) in comparison to the MPA group. As measured by patient diaries and
symptom differences between the two study groups include constipation, hot flash distress and abnormal swe

4.6.H Mirtazapine

4.6.H.1 Major depression, melancholic type

a) Mirtazapine and venlafaxine both were effective in alleviating symptoms of depression in hospitalized pati
be superior with respect to both efficacy and dropout rate due to adverse reactions. In a randomized, double-
(mg)/day and increasing rapidly to as high as 60 mg/day, or venlafaxine, starting at 75 mg/day and increasing
Depression Rating Scale (MADRS) and the Hamilton Rating Scale for Depression (HAM-D-17) improved for b
mirtazapine, although differences were not statistically significant. Sleep disturbances improved more with mi
treated patients (74.4%) than venlafaxine-treated patients (65.8%) reported at least one adverse reaction. Ho
because of adverse events (15.3% vs 5.1%, p=0.037). The most common adverse events in the mirtazapine
sleepiness (7.7%), and nausea (6.4%). In the venlafaxine group, most common were increased sweating (19
(6.3%), and decreased salivation (6.3%) (Guelfi et al, 2001).

4.6.I Paroxetine

Bipolar disorder, depressed phase

Obsessive-compulsive disorder

4.6.I.1 Bipolar disorder, depressed phase

a) Paroxetine and venlafaxine had similar efficacy in the treatment of depression in bipolar patients taking co
week study demonstrated that paroxetine and venlafaxine produced responses in 43% and 48% of the patien
improvement in the Hamilton Rating Scale for Depression (HAM-D) and the Clinical Global Impressions (CGI
and -9.0 for the venlafaxine group. These responses were significantly different compared to baseline, but no
the HAM-D, the Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth
All patients were being treated with 1 or more mood stabilizers for at least 6 months prior to onset of the curre
medication for at least 3 months prior to the start of the study. During the study, doses were adjusted for effic
which could be increased in increments of 75 mg per day (mg/d) every week. The starting dose of paroxetine
doses of venlafaxine and paroxetine were 179 mg/d and 32 mg/d, respectively. There were no significant diff
common adverse events were nausea (20% of all patients), and dizziness (8.3% of all patients). One patient
(13%) in the venlafaxine group switched to either hypomania (2 patients) or full mania (2 patients). Limitations
placebo group, a single-blind study design, and a short follow up period (Vieta et al, 2002).

4.6.I.2 Obsessive-compulsive disorder

a) Venlafaxine extended-release (XR) was as effective as paroxetine in the treatment of patients with obsess
patients (n=150) with OCD and a score of at least 18 (or at least 12, if only obsessions or only compulsions w
venlafaxine XR (initial, 75 milligrams (mg)/day, titrated to 300 mg/day by week 7) or paroxetine (initial, 15 mill
venlafaxine XR treatments were effective, producing mean reductions of 7.8 and 7.2 points, respectively, in th
score from baseline was seen at week 3 for venlafaxine XR- treated patients (p=0.008) and at week 5 for pat
rates between treatment groups. In the venlafaxine XR group, 37% and 25% of patients were partial respond
patients were partial responders and full responders, respectively. Additionally, no significant differences wer
symptoms (as measured by the Hamilton Anxiety Scale and the Hamilton Rating Scale for Depression, respe
included somnolence, sweating, insomnia, and nausea (Denys et al, 2003).

4.6.J Pregabalin

4.6.J.1 Generalized anxiety disorder

a) In a multicenter, randomized, double-blind, placebo-controlled, parallel-group study (n=374), treatment wit
compared with placebo in patients with generalized anxiety disorder (GAD). Patients who were 18 to 65 years
A) score of 20 or greater (with a HAM-A psychic and somatic anxiety factors score of 10 or greater) were elig
randomized to receive 8 weeks of oral pregabalin (150 milligrams (mg) twice daily for the first week then titrat
mg/day for the first week than titrated to a dose range of 75 to 225 mg/day administered in the morning with n
pregabalin arm but not the venlafaxine-XR arm had a significant improvement in least squares (LS) mean cha
treatment with pregabalin significantly improved some secondary investigator-rated efficacy measures includi
scale, and the Hamilton Depression Rating Scale (HAM-D) compared to placebo while treatment with venlafa

significantly improved LS mean change HAM-A total scores compared with venlafaxine-XR (p=0.008) or plac
patients (9.1%) compared with venlafaxine-XR-treated patients (20%) (Kasper et al, 2009).

Table 1			
	Pregabalin (n=121)		Venlafaxine
	LS mean +/- SE	p-value	LS mean +/- SE
HAM-A total score (primary endpoint)			
Baseline	27.6 +/- 0.4	0.028	27.4 +/- 0.4
Endpoint change	-14.5 +/- 0.9		-12 +/- 0.9

venlafaxine (60.9%) arms compared with placebo (42%; all p less than or equal to 0.04). Treatment was well
commonly reported adverse events in the pregabalin arms and nausea, dizziness, and asthenia being the mo
were lower in the pregabalin 400 mg/day group (6.2%) compared with venlafaxine (20.4%; p less than 0.01) a

4.6.K Sertraline

Bipolar disorder, depressed phase

Depression

Depression, Elderly

4.6.K.1 Bipolar disorder, depressed phase

a) There were no significant differences between bupropion, sertraline, and venlafaxine with regard to respo switching into hypomania or mania was significantly higher with venlafaxine compared with bupropion and se outpatients diagnosed with bipolar depression. All patients were receiving at least one mood stabilizer with in bupropion 75 to 450 milligrams (mg)/day (n=51), sertraline 50 to 200 mg/day (n=58), or venlafaxine 37.5 to 3 Depression Symptomatology (IDS), the Young Mania Rating Scale (YMRS), and the Clinical Global Impressi antidepressant response (defined as either a 50% or greater improvement in IDS score or a decrease of at le IDS score less than 12 and/or a CGI-BP depression score of 1 at study endpoint), and antidepressant-relatec score during any point of the trial or a CGI-BP manic severity score of 3 or more or a YMRS score above 13 were 49%, 53%, and 51%, respectively, while remission rates were 41%, 36%, and 34%, respectively. Differe reported. Controlling for lithium use did not alter the results. Based on CGI-BP score, switching to mania or h and sertraline (9%; p less than 0.01 overall). During post hoc analysis, it was demonstrated that the switch ef venlafaxine and sertraline (p=0.01, adjusted for lithium) and bupropion (p less than 0.01, adjusted for lithium) Based on YMRS score, switching occurred in 4%, 7%, and 15% of patients receiving bupropion, sertraline, a (31%) and bupropion (14%) and sertraline (16%) treatment groups remained significant when the combinatio for lithium; p=0.02 when controlled for lithium). Post hoc analysis results again showed that the difference wa history of rapid cycling was also higher with venlafaxine (43%) compared to bupropion (14%) and sertraline (for any reason were 31%, 41%, and 45% in the bupropion, sertraline and venlafaxine groups, respectively (P

4.6.K.2 Depression

a) An 8-week, randomized, double-blind, active-control study of outpatient adults with major depressive diso not significantly different than that of venlafaxine XR (n=76). Patients were randomized to receive capsules c to 3 capsules/day. Primary outcome measure was the change in Quality of Life Enjoyment and Satisfaction C endpoint (8-weeks). Secondary outcome measures were the changes from baseline to endpoint in the scores Impressions - Severity of Illness scale (CGI-S), the Clinical Global Impressions - Improvement scale (CGI-I), 1 (very much improved) or 2 (much improved) on the CGI-I scale, or a reduction of HAM-D-17 score by at lea less. There were no significant differences between study groups with any outcome measures, including rem most common reported adverse effects during active treatment (10% or greater occurrence) were diarrhea, h scores, response rates, and remission rates for the outcome measures (Shelton et al, 2006):

	Endpoint Scores, Response Rates and Remiss
Measure/Sample	Sertraline (n=82)
Q-LES-Q score, mean (SD)	0.69 (0.12)
HAM-D-17 score, mean (SD)	10.8 (6.4)
HAM-D-17 response rate, (N/N)	55%(45/82)
HAM-D-17 remission rate, (N/N)	38% (31/82)
CGI-S score, mean (SD)	2.6 (1.1)
CGI-I score, mean (SD)	2.3 (1.1)
HAM-A score, mean (SD)	9.1 (5.4)
CGI-I = Clinical Global Impressions-Improvement scale; CGI-S = Clinical Global Impressions-Severity of Rating Scale for Depression; Q-LES-Q = Quality of Life Enjoyment and Satisfaction Questionnaire; XR =	

b) In patients with major depressive disorder, almost twice as many experienced a remission with venlafaxin depressive disorder randomly received venlafaxine 37.5 mg twice daily (n=75) or sertraline 50 mg daily (n=72 or the sertraline increased to 50 mg twice daily on day 15. After 8 weeks, patients in both groups showed sig Montgomery- Asberg Depression Rating Scale (p less than 0.05). In the venlafaxine group 83% were respon the venlafaxine group and in 45% of the sertraline group (p=0.008). The most common adverse events were with sertraline (Mehtonen et al, 2000).

4.6.K.3 Depression, Elderly

a) Treatment with venlafaxine had a lower tolerability, but was equally effective to sertraline therapy in elderl study, fifty-two elderly patients (mean age, 82.5 years) with depression received either sertraline (initial, 25 m mg/day, titrated to 150 mg/day) for 10 weeks. No significant differences were found in Hamilton Rating Scale groups. However, early termination and withdrawal rates due to serious adverse events were higher in venlaf tract infection, cerebrovascular accident, hypertension, decreased renal function, rapid atrial fibrillation, anem were observed in both treatment groups. From baseline to endpoint, heart rate increased in the venlafaxine g bpm to 70.9 bpm, respectively). The authors suggest that the lowered tolerability of venlafaxine may be relate

4.6.L Trazodone

4.6.L.1 Depression

a) Venlafaxine produced antidepressant efficacy comparable to trazodone in a double-blind, placebo controll milligrams (mg) per day, trazodone (mean = 300 mg/day) or placebo. Response rates were 72%, 60% and 5 cognitive disturbance and retardation factor as evidenced on the Hamilton Rating Scale for Depression (HAM Nausea was more common in the venlafaxine group compared to dizziness and somnolence in the trazodone

DRUGDEX® Evaluations

DEXMETHYLPHENIDATE

0.0 Overview

1) Class
- **a)** This drug is a member of the following class(es):
  - Amphetamine Related
  - CNS Stimulant

2) Dosing Information
- **a)** Dexmethylphenidate Hydrochloride
  - **1)** Adult
    - **a)** Attention deficit hyperactivity disorder
      - **1)** extended-release: methylphenidate-naive patients, initial 10 mg ORALLY daily in the morning; adjust dose weekly in 10 mg increments; MAX 20 mg/day
      - **2)** extended-release: patients currently using methylphenidate, one-half the total daily dose of racemic methylphenidate; patients currently using dexmethylphenidate immediate-release may be switched to the same daily dose of dexmethylphenidate extended-release; MAX 20 mg/day
  - **2)** Pediatric
    - **a)** safety and efficacy not established in patients under 6 years of age
      - **1)** Attention deficit hyperactivity disorder
        - **a)** immediate-release (ages 6 years and older): methylphenidate-naive patients, initial 2.5 mg ORALLY twice daily; adjust dose weekly in 2.5 to 5 mg increments; MAX 20 mg/day (10 mg twice a day)
        - **b)** immediate-release (ages 6 years and older): patients currently using methylphenidate, one-half the dose of racemic methylphenidate; MAX 20 mg/day (10 mg twice a day)
        - **c)** extended-release (ages 6 years and older): methylphenidate-naive patients, initial 5 mg ORALLY in the morning; adjust dose weekly in 5 mg increments; MAX 20 mg/day(Prod Info FOCALIN XR(R) extended-release oral capsules, 2008)
        - **d)** extended-release (ages 6 years and older): patients currently using methylphenidate, one-half the total daily dose of racemic methylphenidate; patients currently using immediate release dexmethylphenidate may be switched to the same daily dose of dexmethylphenidate extended release (Prod Info FOCALIN XR(R) extended-release oral capsules, 2008)

3) Contraindications
- **a)** Dexmethylphenidate Hydrochloride
  - **1)** agitation, severe; anxiety; or tension; may aggravate symptoms (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
  - **2)** glaucoma (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
  - **3)** hypersensitivity to methylphenidate or other components of the product (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
  - **4)** MAOI use within 14 days; hypertensive crisis may result (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
  - **5)** motor tics (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
  - **6)** Tourette's syndrome, family history or diagnosis of (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)

4) Serious Adverse Effects
- **a)** Dexmethylphenidate Hydrochloride
  - **1)** Mania
  - **2)** Psychotic disorder
  - **3)** Seizure

5) Clinical Applications
- **a)** Dexmethylphenidate Hydrochloride
  - **1)** FDA Approved Indications
    - **a)** Attention deficit hyperactivity disorder

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product Index)

B) Synonyms

Dexmethylphenidate
Dexmethylphenidate HCl
Dexmethylphenidate Hydrochloride

C) Physicochemical Properties

1) Molecular Weight

a) 269.77(Prod Info Focalin™, 2001a)

2) Solubility

a) Systemic: Freely soluble in water and in methanol; soluble in alcohol; slightly soluble in chloroform and in acetone (Prod Info Focalin™, 2001a)

1.2 Storage and Stability

A) Oral route

1) The US manufacturer recommends storage of dexmethylphenidate tablets and capsules at 25 degrees C (77 degrees F), with excursions permitted to 15 to 30 degrees C (59 to 86 degrees F). Tablets should be protected from moisture (Prod Info FOCALIN(TM) XR, 2005; Prod Info Focalin(TM), 2001d).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

1.3.1 Normal Dosage

1.3.1.A Dexmethylphenidate Hydrochloride

1.3.1.A.1 Oral route

1.3.1.A.1.a Attention deficit hyperactivity disorder

1) Extended-Release

a) The recommended starting dose for patients not currently taking dexmethylphenidate or racemic methylphenidate, or for patients who are on stimulants other than methylphenidate, is 10 milligrams (mg)/day in the morning. The dose may be adjusted weekly in 10 mg increments to a maximum of 20 mg/day for adult patients. The patient should be observed for a sufficient duration at a given dose to ensure that a maximal benefit has been achieved before a dose increase is considered (Prod Info FOCALIN(TM) XR, 2005).

b) For patients currently using methylphenidate, the recommended starting dose is half the total daily dose of racemic methylphenidate. Patients using immediate-release dexmethylphenidate may be switched to the same daily dose of extended-release dexmethylphenidate. Maximum recommended dose is 20 milligrams/day (Prod Info FOCALIN (TM) XR, 2005).

c) The treatment duration is unclear, however, it is generally agreed that pharmacological treatment of ADHD may be needed for extended periods. The patient should be periodically reevaluated with periods off medication to assess patient's functioning without pharmacotherapy (Prod Info FOCALIN(TM) XR, 2005).

d) If paradoxical aggravation of symptoms or other adverse events occur, the dosage should be reduced or, if necessary, the drug should be discontinued (Prod Info FOCALIN(TM) XR, 2005).

e) If improvement is not observed after appropriate dosage adjustment over a 1-month period, the drug should be discontinued (Prod Info FOCALIN(TM) XR, 2005).

1.3.2 Dosage in Renal Failure

A) Dexmethylphenidate Hydrochloride

1) Pharmacokinetic data for dexmethylphenidate in renal impairment are unavailable. However, data for racemic methylphenidate indicate that only small amounts are excreted unchanged in the urine (about 1%)

(USPDI, 2001; Prod Info Focalin(TM), 2001); thus, dose adjustments of dexmethylphenidate do not appear to be necessary in this population.

1.3.3 Dosage in Hepatic Insufficiency

A) Dexmethylphenidate Hydrochloride

1) Similar to methylphenidate, dexmethylphenidate undergoes hepatic metabolism (USPDI, 2001); (Prod Info Focalin(TM), 2001). Dose adjustment should be considered in patients with moderate or greater hepatic dysfunction. Specific guidelines for dexmethylphenidate or the racemic compound are unavailable.

1.4 Pediatric Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

1.4.1 Normal Dosage

1.4.1.A Dexmethylphenidate Hydrochloride

1.4.1.A.1 Oral route

1.4.1.A.1.a Attention deficit hyperactivity disorder

1) Immediate-Release

a) The efficacy of dexmethylphenidate has been demonstrated only in patients 6 to 17 years of age. The drug should be given twice daily, at least 4 hours apart; it can be given with or without food (Prod Info Focalin(TM), 2001).

b) In patients not currently receiving racemic methylphenidate, or for those who are on stimulants other than methylphenidate, the manufacturer recommends an initial dose of 2.5 milligrams (mg) twice daily, with dose adjustments in 2.5- to 5-mg increments to a maximum of 10 mg twice daily; dose adjustments may be undertaken at approximately weekly intervals (Prod Info Focalin(TM), 2001). An extended-release methylphenidate formulation (duration, 8 hours) may be preferable, as administration of doses during school can be eliminated; generic formulations are available.

c) For patients who are currently receiving racemic methylphenidate, the initial dose recommended by manufacturer is half the dose of methylphenidate, with a maximum daily dose of 20 mg (10 mg twice daily) (Prod Info Focalin(TM), 2001). However, available data suggest no clinical advantage in switching to the d-enantiomer.

d) The longest duration of effective treatment in clinical studies with dexmethylphenidate has been 6 weeks (Prod Info Focalin(TM), 2001). However, prolonged use may be indicated. Racemic methylphenidate has maintained improvement for up to 2 years.

2) Extended-Release

a) The recommended starting dose for patients not currently taking dexmethylphenidate or racemic methylphenidate, or for patients who are on stimulants other than methylphenidate, is 5 milligrams (mg)/day in the morning. The dose may be adjusted weekly in 5 mg increments to a maximum of 20 mg/day for pediatric patients. The patient should be observed for a sufficient duration at a given dose to ensure that a maximal benefit has been achieved before a dose increase is considered (Prod Info FOCALIN XR(R) extended-release oral capsules, 2008).

b) For patients currently using methylphenidate, the recommended starting dose is half the total daily dose of racemic methylphenidate. Patients using immediate-release dexmethylphenidate may be switched to the same daily dose of extended-release dexmethylphenidate. Maximum recommended dose is 20 milligrams/day (Prod Info FOCALIN XR(R) extended-release oral capsules, 2008).

c) The treatment duration is unclear, however, it is generally agreed that pharmacological treatment of ADHD may be needed for extended periods. The patient should be periodically reevaluated with periods off medication to assess patient's functioning without pharmacotherapy (Prod Info FOCALIN XR(R) extended-release oral capsules, 2008).

d) If paradoxical aggravation of symptoms or other adverse events occur, the dosage should be reduced or, if necessary, the drug should be discontinued (Prod Info FOCALIN XR(R) extended-release oral capsules, 2008).

e) If improvement is not observed after appropriate dosage adjustment over a 1-month period, the drug should be discontinued (Prod Info FOCALIN XR(R) extended-release oral capsules, 2008).

1.4.2 Dosage in Renal Failure

A) Dexmethylphenidate Hydrochloride

1) Pharmacokinetic data for dexmethylphenidate in renal impairment are unavailable. However, data for racemic methylphenidate indicate that only small amounts are excreted unchanged in the urine (about 1%) (USPDI, 2001; Prod Info Focalin(TM), 2001). Thus, dose adjustments of dexmethylphenidate do not appear necessary in this population.

1.4.3 Dosage in Hepatic Insufficiency

A) Dexmethylphenidate Hydrochloride

1) Similar to methylphenidate, dexmethylphenidate undergoes hepatic metabolism (USPDI, 2001; Prod Info Focalin(TM), 2001). Dose adjustment should be considered in patients with moderate or greater hepatic dysfunction. Specific guidelines for dexmethylphenidate or the racemic compound are unavailable.

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Dexmethylphenidate Hydrochloride

a) Initial Response

1) Attention-deficit hyperactivity disorder, oral extended-release tablets: 1 hour (Prod Info FOCALIN (TM) XR, 2005)

a) Value represents time to a significant treatment effect in pediatric patients after a single dose of 20 milligrams (Prod Info FOCALIN(TM) XR, 2005).

2) Attention-deficit hyperactivity disorder, oral immediate-release tablets: within 4 weeks (sustained improvement) (Anon, 2001).

a) Value represents time to significant symptom improvement during continuous twice-daily administration.

B) Duration

1) Dexmethylphenidate Hydrochloride

a) Multiple Dose

1) Attention deficit hyperactivity disorder, ORAL: up to 6.5 hours (acute effects) (Anon, 1999).

2) Attention deficit hyperactivity disorder, Oral: 12 hours in pediatric patients 6 to12 years old (Prod Info FOCALIN(TM) XR, 2005)

a) Represents interpretation of data from one unpublished study, which suggested a longer duration of action of dexmethylphenidate than racemic methylphenidate in ADHD (Anon, 1999). In this study, control of symptoms with dexmethylphenidate was seen at all time points, but there was failure of methylphenidate to control symptoms at the last measurements (5.5 to 6.5 hours postdose). However, specific time points evaluated in the study, the duration of action of methylphenidate, and statistical comparisons at these time points are not available; thus, the difference in duration between these agents in this study is unknown. In other studies, racemic methylphenidate has shown a duration of 4 to 6 hours, and the difference in durations between these agents must be small, and may not be clinically relevant. Extended-release methylphenidate is often used in ADHD, which has a longer duration than that reported for dexmethylphenidate (8 hours).

2.2 Drug Concentration Levels

A) Dexmethylphenidate Hydrochloride

1) Therapeutic Drug Concentration

a) Not established; plasma-level monitoring is not used clinically.

2) Time to Peak Concentration

a) Oral, immediate-release tablet: 1 to 1.5 hours (Prod Info Focalin™, 2001a).

1) This value is similar to that reported for racemic methylphenidate (about 2 hours).

2) Following oral doses of 2.5, 5, and 10 mg in children (as a capsule formulation), peak plasma levels and AUCs of dexmethylphenidate were proportional to the dose; plasma levels were similar to those observed after oral racemic methylphenidate 5, 10, and 20 mg (Prod Info Focalin™, 2001a).

3) No significant accumulation of dexmethylphenidate has been observed with repeated twice-daily doses compared to single doses in ADHD patients (Prod Info Focalin™, 2001a).

b) Oral, extended-release tablet: 1.5 hours (first peak) and 6.5 hours (second peak) (Prod Info FOCALIN (TM) XR, 2005).

1) The mean time to the first peak (tmax1) (1.5 hours) is similar to the tmax for the immediate-release formulation. The time to the second peak (tmax2) (6.5 hours) is slightly longer for the extended-release formulation given once-daily compared to the immediate-release formulation given in 2 doses 4 hours apart (Prod Info FOCALIN(TM) XR, 2005).

3) Area Under the Curve

a) The AUC after administration of dexmethylphenidate hydrochloride extended-release tablets given once daily is equivalent to the same total dose of dexmethylphenidate hydrochloride immediate-release tablets given in 2 doses 4 hours apart; variability in AUC is similar between the extended- and immediate-release tablets with approximately a three-fold range in each (Prod Info FOCALIN(TM) XR, 2005).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Dexmethylphenidate Hydrochloride

1) Bioavailability

a) Oral, various: mean absolute bioavailability 22 to 25% (Prod Info FOCALIN(TM) XR, 2005).

1) Dexmethylphenidate is well absorbed after oral administration with approximately 90% recovered in the urine. However, due to first-pass metabolism, the mean absolute bioavailability when administered in various formulations was 22 to 25% (Prod Info FOCALIN(TM) XR, 2005).

2) Effects of Food

a) immediate-release tablet, delayed absorption (Prod Info Focalin™, 2001a).

1) In an unpublished study, administration of dexmethylphenidate with food had no significant effect on extent of absorption compared to the fasting state (based on peak plasma levels and AUC values); however, time to peak plasma levels was prolonged when given with food (mean, 2.9 versus 1.5 hours) (Prod Info Focalin™, 2001a). Dexmethylphenidate can be given with or without food.

b) extended-release tablet, unknown (Prod Info FOCALIN(TM) XR, 2005)

1) No food effect study was performed with the extended-release formulation; administration times relative to meals and meal composition may need to be individually titrated (Prod Info FOCALIN (TM) XR, 2005).

2) Effect of food: oral, racemic methylphenidate extended release tablets, following high fat breakfast, delayed absorption and second peak concentration is approximately 25% lower. Can be administered with or without food (Prod Info FOCALIN(TM) XR, 2005).

2.3.2 Distribution

A) Distribution Sites

1) Dexmethylphenidate Hydrochloride

a) Protein Binding

1) A specific value for dexmethylphenidate is unavailable. However, protein binding of racemic methylphenidate is minimal (12 to 15%) .(Prod Info FOCALIN(TM) XR, 2005)

B) Distribution Kinetics

1) Dexmethylphenidate Hydrochloride

a) Volume of Distribution

1) 2.65 L/kg (+/- 1.1 L/kg) (Prod Info FOCALIN(TM) XR, 2005).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) Dexmethylphenidate Hydrochloride

a) LIVER, extensive (Prod Info Focalin™, 2001a).

1) The primary metabolic pathway is deesterification to the inactive metabolite d-ritalinic acid (d-alpha-phenyl piperidine acetic acid) (Prod Info Focalin™, 2001a).

2) Inhibition of cytochrome P450 isozymes was not observed with dexmethylphenidate in vitro (Prod Info Focalin™, 2001a).

3) Bioconversion to l-dexmethylphenidate is negligible (Prod Info Focalin™, 2001a) and of no

clinical consequence.

B) Metabolites

1) Dexmethylphenidate Hydrochloride

a) d-Ritalinic acid (inactive) (Prod Info Focalin™, 2001a).

2.3.4 Excretion

A) Kidney

1) Dexmethylphenidate Hydrochloride

a) Renal Clearance (rate)

1) Intravenous dexmethylphenidate was eliminated with a mean clearance of 0.56 +/- 0.18 liter/minute (Prod Info FOCALIN(TM) XR, 2005)

b) Renal Excretion (%)

1) minimal unchanged (Prod Info Focalin™, 2001a).

c) Specific renal excretion data for dexmethylphenidate are unavailable. However, approximately 90% of an oral dose of racemic methylphenidate appears in the urine, mainly as ritalinic acid (about 80%); 0.5% appears as unchanged methylphenidate following an intravenous dose (Prod Info FOCALIN(TM) XR, 2005; Prod Info Focalin™, 2001a).

2.3.5 Elimination Half-life

A) Parent Compound

1) Dexmethylphenidate Hydrochloride

a) ELIMINATION HALF-LIFE

1) approximately 3 hours (Prod Info FOCALIN(TM) XR, 2005; Prod Info Focalin™, 2001a).

a) The mean terminal elimination half-life of dexmethylphenidate was just over 3 hours in healthy adults and typically varied between 2 and 4.5 hours; children displayed shorter half-lives with means of 2 to 3 hours (Prod Info FOCALIN(TM) XR, 2005).

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING

1) Dexmethylphenidate Hydrochloride

a) Oral (Capsule, Extended Release; Tablet)

1) Dexmethylphenidate hydrochloride should be given cautiously to patients with a history of drug dependence or alcoholism. Chronic, abusive use can lead to marked tolerance and psychological dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal from abusive use since severe depression may occur. Withdrawal following chronic therapeutic use may unmask symptoms of the underlying disorder that may require follow-up (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006).

3.1 Contraindications

A) Dexmethylphenidate Hydrochloride

1) agitation, severe; anxiety; or tension; may aggravate symptoms (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)

2) glaucoma (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)

3) hypersensitivity to methylphenidate or other components of the product (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)

4) MAOI use within 14 days; hypertensive crisis may result (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)

5) motor tics (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)

6) Tourette's syndrome, family history or diagnosis of (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)

3.2 Precautions

A) Dexmethylphenidate Hydrochloride

1) cardiac abnormalities, structural; sudden death has been reported in association with CNS stimulant use(Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
2) conditions which may be compromised by increases in blood pressure or heart rate, such as pre-existing hypertension, heart failure, recent myocardial infarction, or hyperthyroidism (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
3) depression, severe; do not use to treat (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
4) drug dependence or alcoholism, history of; potential for abuse (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
5) EEG abnormalities, especially history of; may lower convulsive threshold (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
6) fatigue, normal; do not use to treat (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
7) psychosis; may exacerbate behavior disturbance and thought disorder (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)
8) seizures, especially history of; may lower convulsive threshold (Prod Info FOCALIN(TM) XR extended-release oral capsules, 2006)

3.3 Adverse Reactions

Cardiovascular Effects

Endocrine/Metabolic Effects

Gastrointestinal Effects

Hematologic Effects

Neurologic Effects

Ophthalmic Effects

Psychiatric Effects

Other

3.3.1 Cardiovascular Effects

3.3.1.A Dexmethylphenidate Hydrochloride

3.3.1.A.1 Cardiovascular finding

a) Modest increases in heart rate (up to 5 beats per minute) and systolic/diastolic blood pressure (up to 3 mmHg) have been reported during dexmethylphenidate therapy in children/adolescents with ADHD (unpublished clinical studies) (Prod Info Focalin(TM), 2001). TACHYCARDIA has rarely necessitated withdrawal of treatment (Prod Info Focalin(TM), 2001).

3.3.3 Endocrine/Metabolic Effects

3.3.3.A Dexmethylphenidate Hydrochloride

3.3.3.A.1 Metabolic finding

a) Whether prolonged use of methylphenidate (or dexmethylphenidate) can significantly limit height and body weight remains controversial. Monitoring of weight and height is indicated in preadolescent children. Early adolescent growth does not appear to be affected by methylphenidate.

3.3.4 Gastrointestinal Effects

3.3.4.A Dexmethylphenidate Hydrochloride

Abdominal pain

Loss of appetite

Nausea

3.3.4.A.1 Abdominal pain

a) Incidence: 15% (Prod Info FOCALIN(R) oral tablets, 2007)

b) In unpublished clinical-trial data for dexmethylphenidate in children/adolescents with ADHD, abdominal pain was reported at least once during treatment in 15% of patients. Incidences of these effects were at least 50% lower in placebo recipients (Prod Info FOCALIN(R) oral tablets, 2007). There is no demonstrated evidence of a lower frequency of GI effects in patients treated with dexmethylphenidate compared to racemic methylphenidate.

3.3.4.A.2 Loss of appetite

a) Incidence: 6% (Prod Info FOCALIN(R) oral tablets, 2007)

b) In unpublished clinical-trial data for dexmethylphenidate in children/adolescents with ADHD, anorexia was reported at least once during treatment in 6% of patients. Incidences of these effects were at least 50% lower in placebo recipients (Prod Info FOCALIN(R) oral tablets, 2007). There is no demonstrated evidence of a lower frequency of GI effects in patients treated with dexmethylphenidate compared to racemic methylphenidate.

3.3.4.A.3 Nausea

a) Incidence: 9% (Prod Info FOCALIN(R) oral tablets, 2007)

b) In unpublished clinical-trial data for dexmethylphenidate in children/adolescents with ADHD, nausea was reported at least once during treatment in 9% of patients. Incidences of these effects were at least 50% lower in placebo recipients (Prod Info FOCALIN(R) oral tablets, 2007). There is no demonstrated evidence of a lower frequency of GI effects in patients treated with dexmethylphenidate compared to racemic methylphenidate.

3.3.5 Hematologic Effects

3.3.5.A Dexmethylphenidate Hydrochloride

3.3.5.A.1 Hematology finding

a) Thrombocytopenia and anemia have occurred infrequently during racemic methylphenidate therapy (USPDI, 2001); (Prod Info Focalin(TM), 2001). The manufacturer of dexmethylphenidate has not disclosed the frequency of these effects in clinical trials, although this data is available from extensive premarketing safety evaluations (Prod Info Focalin(TM), 2001).

3.3.9 Neurologic Effects

3.3.9.A Dexmethylphenidate Hydrochloride

Insomnia

Spasmodic movement, Vocal or motor tics

3.3.9.A.1 Insomnia

a) Nervousness and insomnia have occurred relatively frequently with use of racemic methylphenidate in children and adolescents, and may be more common in children (USPDI, 2001); (Prod Info Focalin (TM), 2001).

b) In clinical studies specifically with dexmethylphenidate in ADHD, the manufacturer indicates that motor or vocal tics and insomnia have rarely (1%) necessitated therapy discontinuation (Prod Info Focalin(TM), 2001). However, the manufacturer has chosen not to disclose the frequency of other CNS effects in clinical trials, although this data was available from extensive premarketing safety evaluations (Prod Info Focalin(TM), 2001).

c) Although dexmethylphenidate is claimed to potentially produced fewer adverse CNS effects (eg, insomnia) than racemic methylphenidate (Anon, 2001a), this has not been demonstrated.

3.3.9.A.2 Spasmodic movement, Vocal or motor tics

a) In clinical studies specifically with dexmethylphenidate in ADHD, the manufacturer indicates that motor or vocal tics and insomnia have rarely (1%) necessitated therapy discontinuation (Prod Info Focalin(TM), 2001). However, the manufacturer has chosen not to disclose the frequency of other CNS effects in clinical trials, although this data was available from extensive premarketing safety evaluations (Prod Info Focalin(TM), 2001).

3.3.10 Ophthalmic Effects

3.3.10.A Dexmethylphenidate Hydrochloride

3.3.10.A.1 Eye / vision finding

a) Similar to racemic methylphenidate, dexmethylphenidate is capable of infrequently causing blurring of vision and other visual disturbances (USPDI, 2001); (Prod Info Focalin(TM), 2001). However, specific incidence data for these effects were not disclosed by the manufacturer of dexmethylphenidate.

3.3.12 Psychiatric Effects

3.3.12.A Dexmethylphenidate Hydrochloride

Mania

Psychotic disorder

Seizure

3.3.12.A.1 Mania

a) In a review of 49 randomized, controlled pediatric ADHD clinical trials involving pscyhostimulant medications (atomoxetine hydrochloride, methylphenidate hydrochloride, modafinil and dextromethylphenidate hydrochloride), the rate of psychosis/mania events in pediatric subjects receiving active drug was 1.48 (95% CI, 0.74 to 2.65) per 100 person-years, with no comparable adverse events recorded in the placebo group. A request from the US Food and Drug Administration to manufacturers of marketed ADHD drugs for submission of postmarketing case reports of psychosis or mania events between 2000 and 2005, yielded a total of 865 reports (pediatrics and adults) in which signs and/or symptoms of psychoses or mania were reported. The majority of reports involved pediatric subjects, with almost half of the reports in children 10 years-old or younger, and approximately 90% of cases involving no prior history of similar psychiatric conditions. Visual and/or tactile sensations of insects, snakes, or worms were commonly reported. Positive rechallenge was reported for each of the psychostimulant medications (methylphenidate hydrochloride, atomoxetine hydrochloride, and mixed salts of a single entity amphetamine product) included in the analysis; and in many cases a strong temporal association was identified. The onset of psychiatric symptoms ranged from days to weeks, but in some cases it was months or years from the start of ADHD treatment and symptom onset (Mosholder et al, 2009).

3.3.12.A.2 Psychotic disorder

a) In a review of 49 randomized, controlled pediatric ADHD clinical trials involving pscyhostimulant medications (atomoxetine hydrochloride, methylphenidate hydrochloride, modafinil and dextromethylphenidate hydrochloride), the rate of psychosis/mania events in pediatric subjects receiving active drug was 1.48 (95% CI, 0.74 to 2.65) per 100 person-years, with no comparable adverse events recorded in the placebo group. A request from the US Food and Drug Administration to manufacturers of marketed ADHD drugs for submission of postmarketing case reports of psychosis or mania events between 2000 and 2005, yielded a total of 865 reports (pediatrics and adults) in which signs and/or symptoms of psychoses or mania were reported. The majority of reports involved pediatric subjects, with almost half of the reports in children 10 years-old or younger, and approximately 90% of cases involving no prior history of similar psychiatric conditions. Visual and/or tactile sensations of insects, snakes, or worms were commonly reported. Positive rechallenge was reported for each of the psychostimulant medications (methylphenidate hydrochloride, atomoxetine hydrochloride, and mixed salts of a single entity amphetamine product) included in the analysis; and in many cases a strong temporal association was identified. The onset of psychiatric symptoms ranged from days to weeks, but in some cases it was months or years from the start of ADHD treatment and symptom onset (Mosholder et al, 2009).

b) Seizures and psychosis have occurred rarely with racemic methylphenidate (USPDI, 2001)

3.3.12.A.3 Seizure

a) Seizures and psychosis have occurred rarely with racemic methylphenidate (USPDI, 2001)

3.3.16 Other

3.3.16.A Dexmethylphenidate Hydrochloride

Drug dependence

Fever

3.3.16.A.1 Drug dependence

a) Similar to methylphenidate, both psychological and physical dependence can occur during high-dose and/or prolonged use of dexmethylphenidate. The manufacturer (Prod Info Focalin(TM), 2001) suggests only the risk of psychological dependence.

b) Slow tapering of the dose is required following long-term therapy or use of high doses to minimize withdrawal symptoms, which can include unusual tiredness, severe depression, and unusual behavior (USPDI, 2001).

3.3.16.A.2 Fever

a) In unpublished clinical-trial data for dexmethylphenidate in children/adolescents with ADHD, fever was reported at least once during treatment in 5% of patients; fever occurred in 1% of placebo recipients (Prod Info Focalin(TM), 2001).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info FOCALIN XR, 2008) (All Trimesters)

a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other) and there are no controlled studies in women or studies in women and animals are not available. Drugs should be given only if the potential benefit justifies the potential risk to the fetus.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

2) Crosses Placenta: Unknown

3) Clinical Management

a) Although a causal relationship between dexmethylphenidate and teratogenic effects have not been found, the safe use of dexmethylphenidate during pregnancy has yet to be confirmed. Until additional data are available, dexmethylphenidate should be used in pregnant women only if the benefit to the pregnant woman outweighs the potential risk to the fetus (Prod Info FOCALIN XR, 2008).

4) Literature Reports

a) No human studies of pregnancy outcomes after exposure to dexmethylphenidate have been published, and there are no reports of outcomes after inadvertent exposure during pregnancy. Adequate studies to establish safe use of dexmethylphenidate during pregnancy have not been conducted (Prod Info FOCALIN XR, 2008). One source describes a series of women (n=11) who used racemic methylphenidate (dose unspecified) during the first 4 months of pregnancy; no birth defects or other abnormalities were reported in any of the infants and all 11 were considered normal (Heinonen et al, 1977). A later report discussed the outcomes of another 38 women who used racemic methylphenidate during pregnancy (DeBooy et al, 1993). Although infants in these reports were more likely to be premature, growth retarded, and to show signs of neonatal withdrawal, no increase in congenital abnormalities was identified; however, this number is so small that no pattern or estimate of risk can be determined at this time. No teratogenicity was observed in rats and rabbits treated with dexmethylphenidate in doses up to 20 and 100 milligrams/kilogram (mg/kg) daily, respectively, during the period of organogenesis; however, delayed fetal skeletal ossification was seen at the highest dose in rats. However, doses of 200 mg/kg/day of racemic methylphenidate have produced teratogenic effects in rabbits throughout organogenesis (Prod Info FOCALIN XR, 2008).

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk when used during breastfeeding. Weigh the potential benefits of drug treatment against potential risks before prescribing this drug during breastfeeding.

2) Clinical Management

a) It is not known whether dexmethylphenidate is excreted into human breast milk and the potential for adverse effects in the nursing infant from exposure to the drug are unknown (Prod Info FOCALIN XR, 2008).

3) Literature Reports

a) Four published case reports indicate that maternal doses of racemic methylphenidate of 35 to 80 mg/day during breastfeeding resulted in milk concentrations that ranged from undetectable to 15.4 ng/mL (calculated infant daily dose approximately 0.4 to 2.9 ug/kg/day or approximately 0.2% to 0.7% of the adjusted maternal weight dose) for an exclusively breastfed infant (Prod Info FOCALIN XR, 2008).

3.5 Drug Interactions

3.5.1 Drug-Drug Combinations

Amitriptyline

Amoxapine

Brofaromine

Clomipramine

Clorgyline

Desipramine

Dicumarol

Dothiepin

Doxepin

Furazolidone

Imipramine

Iproniazid

Isocarboxazid

Lazabemide

Linezolid

Lofepramine

Moclobemide

Nialamide

Nortriptyline

Opipramol

Pargyline

Phenelzine

Phenobarbital

Phenytoin

Primidone

Procarbazine

Protriptyline

Rasagiline

Selegiline

Toloxatone

Tranylcypromine

Trimipramine

Warfarin

3.5.1.A Amitriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may occur with combined therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depression concluded that although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated little advantage of drug over placebo and did not appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.B Amoxapine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other

sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may occur with combined therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depression concluded that although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated little advantage of drug over placebo and did not appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.C Brofaromine

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.D Clomipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline

results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may occur with combined therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depression concluded that although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated little advantage of drug over placebo and did not appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.E Clorgyline

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)

2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.

7) Probable Mechanism: unknown

3.5.1.F Desipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as

high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may occur with combined therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depression concluded that although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated little advantage of drug over placebo and did not appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.G Dicumarol

1) Interaction Effect: an increased risk of bleeding
2) Summary: Dexmethylphenidate may inhibit the metabolism of coumarin anticoagulants, such as dicumarol, potentially resulting in an increased risk of bleeding. Dicumarol dosage may need to be reduced during concurrent dexmethylphenidate therapy. When initiating or discontinuing dexmethylphenidate therapy, it may be necessary to adjust the dicumarol dose and monitor coagulation times (Prod Info FOCALIN(R) XR extended-release oral capsules, 2007).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Consider reducing the dicumarol dose during concomitant dexmethylphenidate therapy due to an increased risk of bleeding. Adjust the dose as needed and monitor coagulation times when initiating or discontinuing dexmethylphenidate treatment (Prod Info FOCALIN(R) XR extended-release oral capsules, 2007).
7) Probable Mechanism: inhibition of dicumarol metabolism

3.5.1.H Dothiepin

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.P Lofepramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the

methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may occur with combined therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depression concluded that although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated little advantage of drug over placebo and did not appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.Q Moclobemide

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.R Nialamide

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.S Nortriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism

of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may occur with combined therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depression concluded that although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated little advantage of drug over placebo and did not appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.T Opipramol

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).

3.5.1.U Pargyline

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by

symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.V Phenelzine
1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.W Phenobarbital
1) Interaction Effect: increase in phenobarbital plasma concentrations
2) Summary: Pharmacologic studies have demonstrated that dexmethylphenidate may inhibit the metabolism of anticonvulsants, such as phenobarbital. Dose adjustments of phenobarbital may be necessary (Prod Info Focalin(TM), 2001c).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Downward dose adjustments of phenobarbital may be required when given concomitantly with dexmethylphenidate.
7) Probable Mechanism: inhibition of phenobarbital metabolism by dexmethylphenidate

3.5.1.X Phenytoin
1) Interaction Effect: increase in phenytoin plasma concentrations
2) Summary: Pharmacologic studies have demonstrated that dexmethylphenidate may inhibit the metabolism of anticonvulsants, such as phenytoin. Dose adjustments of phenytoin may be necessary (Prod Info Focalin(TM), 2001).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Downward dose adjustments of phenytoin may be required when given concomitantly with dexmethylphenidate.
7) Probable Mechanism: inhibition of phenytoin metabolism by dexmethylphenidate

3.5.1.Y Primidone
1) Interaction Effect: increase in primidone plasma concentrations
2) Summary: Pharmacologic studies have demonstrated that dexmethylphenidate may inhibit the metabolism of anticonvulsants, such as primidone. Dose adjustments of primidone may be necessary (Prod Info Focalin(TM), 2001a).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Downward dose adjustments of primidone may be required when given concomitantly with dexmethylphenidate.
7) Probable Mechanism: inhibition of primidone metabolism by dexmethylphenidate

3.5.1.Z Procarbazine
1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid

5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.AA Protriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may occur with combined therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depression concluded that although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated little advantage of drug over placebo and did not appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.AB Rasagiline

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.AC Selegiline

1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)

2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.AD Toloxatone
1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.AE Tranylcypromine
1) Interaction Effect: hypertensive crisis (headache, palpitation, and neck stiffness)
2) Summary: Monoamine oxidase inhibitors should not be administered with sympathomimetic drugs such as dexmethylphenidate. Coadministration may result in hypertensive crisis, which is characterized by symptoms such as headache, palpitation, neck stiffness, nausea, and vomiting. Hypertensive crisis associated with monoamine oxidase inhibitors has been fatal (Prod Info Focalin(TM), 2001b).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of monoamine oxidase inhibitors and dexmethylphenidate is contraindicated. If dexmethylphenidate is to be initiated, the monoamine oxidase inhibitor must be discontinued for a minimum of 14 days.
7) Probable Mechanism: unknown

3.5.1.AF Trimipramine
1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported to result in enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs frequently lead to moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been reported during therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympathomimetic agents could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agents. Additionally, coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism

of some tricyclic antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in blood pressure such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine given for at least four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may occur with combined therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depression concluded that although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated little advantage of drug over placebo and did not appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.AG Warfarin
1) Interaction Effect: an increased risk of bleeding
2) Summary: Dexmethylphenidate may inhibit the metabolism of coumarin anticoagulants, such as warfarin, potentially resulting in an increased risk of bleeding. Warfarin dosage may need to be reduced during concurrent dexmethylphenidate therapy. When initiating or discontinuing dexmethylphenidate therapy, it may be necessary to adjust the warfarin dose and monitor coagulation times (Prod Info FOCALIN(R) XR extended-release oral capsules, 2007).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Consider reducing the warfarin dose during concomitant dexmethylphenidate therapy due to an increased risk of bleeding. Adjust the dose as needed and monitor coagulation times when initiating or discontinuing dexmethylphenidate treatment (Prod Info FOCALIN(R) XR extended-release oral capsules, 2007).
7) Probable Mechanism: inhibition of warfarin metabolism

4.0 Clinical Applications

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters
A) Dexmethylphenidate Hydrochloride
1) Therapeutic
a) Physical Findings
1) Improvement in mental and behavioral symptoms of attention deficit hyperactivity disorder (ADHD), including inappropriate inattention, impulsivity, hyperactivity, and cognitive performance.
a) For the inattentive type of ADHD, these include lack of sustained attention, no attention to details, inability to follow through on tasks, poor listener, avoidance of tasks requiring sustained mental effort, and easily distracted.
b) For the hyperactive-impulsive type, these include fidgeting or squirming, excessive talking, leaving seat, inappropriate climbing or running, intrusiveness, and difficulty with quiet activities.
c) If symptoms do not improve within one month (including appropriate dose adjustments), the drug should be discontinued (Prod Info FOCALIN(R) oral tablets, 2007a).
2) Periodic reassessment of the need for continued dexmethylphenidate treatment (by temporarily withdrawing therapy and monitoring for recurrence of behavioral symptoms and their severity; slow dose-tapering may be indicated to prevent withdrawal symptoms) (Prod Info FOCALIN(R) oral tablets,

2007a).

2) Toxic

a) Laboratory Parameters

1) Monitor complete blood count with differential and platelets periodically during extended therapy (Prod Info FOCALIN(R) oral tablets, 2007a).

b) Physical Findings

1) The American Academy of Pediatrics (AAP) does not recommend the routine use of electrocardiograms (ECGS) or routine subspecialty cardiology evaluations (which were previously recommended by the American Heart Association (AHA) scientific statement to detect cardiac conditions that might place the child at risk for sudden cardiac death) before initiating stimulant therapy to treat attention-deficit/hyperactivity disorder ADHD in most children. The APA cited specific reasons for changing the recommendation including: lack of evidence establishing a relationship between stimulant drugs used to treat ADHD and sudden cardiac death (SCD), the frequency of sudden unexpected deaths among patients taking stimulant drugs is not higher than that in the general population of children, and lack of cost-effective analysis to support ECG screening or special evaluation by pediatric cardiologist (Perrin et al, 2008).

2) Based on the American Academy of Pediatrics (AAP) and the American Heart Association (AHA) consensus statements, the following cardiac monitoring recommendations have been established to assist clinicians in the evaluation of children treated with stimulant drugs, including dexmethylphenidate, for ADHD (Perrin et al, 2008; Vetter et al, 2008):

- Conduct a thorough examination prior to initiating dexmethylphenidate therapy for a diagnosis of ADHD. Special attention should be given to symptoms indicative of a cardiac condition, including palpitations, near syncope, or syncope.
- Obtain a complete family and patient history for conditions associated with SCD, and determine current use of any other prescription or over-the-counter medications.
- Conduct a complete physical evaluation of the patient for hypertension, cardiac murmurs, physical findings associated with Marfan syndrome, and signs of irregular cardiac rhythms.
- Perform further evaluation if family history, patient history or physical exam is suggestive of cardiac disease during initial visit or at follow up visits, and if indicated, consult pediatric cardiologist .
- Continue to assess the patient for cardiac symptoms and any changes in family history at follow up visits.
- Blood pressure and heart rate should be evaluated at baseline, during routine follow-up within 1 to 3 months, and at follow up visits every 6 to 12 months. Increases in blood pressure and heart rate have been reported with stimulant use.

3) Assess growth determinations (body weight and height) periodically (Prod Info FOCALIN(R) oral tablets, 2007a).

4) Determine the amount and frequency of medication during prolonged treatment (for detection of potential tolerance/dependence).

4.2 Patient Instructions

A) Dexmethylphenidate (By mouth)

Dexmethylphenidate

Treats attention deficit hyperactivity disorder (ADHD).

When This Medicine Should Not Be Used:
You should not use this medicine if you or your child have had an allergic reaction to dexmethylphenidate. You should not use this medicine if you have glaucoma, or if you are anxious, tense, or agitated most of the time. You should not use this medicine if you have muscle tics or Tourette's syndrome, a condition that causes you to have muscle twitches or to makes sounds you are not able to control. Do not use this medicine if you have taken an MAO inhibitor (Eldepryl®, Marplan®, Nardil®, Parnate®) within the past 14 days. This medicine should not be given to a child under 6 years of age unless your doctor tells you otherwise.

How to Use This Medicine:
Tablet, Long Acting Capsule

Your doctor will tell you how much of this medicine to use and how often. Do not use more medicine or use it more often than your doctor tells you to.
This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your doctor or pharmacist if you have any questions. Ask your pharmacist for the Medication Guide if you do not have one. Your doctor might ask you to sign some forms to show that you understand this information.
You may take this medicine with or without food.
This medicine is usually given once daily. Because dexmethylphenidate can cause a loss of appetite, it is best to take the medicine after eating or just before your morning meal, unless your doctor tells you otherwise.
Swallow the extended-release capsule whole. Do not crush, break, or chew it.
If you cannot swallow the extended-release capsule, you may open it and pour the medicine into a small amount of soft food such as pudding, yogurt, or applesauce. Stir this mixture well and swallow it without

chewing.
Always take this medicine with a full glass of liquid (water, milk, or juice).

If a Dose is Missed:
If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next dose, wait until then to use the medicine and skip the missed dose. Do not use extra medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:
Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after you have finished your treatment. You will also need to throw away old medicine after the expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, and herbal products.
Make sure your doctor knows if you are also using blood pressure medicines, blood thinners (such as Coumadin®, warfarin), clonidine (Catapres®, Clorpres®, Combipres®), or medicines to treat seizures (such as Dilantin®, Luminal®, Mysoline®). Tell your doctor if you use medicines for depression (such as amitriptyline, imipramine, trazodone, Celexa®, Effexor®, Luvox®, Norpramin®, Paxil®, Prozac®, Serzone®, Vivactil®, or Zoloft®).
Tell your doctor if you use cold or allergy medicines, or antacids or stomach acid reducers (such as Axid®, Prilosec®, Tagamet®, or Zantac®).

Warnings While Using This Medicine:
Make sure your doctor knows if you are pregnant, planning to become pregnant, or breastfeeding, or if you or your child have kidney problems, liver problems, heart disease, heart rhythm problems, or high blood pressure. Your doctor should know if you or your child have epilepsy, a history of seizures, depression or mental illness, or drug or alcohol problems. Also tell your doctor if you or anyone in your family has tried to commit suicide.
This medicine may be habit-forming. If you feel that the medicine is not working as well, do not use more than your prescribed dose. Call your doctor for instructions.
This medicine may make you dizzy or drowsy. Avoid driving, using machines, or doing anything else that could be dangerous if you are not alert.
This medicine may cause slow growth. If your child is using this medicine, the doctor will need to keep track of your child's height and weight to make sure that your child is growing properly.
Your doctor will need to check your progress at regular visits while you are using this medicine. Be sure to keep all appointments.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, chest tightness, trouble breathing.
Blurred vision, trouble seeing.
Chest pain or shortness of breath.
Fast, pounding, or irregular heartbeat.
Lightheadedness, dizziness, or fainting.
Mood or mental changes, confusion, or unusual behavior.
Seizures.
Tremors or shaking.
Uncontrollable muscle movements or twitching.
Unusual bleeding, bruising, or weakness.
Vomiting, agitation, confusion, sweating, fever.

If you notice these less serious side effects, talk with your doctor:
Dry mouth or nose.
Feeling restless or nervous.
Headache.
Nausea, loss of appetite, or stomach pain.
Trouble sleeping.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) SUMMARY

1) Clinical data for dexmethylphenidate at present do not support its use over methylphenidate in ADHD. It is not

recommended for the hospital formulary.

B) ATTENTION-DEFICIT HYPERACTIVITY DISORDER

1) Pharmacologic therapy is indicated as an adjunct to other measures (eg, counseling) in patients with attention-deficit hyperactivity disorder (ADHD). The mainstays of drug therapy are the stimulants methylphenidate, dextroamphetamine, and pemoline; these agents are similarly effective, although pemoline is used less frequently initially due to its slow onset. In patients not responding well to stimulants, bupropion, desipramine, clonidine, or MAO inhibitors may find usefulness, although adverse effects may prove problematic.

2) Dexmethylphenidate, the d-enantiomer of methylphenidate, is indicated for the treatment of ADHD in patients aged 6 years and older. Two placebo-controlled studies in patients meeting DSM-IV criteria for ADHD demonstrated dexmethylphenidate's effectiveness in the treatment of ADHD in patients 6 years of age and older.

3) A slightly longer duration of action has been reported for dexmethylphenidate compared to regular-release methylphenidate, although this appears to be small and is probably of no clinical relevance; both agents are recommended twice daily at similar intervals. Extended-release methylphenidate is used commonly in children to eliminate the need for methylphenidate dosing at school, and has a duration exceeding that of methylphenidate and dexmethylphenidate by at least two hours. Both regular-release and extended-release methylphenidate products are available generically at a lower cost than dexmethylphenidate.

4.4 Mechanism of Action / Pharmacology

A) Dexmethylphenidate Hydrochloride

1) MECHANISM OF ACTION

a) Dexmethylphenidate is the d-enantiomer (also known as d-threo-enantiomer) of methylphenidate (Ritalin (R)), the latter of which exists as the racemate (d,l-enantiomers in a 1:1 ratio) (Anon, 1999; Prod Info Focalin™, 2001a). Dexmethylphenidate accounts for most or all clinical effects of racemic methylphenidate (Anon, 2001; Prod Info Focalin™, 2001a).

b) Dexmethylphenidate is claimed to have efficacy similar to or greater than methylphenidate in attention-deficit hyperactivity disorder (ADHD), with a lower propensity for adverse effects; as it is one of the quantitatively equal enantiomers, it can be given in half the dose of the racemic compound, and this is also claimed to be an advantage (Anon, 2001a; Anon, 2001; Anon, 2000).

c) The mechanism of racemic methylphenidate in ADHD has not been fully elucidated. Both methylphenidate and dexmethylphenidate appear to inhibit reuptake of dopamine and norepinephrine into presynaptic neurons (Prod Info Focalin™, 2001a), increasing availability of these neurotransmitters in the extraneuronal space.

4.5 Therapeutic Uses

4.5.A Dexmethylphenidate Hydrochloride

4.5.A.1 Attention deficit hyperactivity disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes (extended-release only); Pediatric, yes (age 6 yr and older)
Efficacy: Adult, Evidence favors efficacy; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Extended-release dexmethylphenidate was superior to placebo for the treatment of attention deficit/hyperactivity disorder (ADHD) in children (Silva et al, 2008; Brams et al, 2008; Prod Info FOCALIN XR(R) extended-release oral capsules, 2008).

Fixed-dose dexmethylphenidate extended-release (ER) was superior to placebo for the treatment of attention-deficit/hyperactivity disorder (ADHD) in adults in a 5-week, randomized double-blind, placebo-controlled trial (n=218) (Spencer et al, 2007).

Dexmethylphenidate extended-release (ER) was superior to placebo for the treatment of pediatric ADHD in a 7-week , randomized, double-blind, placebo-controlled study (n=97) (Greenhill et al, 2006).

Results of two unpublished studies suggest the efficacy of oral immediate-release dexmethylphenidate in children and adolescents with ADHD (Prod Info Focalin(TM), 2001)

The efficacy of dexmethylphenidate is similar to that of racemic methylphenidate

c) Adult:

1) Evaluated Data

a) There are no studies evaluating the efficacy of immediate-release dexmethylphenidate in adults with attention-deficit hyperactivity disorder (ADHD).

2) Clinical Study Summaries

a) In an unpublished study, dexmethylphenidate extended-release was found to be more effective than placebo for the treatment of adults (ages 18 to 60) who met DSM-IV criteria for attention-deficit hyperactivity disorder (ADHD). In a randomized, double-blind, parallel-group study, patients (n=221) were randomized to either a fixed dose (20, 30, or 40 milligrams (mg)/day) of dexmethylphenidate extended-release or placebo once daily for 5 weeks. Treatment was initiated

at 10 mg/day and was titrated in increments of 10 mg weekly to the assigned fixed dose. Efficacy was measured by comparing the mean change in signs and symptoms of ADHD from baseline to endpoint using an intent-to-treat analysis of the investigator-administered DSM-IV ADHD Disorder Rating Scale. All 3 doses were found to be superior to placebo, with no apparent advantage with increasing dose (Prod Info FOCALIN(TM) XR, 2005).

3) Extended-Release

a) Fixed-dose dexmethylphenidate extended-release (ER) was superior to placebo for the treatment of attention-deficit/hyperactivity disorder (ADHD) in adults in a 5-week, multicenter, randomized double-blind, parallel-group, placebo-controlled trial (n=218). Adult patients aged 18 to 60 years (yr) (mean, 38.7 years) who met the following criteria were included: a DSM-IV diagnosis of ADHD of any subtype with childhood onset of symptoms, a total score of at least 24 at screening and at baseline on the DSM-IV ADHD rating scale (RS), and a Global Assessment of Functioning (GAF) score of 60 or less. All patients were required to discontinue all psychotropic medications within 1 to 4 weeks prior to the screening visit. Patients were equally randomized to dexmethylphenidate ER 20 milligrams (mg) (n=58), 30 mg (n=55) or 40 mg (n=55) daily or to placebo (n=53) for 5 weeks. The primary outcome was the change from baseline to final visit in the DSM-IV ADHD-RS total score. Analysis was performed on the modified intent-to-treat population, defined as all randomized patients who received at least 1 dose of study medication and had at least 1 pre- and post randomization assessment for change in DSM-IV ADHD-RS total score. The analysis revealed that all doses of dexmethylphenidate ER were superior to placebo for improvement of DSM-IV ADHD-RS total score. The mean change from baseline to final visit in DSM-IV ADHD-RS total score was 13.7 (from 36.8 to 23.1; p=0.006) for dexmethylphenidate ER 20 mg, 13.4 (from 36.9 to 23.5; p=0.012) for 30 mg, 16.9 (36.9 to 20; p=0.001) for 40 mg, and 7.9 (37.5 to 29.6) for placebo. The most common adverse effects were headache (31.5% vs 18.9%), decreased appetite (18.2% vs 11.3%), insomnia (16.4% vs 11.3%), dry mouth (15.8% vs 3.8%; p less than 0.05), and jitteriness (12.1% vs 1.9%; p less than 0.05) in the consolidated dexmethylphenidate ER groups compared with the placebo group. The authors note limitations of short study duration and insufficient power for direct comparison between doses (Spencer et al, 2007).

d) Pediatric:

1) Evaluated Data

a) No studies with dexmethylphenidate immediate-release have been published. In studies sponsored by the manufacturer, dexmethylphenidate 5 to 20 milligrams (mg) daily was reported statistically superior to placebo in children/adolescents (6 to 17 years) with attention-deficit hyperactivity disorder (ADHD), based on various behavior scales (Anon, 1999; Anon, 1999a; Anon, 2001; Prod Info Focalin(TM), 2001). One of these studies employed short-term (2-week) drug withdrawal following open-label treatment, where failure rates were lower in children continuing dexmethylphenidate (about 20%) compared to those given placebo (63%)(Prod Info Focalin(TM), 2001).

b) However, data released for these studies are incomplete, and the actual number of trials conducted is unclear. Pertinent clinical details not provided include demographic data (importantly, baseline severity of ADHD in each group), doses associated with response (or mean or maximum effective doses), specific statistical-analysis data (or tests used), and details of evaluation methods.

c) Dexmethylphenidate has been compared with methylphenidate in at least one of these studies, although comparative efficacy results were not reported. Press releases from the manufacturer regarding these comparisons are unclear and confusing (Anon, 1999; Anon, 2001; Anon, 1999b). Overall, the two drugs appear similarly effective, with a similar adverse-effect profile. Although dexmethylphenidate can be given in half the dose of methylphenidate, this is not a clinical advantage.

2) Immediate Release

a) One unpublished, placebo-controlled study from the package insert involving 132 patients with ADHD (6 to 17 years) reported significantly greater improvement of symptom scores from baseline on the Swanson, Noland, and Pelham (SNAP)-ADHD rating scale with dexmethylphenidate 5 to 20 mg daily (two divided doses, 3.5 to 5.5 hours apart) than with placebo (mean change, -0.7 versus -0.2). This study assessed improvements over 4 weeks. Patients included had all subtypes of ADHD (combined type, inattentive type, hyperactive-impulsive type) (Prod Info Focalin(TM), 2001). This trial directly compared dexmethylphenidate to racemic methylphenidate (10 to 40 mg daily), although no results for methylphenidate were provided.

3) Extended-Release

a) A randomized, double-blind, placebo-controlled, crossover study revealed extended-release dexmethylphenidate was superior to placebo for the treatment of attention deficit/hyperactivity disorder (ADHD) in children (n=68). Children aged 6 to 12 years (mean 9.5 years; 66.2% male) who met Diagnostic and Statistical Manual of Mental Disorders-IV (DSM-IV) criteria for any type of ADHD, who were clinically and behaviorally stable and without medication changes for at least 2 weeks were randomized to receive dexmethylphenidate extended release (d-MPH-ER) 20 milligram (mg) capsules daily for 7 days or to placebo, with treatment crossover, beginning on day 8 for an additional 7 days. Efficacy was assessed as change in the Swanson, Kotkin, Agler, M-Flynn and Pelham rating scale (SKAMP)-combined score from predose to time points 0.5, 1, 3, 4,

5, 7, 9, 10, 11 and 12 hours (hr), and math test performance in a laboratory classroom setting, with the SKAMP scale defined as 13 items of measurement that provides individual and combined scores on the core ADHD symptoms of attention and deportment. The intent-to-treat analysis revealed that d-MPH-ER was significantly superior to placebo in improvement of the SKAMP-combined score from predose to 0.5 hr postdose (adjusted mean change of score, -2.242 versus 3.493; p=0.001) and at all other time points (p less than or equal to 0.001). D-MPH-ER was associated with 8.6% improvement in SKAMP-combined score compared to 66.7% worsening with placebo. Change from predose in individual SKAMP attention scores (p less than or equal to 0.001) and deportment scores (p=0.003 or less) were significantly improved at all time points. Math test performance scores were significantly improved at all postdose time points in attempted test questions (p less than 0.001) and correctly-answered test questions (p less than 0.001). The most common adverse effect was upper respiratory tract infection, not otherwise specified (d-MPH-ER, 4.4% vs placebo, 7.4%). One serious adverse effect of 3+ proteinuria was reported during the d-MPH-ER phase, which was not attributed to study medication and resolved without sequelae (Silva et al, 2008).

b) A randomized, double-blind, placebo-controlled, crossover study revealed that extended-release dexmethylphenidate was superior to placebo for the treatment of attention deficit/hyperactivity disorder (ADHD) in children (n=86); however, the study was underpowered. Children (mean age 9.5 years (yr), range 6 to 12 yr, 61.6% male) diagnosed with any type of ADHD using the DSM-IV criteria, who were clinically and behaviorally stable and without medication changes for at least 2 weeks were randomized to receive dexmethylphenidate extended release (d-MPH-ER) 20 milligram (mg) capsules daily for 7 days or to placebo, with treatment crossover, beginning on day 8 for an additional 7 days. The primary outcome was change in the Swanson, Kotkin, Agler, M-Flynn and Pelham rating scale (SKAMP)-combined score from predose to 0.5 hours (hr) postdose, during an 8-hr laboratory classroom setting, with the SKAMP scale defined as 13 items of measurement that provides individual and combined scores on the core ADHD symptoms of attention and deportment. The intent-to-treat analysis revealed d-MPH-ER was significantly superior to placebo in improvement of the SKAMP-combined score from predose to 0.5 hr postdose with an adjusted mean change score of -0.969 vs 3.336 (p less than 0.001), and at all other postdose time points (1, 2, 4, 6, 8 hr) (p less than 0.001). Change in individual SKAMP attention and deportment scores were significantly improved at all time points (p less than or equal to 0.001). In addition, change from baseline in the Conners' ADHD/DSM-IV scale for parents (CADS-P), which assesses the childs' behavior with and without treatment, was significantly improved with d-MPH-ER compared with placebo (adjusted least-square mean -16.38 vs -4.62; difference, -11.76; 95% confidence interval (CI), -15.36 to -8.16; p less than 0.001). Dexmethylphenidate was associated with higher incidence of headache (3.5% vs 2.3%) compared with placebo (Brams et al, 2008).

c) Dexmethylphenidate extended-release (ER) was superior to placebo for the treatment of pediatric ADHD in a 7-week, multicenter, randomized, double-blind, placebo-controlled, parallel-group, two-phase study (n=97). Pediatric patients aged 6 to 17 years (yr) who met DSM-IV criteria for ADHD of any type were eligible. All patients must be functioning at an age-appropriate academic level and the use of psychotropic medications or initiation of psychotropic medications within the past 3 months was not allowed. Any current treatment for ADHD was discontinued at least 7 days before baseline during the pre-randomization phase (up to 2 weeks). At the end of the pre-randomization phase, patients were randomized to receive either dexmethylphenidate ER 5 mg (n=52) or placebo (n=45) daily. In the double-blind treatment-phase, patients proceeded with dose titration to 5 or 10 mg/day for week 2; 5, 10 or 15 mg/day for week 3; then 5, 10, 15 or 20 mg/day for week 4. For treatment weeks 5 to 7, doses were titrated and maintained at optimal doses of 5, 10, 15, 20 or 30 mg/day. The mean final dexmethylphenidate ER dose was 24 +/- 7.1 mg/day. The primary outcome was the change from baseline to final visit in the Conners ADHD/DSM-IV Scale-Teacher version (CADS-T) total subscale score. Analysis was performed on the modified intent-to-treat population, defined as patients who received at least 1 dose of study medication and had at least 1 postbaseline CADS-T measurement. The analysis revealed that dexmethylphenidate ER was significantly superior to placebo in improvement from baseline to final visit in the CADS-T total score. The adjusted mean change in CADS-T total score from baseline to final visit was 16.3 in the dexmethylphenidate ER group compared with 5.7 in the placebo group (p less than 0.001). Similarly, dexmethylphenidate ER was superior to placebo in secondary outcome measures of mean change from baseline in the CADS-T Inattentive subscale score (8.1 vs 3.3; p=0.001) and in the Hyperactive-Impulsive subscale score (8.2 vs 2.5; p less than or equal to 0.001), respectively. The most common adverse effects attributed to study medication were decreased appetite (28.3% vs 6.4%), headache (24.5% vs 10.63%), nausea (11.3 vs 6.4%) and insomnia (7.5% vs 6.4%) in the dexmethylphenidate ER and placebo groups, respectively. No serious adverse events were reported. The authors note study limitations of short study duration and small sample size (Greenhill et al, 2006).

4.6 Comparative Efficacy / Evaluation With Other Therapies

4.6.A Methylphenidate

4.6.A.1 Attention deficit hyperactivity disorder

a) No comparisons with methylphenidate have been published, and data released by the manufacturer have not emphasized comparative efficacy, although this data is available. In a completed 4- week, placebo-controlled study described in the package insert (Prod Info Focalin(TM), 2001d), dexmethylphenidate 5 to 20 milligrams (mg) daily was compared to methylphenidate 10 to 40 mg daily (each in two divided doses) in patients with ADHD (n=132, 6 to 17 years of age). Patients included had all subtypes of ADHD (combined type, inattentive type, hyperactive-impulsive type). Dexmethylphenidate was reported to provide significantly greater improvement of symptom scores from baseline on the Swanson, Noland, and Pelham (SNAP)-ADHD rating scale compared to placebo (mean change, -0.7 versus -0.2). Although methylphenidate was the comparator, no results for methylphenidate were provided.

b) In manufacturer releases, apparently referring to the same package insert trial described above, the efficacy and safety of dexmethylphenidate were reported similar to methylphenidate (Anon, 2001)(Anon, 2001a). Earlier releases also did not indicate a significant difference in efficacy between the two drugs (Anon, 1999; Anon, 1999a), although they were carefully prepared to avoid this conclusion.

c) One manufacturer release suggested a longer duration of action of dexmethylphenidate in ADHD; in this study, control of symptoms with dexmethylphenidate was reportedly seen at all time points, but there was failure of methylphenidate to control symptoms at the last measurements (5.5 to 6.5 hours postdose) (Anon, 1999). However, the duration of action of methylphenidate was not given, precluding assessment of the duration of methylphenidate relative to dexmethylphenidate. The duration of dexmethylphenidate in this trial was similar to that of methylphenidate in other studies (4 to 6 hours), suggesting this difference is small. No study has provided comparative improvements in symptom scores from baseline, or statistical comparisons at all time points.

d) Available studies have not indicated a more favorable adverse- effect profile for dexmethylphenidate compared to methylphenidate (Anon, 1999a); (Anon, 2001).

DRUGDEX® Evaluations

ZIPRASIDONE

0.0 Overview

1) Class

a) This drug is a member of the following class(es):
Antipsychotic
Benzisothiazoyl

2) Dosing Information

a) Ziprasidone Hydrochloride

1) Adult

a) Bipolar I disorder, acute manic or mixed episodes

1) day 1, 40 mg twice daily with food; day 2, 60 or 80 mg twice daily; then adjust to 40 to 80 mg twice daily (Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Schizophrenia

1) initial, 20 mg ORALLY twice a day with food; may increase dosage every 2 days up to 80 mg twice a day (Prod Info GEODON(R) oral capsules, IM injection, 2007)

2) maintenance, 20 to 80 mg ORALLY twice a day (MAX recommended dose is 80 mg twice a day); to ensure use of the lowest effective dose, observe for improvement for several weeks before upward dosage adjustment (Prod Info GEODON(R) oral capsules, IM injection, 2007)

[redacted] capsules, IM injection, 2007)

b) Ziprasidone Mesylate

1) Adult

a) Agitation, acute - Schizophrenia

1) 10 mg IM every 2 hr (MAX dose 40 mg/day) OR 20 mg IM every 4 hr (MAX dose 40 mg/day); oral ziprasidone should replace IM administration as soon as possible; IM administration for more than 3 consecutive days has not been studied (Prod Info GEODON(R) oral capsules, IM injection, 2007)

2) Pediatric

a) safety and effectiveness in pediatric patients have not been established (Prod Info GEODON(R) oral capsules, IM injection, 2007)

3) Contraindications

a) Ziprasidone Hydrochloride

1) cardiac arrhythmias, history (Prod Info GEODON(R) oral capsules, IM injection, 2008)

2) concomitant administration with arsenic trioxide, chlorpromazine, dofetilide, dolasetron mesylate, droperidol, gatifloxacin, halofantrine, levomethadyl acetate, mefloquine, mesoridazine, moxifloxacin, pentamidine, pimozide, probucol, quinidine, sotalol, sparfloxacin, tacrolimus, thioridazine, class Ia and III antiarrhythmics, and other drugs that cause QT prolongation; possible additive QT prolongation effect (Prod Info GEODON(R) oral capsules, IM injection, 2008)

3) heart failure, uncompensated (Prod Info GEODON(R) oral capsules, IM injection, 2008)

4) hypersensitivity to ziprasidone (Prod Info GEODON(R) oral capsules, IM injection, 2008)

5) myocardial infarction, acute and recent (Prod Info GEODON(R) oral capsules, IM injection, 2008)

6) QT prolongation history including congenital long QT syndrome (Prod Info GEODON(R) oral capsules, IM injection, 2008)

b) Ziprasidone Mesylate

1) cardiac arrhythmias, history (Prod Info GEODON(R) oral capsules, IM injection, 2007)

2) concomitant use with arsenic trioxide, chlorpromazine, dofetilide, dolasetron mesylate, droperidol, gatifloxacin, halofantrine, levomethadyl acetate, mefloquine, mesoridazine, moxifloxacin, pentamidine, pimozide, probucol, quinidine, sotalol, sparfloxacin, tacrolimus, thioridazine, Class Ia and III antiarrhythmics, and other drugs that cause QT prolongation; possible additive QT prolongation effect (Prod Info GEODON(R) oral capsules, IM injection, 2008)

3) heart failure, uncompensated (Prod Info GEODON(R) oral capsules, IM injection, 2008)

4) hypersensitivity to ziprasidone (Prod Info GEODON(R) oral capsules, IM injection, 2008)

5) myocardial infarction, acute and recent (Prod Info GEODON(R) oral capsules, IM injection, 2008)

6) QT prolongation, history including congenital long QT syndrome (Prod Info GEODON(R) oral capsules, IM injection, 2008)

4) Serious Adverse Effects

a) Ziprasidone Hydrochloride

1) Death

2) Diabetes mellitus

3) Hyperglycemia

4) Neuroleptic malignant syndrome

5) Priapism

6) Prolonged QT interval
7) Seizure
8) Syncope
9) Tardive dyskinesia
10) Torsades de pointes

b) Ziprasidone Mesylate
1) Death
2) Diabetes mellitus
3) Hyperglycemia
4) Priapism
5) Prolonged QT interval
6) Seizure
7) Syncope
8) Tardive dyskinesia
9) Torsades de pointes

5) Clinical Applications
a) Ziprasidone Hydrochloride
1) FDA Approved Indications
a) Bipolar I disorder, acute manic or mixed episodes
b) Schizophrenia

b) Ziprasidone Mesylate
1) FDA Approved Indications
a) Agitation, acute - Schizophrenia

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product Index)

B) Synonyms
Ziprasidone
Ziprasidone HCl
Ziprasidone Hydrochloride
Ziprasidone Mesylate

C) Physicochemical Properties
1) Molecular Weight
a) 467.42(Prod Info Geodon™, 2001)

1.2 Storage and Stability

A) Ziprasidone Hydrochloride
1) Preparation
a) Oral route
1) Oral ziprasidone hydrochloride capsules should be taken with food (Prod Info GEODON(R) oral capsules, IM injection, 2007).

B) Ziprasidone Mesylate
1) Preparation
a) Intramuscular route
1) Preparation
a) Reconstitute 20 milligram (mg) ziprasidone mesylate vials with 1.2 milliliters (mL) of sterile water for injection. Shake vigorously until all drug is dissolved. Reconstituted solution contains 20 mg/mL, and any unused portion should be discarded (Prod Info GEODON(R) oral capsules, IM injection, 2007).
2) Administration
a) Ziprasidone mesylate injection should only be administered by intramuscular injection (IM) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

C) Ziprasidone Hydrochloride
1) Oral route
a) Capsule
1) Ziprasidone hydrochloride capsules should be stored at 25 degrees Celsius (77 degrees

Fahrenheit); excursions permitted between 15 and 30 degrees Celsius (59 to 86 degrees Fahrenheit) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

D) Ziprasidone Mesylate

1) Intramuscular route

a) Powder for Solution

1) Ziprasidone mesylate for injection, in dry form, should be protected from light and stored at 25 degrees Celsius (77 degrees Fahrenheit); excursions permitted between 15 and 30 degrees Celsius (59 to 86 degrees Fahrenheit). The reconstituted solution is stable for up to 7 days if refrigerated (2 to 8 degrees Celsius (36 to 46 degrees Fahrenheit)) or for up to 24 hours between 15 and 30 degrees Celsius (59 to 86 degrees Fahrenheit) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Geriatric Patients

1.3.1 Normal Dosage

Ziprasidone Hydrochloride

Ziprasidone Mesylate

1.3.1.A Ziprasidone Hydrochloride

1.3.1.A.1 Oral route

Bipolar I disorder, acute manic or mixed episodes

Schizophrenia

1.3.1.A.1.a Bipolar I disorder, acute manic or mixed episodes

1) For bipolar mania, the recommended initial dose is 40 milligrams twice daily with food. On the second day of treatment, the dose should be increased to 60 or 80 milligrams twice daily and thereafter adjusted according to tolerance and efficacy within the range of 40 to 80 milligrams twice daily. There are no recommendations for maintenance treatment (Prod Info GEODON(R) oral capsules, IM injection, 2007).

1.3.1.A.1.b Schizophrenia

1) For schizophrenia the initial daily dose is 20 milligrams (mg) twice daily with food. In some patients daily dosage may be adjusted up to 80 mg twice daily. Adjustments, if indicated, should occur at intervals of not less than 2 days. Efficacy in short-term clinical trials occurred with dosages between 20 to 100 mg twice daily. Initial dosages above 80 mg twice daily are not recommended and the safety of dosages above 100 mg twice daily have not been evaluated. To ensure the lowest effective dose, patients should be observed for improvement for several weeks before upward dosage adjustment (Prod Info GEODON(R) oral capsules, IM injection, 2007).

1.3.1.B Ziprasidone Mesylate

1.3.1.B.1 Intramuscular route

1.3.1.B.1.a Agitation, acute - Schizophrenia

1) For acute agitation in schizophrenia the recommended intramuscular dose of ziprasidone mesylate is 10 to 20 milligrams (mg) as needed to a maximum daily dose of 40 mg. The 10 mg dose may be given every 2 hours and 20 mg dose may be given every 4 hours (maximum dose=40 mg/day). Intramuscular dosing of ziprasidone for more than 3 days has not been studied. If long-

term therapy is indicated, oral ziprasidone should replace intramuscular administration as soon as possible (Prod Info GEODON(R) oral capsules, IM injection, 2007).
2) Ziprasidone 10 milligrams (mg) intramuscularly (IM) produced a rapid reduction in symptoms of acute agitation and was significantly more effective (p less than 0.01) compared to a 2 mg IM dose up to 4 hours after the first injection (Lesem et al, 2001).

1.3.2 Dosage in Renal Failure
A) Ziprasidone Hydrochloride
1) No dosage adjustment should be necessary for mild-to-moderate renal impairment. No clinically significant effect on oral ziprasidone pharmacokinetics was found in these patients (Prod Info GEODON(R) oral capsules, IM injection, 2007; Aweeka et al, 2000).
B) Ziprasidone Mesylate
1) Ziprasidone mesylate for injection should be used with caution in patients with impaired renal function as the injection contains a cyclodextrin sodium excipient that is eliminated by renal filtration (Prod Info GEODON(R) oral capsules, IM injection, 2007).

1.3.3 Dosage in Hepatic Insufficiency
A) Ziprasidone Hydrochloride
1) No dosage adjustment is necessary for mild-to-moderate hepatic impairment (chronic and stable, Child-Pugh classification A or B); the pharmacokinetics of ziprasidone were not significantly different in subjects with mild-to-moderate liver disease (Prod Info GEODON(R) oral capsules, IM injection, 2007; Everson et al, 2000).

1.3.4 Dosage in Geriatric Patients
A) Ziprasidone Hydrochloride
1) No dosage adjustment is thought to be necessary for elderly patients; no clinically significant difference in ziprasidone pharmacokinetics was found between healthy young and elderly volunteers (Prod Info GEODON(R) oral capsules, IM injection, 2007; Wilner et al, 2000).
B) Ziprasidone Mesylate
1) Intramuscular ziprasidone mesylate has not been systematically evaluated in elderly patients. Dosage adjustment is not necessary in the elderly for oral ziprasidone hydrochloride; no clinically significant difference in pharmacokinetics was found between healthy young and elderly volunteers (Prod Info GEODON(R) oral capsules, IM injection, 2007).

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration
A) Onset
1) Peak Response
a) SCHIZOPHRENIA, ORAL: 4 weeks (Harrigan et al, 1996).

2.2 Drug Concentration Levels
A) Time to Peak Concentration
1) ORAL: 4 to 5 hours (Miceli et al, 2000a; Ereshefsky, 1996; Miceli et al, 1995).
a) Fed, 4.5 hours; fasted, 3.6 hours (Hamelin et al, 1998).
2) INTRAMUSCULAR: 60 minutes (Prod Info Geodon(R), 2002ae).
B) Area Under the Curve
1) 627.2 ng x hr/mL fed; 371.0 ng x hr/mL fasted (Hamelin et al, 1998).
a) Oral, fed, multiple-dose: 109.8 to 1027.9 ng x hr/mL (10 to 120 mg/day) (Miceli et al, 2000a).
b) Steady-state pharmacokinetics of ziprasidone did not differ between genders (Caccia, 2000).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

Extracorporeal Elimination

2.3.1 Absorption

A) Bioavailability
- **1)** ORAL: 60% (Ereshefsky, 1996; Miceli et al, 1995).
- **2)** INTRAMUSCULAR: 100% (Prod Info Geodon(R), 2002ae).

B) Effects of Food
- **1)** increased bioavailability (Ereshefsky, 1996; Miceli et al, 1995).
  - **a)** Dosing concurrent with high-fat meals increases systemic exposure to the drug, including area under the time-concentration curve, maximum concentration, and time to maximum concentration, while decreasing half-life (Caccia, 2000; Hamelin et al, 1998).

2.3.2 Distribution

A) Distribution Sites
- **1)** Protein Binding
  - **a)** Greater than 99% (Prod Info Geodon(R), 2002ae; Aweeka et al, 2000a; Everson et al, 2000a; Ereshefsky, 1996).

B) Distribution Kinetics
- **1)** Volume of Distribution
  - **a)** 1.5 L/kg (Prod Info Geodon(R), 2002ae).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics
- **1)** LIVER, (Prod Info Geodon(R), 2002ae; Ereshefsky, 1996).
  - **a)** CYP3A4 is the predominant isoenzyme involved in ZIPRASIDONE metabolism (Prakash et al, 2000; Caccia, 2000).
  - **b)** ZIPRASIDONE does not cause clinically significant inhibition of CYP2D6 (Wilner et al, 2000a; Prakash et al, 2000).

B) Metabolites
- **1)** Metabolites inactive at 5HT-2A/dopamine D2 receptors (Ereshefsky, 1996).
- **2)** Ziprasidone sulfoxide (major) (Prod Info Geodon(R), 2002ae; Prakash et al, 2000).
- **3)** Benzisothiazole sulphoxide (Prod Info Geodon(R), 2002ae).
- **4)** Benzisothiazole sulphone (Prod Info Geodon(R), 2002ae).
- **5)** S-methyldihydroziprasidone (Prod Info Geodon(R), 2002ae).
- **6)** Ziprasidone sulfone (Prakash et al, 2000).
- **7)** Oxindole acetic acid (Prakash et al, 2000).
- **8)** Benzisothiazole piperazine (Prakash et al, 2000).

2.3.4 Excretion

A) Kidney
- **1)** RENAL EXCRETION: less than 1% (Prod Info Geodon(R), 2002ae).
  - **a)** Less than 1% of an oral dose of ziprasidone is renally excreted as unchanged drug (Prod Info Geodon(R), 2002ae).

2.3.5 Elimination Half-life

A) Parent Compound
- **1)** ELIMINATION HALF-LIFE
  - **a)** 7 hours oral; 2 to 5 hours intramuscular (Prod Info Geodon(R), 2002ae).
    - **1)** Fed, 4.65 hours; fasted, 6.63 hours (Hamelin et al, 1998).
    - **2)** Half-life dose-dependent at steady-state (not observed with single doses). Single doses, 5 to 60 mg: 3 to 4 hours. Multiple dosing: 4 to 5 hours with 5 mg twice daily, 20 mg twice daily; 8.8 hours with 40 mg twice daily; 10 hours with 60 mg twice daily (Miceli et al, 2000a; Miceli et al, 1995; Ereshefsky, 1996). These changes have minimal clinical relevance.
    - **3)** The half-life increased from 4 to 5 hours (10 to 40 mg/day-dose) to 9 to 10 hours at 80 to 120 mg/day dosing due to an additional elimination phase that becomes apparent only after repeated administration. The extended elimination period was not due to a decrease in clearance with higher doses (Caccia, 2000).

2.3.6 Extracorporeal Elimination

A) Hemodialysis
- **1)** Dialyzable: No (Aweeka et al, 2000a).

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING

1) Ziprasidone Hydrochloride

a) Oral (Capsule)

1) Increased Mortality in Elderly Patients with Dementia-Related Psychosis: Elderly patients with dementia-related psychosis treated with antipsychotic drugs are at an increased risk of death. Analyses of seventeen placebo-controlled trials (modal duration of 10 weeks), largely in patients taking atypical antipsychotic drugs, revealed a risk of death in drug-treated patients of between 1.6 times to 1.7 times the risk of death in placebo-treated patients. Over the course of a typical 10-week controlled trial, the rate of death in drug-treated patients was about 4.5%, compared to a rate of about 2.6% in the placebo group. Although the causes of death were varied, most of the deaths appeared to be either cardiovascular (eg, heart failure, sudden death) or infectious (eg, pneumonia) in nature. Observational studies suggest that, similar to atypical antipsychotic drugs, treatment with conventional antipsychotic drugs may increase mortality. The extent to which the findings of increased mortality in observational studies may be attributed to the antipsychotic drug as opposed to some characteristic(s) of the patients is not clear. Ziprasidone hydrochloride is not approved for the treatment of patients with dementia-related psychosis (Prod Info GEODON(R) oral capsules, IM injection, 2008).

2) Ziprasidone Mesylate

a) Intramuscular (Powder for Solution)

1) Increased Mortality in Elderly Patients with Dementia-Related Psychosis: Elderly patients with dementia-related psychosis treated with antipsychotic drugs are at an increased risk of death. Analyses of seventeen placebo-controlled trials (modal duration of 10 weeks), largely in patients taking atypical antipsychotic drugs, revealed a risk of death in drug-treated patients of between 1.6 times to 1.7 times the risk of death in placebo-treated patients. Over the course of a typical 10-week controlled trial, the rate of death in drug-treated patients was about 4.5%, compared to a rate of about 2.6% in the placebo group. Observational studies suggest that, similar to atypical antipsychotic drugs, treatment with conventional antipsychotic drugs may increase mortality. The extent to which the findings of increased mortality in observational studies may be attributed to the antipsychotic drug as opposed to some characteristic(s) of the patients is not clear. Ziprasidone mesylate is not approved for the treatment of patients with dementia-related psychosis (Prod Info GEODON(R) oral capsules, IM injection, 2008).

3.1 Contraindications

A) Ziprasidone Hydrochloride

1) cardiac arrhythmias, history (Prod Info GEODON(R) oral capsules, IM injection, 2008)

2) concomitant administration with arsenic trioxide, chlorpromazine, dofetilide, dolasetron mesylate, droperidol, gatifloxacin, halofantrine, levomethadyl acetate, mefloquine, mesoridazine, moxifloxacin, pentamidine, pimozide, probucol, quinidine, sotalol, sparfloxacin, tacrolimus, thioridazine, class Ia and III antiarrhythmics, and other drugs that cause QT prolongation; possible additive QT prolongation effect (Prod Info GEODON(R) oral capsules, IM injection, 2008)

3) heart failure, uncompensated (Prod Info GEODON(R) oral capsules, IM injection, 2008)

4) hypersensitivity to ziprasidone (Prod Info GEODON(R) oral capsules, IM injection, 2008)

5) myocardial infarction, acute and recent (Prod Info GEODON(R) oral capsules, IM injection, 2008)

6) QT prolongation history including congenital long QT syndrome (Prod Info GEODON(R) oral capsules, IM injection, 2008)

B) Ziprasidone Mesylate

1) cardiac arrhythmias, history (Prod Info GEODON(R) oral capsules, IM injection, 2007)

2) concomitant use with arsenic trioxide, chlorpromazine, dofetilide, dolasetron mesylate, droperidol, gatifloxacin, halofantrine, levomethadyl acetate, mefloquine, mesoridazine, moxifloxacin, pentamidine, pimozide, probucol, quinidine, sotalol, sparfloxacin, tacrolimus, thioridazine, Class Ia and III antiarrhythmics, and other drugs that cause QT prolongation; possible additive QT prolongation effect (Prod Info GEODON(R) oral capsules, IM injection, 2008)

3) heart failure, uncompensated (Prod Info GEODON(R) oral capsules, IM injection, 2008)
4) hypersensitivity to ziprasidone (Prod Info GEODON(R) oral capsules, IM injection, 2008)
5) myocardial infarction, acute and recent (Prod Info GEODON(R) oral capsules, IM injection, 2008)
6) QT prolongation, history including congenital long QT syndrome (Prod Info GEODON(R) oral capsules, IM injection, 2008)

3.2 Precautions

A) Ziprasidone Hydrochloride

1) elderly patients with dementia-related psychosis (unapproved use); increased risk of death; most deaths were attributed to cardiovascular events (eg, heart failure or sudden death) or infections (eg, pneumonia) (Prod Info GEODON(R) oral capsules, IM injection, 2008)
2) bradycardia; increased risk of torsades de pointes and/or sudden death (Prod Info GEODON(R) oral capsules, IM injection, 2008)
3) cardiovascular or cerebrovascular disease or conditions that predispose patients to hypotension (eg, dehydration, hypovolemia, antihypertensive medications); increased risk of orthostatic hypotension and syncope (Prod Info GEODON(R) oral capsules, IM injection, 2008)
4) conditions that may contribute to elevated body temperature (eg, strenuous exercise, extreme heat exposure, dehydration, concomitant anticholinergic use); disruption of body temperature regulation has been reported with antipsychotic agents (Prod Info GEODON(R) oral capsules, IM injection, 2008)
5) diabetes mellitus or risk factors for diabetes mellitus; increased risk of severe hyperglycemia; monitor blood glucose (Prod Info GEODON(R) oral capsules, IM injection, 2008)
6) esophageal dysmotility and aspiration may occur, use cautiously in patients at risk for aspiration pneumonia (Prod Info GEODON(R) oral capsules, IM injection, 2008)
7) elderly patients, especially elderly women are at increased risk of tardive dyskinesia (Prod Info GEODON(R) oral capsules, IM injection, 2008)
8) hyperglycemia (some cases extreme and associated with ketoacidosis, hyperosmolar coma, or death) is a risk (Prod Info GEODON(R) oral capsules, IM injection, 2008)
9) hypokalemia or hypomagnesemia, preexisting; increased risk of torsades de pointes and/or sudden death (Prod Info GEODON(R) oral capsules, IM injection, 2008)
10) increased duration of therapy and/or higher cumulative doses; increased risk of tardive dyskinesia (Prod Info GEODON(R) oral capsules, IM injection, 2008)
11) neuroleptic malignant syndrome, potentially fatal, has been reported in association with antipsychotics drugs; immediately discontinue drug (Prod Info GEODON(R) oral capsules, IM injection, 2008)
12) priapism has been reported rarely (Prod Info GEODON(R) oral capsules, IM injection, 2008)
13) rash and/or urticaria have been reported, discontinue if associated with systemic illness (eg, elevated WBC counts) (Prod Info GEODON(R) oral capsules, IM injection, 2008)
14) seizure disorder, history, or conditions which lower the seizure threshold (Prod Info GEODON(R) oral capsules, IM injection, 2008)
15) tardive dyskinesia, potentially irreversible, may occur (Prod Info GEODON(R) oral capsules, IM injection, 2008)

B) Ziprasidone Mesylate

1) elderly patients with dementia-related psychosis (unapproved use); increased risk of death; most deaths were attributed to cardiovascular events (eg, heart failure or sudden death) or infections (eg, pneumonia) (Prod Info GEODON(R) oral capsules, IM injection, 2008)
2) bradycardia; increased risk of torsades de pointes and/or sudden death (Prod Info GEODON(R) oral capsules, IM injection, 2008)
3) cardiovascular or cerebrovascular disease or conditions that predispose patients to hypotension (eg, dehydration, hypovolemia, antihypertensive medications); increased risk of orthostatic hypotension and syncope (Prod Info GEODON(R) oral capsules, IM injection, 2008)
4) conditions that may contribute to elevated body temperature (eg, strenuous exercise, extreme heat exposure, dehydration, concomitant anticholinergic use); disruption of body temperature regulation has been reported with antipsychotic agents (Prod Info GEODON(R) oral capsules, IM injection, 2008)
5) diabetes mellitus or risk factors for diabetes mellitus; increased risk of severe hyperglycemia; monitor blood glucose (Prod Info GEODON(R) oral capsules, IM injection, 2008)
6) esophageal dysmotility and aspiration may occur, use cautiously in patients at risk for aspiration pneumonia (Prod Info GEODON(R) oral capsules, IM injection, 2008)
7) elderly patients, especially elderly women are at increased risk of tardive dyskinesia (Prod Info GEODON(R) oral capsules, IM injection, 2008)
8) hyperglycemia (some cases extreme and associated with ketoacidosis, hyperosmolar coma, or death) is a risk (Prod Info GEODON(R) oral capsules, IM injection, 2008)
9) hypokalemia or hypomagnesemia, preexisting; increased risk of torsades de pointes and/or sudden death (Prod Info GEODON(R) oral capsules, IM injection, 2008)
10) increased duration of therapy and/or higher cumulative doses; increased risk of tardive dyskinesia (Prod Info GEODON(R) oral capsules, IM injection, 2008)
11) neuroleptic malignant syndrome, potentially fatal, has been reported in association with antipsychotics drugs; immediately discontinue drug (Prod Info GEODON(R) oral capsules, IM injection, 2008)
12) priapism has been reported rarely (Prod Info GEODON(R) oral capsules, IM injection, 2008)
13) rash and/or urticaria have been reported, discontinue if associated with systemic illness (eg, elevated WBC

counts) (Prod Info GEODON(R) oral capsules, IM injection, 2008)
14) seizure disorder, history, or conditions which lower the seizure threshold; use caution (Prod Info GEODON (R) oral capsules, IM injection, 2008)
15) tardive dyskinesia, potentially irreversible, may occur (Prod Info GEODON(R) oral capsules, IM injection, 2008)

3.3 Adverse Reactions

Cardiovascular Effects

Dermatologic Effects

Endocrine/Metabolic Effects

Musculoskeletal Effects

Neurologic Effects

Ophthalmic Effects

Psychiatric Effects

Reproductive Effects

Respiratory Effects

Other

3.3.1 Cardiovascular Effects

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.1.A Ziprasidone Hydrochloride

Hypertension

Orthostatic hypotension

Prolonged QT interval

Syncope

Tachycardia

Torsades de pointes

3.3.1.A.1 Hypertension
a) Incidence: bipolar mania, 3%; schizophrenia, not reported (Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) The incidence of hypertension reported in short-term trials of patients with bipolar mania was 3% for ziprasidone hydrochloride-treated subjects (n=279) versus 2% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.1.A.2 Orthostatic hypotension

a) Incidence: frequent (Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Postural hypotension has been reported in both premarketing and postmarketing oral ziprasidone hydrochloride use and may be dose-dependent (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.1.A.3 Prolonged QT interval

a) Incidence: 0.06%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) QT prolongation is dose-related. It is not yet known whether ziprasidone hydrochloride will cause torsades de pointes or increase the rate of sudden death. In clinical trials, oral ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with oral ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine. During clinical trials, clinically significant QTc interval increases (defined as greater than 500 msec) occurred in 0.06% (2 out of 2988) of patients on ziprasidone hydrochloride compared with 0.23% (1 out of 440) patients on placebo. Ziprasidone was not suspected to have caused the QTc prolongation (Prod Info GEODON(R) oral capsules, IM injection, 2007).

1) The risk of QT prolongation and arrhythmia are increased when potassium and magnesium levels are low. Other risk factors include bradycardia, concomitant use of other drugs that prolong QTc interval, and presence of congenital prolongation of the QT interval. Baseline serum potassium and magnesium measurements should be obtained in patients who are at risk for significant electrolyte disturbances before starting ziprasidone. Before starting treatment with ziprasidone, hypokalemia and hypomagnesemia should be corrected. Electrolytes should be periodically monitored during therapy. Avoid ziprasidone in patients with histories of significant cardiovascular illness (QT prolongation, recent acute myocardial infarction, uncompensated heart failure, or cardiac arrhythmia). Further evaluation, such as Holter monitor, maybe be necessary in patients who experience symptoms (dizziness, palpitations, or syncope) suggestive of torsade de pointes. If the QTc measurement consistently exceeds 500 milliseconds, then ziprasidone should be discontinued (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000).

3.3.1.A.4 Syncope

a) Incidence: 0.6%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Syncope, which may be more prevalent during initial dose-titrations, was reported by 0.6% of patients taking ziprasidone. Patients experiencing syncope may need further evaluation, such as Holter monitoring, to rule out torsade de pointes (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) The rare occurrence of syncope has been reported during postmarketing use of ziprasidone (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.1.A.5 Tachycardia

a) Incidence: bipolar mania, not reported; schizophrenia, 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) In short-term trials, the incidence of tachycardia was 2% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 1% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) During schizophrenia trials, a mean increase in heart rate of 1.4 beats per minute in the ziprasidone group compared with 0.2 beats per minute in the placebo group. The occurrence of tachycardia has been reported during postmarketing use of ziprasidone (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.1.A.6 Torsades de pointes

a) Incidence: rare(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Although the development of torsades de pointes, in the presence of other multiple confounding factors, has been observed during postmarketing use of ziprasidone, a causal relationship has not been confirmed. In premarketing studies, the development of torsades de pointes was not observed. Ziprasidone does have the capacity to prolong the QT/QTc interval and prolongation of the QTc interval has been associated with the development of torsade de pointes-type arrhythmias. However, the association between ziprasidone use and the possible development of torsades de pointes has yet to be determined (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) In a case report of a 28 year-old female, Q-T prolongation occurred separately during two hospital admissions, and asymptomatic non-sustained polymorphic ventricular tachycardia occurred during the second admission while using ziprasidone concurrently with other potentially arrhythmogenic medications (lithium, ciprofloxacin, fluconazole, fluoxetine, and trazodone). Upon discontinuation of

ziprasidone and the other medications, the patient's Q-T interval shortened. The patient had a medical history of systemic lupus erythematosus, hypothyroidism, and a complicated history of mood disorders with psychotic features, post traumatic stress disorder, and borderline personality disorder. During the first incidence of Q-T prolongation (600 milliseconds (msec) at 68 bpm) associated with ziprasidone, the patient was lithium toxic and hypokalemic; either of which have been associated with Q-T interval abnormalities and arrhythmias. Discontinuation of ziprasidone and lithium, coupled with emergency dialysis for lithium toxicity, resulted in a decrease in Q-T interval (440 msec at 77 bpm). Two weeks later, the patient was readmitted with complaints of chest pain and an electrocardiogram revealed prolonged Q-T interval (540 msec at 58 bpm). The patient experienced a gradual lowering of potassium levels and further prolongation of Q-T interval after the interchange of ziprasidone for olanzapine coupled with the concurrent initiation of fluconazole, ciprofloxacin, trazodone, and levetiracetam. On the third day, telemetry revealed an asymptomatic non-sustained polymorphic ventricular tachycardia. She was treated by discontinuing ziprasidone, trazodone, and fluconazole, and starting metoprolol. The QT interval remained prolonged at 455 to 480 msec for the remainder of her hospitalization with no subsequent arrhythmias (Heinrich et al, 2006).

3.3.1.B Ziprasidone Mesylate

Hypertension

Orthostatic hypotension

Prolonged QT interval

Syncope

Tachycardia

Torsades de pointes

3.3.1.B.1 Hypertension

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Hypertension was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.1.B.2 Orthostatic hypotension

a) Incidence: up to 5%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Postural hypotension, reported in up to 5% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate, has also been observed during postmarketing use (Prod Info GEODON (R) oral capsules, IM injection, 2007).

3.3.1.B.3 Prolonged QT interval

a) In a study of the QT/QTc prolongation effects of intramuscular ziprasidone mesylate, the mean increase in QTc from baseline to time of maximum plasma concentration following two injections of intramuscular ziprasidone mesylate (20 mg then 30 mg, given four hours apart) was 4.6 msec and 12.8 msec following the first and second injections, respectively, compared to 6 msec and 14.7 msec for the first and second injections, respectively, of haloperidol (7.5 mg then 10 mg, given four hours apart). No patients experienced a QTc interval exceeding 500 msec in this study (Prod Info GEODON(R) oral capsules, IM injection, 2007).

b) QT prolongation is dose-related. It is not yet known whether ziprasidone mesylate will cause torsades de pointes or increase the rate of sudden death. In clinical trials, oral ziprasidone hydrochloride increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with oral ziprasidone hydrochloride than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine. During clinical trials, clinically significant QTc interval increases (defined as greater than 500 msec) occurred in 0.06% (2 out of 2988) of patients on ziprasidone hydrochloride compared with 0.23% (1 out of 440) patients on placebo. Ziprasidone was not suspected to have caused the QTc prolongation (Prod Info GEODON(R) oral capsules, IM injection, 2007).

1) The risk of QT prolongation and arrhythmia are increased when potassium and magnesium levels are low. Other risk factors include bradycardia, concomitant use of other drugs that prolong QTc interval, and presence of congenital prolongation of the QT interval. Baseline serum potassium and magnesium measurements should be obtained in patients who are at risk for significant electrolyte disturbances before starting ziprasidone. Before starting treatment with ziprasidone,

hypokalemia and hypomagnesemia should be corrected. Electrolytes should be periodically monitored during therapy. Avoid ziprasidone in patients with histories of significant cardiovascular illness (QT prolongation, recent acute myocardial infarction, uncompensated heart failure, or cardiac arrhythmia). Further evaluation, such as Holter monitor, maybe be necessary in patients who experience symptoms (dizziness, palpitations, or syncope) suggestive of torsade de pointes. If the QTc measurement consistently exceeds 500 milliseconds, then ziprasidone should be discontinued (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000).

3.3.1.B.4 Syncope

a) Incidence: 0.6%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Syncope, which may be more prevalent during initial dose-titrations, was reported by 0.6% of patients taking ziprasidone. Patients experiencing syncope may need further evaluation, such as Holter monitoring, to rule out torsade de pointes (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) The rare occurrence of syncope has been reported during postmarketing use of ziprasidone (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.1.B.5 Tachycardia

a) Tachycardia, reported in 2% of patients with schizophrenia during short-term oral placebo-controlled trials, has been reported in postmarketing ziprasidone use (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.1.B.6 Torsades de pointes

a) Incidence: rare(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Although the development of torsades de pointes, in the presence of other multiple confounding factors, has been observed during postmarketing use of ziprasidone, a causal relationship has not been confirmed. In premarketing studies, the development of torsades de pointes was not observed. Ziprasidone does have the capacity to prolong the QT/QTc interval and prolongation of the QTc interval has been associated with the development of torsade de pointes-type arrhythmias. However, the association between ziprasidone use and the possible development of torsades de pointes has yet to be determined (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.2 Dermatologic Effects

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.2.A Ziprasidone Hydrochloride

3.3.2.A.1 Rash

a) Incidence: 5%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Development of a dose-dependent rash and/or urticaria was reported in about 5% of patients during premarketing trials with ziprasidone hydrochloride and was one of the more common reasons given for study dropouts (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.2.B Ziprasidone Mesylate

Furunculosis

Injection site pain

Sweating symptom

3.3.2.B.1 Furunculosis

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Furunculosis was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.2.B.2 Injection site pain

a) Incidence: 7% to9%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Pain at the site of injection was reported in 7% to 9% of patients during short-term fixed-dose

intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.2.B.3 Sweating symptom

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Sweating was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.3 Endocrine/Metabolic Effects

Ziprasidone

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.3.A Ziprasidone

3.3.3.A.1 Diabetes mellitus

See Drug Consult reference: ATYPICAL ANTIPSYCHOTIC AGENTS - EFFECT ON GLUCOSE AND RISK OF DIABETES

3.3.3.B Ziprasidone Hydrochloride

Diabetes mellitus

Hyperglycemia

Increased prolactin level

Metabolic syndrome

Weight gain

3.3.3.B.1 Diabetes mellitus

a) Although there have been few reports of hyperglycemia or diabetes in patients treated with ziprasidone hydrochloride, increased risk has been clearly associated with other drugs of this class (atypical antipsychotics). Data are presently insufficient to exclude the possibility of increased risk of diabetes due to ziprasidone treatment. Before starting an atypical antipsychotic, patients with risk factors for diabetes should undergo fasting blood glucose testing, with periodic re-testing. All patients receiving an atypical antipsychotic should be monitored for symptoms of hyperglycemia (polydipsia, polyuria, polyphagia, weakness), and should be given blood glucose tests if such symptoms are seen. In some patients, resolution of hyperglycemia has occurred with discontinuation of the atypical antipsychotic; in other cases, it has not (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.3.B.2 Hyperglycemia

a) Although there have been few reports of hyperglycemia or diabetes in patients treated with ziprasidone hydrochloride, increased risk has been clearly associated with other drugs of this class (atypical antipsychotics). In the patients treated with atypical antipsychotics, ketoacidosis, hyperosmolar coma or death occurred. Data are presently insufficient to exclude the possibility of increased risk of diabetes due to ziprasidone treatment. Before starting an atypical antipsychotic, patients with risk factors for diabetes should undergo fasting blood glucose testing, with periodic re-testing. All patients receiving an atypical antipsychotic should be monitored for symptoms of hyperglycemia (polydipsia, polyuria, polyphagia, weakness), and should be given blood glucose tests if such symptoms are seen. In some patients, resolution of hyperglycemia has occurred with discontinuation of the atypical antipsychotic; in other cases, it has not (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.3.B.3 Increased prolactin level

a) Ziprasidone, like other drugs that antagonize dopamine D2 receptors, have the potential ot increase prolactin levels; however, the clinical significance is unknown (Prod Info GEODON(R) oral capsules, IM injection, 2007). Prolactin level increases are usually small and seen mainly with higher doses of ziprasidone (Anon, 1996a; Kerwin & Taylor, 1996a). The changes are transient and return to baseline

within 12 hours of ziprasidone administration (Miceli et al, 2000; Goff et al, 1998a).

3.3.3.B.4 Metabolic syndrome

See Drug Consult reference: ANTIPSYCHOTIC AGENTS - METABOLIC SYNDROME

3.3.3.B.5 Weight gain

a) Incidence: 0.4%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Weight gain was reported in 0.4% and 0.4% of patients on ziprasidone-treated and placebo-treated patients, respectively (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) Based on 4 short-term clinical trials (4 to 6 week duration) related to schizophrenia, incidence of weight gain amounting to 7% or more of baseline body weight was 10% for subjects receiving oral ziprasidone hydrochloride compared with 4% for those receiving placebo. Median weight gain of 0.5 kg and 0 kg occurred in the ziprasidone and placebo groups, respectively. Data collected during long-term therapy showed mean weight gain from baseline to be 1.4 kg for patients with initial low BMI (less than 23), no mean weight change for those with normal BMI (23 to 27), and 1.3 kg weight loss for patients with initially high BMI (greater than 27) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

d) Compared to other atypical antipsychotics in a systemic review, ziprasidone is associated with a low risk of weight gain (Kingsbury et al, 2001; Taylor & McAskill, 2000).

3.3.3.C Ziprasidone Mesylate

Diabetes mellitus

Hyperglycemia

Increased prolactin level

Metabolic syndrome

3.3.3.C.1 Diabetes mellitus

a) Although there have been few reports of hyperglycemia or diabetes in patients treated with ziprasidone mesylate, increased risk has been clearly associated with other drugs of this class (atypical antipsychotics). Data are presently insufficient to exclude the possibility of increased risk of diabetes due to ziprasidone treatment. Before starting an atypical antipsychotic, patients with risk factors for diabetes should undergo fasting blood glucose testing, with periodic re-testing. All patients receiving an atypical antipsychotic should be monitored for symptoms of hyperglycemia (polydipsia, polyuria, polyphagia, weakness), and should be given blood glucose tests if such symptoms are seen. In some patients, resolution of hyperglycemia has occurred with discontinuation of the atypical antipsychotic; in other cases, it has not (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.3.C.2 Hyperglycemia

a) Although there have been few reports of hyperglycemia or diabetes in patients treated with ziprasidone mesylate, increased risk has been clearly associated with other drugs of this class (atypical antipsychotics). In the patients treated with atypical antipsychotics, ketoacidosis, hyperosmolar coma or death occurred. Data are presently insufficient to exclude the possibility of increased risk of diabetes due to ziprasidone treatment. Before starting an atypical antipsychotic, patients with risk factors for diabetes should undergo fasting blood glucose testing, with periodic re-testing. All patients receiving an atypical antipsychotic should be monitored for symptoms of hyperglycemia (polydipsia, polyuria, polyphagia, weakness), and should be given blood glucose tests if such symptoms are seen. In some patients, resolution of hyperglycemia has occurred with discontinuation of the atypical antipsychotic; in other cases, it has not (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.3.C.3 Increased prolactin level

a) Ziprasidone, like other drugs that antagonize dopamine D2 receptors, have the potential ot increase prolactin levels; however, the clinical significance is unknown (Prod Info GEODON(R) oral capsules, IM injection, 2007). Prolactin level increases are usually small and seen mainly with higher doses of ziprasidone (Anon, 1996a; Kerwin & Taylor, 1996a). The changes are transient and return to baseline within 12 hours of ziprasidone administration (Miceli et al, 2000; Goff et al, 1998a).

3.3.3.C.4 Metabolic syndrome

See Drug Consult reference: ANTIPSYCHOTIC AGENTS - METABOLIC SYNDROME

3.3.4 Gastrointestinal Effects

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.4.A Ziprasidone Hydrochloride

Abdominal pain

Constipation

Diarrhea

Indigestion

Loss of appetite

Nausea

Vomiting

Xerostomia

3.3.4.A.1 Abdominal pain

a) Incidence: bipolar mania, not reported; schizophrenia, frequent(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) Abdominal pain was frequently observed during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.A.2 Constipation

a) Incidence: bipolar mania, not reported; schizophrenia, 9%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) In short-term trials, the incidence of constipation was 9% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 8% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.A.3 Diarrhea

a) Incidence: bipolar mania and schizophrenia, 5%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) The incidence of diarrhea reported in short-term trials of patients with bipolar mania was 5% for ziprasidone hydrochloride-treated subjects (n=279) versus 4% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2007).
c) In short-term trials, the incidence of diarrhea was 5% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 4% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.A.4 Indigestion

a) Incidence: bipolar mania, not reported; schizophrenia, 8%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) In short-term trials, the incidence of dyspepsia was 8% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 7% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.A.5 Loss of appetite

a) Incidence: bipolar mania, not reported; schizophrenia, 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) In short-term trials, the incidence of anorexia was 2% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 1% for placebo-treated subjects (n=273). (Prod Info GEODON (R) oral capsules, IM injection, 2007).
c) Anorexia was frequently observed during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day (Prod Info GEODON(R) oral capsules, IM injection, 2007).
d) An analysis of four short-term, fixed-dose, placebo-controlled studies of patients with schizophrenia

revealed a dependent relationship between the development of anorexia and the dose of ziprasidone hydrochloride (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.A.6 Nausea

a) Incidence: bipolar mania and schizophrenia, 10%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) The incidence of nausea reported in short-term trials of patients with bipolar mania was 10% for ziprasidone hydrochloride-treated subjects (n=279) versus 7% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) In short-term trials, the incidence of nausea was 10% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 7% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.A.7 Vomiting

a) Incidence: bipolar mania, 5%; schizophrenia, frequent(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) The incidence of vomiting reported in short-term trials of patients with bipolar mania was 5% for ziprasidone hydrochloride-treated subjects (n=279) versus 2% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) Vomiting was frequently observed during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day and was one of the more common reasons given for study dropouts during the bipolar mania trials(Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.A.8 Xerostomia

a) Incidence: bipolar mania, 5%; schizophrenia, 4%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) The incidence of dry mouth reported in short-term trials of patients with bipolar mania was 5% for ziprasidone hydrochloride-treated subjects (n=279) versus 4% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) In short-term trials, the incidence of dry mouth was 4% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 2% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

d) An analysis of four short-term, fixed-dose, placebo-controlled studies of patients with schizophrenia revealed a dependent relationship between the development of dry mouth and the dose of ziprasidone hydrochloride (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.B Ziprasidone Mesylate

Abdominal pain

Constipation

Diarrhea

Indigestion

Loss of appetite

Nausea

Vomiting

3.3.4.B.1 Abdominal pain

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Abdominal pain was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.B.2 Constipation

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Constipation was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.B.3 Diarrhea

a) Incidence: up to 3%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) Diarrhea was reported in up to 3% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.B.4 Indigestion
a) Incidence: 1% to 3%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) Dyspepsia was reported in 1% to 3% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.B.5 Loss of appetite
a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) Anorexia was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.B.6 Nausea
a) Incidence: 4% to 12%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) Nausea was reported in 4% to 12% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.4.B.7 Vomiting
a) Incidence: up to 3%(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) Vomiting was reported in up to 3% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.6 Hepatic Effects

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.6.A Ziprasidone Hydrochloride

3.3.6.A.1 Increased liver enzymes
a) No overt cases of hepatotoxicity have been reported. Occasional rises in liver enzymes have been reported with ziprasidone use but have not been clinically significant (Brown et al, 1999; Citrome, 1997; Kerwin & Taylor, 1996a).
b) Two patients in a clinical trial of ziprasidone were discontinued because of abnormal laboratory results. One patient had elevated gamma-glutamyl transpeptidase (GGT) and serum glutamic-pyruvic transaminase (SGPT/ALT) after 7 days of treatment with ziprasidone 10 milligrams/day, and one patient showed elevations of both serum glutamic-oxaloacetic transaminase (SGOT/AST) and SGPT/ALT after 8 days of treatment with ziprasidone 40 milligrams/day. Both patients had elevated GGT values at baseline. At follow-up, all values had returned or were returning to normal (Goff et al, 1998a).

3.3.6.B Ziprasidone Mesylate

3.3.6.B.1 Increased liver enzymes
a) No overt cases of hepatotoxicity have been reported. Occasional rises in liver enzymes have been reported with ziprasidone use but have not been clinically significant (Brown et al, 1999; Citrome, 1997; Kerwin & Taylor, 1996a).

3.3.8 Musculoskeletal Effects

3.3.8.A Ziprasidone Hydrochloride

Myalgia

Rhabdomyolysis, following correction of hyponatremia secondary to psychogenic polydipsia

3.3.8.A.1 Myalgia
a) Incidence: bipolar mania, 2%; schizophrenia, frequent(Prod Info GEODON(R) oral capsules, IM injection, 2007)
b) The incidence of myalgia reported in short-term trials of patients with bipolar mania was 2% for ziprasidone hydrochloride-treated subjects (n=279) versus 0% for placebo-treated patients (n=136)

(Prod Info GEODON(R) oral capsules, IM injection, 2007).
c) Myalgia was frequently observed during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.8.A.2 Rhabdomyolysis, following correction of hyponatremia secondary to psychogenic polydipsia

a) Rhabdomyolysis, possibly complicated by ziprasidone therapy, was observed in one patient following the correction of hyponatremia secondary to psychogenic polydipsia. The 50-year-old Caucasian male had begun ziprasidone therapy (40 mg twice daily) for the treatment of chronic paranoid schizophrenia three weeks before presenting with hyponatremia secondary to psychogenic polydipsia. Following the discontinuation of ziprasidone and the correction of hyponatremia via sodium chloride 0.9% administration and oral water restriction, the man developed rhabdomyolysis secondary to hyponatremia correction which manifested as an unexplained increase in serum alanine and aspartate aminotransferase levels and total serum creatine kinase elevated to 67,259 International Units/L. Following resolution of rhabdomyolysis, ziprasidone therapy was reinitiated at a dose of 80 mg twice daily with no recurrence of increased serum creatine kinase levels. While the author notes that hyponatremia secondary to psychogenic polydipsia or its correction was most likely the primary cause of rhabdomyolysis in this patient, he also asserts that a review of the literature allows supposition that the development of rhabdomyolysis may have been complicated by the prior use of ziprasidone. The use of the Naranjo probability scale indicated a possible relationship between the use of ziprasidone and the subsequent development of rhabdomyolysis (Zaidi, 2005).

3.3.9 Neurologic Effects

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.9.A Ziprasidone Hydrochloride

Akathisia

Asthenia

Disturbance in speech

Dizziness

Dystonia

Extrapyramidal disease

Headache

Insomnia

Neuroleptic malignant syndrome

Paresthesia

Seizure

Somnolence

Tardive dyskinesia

3.3.9.A.1 Akathisia

a) Incidence: bipolar mania, 10%; schizophrenia, 8%(Prod Info GEODON(R) oral capsules, IM

injection, 2008a)
b) The incidence of akathisia reported in short-term trials of patients with bipolar mania was 10% for ziprasidone hydrochloride-treated subjects (n=279) versus 5% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
c) In short-term trials, the incidence of akathisia was 8% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 7% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
d) Akathisia was one of the more common reasons given for study dropouts during the bipolar mania trials (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.2 Asthenia
a) Incidence: bipolar mania, 6%; schizophrenia, 5%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)
b) The incidence of asthenia reported in short-term trials of patients with bipolar mania was 6% for ziprasidone hydrochloride-treated subjects (n=279) versus 2% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
c) In short-term trials, the incidence of asthenia was 5% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 3% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.3 Disturbance in speech
a) Incidence: bipolar mania, 2%; schizophrenia, not reported(Prod Info GEODON(R) oral capsules, IM injection, 2008a)
b) The incidence of speech disorder reported in short-term trials of patients with bipolar mania was 2% for ziprasidone hydrochloride-treated subjects (n=279) versus 0% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.4 Dizziness
a) Incidence: bipolar mania, 16%; schizophrenia, 8%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)
b) The incidence of dizziness and lightheadedness reported in short-term trials of patients with bipolar mania was 16% for ziprasidone hydrochloride-treated subjects (n=279) versus 7% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
c) In short-term trials, the incidence of dizziness and lightheadedness was 8% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 6% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
d) Dizziness may be more prevalent during initial ziprasidone hydrochloride dose-titrations and is dose-dependent. Patients experiencing continued dizziness may need further evaluation, such as Holter monitoring, to rule out torsade de pointes (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.5 Dystonia
a) During the first few days after initiating treatment with an antipsychotic medication, symptoms of dystonia may occur in susceptible individuals. Symptoms may include spasm of neck muscles, which may progress to tightening of the throat, swallowing difficulty, breathing difficulty, and/or protrusion of the tongue. These symptoms can occur at low doses but most often occur (and occur with greater severity) with high potency and at higher doses of first generation antipsychotic medications. Males and younger age groups appear to be at greater risk for developing acute dystonia (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.6 Extrapyramidal disease
a) Incidence: bipolar mania, 31%; schizophrenia, 14%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)
b) General
1) In clinical trial adverse effect reports for ziprasidone hydrochloride, the manufacturer defines extrapyramidal symptoms to collectively include the following: Extrapyramidal syndrome, hypertonia, dystonia, dyskinesia, hypokinesia, tremor, paralysis, and twitching (Prod Info GEODON (R) oral capsules, IM injection, 2008a).
2) The incidence of extrapyramidal symptoms (EPS) reported in short-term trials of patients with bipolar mania was 31% for ziprasidone hydrochloride-treated subjects (n=279) versus 12% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
3) In short-term trials, the incidence of extrapyramidal symptoms (EPS) was 14% among ziprasidone hydrochloride -treated schizophrenia subjects (n=702) versus 8% for placebo-treated subjects (n=273). However, objectively collected data on the Simpson-Angus Rating Scale for EPS and the Barnes Akathisia Scale did not generally indicate a difference between the ziprasidone hydrochloride and placebo groups in these trials (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
c) Hypertonia
1) Hypertonia occurred at a frequency of less than 10% in bipolar mania trials and less than 5% in

schizophrenia trials. Hypertonia was frequently (occurred in at least 1 of 100 people) observed during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

2) An analysis of four short-term, fixed-dose, placebo-controlled studies of patients with schizophrenia revealed a dependent relationship between the development of hypertonia and the dose of ziprasidone hydrochloride (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

d) Hypokinesia

1) Hypokinesia occurred at a frequency of less than 10% in bipolar mania trials and less than 5% in schizophrenia trials. Hypokinesia was frequently (occurred in at least 1 of 100 people) observed during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day (Prod Info GEODON(R) oral capsules, IM injection, 2007).

e) Tremor

1) Tremor occurred at a frequency of less than 10% in bipolar mania trials and less than 5% in schizophrenia trials. Tremor was frequently (occurred in at least 1 of 100 people) observed during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

2) An analysis of four short-term, fixed-dose, placebo-controlled studies of patients with schizophrenia revealed a dependent relationship between the development of tremor and the dose of ziprasidone hydrochloride (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

f) Twitching

1) Twitching occurred at a frequency of less than 10% in bipolar mania trials and less than 5% in schizophrenia trials. Twitching was frequently (occurred in at least 1 of 100 people) observed during premarketing schizophrenia clinical trial at multiple doses greater than 4 milligrams/day (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

See Drug Consult reference: NEUROLEPTIC-INDUCED EXTRAPYRAMIDAL REACTIONS

3.3.9.A.7 Headache

a) Incidence: bipolar mania, 18%; schizophrenia, not reported(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) The incidence of headache reported in short-term trials of patients with bipolar mania was 18% for ziprasidone hydrochloride-treated subjects (n=279) versus 17% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.8 Insomnia

a) Incidence: rare(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Although no causal relationship has been established, rare postmarketing reports of insomnia with ziprasidone use have been observed (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.9 Neuroleptic malignant syndrome

a) Incidence: rare(Murty et al, 2002)

b) Neuroleptic malignant syndrome (NMS) developed in a 49-year-old female patient after receiving ziprasidone (20 to 60 mg twice daily) for the treatment of recurrent psychotic depression. Symptoms included agitation, disorganized thoughts, sweating, tachycardia, hypertension, elevated liver enzymes, and hyponatremia. Although there was no evidence of fever or muscle rigidity, a diagnosis of rhabdomyolysis secondary to NMS was made. All medications were stopped and the symptoms resolved over the next 6 days following aggressive treatment including intravenous hydration and electrolyte replacement (Murty et al, 2002).

3.3.9.A.10 Paresthesia

a) Incidence: frequent(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Paresthesia was frequently (occurred in at least 1 of 100 people) reported in oral ziprasidone hydrochloride-treated patients during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day, although causality was not determined (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.11 Seizure

a) Incidence: 0.4%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Seizures were reported in 0.4% of ziprasidone hydrochloride-treated patients during clinical trials, although confounding factors may have contributed to the occurrence in many of these cases (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.12 Somnolence

a) Incidence: bipolar mania, 31%; schizophrenia, 14%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) The incidence of somnolence reported in short-term trials of patients with bipolar mania was 31% for ziprasidone hydrochloride-treated subjects (n=279) versus 12% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

c) In short-term trials, the incidence of somnolence was 14% among ziprasidone hydrochloride-treated

schizophrenia subjects (n=702) versus 7% for placebo-treated subjects (n=273). The frequency of somnolence appears to be dose-dependent (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
d) Somnolence may be more prevalent during initial ziprasidone hydrochloride dose-titrations and is dose-dependent. During short-term clinical trials, 0.3% discontinued therapy due to somnolence (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.A.13 Tardive dyskinesia

a) The use of antipsychotic drugs, such as ziprasidone hydrochloride, is a risk factor for the development of tardive dyskinesia. The risk of developing the syndrome increases with duration of treatment and total cumulative dose. The incidence of the syndrome appears to be highest among the elderly, particularly women. However, any patient may be at risk to develop the syndrome, even after a comparatively brief treatment period at a low dose (Prod Info GEODON(R) oral capsules, IM injection, 2008a).
b) Tardive dyskinesia developed in a 70-year-old woman nine weeks following the initiation of ziprasidone therapy (100 milligrams/day) for the treatment of major depression with mood-congruent psychotic features. Symptoms included repetitive, involuntary jaw and toe movements (Keck et al, 2004).

3.3.9.B Ziprasidone Mesylate

Akathisia

Asthenia

Disturbance in speech

Dizziness

Dystonia

Extrapyramidal disease

Headache

Insomnia

Paresthesia

Seizure

Somnolence

Tardive dyskinesia

3.3.9.B.1 Akathisia

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)
b) Akathisia was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.2 Asthenia

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)
b) Asthenia was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.3 Disturbance in speech

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)
b) Speech disorder was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.4 Dizziness

a) Incidence: 3% to 10%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Dizziness was reported in 3% to 10% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.5 Dystonia

a) During the first few days of treatment with an antipsychotic medication, symptoms of dystonia may occur in susceptible individuals. Symptoms may include spasm of neck muscles, which may progress to tightening of the throat, swallowing difficulty, breathing difficulty, and/or protrusion of the tongue. These symptoms can occur at low doses but most often occur (and occur with greater severity) with high potency and at higher doses of first generation antipsychotic medications. Males and younger age groups appear to be at greater risk for developing acute dystonia (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.6 Extrapyramidal disease

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Extrapyramidal syndrome was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a). See Drug Consult reference: NEUROLEPTIC-INDUCED EXTRAPYRAMIDAL REACTIONS

3.3.9.B.7 Headache

a) Incidence: 3% to 13%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Headache was reported in 3% to 13% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.8 Insomnia

a) Incidence: up to 3%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Insomnia was reported in up to 3% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

c) Although no causal relationship has been established, postmarketing reports of insomnia with ziprasidone use have been observed (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.9 Paresthesia

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Paresthesia was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.10 Seizure

a) Incidence: 0.4%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Seizures were reported in 0.4% of ziprasidone mesylate-treated patients during clinical trials, although confounding factors may have contributed to the occurrence in many of these cases (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.11 Somnolence

a) Incidence: 8% to 20%(Prod Info GEODON(R) oral capsules, IM injection, 2008a)

b) Somnolence was reported in 8% to 20% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.9.B.12 Tardive dyskinesia

a) The use of antipsychotic drugs, such as ziprasidone mesylate, is a risk factor for the development of tardive dyskinesia. The risk of developing the syndrome increases with duration of treatment and total cumulative dose. The incidence of the syndrome appears to be highest among the elderly, particularly women. However, any patient may be at risk to develop the syndrome, even after a comparatively brief treatment period at a low dose (Prod Info GEODON(R) oral capsules, IM injection, 2008a).

3.3.10 Ophthalmic Effects

3.3.10.A Ziprasidone Hydrochloride

Abnormal vision

Oculogyric crisis

3.3.10.A.1 Abnormal vision

a) Incidence: bipolar mania, 6%; schizophrenia, 3%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) The incidence of abnormal vision reported in short-term trials of patients with bipolar mania was 6%

for ziprasidone hydrochloride-treated subjects (n=279) versus 3% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2007).
c) In short-term trials, the incidence of abnormal vision was 3% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 2% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).
d) An analysis of four short-term, fixed-dose, placebo-controlled studies of patients with schizophrenia revealed a dependent relationship between the development of abnormal vision and the dose of ziprasidone hydrochloride (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.10.A.2 Oculogyric crisis

a) Oculogyric crisis developed in an 11-year-old boy after receiving ziprasidone 20 milligrams (mg) twice daily for the treatment of pervasive developmental disorder and psychotic symptoms. Six weeks following initiation of ziprasidone therapy, the child had a sudden onset of dystonic upward deviation of the eyes. Ziprasidone was discontinued and the patient was treated with oral diphenhydramine 50 mg every 4 hours. Symptoms subsided within 30 minutes of the first dose and completely resolved within 24 hours (Ramos et al, 2003).

3.3.12 Psychiatric Effects

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.12.A Ziprasidone Hydrochloride

At risk for suicide

Mania

3.3.12.A.1 At risk for suicide

a) Because an attempt at suicide is inherently possible in patients with a psychotic illness or bipolar disorder, high-risk patients on drug therapy should receive close supervision. Also, in order to reduce the risk of overdose, ziprasidone prescriptions should be written for the smallest quantity of capsules consistent with good patient management (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.12.A.2 Mania

a) Summary
1) There have been several case reports of mania/hypomania associated ziprasidone use, including reports during postmarketing use (Prod Info GEODON(R) oral capsules, IM injection, 2007; Brieger, 2004; Baldassano et al, 2003).
b) Hypomania developed in a 40-year-old man on two occasions following the initiation and reinitiation of ziprasidone therapy for the treatment bipolar schizoaffective disorder. Hypomania developed eight days after ziprasidone (100 milligrams (mg)/day) was initiated with ongoing venlafaxine (150 mg/day) and valproate (1200 mg/day) therapy. Symptoms included decreased need for sleep, recklessness, talkativeness, high self-esteem and racing thoughts. Ziprasidone was stopped on day 10 after a worsening of symptoms. However, 6 weeks later, the patient was restarted on ziprasidone treatment (120 mg/day) and again developed a hypomanic episode after eight days of treatment. A dysphoric mood rather than euphoric mood marked this episode and ziprasidone was again discontinued. Symptoms of hypomania resolved within 24 hours on both occasions (Brieger, 2004).
c) Four cases of mania related to the initiation of ziprasidone administration have been reported in bipolar patients. Three of the cases occurred in males 25, 26 and 45 years of age and the other case occurred in a 29-year-old female. In each case the patients were receiving multiple psychotropic medications prior to ziprasidone administration. Each patient received an initial ziprasidone dose of 20 milligrams (mg) twice a day. Manic symptoms occurred within 3 to 7 days in each of the male patients at this dosage. With the woman patient, ziprasidone dosage was increased to 100 mg/day over a period of 5 days and on the fifth day of treatment she developed manic symptoms. Within 3 to 7 days of dosage reduction or discontinuation of ziprasidone, all of the patient's manic symptoms improved. The authors speculated that ziprasidone's potent inhibition of noradrenergic and serotonergic reuptake sites may play a role in the observed switch from bipolar depression to mania (Baldassano et al, 2003).

3.3.12.B Ziprasidone Mesylate

Agitation

At risk for suicide

Personality disorder

3.3.12.B.1 Agitation

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Agitation was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.12.B.2 At risk for suicide

a) Because an attempt at suicide is inherently possible in patients with a psychotic illness or bipolar disorder, high-risk patients on drug therapy should receive close supervision (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.12.B.3 Personality disorder

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Personality disorder was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.14 Reproductive Effects

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.14.A Ziprasidone Hydrochloride

3.3.14.A.1 Priapism

a) Incidence: rare(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Although no causal relationship has been established, rare postmarketing reports of priapism with ziprasidone use have been observed and one case was reported during premarketing trials. Surgical intervention may be required in severe cases (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) An African American male developed priapism on two occasions after receiving risperidone and again after receiving ziprasidone for the treatment of schizophrenia. Following risperidone treatment (4 milligrams (mg) twice daily) the man developed an erection lasting 13 hours, which resolved upon irrigation of the corpora with phenylephrine 200 micrograms. Following discontinuation of risperidone, the patient developed another unwanted erection after an increase in his ziprasidone dose from 20 mg twice daily to 40 mg twice daily. This erection lasted 2 hours and resolved upon urination. He experienced several more unwanted erections until the ziprasidone was discontinued and the priapism quickly resolved (Reeves et al, 2002).

3.3.14.B Ziprasidone Mesylate

Dysmenorrhea

Priapism

3.3.14.B.1 Dysmenorrhea

a) Incidence: up to 2%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Dysmenorrhea was reported in up to 2% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.14.B.2 Priapism

a) Incidence: up to 1%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) Priapism, reported in up to 1% of patients during short-term fixed-dose intramuscular trials of ziprasidone mesylate, has also been observed during postmarketing use. Surgical intervention may be required in severe cases (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.15 Respiratory Effects

3.3.15.A Ziprasidone Hydrochloride

Cough

Dyspnea

Respiratory tract infection

Rhinitis

3.3.15.A.1 Cough

a) Incidence: bipolar mania, not reported; schizophrenia, 3%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) In short-term trials, the incidence of cough was 3% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 1% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.15.A.2 Dyspnea

a) Incidence: bipolar mania, 2%; schizophrenia, frequent(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) The incidence of dyspnea reported in short-term trials of patients with bipolar mania was 2% for ziprasidone hydrochloride-treated subjects (n=279) versus 1% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) Dyspnea was frequently observed during premarketing schizophrenia clinical trials at multiple doses greater than 4 milligrams/day (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.15.A.3 Respiratory tract infection

a) Incidence: bipolar mania, not reported; schizophrenia, 8%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) In short-term trials, the incidence of respiratory tract infection was 8% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 3% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.15.A.4 Rhinitis

a) Incidence: bipolar mania, not reported; schizophrenia, 4%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) In short-term trials, the incidence of rhinitis was 4% among ziprasidone hydrochloride-treated schizophrenia subjects (n=702) versus 2% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) An analysis of four short-term, fixed-dose, placebo-controlled studies of patients with schizophrenia revealed a dependent relationship between the development of rhinitis and the dose of ziprasidone hydrochloride (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.16 Other

Ziprasidone Hydrochloride

Ziprasidone Mesylate

3.3.16.A Ziprasidone Hydrochloride

Accidental injury

Death

3.3.16.A.1 Accidental injury

a) Incidence: bipolar mania and schizophrenia, 4%(Prod Info GEODON(R) oral capsules, IM injection, 2007)

b) The incidence of accidental injuries reported in short-term trials of patients with bipolar mania was 4% for ziprasidone hydrochloride-treated subjects (n=279) versus 1% for placebo-treated patients (n=136) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) In short-term trials, the incidence of accidental injuries was 4% among ziprasidone hydrochloride-

treated schizophrenia subjects (n=702) versus 2% for placebo-treated subjects (n=273) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3.3.16.A.2 Death

a) Results of a population-based, retrospective cohort study demonstrated that the use of conventional antipsychotics was associated with an even greater risk for death than atypical antipsychotics when administered to elderly patients (aged 66 years and older) with dementia. Atypical versus no antipsychotic use and conventional versus atypical antipsychotic use pair-wise comparisons were made. A total of 27,259 matched pairs were identified and the dementia cohort was stratified based on place of residence (community versus long-term care facilities). In order to adjust for difference in baseline health status, propensity score matching was used. The primary outcome of the study was all-cause mortality. The risk for death was evaluated at 30, 60, 120, and 180 days after the antipsychotic medications were initially dispensed. There was a statistically significant increase in the risk for death at 30 days associated with new use of atypical antipsychotic medications compared with nonuse in both the community-dwelling cohort (adjusted hazard ratio (HR), 1.31 (95% confidence interval (CI), 1.02 to 1.70); absolute risk difference, 0.2 percentage point) and long-term care cohort (adjusted HR, 1.55 (95% CI, 1.15 to 2.07); absolute risk difference, 1.2 percentage points). For both cohorts, the risk associated with atypical antipsychotics appeared to persist to 180 days. The risk for death associated with conventional antipsychotics was even greater than the risk identified with atypical antipsychotics. At 30 days, the adjusted HR for the community-dwelling cohort was 1.55 (95% CI, 1.19 to 2.02) and 1.26 (95% CI, 1.04 to 1.53) for the long-term care cohort (adjusted risk difference for both was 1.1 percentage points). The risk appeared to persist to 180 days for both groups. Some important limitations to the study include unknown or unmeasured confounders may influence the results and cause of death could not be examined (Gill et al, 2007).

b) Results of a population-based, retrospective cohort study demonstrated comparable to possibly greater risk of death associated with the use of conventional antipsychotic medications in the elderly (aged 65 years and older) compared with atypical antipsychotic medications. The analysis excluded patients with cancer and included only new users of antipsychotic medications. The primary study outcome was 180-day all-cause mortality. A set of potential confounders was measured based on healthcare utilization data within 6 months before the initiation of antipsychotic medications. Of the 37,241 elderly patients identified, 12,882 and 24,359 received conventional and atypical antipsychotic medications, respectively. The risk of death in the conventional drug group within the first 180 days was 14.1% compared with 9.6% in the atypical drug group (unadjusted mortality ratio, 1.47; 95% confidence interval (CI), 1.39 to 1.56). In the multi-variable analysis which controlled for potential confounders, the adjusted mortality ratio for the risk of death within 180 days for conventional versus atypical drug therapy was 1.32 (95% CI, 1.23 to 1.42). When the most frequently prescribed conventional antipsychotic drugs were compared with risperidone, the mortality ratio associated with haloperidol was 2.14 (95% CI, 1.86 to 2.45) and loxapine was 1.29 (95% CI, 1.19 to 1.40), while there was no difference associated with olanzapine. The increased mortality risk for conventional versus atypical drug therapy was greatest when doses higher (above median) doses were used (mortality ratio 1.67; 95% CI, 1.5 to 1.86) and also during the first 40 days of therapy (mortality ratio 1.6; 95% CI, 1.42 to 1.8). Confirmatory analyses consisting of multi-variable Cox regression, propensity score, and instrumental variable estimation confirmed the results of the study (Schneeweiss et al, 2007).

c) The results of a retrospective cohort study indicate that conventional antipsychotic agents are at least as likely as atypical antipsychotic agents to increase the risk of death among elderly patients 65 years of age or older. The study included 9,142 new users of conventional agents (mean age, 83.2 years) and 13,748 new users of atypical agents (mean age, 83.5 years). A higher adjusted relative risk of death was associated with the use of conventional antipsychotics as compared with atypical antipsychotics at all time points studied after beginning therapy (within 180 days: RR, 1.37; 95% CI=1.27 to 1.49; less than 40 days: RR, 1.56; 95% CI=1.37 to 1.78; 40 to 79 days: RR, 1.37; 95% CI=1.19 to 1.59; 80 to 180 days: RR, 1.27; 95% CI=1.14 to 1.41). In addition, the adjusted risks of death observed in patients with dementia (RR, 1.29; 95% CI=1.15 to 1.45), without dementia (RR, 1.45; 95% CI=1.30 to 1.63), in a nursing home (RR, 1.26; 95% CI=1.08 to 1.47), or not in a nursing home (RR, 1.42; 95% CI=1.29 to 1.56) were also higher with the use of conventional antipsychotic therapy as compared with atypical antipsychotic use. This risk appeared to be dose-related and was greater with the use of higher dose (ie, greater than the median) conventional antipsychotics (RR, 1.73; 95% CI=1.57 to 1.90). Additional studies which specifically investigate the optimum care of elderly patients requiring antipsychotic therapy are needed so that appropriate guidance regarding therapeutic intervention can be provided (Wang et al, 2005).

3.3.16.B Ziprasidone Mesylate

3.3.16.B.1 Death

a) Results of a population-based, retrospective cohort study demonstrated that the use of conventional antipsychotics was associated with an even greater risk for death than atypical antipsychotics when administered to elderly patients (aged 66 years and older) with dementia. Atypical versus no antipsychotic use and conventional versus atypical antipsychotic use pair-wise comparisons were made. A total of 27,259 matched pairs were identified and the dementia cohort was stratified based on

place of residence (community versus long-term care facilities). In order to adjust for difference in baseline health status, propensity score matching was used. The primary outcome of the study was all-cause mortality. The risk for death was evaluated at 30, 60, 120, and 180 days after the antipsychotic medications were initially dispensed. There was a statistically significant increase in the risk for death at 30 days associated with new use of atypical antipsychotic medications compared with nonuse in both the community-dwelling cohort (adjusted hazard ratio (HR), 1.31 (95% confidence interval (CI), 1.02 to 1.70); absolute risk difference, 0.2 percentage point) and long-term care cohort (adjusted HR, 1.55 (95% CI, 1.15 to 2.07); absolute risk difference, 1.2 percentage points). For both cohorts, the risk associated with atypical antipsychotics appeared to persist to 180 days. The risk for death associated with conventional antipsychotics was even greater than the risk identified with atypical antipsychotics. At 30 days, the adjusted HR for the community-dwelling cohort was 1.55 (95% CI, 1.19 to 2.02) and 1.26 (95% CI, 1.04 to 1.53) for the long-term care cohort (adjusted risk difference for both was 1.1 percentage points). The risk appeared to persist to 180 days for both groups. Some important limitations to the study include unknown or unmeasured confounders may influence the results and cause of death could not be examined (Gill et al, 2007).

b) Results of a population-based, retrospective cohort study demonstrated comparable to possibly greater risk of death associated with the use of conventional antipsychotic medications in the elderly (aged 65 years and older) compared with atypical antipsychotic medications. The analysis excluded patients with cancer and included only new users of antipsychotic medications. The primary study outcome was 180-day all-cause mortality. A set of potential confounders was measured based on healthcare utilization data within 6 months before the initiation of antipsychotic medications. Of the 37,241 elderly patients identified, 12,882 and 24,359 received conventional and atypical antipsychotic medications, respectively. The risk of death in the conventional drug group within the first 180 days was 14.1% compared with 9.6% in the atypical drug group (unadjusted mortality ratio, 1.47; 95% confidence interval (CI), 1.39 to 1.56). In the multi-variable analysis which controlled for potential confounders, the adjusted mortality ratio for the risk of death within 180 days for conventional versus atypical drug therapy was 1.32 (95% CI, 1.23 to 1.42). When the most frequently prescribed conventional antipsychotic drugs were compared with risperidone, the mortality ratio associated with haloperidol was 2.14 (95% CI, 1.86 to 2.45) and loxapine was 1.29 (95% CI, 1.19 to 1.40), while there was no difference associated with olanzapine. The increased mortality risk for conventional versus atypical drug therapy was greatest when doses higher (above median) doses were used (mortality ratio 1.67; 95% CI, 1.5 to 1.86) and also during the first 40 days of therapy (mortality ratio 1.6; 95% CI, 1.42 to 1.8). Confirmatory analyses consisting of multi-variable Cox regression, propensity score, and instrumental variable estimation confirmed the results of the study (Schneeweiss et al, 2007).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info Geodon(R), 2002ad) (All Trimesters)

a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other) and there are no controlled studies in women or studies in women and animals are not available. Drugs should be given only if the potential benefit justifies the potential risk to the fetus.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

2) Crosses Placenta: Unknown

3) Clinical Management

a) There is insufficient clinical experience with the use of ziprasidone in pregnant patients to confirm its safety in that patient population. Until additional data are available, caution should be exercised with the use of ziprasidone in pregnancy. Detailed fetal ultrasonography is recommended for monitoring fetal outcome following inadvertent exposure (Schaefer, 2001).

4) Literature Reports

a) No human studies of pregnancy outcomes after exposure to ziprasidone have been published, and there are no reports of outcomes after inadvertent exposure during pregnancy.

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk when used during breastfeeding. Weigh the potential benefits of drug treatment against potential risks before prescribing this drug during breastfeeding.

2) Clinical Management

a) It is not known whether ziprasidone or its metabolites are excreted into human breast milk, and the potential for adverse effects in the nursing infant from exposure to the drug are unknown. The manufacturer recommends that women receiving ziprasidone not breast feed their infants (Prod Info Ziprasidone(R), 2002).

3) Literature Reports

a) No reports describing the use of ziprasidone during human lactation or measuring the amount, if any, of the drug excreted into milk have been located.

3.5 Drug Interactions

3.5.1 Drug-Drug Combinations

Acecainide

Ajmaline

Ajmaline

Amiodarone

Amisulpride

Amitriptyline

Amoxapine

Aprindine

Arsenic Trioxide

Arsenic Trioxide

Astemizole

Azimilide

Zolmitriptan

Zotepine

3.5.1.A Acecainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.B Ajmaline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including Class IA antiarrhythmic agents (Prod Info Geodon(R), 2002j).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and ziprasidone is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.C Ajmaline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999e; O'Brien et al, 1999d; Prod Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001i; Duenas-Laita et al, 1999f; Agelink et al, 2001d; Lande et al, 1992f; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman,

2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible for the plasma level changes than an elimination alteration (Young et al, 1993).

3.5.1.D Amiodarone
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.E Amisulpride
1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Coadministration of ziprasidone with other drugs that potentially prolong the QTc interval, such as amisulpride, is contraindicated (Prod Info Solian(R), 1999d; Prod Info Geodon(R), 2002t).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with agents that prolong the QT interval, such as amisulpride, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Ziprasidone prolongs the QTc in some patients in a dose-related manner. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams) (Prod Info Geodon(R), 2002s).

3.5.1.F Amitriptyline
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though no formal drug interaction studies have been done, it is recommended that concurrent use with other agents that may prolong QTc interval be avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982).
3) Severity: major
4) Onset: unspecified

5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent administration of ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection, 2007).
7) Probable Mechanism: additive cardiac effects

3.5.1.G Amoxapine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though no formal drug interaction studies have been done, it is recommended that concurrent use with other agents that may prolong QTc interval be avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent administration of ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection, 2007).
7) Probable Mechanism: additive cardiac effects

3.5.1.H Aprindine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the coadministration of Class I antiarrhythmics and other drugs known to prolong the QTc interval, such as ziprasidone is contraindicated (Prod Info Geodon(TM), 2002j; Prod Info Tambocor(R) flecainide acetate, 1998).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class I antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.I Arsenic Trioxide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs, such as arsenic trioxide, which are also known to prolong the QTc interval (Prod Info Geodon(R), 2002i; Prod Info Trisenox(R), 2000).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as arsenic trioxide, is contraindicated.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002h).
b) QT/QTc prolongation should be expected during treatment with arsenic trioxide and torsade de pointes as well as complete heart block has been reported. Over 460 ECG tracings from 40 patients with refractory or relapsed APL treated with arsenic trioxide were evaluated for QTc prolongation. Sixteen of 40 patients (40%) had at least one ECG tracing with a QTc interval greater than 500 msec. Prolongation of the QTc was observed between 1 and 5 weeks after arsenic trioxide infusion, and then returned towards baseline by the end of 8 weeks after arsenic trioxide infusion. In these ECG evaluations, women did not experience more pronounced QT prolongation than men, and there was no correlation with age (Prod Info Trisenox(R), 2001).

3.5.1.J Arsenic Trioxide
1) Interaction Effect: prolongation of the QTc interval and/or torsades de pointes
2) Summary: Arsenic trioxide can prolong the QT interval in some patients, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes and should not be administered with other drugs that may prolong the QT interval (Prod Info Trisenox(R), 2001b). Several antipsychotic agents have

demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999a), haloperidol (O'Brien et al, 1999a), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), risperidone (Duenas-Laita et al, 1999c), sertindole (Agelink et al, 2001b), quetiapine (Owens, 2001d), sultopride (Lande et al, 1992c), ziprasidone (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of arsenic trioxide and antipsychotics is not recommended.
7) Probable Mechanism: additive effects on QTc prolongation
8) Literature Reports
a) QT/QTc prolongation should be expected during treatment with arsenic trioxide and torsade de pointes as well as complete heart block has been reported. Over 460 ECG tracings from 40 patients with refractory or relapsed APL treated with arsenic trioxide were evaluated for QTc prolongation. Sixteen of 40 patients (40%) had at least one ECG tracing with a QTc interval greater than 500 msec. Prolongation of the QTc was observed between 1 and 5 weeks after arsenic trioxide infusion, and then returned towards baseline by the end of 8 weeks after arsenic trioxide infusion. In these ECG evaluations, women did not experience more pronounced QT prolongation than men, and there was no correlation with age (Prod Info Trisenox(R), 2001a).

3.5.1.K Astemizole
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including astemizole (Prod Info Geodon(TM), 2002z).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and astemizole is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.L Azimilide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.M Bepridil
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Some antipsychotic agents prolong the QT interval and an additive effect would be anticipated if administered with other agents which lengthen the QT interval (Prod Info Geodon(TM), 2002d; Agelink et al, 2001; Owens, 2001a; Prod Info Orap(R), 1999c; Prod Info Haldol(R), 1998). In U.S. clinical trials, bepridil increased QT and QTc intervals which was associated with torsades de pointes in approximately 1% of patients. Other drugs that increase the QT interval may exaggerate the prolongation of the QT interval observed with bepridil (Prod Info Vascor(R), 1997). Pimozide is contraindicated in patients taking other drugs which may prolong the QT interval (Prod Info Orap(R), 1999c).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of antipsychotics and agents that prolong the QT interval, such as bepridil, is contraindicated. In particular, pimozide is contraindicated in individuals with congenital QT syndrome, patients with a history of cardiac arrhythmias, or patients taking other drugs which may prolong the QT interval.
7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999b).

b) Sometimes fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone therapeutically (Duenas-Laita et al, 1999a; Ravin & Levenson, 1997a).

3.5.1.N Bretylium

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.O Carbamazepine

1) Interaction Effect: decreased ziprasidone plasma concentrations

2) Summary: Ziprasidone is metabolized primarily by CYP3A4. The concomitant use of carbamazepine (a CYP3A4 inducer) 200 mg twice daily for 21 days decreased the ziprasidone AUC by approximately 35%. Therefore, caution should be used when carbamazepine and ziprasidone are coadministered due to the potential for reduced ziprasidone plasma concentrations (Prod Info GEODON(R) oral capsules, IM injection, 2008).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Use caution when prescribing carbamazepine to a patient who takes ziprasidone. Concomitant use of carbamazepine and ziprasidone has resulted in decreased ziprasidone plasma concentrations (Prod Info GEODON(R) oral capsules, IM injection, 2008).

7) Probable Mechanism: induction of CYP3A4-mediated ziprasidone metabolism by carbamazepine

3.5.1.P Chloral Hydrate

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including chloral hydrate (Prod Info Geodon(TM), 2002k; Young et al, 1986).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone and chloral hydrate is contraindicated.

7) Probable Mechanism: additive cardiac effects

3.5.1.Q Chloroquine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including chloroquine (Prod Info Geodon(TM), 2002l). Chloroquine has been shown to prolong the QTc interval at the recommended therapeutic dose (Prod Info Aralen(R), 1999).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone and chloroquine is contraindicated.

7) Probable Mechanism: additive cardiac effects

3.5.1.R Chlorpromazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects on the QT interval and is not recommended. Q and T wave distortions have been observed in patients taking phenothiazines (Prod Info Compazine(R), 2002; Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, though no reports are available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999), haloperidol (O'Brien et al, 1999), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001c), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), sultopride (Lande et al, 1992), ziprasidone (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phenothiazines and antipsychotics, is not recommended.

7) Probable Mechanism: additive QT prolongation

3.5.1.S Chlorpromazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and phenothiazines is contraindicated (Prod Info Compazine(R), 2002a; Prod Info Geodon(R), 2002w).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone and other drugs that may prolong the QT interval, such as phenothiazines, is contraindicated.

7) Probable Mechanism: additive QT prolongation

3.5.1.T Cisapride

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Some antipsychotic agents prolong the QT interval and an additive effect would be anticipated if administered with other agents which lengthen the QT interval (Prod Info Geodon(TM), 2002c; Owens, 2001; Prod Info Orap(R), 1999a). Torsades de pointes and QT prolongation have been reported with cisapride (Prod Info Propulsid(R), 2000).

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of antipsychotics and agents that prolong the QT interval, such as cisapride, is contraindicated. In particular, pimozide is contraindicated in individuals with congenital QT syndrome, patients with a history of cardiac arrhythmias, or patients taking other drugs which may prolong the QT interval.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

b) Fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone (Duenas-Laita et al, 1999; Ravin & Levenson, 1997).

3.5.1.U Clarithromycin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including clarithromycin (Prod Info Geodon(TM), 2002s; Prod Info Biaxin(R), 2002).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone and clarithromycin is contraindicated.

7) Probable Mechanism: additive cardiac effects

3.5.1.V Desipramine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though no formal drug interaction studies have been done, it is recommended that concurrent use with other agents that may prolong QTc interval be avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent administration of ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection, 2007).

7) Probable Mechanism: additive cardiac effects

3.5.1.W Disopyramide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including Class IA antiarrhythmic agents (Prod Info Geodon(R), 2002j).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and ziprasidone is contraindicated.

7) Probable Mechanism: additive cardiac effects

3.5.1.X Disopyramide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999e; O'Brien et al, 1999d; Prod Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001i; Duenas-Laita et al, 1999f; Agelink et al, 2001d; Lande et al, 1992f; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is not recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).

b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).

c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible for the plasma level changes than an elimination alteration (Young et al, 1993).

3.5.1.Y Dofetilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).

3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.Z Dolasetron
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval (Prod Info Geodon(R), 2002f).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as dolasetron, is contraindicated.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002e).

3.5.1.AA Doxepin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though no formal drug interaction studies have been done, it is recommended that concurrent use with other agents that may prolong QTc interval be avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent administration of ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection, 2007).
7) Probable Mechanism: additive cardiac effects

3.5.1.AB Droperidol
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Droperidol has been shown to prolong the QTc interval at the recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadministration of droperidol and other drugs known to prolong the QTc interval, including ziprasidone, is contraindicated (Prod Info Inapsine(R), 2001; Prod Info Geodon(TM), 2002b).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as droperidol and ziprasidone, is contraindicated.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(TM), 2002a).

3.5.1.AC Enflurane

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which may also prolong the QTc interval, including enflurane (Prod Info Geodon(R), 2002o; Owens, 2001f).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as enflurane, is contraindicated.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias ((Anon, 2000)). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002n).

3.5.1.AD Erythromycin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval (Prod Info Geodon(TM), 2002t). Erythromycin significantly increased the mean QTc interval versus baseline in a retrospective study of 49 patients (Oberg & Bauman, 1995a). Erythromycin has demonstrated QTc prolongation in combination with other drugs that prolong the QT interval (Prod Info PCE(R), 1997).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as erythromycin, is contraindicated.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Erythromycin significantly increased the QTc interval compared with baseline in a retrospective study of 49 patients. The erythromycin dose was 500 milligrams or 1 gram four times daily, with a mean of 15 doses received. Patients (n equal to 9) who received 60 mg/kg/day or more all developed increases in QT interval of 15% or greater. For all patients, the mean QTc interval increased from 432 milliseconds (msec) at baseline to 483 msec (p less than 0.01). In patients with delayed repolarization at baseline (n equal to 9), the QTc interval increased from 473 msec to 525 msec (p less than 0.01). In patients with heart disease (n equal to 30), all experienced an increase in QTc interval (mean of 15%), compared with an increase of 8% in patients without heart disease (p less than 0.05). In 5 patients (10%), the QTc interval was severely prolonged. One patient developed torsades de pointes attributed to erythromycin. Of 16 patients receiving cotrimoxazole concomitantly, 8 developed QT prolongation of 15% or greater (Oberg & Bauman, 1995).

3.5.1.AE Flecainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, the coadministration of Class I antiarrhythmics and other drugs known to prolong the QTc interval, such as ziprasidone is contraindicated (Prod Info Geodon(TM), 2002j; Prod Info Tambocor(R) flecainide acetate, 1998).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone and Class I antiarrhythmic agents is contraindicated.

7) Probable Mechanism: additive cardiac effects

3.5.1.AF Fluconazole

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval (Prod Info Geodon(TM), 2002). Case reports have described QT prolongation and torsades de pointes associated with fluconazole

(Khazan & Mathis, 2002; Wassmann et al, 1999).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as fluconazole, is contraindicated.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002).

3.5.1.AG Fluoxetine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including fluoxetine (Prod Info Geodon(TM), 2002v; Prod Info Prozac(R), 2001).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as fluoxetine, is not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002p).

3.5.1.AH Foscarnet
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval (Prod Info Geodon(TM), 2002u; Prod Info Foscavir(R), 2000).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as foscarnet, is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.AI Gatifloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including gatifloxacin (Prod Info Geodon(TM), 2002i).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and gatifloxacin is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.AJ Gemifloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although pharmacokinetic studies between ziprasidone and gemifloxacin, which may prolong the QT interval, have not been performed, gemifloxacin should not be used in patients receiving ziprasidone (Prod Info Factive(R), 2003; Prod Info Geodon(R), 2002a).

3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of ziprasidone with a drug that may prolong the QT interval, such as gemifloxacin, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AK Halofantrine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Halofantrine can prolong the QT interval in some patients, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Because ziprasidone may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of halofantrine with ziprasidone is contraindicated (Prod Info Halfan(R), 1998; Prod Info Geodon(TM), 2002n).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as halofantrine, is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.AL Haloperidol

1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Balk, 2003a; Prod Info Haldol(R), 2001). Coadministration of ziprasidone with drugs that potentially prolong the QTc interval, such as haloperidol, is contraindicated (Prod Info Geodon(R), 2002d).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with agents that prolong the QT interval, such as haloperidol, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports

a) Seven patients developed torsade de pointes after therapeutic use of haloperidol in high doses. Three patients developed the dysrhythmia after administration of 211 milligrams (mg) to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episodes, but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol (Metzger & Friedman, 1993; Wilt et al, 1993). Torsades de pointes developed in 8 of 223 critically ill patients in intensive care units. Patients who received intravenous haloperidol greater than 35 mg/day or had a QTc interval prolongation of greater than 500 milliseconds were at greatest risk (Sharma et al, 1998).

b) Numerous case reports have described significant QTc prolongation and torsades de pointes (TdP) associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dose as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, screen patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003).

c) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias ((Anon, 2000)). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002c).

3.5.1.AM Halothane

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which may also prolong the QTc interval, including halothane (Prod Info Geodon(R), 2002ac; Owens, 2001j).
3) Severity: contraindicated
4) Onset: unspecified

5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as halothane, is contraindicated.
7) Probable Mechanism: additive effect on QT interval
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias ((Anon, 2000)). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002ab).

3.5.1.AN Hydroquinidine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including Class IA antiarrhythmic agents (Prod Info Geodon(R), 2002j).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and ziprasidone is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.AO Hydroquinidine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999e; O'Brien et al, 1999d; Prod Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001i; Duenas-Laita et al, 1999f; Agelink et al, 2001d; Lande et al, 1992f; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible for the plasma level changes than an elimination alteration (Young et al, 1993).

3.5.1.AP Ibutilide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).
3) Severity: contraindicated
4) Onset: unspecified

5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.AQ Iloperidone
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Due to the potential for additive effects on the QT interval and increased risk of torsade de pointes, caution should be used when iloperidone and drugs that prolong the QT interval are given concomitantly. Consideration should be given to monitoring cardiac function periodically with on-treatment ECGs and evaluating electrolyte (ie, magnesium, potassium) levels. Discontinue iloperidone in patients with persistent QTc measurements greater than 500 msec (Prod Info FANAPT(TM) oral tablets, 2009).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of iloperidone and drugs that prolong the QT interval may result in additive effects on the QT interval and an increased risk of torsade de pointes. Iloperidone should be avoided in patients with significant cardiovascular illness, eg, cardiac arrhythmia, QT prolongation, recent acute myocardial infarction, and uncompensated heart failure. If concomitant use is necessary, consider monitoring cardiac function periodically with on-treatment ECGs and evaluating electrolyte (ie, magnesium, potassium) levels. Discontinue iloperidone in patients with persistent QTc measurements greater than 500 msec(Prod Info FANAPT(TM) oral tablets, 2009).
7) Probable Mechanism: additive effects on the QT interval
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).

3.5.1.AR Imipramine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though no formal drug interaction studies have been done, it is recommended that concurrent use with other agents that may prolong QTc interval be avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent administration of ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection, 2007).
7) Probable Mechanism: additive cardiac effects

3.5.1.AS Isoflurane
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which may also prolong the QTc interval, including isoflurane (Prod Info Geodon(R), 2002v; Owens, 2001h).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as isoflurane, is contraindicated.
7) Probable Mechanism: additive effect on QT interval
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002u).

3.5.1.AT Isradipine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including isradipine (Prod Info Geodon(TM), 2002q; Prod Info DynaCirc(R), 2000).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as isradipine, is contraindicated.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(TM), 2002p).

3.5.1.AU Lapatinib

1) Interaction Effect: an increased risk of QT interval prolongation

2) Summary: Due to the potential for additive effects on the QT interval and increased risk of torsade de pointes, caution should be used when lapatinib and drugs that prolong the QT interval are given concomitantly. Consideration should be given to monitoring cardiac function periodically with on-treatment ECGs and evaluating electrolyte (ie, magnesium, potassium) levels (Prod Info TYKERB oral tablets, 2008). Thirteen patients had either QTcF (corrected QT by the Friedericia method) greater than 480 msec or an increase in QTcF of greater than 60 msec in an uncontrolled, open-label, dose escalation study in advanced cancer patients (n=81) who received lapatinib doses ranging from 175 mg/day to 1800 mg/day, with serial ECGs collected on days 1 and 14 (Prod Info TYKERB oral tablets, 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Concomitant use of lapatinib and drugs that prolong the QT interval may result in additive effects on the QT interval and an increased risk of torsade de pointes. Therefore, caution should be used when these agents are given concomitantly. Consider monitoring cardiac function periodically with on-treatment ECGs and evaluating electrolyte (ie, magnesium, potassium) levels (Prod Info TYKERB oral tablets, 2008).

7) Probable Mechanism: additive effects on the QT interval

3.5.1.AV Levofloxacin

1) Interaction Effect: increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Although no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including levofloxacin (Prod Info Geodon(R) Capsules & Geodon(R) for Injection, 2004; Prod Info Levaquin, 2004).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone and levofloxacin is not recommended.

7) Probable Mechanism: additive QT prolongation effects

3.5.1.AW Levomethadyl

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Any drug known to have the potential to prolong the QT interval should not be used with levomethadyl. Possible pharmacodynamic interactions can occur between levomethadyl and potentially arrhythmogenic agents such as ziprasidone that prolong the QT interval (Prod Info Orlaam(R), 2001).

3) Severity: contraindicated

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Levomethadyl is contraindicated in patients being treated with ziprasidone as it may precipitate QT prolongation and interact with levomethadyl.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether

ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002m).

3.5.1.AX Lidoflazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Lidoflazine has been shown to prolong the QTc interval at the recommended therapeutic dose (Hanley & Hampton, 1983). Even though no formal drug interaction studies have been done, the coadministration of ziprasidone and other drugs known to prolong the QTc interval, including lidoflazine, is contraindicated (Prod Info Geodon(TM), 2002f).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as lidoflazine, is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.AY Lorcainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the coadministration of Class I antiarrhythmics and other drugs known to prolong the QTc interval, such as ziprasidone is contraindicated (Prod Info Geodon(TM), 2002j; Prod Info Tambocor(R) flecainide acetate, 1998).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class I antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.AZ Lumefantrine

1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Due to the potential for additive effects on QT interval prolongation, concomitant use of artemether/lumefantrine with drugs that prolong the QT interval should be avoided (Prod Info COARTEM(R) oral tablets, 2009).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of artemether/lumefantrine with drugs that prolong the QT interval should be avoided due to the potential for additive effects on QT interval prolongation (Prod Info COARTEM(R) oral tablets, 2009).
7) Probable Mechanism: additive effects on QT interval prolongation
8) Literature Reports
a) Concurrent administration of a single dose of IV quinine 10 mg/kg with the final dose of a 6-dose regimen of artemether/lumfantrine did not alter the systemic exposure to quinine, lumefantrine, or dihydroartemisinin (active metabolite of artemether). Although artemether exposure was decreased, it was not believed to be clinically significant. The effects on QT prolongation were not reported in this study (Prod Info COARTEM(R) oral tablets, 2009).

3.5.1.BA Mefloquine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including mefloquine (Prod Info Geodon(TM), 2002o; Davis et al, 1996).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and mefloquine is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BB Mesoridazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although citing no data, the manufacturer of mesoridazine states that concomitant use with

other drugs which prolong the QT interval is contraindicated (Prod Info Serentil(R), 2001). Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999c), haloperidol (O'Brien et al, 1999c), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001g), risperidone (Duenas-Laita et al, 1999e), sertindole (Agelink et al, 2001c), sultopride (Lande et al, 1992e), ziprasidone (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2004).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as antipsychotics and mesoridazine, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.BC Mesoridazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and phenothiazines is contraindicated (Prod Info Compazine(R), 2002a; Prod Info Geodon(R), 2002w).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and other drugs that may prolong the QT interval, such as phenothiazines, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.BD Methadone
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Cases of QT interval prolongation and serious arrhythmias, including torsade de pointes, have been reported with methadone use (Prod Info DOLOPHINE(R) HYDROCHLORIDE oral tablets, 2006). Ziprasidone use is associated with dose-related QT interval prolongation. Due to the potential for additive effects on QT interval prolongation, concurrent use of methadone and ziprasidone is contraindicated (Prod Info GEODON(R) oral capsule, GEODON(R) intramuscular powder for solution, 2005).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of methadone and ziprasidone is contraindicated due to the potential for additive effects on QT interval prolongation (Prod Info GEODON(R) oral capsule, GEODON(R) intramuscular powder for solution, 2005).
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.BE Moxifloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including moxifloxacin (Prod Info Geodon(TM), 2002g).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and moxifloxacin is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BF Nilotinib
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Due to the potential for additive effects on the QT interval and increased risk of torsade de pointes, concomitant use of nilotinib with drugs that prolong the QT interval should be avoided. However, if concomitant use is required, the patient should be closely monitored for prolongation of the QT interval (Prod Info TASIGNA(R) oral capsules, 2007).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of nilotinib with drugs that prolong the QT interval should be avoided due to the potential for additive effects on the QT interval and increased risk of torsade de pointes. However, if concurrent therapy is required, monitor patient closely for prolongation of the QT interval (Prod Info TASIGNA(R) oral capsules, 2007).
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.BG Nortriptyline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though no formal drug interaction studies have been done, it is recommended that concurrent use with other agents that may prolong QTc interval be avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent administration of ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection, 2007).
7) Probable Mechanism: additive cardiac effects

3.5.1.BH Octreotide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Octreotide has been shown to prolong the QTc interval at the recommended therapeutic dose (Prod Info Sandostatin(R), 1999). Even though no formal drug interaction studies have been done, the coadministration of ziprasidone and other drugs known to prolong the QTc interval, including octreotide, is contraindicated (Prod Info Geodon(TM) ziprasidone, 2002b).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as octreotide, is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BI Pentamidine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and pentamidine is contraindicated (Prod Info Geodon(TM) ziprasidone, 2002). Pentamidine has been shown to prolong the QTc interval at the recommended therapeutic dose (Lindsay et al, 1990).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as pentamidine, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.BJ Pimozide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including pimozide (Prod Info Geodon(TM), 2002w).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and pimozide is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BK Pirmenol
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including Class IA antiarrhythmic agents (Prod Info Geodon(R), 2002j).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and ziprasidone is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BL Pirmenol
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac

arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999e; O'Brien et al, 1999d; Prod Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001i; Duenas-Laita et al, 1999f; Agelink et al, 2001d; Lande et al, 1992f; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible for the plasma level changes than an elimination alteration (Young et al, 1993).

3.5.1.BM Prajmaline
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including Class IA antiarrhythmic agents (Prod Info Geodon(R), 2002j).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and ziprasidone is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BN Prajmaline
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999e; O'Brien et al, 1999d; Prod Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001i; Duenas-Laita et al, 1999f; Agelink et al, 2001d; Lande et al, 1992f; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).

c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible for the plasma level changes than an elimination alteration (Young et al, 1993).

3.5.1.BO Probucol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including probucol (Prod Info Geodon(TM), 2002y). Probucol has been shown to prolong the QTc interval (Gohn & Simmons, 1992; Prod Info Lorelco(R), 1991).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as probucol, is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BP Procainamide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc interval, including Class IA antiarrhythmic agents (Prod Info Geodon(R), 2002j).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and ziprasidone is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BQ Procainamide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999e; O'Brien et al, 1999d; Prod Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001i; Duenas-Laita et al, 1999f; Agelink et al, 2001d; Lande et al, 1992f; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports

a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).

b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).

c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration

(Tmax) were not significantly changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible for the plasma level changes than an elimination alteration (Young et al, 1993).

3.5.1.BR Prochlorperazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects on the QT interval and is not recommended. Q and T wave distortions have been observed in patients taking phenothiazines (Prod Info Compazine(R), 2002; Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, though no reports are available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999), haloperidol (O'Brien et al, 1999), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001c), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), sultopride (Lande et al, 1992), ziprasidone (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phenothiazines and antipsychotics, is not recommended.
7) Probable Mechanism: additive QT prolongation

3.5.1.BS Prochlorperazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and phenothiazines is contraindicated (Prod Info Compazine(R), 2002a; Prod Info Geodon(R), 2002w).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and other drugs that may prolong the QT interval, such as phenothiazines, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.BT Propafenone

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the coadministration of Class I antiarrhythmics and other drugs known to prolong the QTc interval, such as ziprasidone is contraindicated (Prod Info Geodon(TM), 2002j; Prod Info Tambocor(R) flecainide acetate, 1998).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class I antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BU Protriptyline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though no formal drug interaction studies have been done, it is recommended that concurrent use with other agents that may prolong QTc interval be avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent administration of ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection, 2007).
7) Probable Mechanism: additive cardiac effects

3.5.1.BV Quinidine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, the manufacturer of ziprasidone warns against its administration with other drugs which are also known to prolong the QTc

interval, including Class IA antiarrhythmic agents (Prod Info Geodon(R), 2002j).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and ziprasidone is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.BW Ranolazine
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Treatment with ranolazine has been associated with QTc prolongation (Prod Info RANEXA(R) extended-release oral tablets, 2008). Ziprasidone use is associated with dose-related QT interval prolongation (Prod Info GEODON(R) oral capsules, IM injection, 2008). Concurrent use of ranolazine and ziprasidone is contraindicated due to the potential for additive effects on QT interval prolongation (Prod Info GEODON(R) oral capsules, IM injection, 2008).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of ranolazine and ziprasidone is contraindicated due to the potential for additive effects on QT interval prolongation (Prod Info GEODON(R) oral capsules, IM injection, 2008).
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.BX Sematilide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.BY Sertindole
1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval (Brown & Levin, 1998a; Prod Info Geodon(R), 2002aa).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with agents that prolong the QT interval, such as sertindole is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) The overall incidence of QT interval prolongation with sertindole is estimated at 1.9% to 4%, and the potential risk of developing torsades de pointes has been estimated at 0.13% to 0.21% (Brown & Levin, 1998). Periodic electrocardiographic monitoring is required in the United Kingdom per sertindole's official labeling (Cardoni & Myer, 1997).
b) Thirty, otherwise healthy, schizophrenic patients participated in an open, dose titration (4 to 16 mg/day) study to determine the cardiovascular effects of sertindole. At the end of the 3-week study it was concluded that resting heart rate and frequency corrected QT times increased in a dose-related manner, while there was no change in PQ-conduction times, autonomic parasympathetic tone, or blood pressure. Conduction times increased an average 3.5% to 6.5% over the dosing range (Agelink et al, 2001e).
c) Ziprasidone prolongs the QTc in some patients in a dose-related manner. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams) (Prod Info Geodon(R), 2002z).

3.5.1.BZ Sotalol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.CA Sparfloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including sparfloxacin (Prod Info Geodon(TM), 2002x).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and sparfloxacin is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.CB Spiramycin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Spiramycin has been shown to prolong the QTc interval at the recommended therapeutic dose (Stramba-Badiale et al, 1997). Even though no formal drug interaction studies have been done, the coadministration of ziprasidone and other drugs known to prolong the QTc interval, including spiramycin, is not recommended (Prod Info Geodon(TM) ziprasidone, 2002a).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as spiramycin, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.CC Sultopride
1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval (Lande et al, 1992b; Montaz et al, 1992a; Harry, 1997a; Prod Info Geodon(R), 2002l).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that prolong the QT interval, such as sultopride, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Sultopride may induce prolongation of the QT interval and ventricular arrhythmias including torsades de pointes following therapeutic or toxic doses (Lande et al, 1992a; Montaz et al, 1992; Harry, 1997).
b) Ziprasidone prolongs the QTc in some patients in a dose-related manner. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams) (Prod Info Geodon(R), 2002k).

3.5.1.CD Sunitinib
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Sunitinib has been associated with prolongation of the QT interval in a dose dependent manner, with torsade de pointes occurring in less than 0.1% patients exposed to sunitinib. Due to the potential for additive effects on the QT interval and increased risk for torsade de pointes, caution should be used when sunitinib and ziprasidone are given concomitantly. Consideration should be given to monitoring cardiac function periodically with on-treatment ECGs and evaluating electrolyte (ie, magnesium, potassium)

levels (Prod Info SUTENT(R) oral capsules, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of sunitinib and ziprasidone may result in additive effects on the QT interval and an increased risk of torsade de pointes. Therefore, caution should be used when these agents are given concomitantly. Consider monitoring cardiac function periodically with on-treatment ECGs and evaluating electrolyte (ie, magnesium, potassium) levels (Prod Info SUTENT(R) oral capsules, 2008).
7) Probable Mechanism: additive effects on the QT interval

3.5.1.CE Tacrolimus
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including tacrolimus (Prod Info Geodon(TM), 2002r).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and tacrolimus is contraindicated.
7) Probable Mechanism: additive cardiac effects

3.5.1.CF Tedisamil
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and Class III antiarrhythmic agents is contraindicated (Prod Info Geodon(TM), 2002m). Bretylium should not be used with other drugs known to prolong the QTc interval , including ziprasidone (Yamreudeewong et al, 2003a).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and Class III antiarrhythmic agents is contraindicated.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Concurrent use of class III antiarrhythmic agents, and other drugs that can prolong the QT interval, such as ziprasidone, is not recommended. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003).

3.5.1.CG Telithromycin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including telithromycin (Prod Info Geodon(TM), 2002h; Owens, 2001b).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as telithromycin, is contraindicated.
7) Probable Mechanism: additive effect on QT interval
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002g).

3.5.1.CH Terfenadine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Some antipsychotics have been shown to prolong the QTc interval at the recommended therapeutic dose (Prod Info Geodon(TM), 2002aa; Owens, 2001k; Prod Info Orap(R), 1999e). Even though no formal drug interaction studies have been done, the coadministration of terfenadine and other drugs known to prolong the QTc interval, including antipsychotics, is contraindicated (Anon, 1997).
3) Severity: contraindicated

4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of terfenadine with any drug that prolongs the QT interval, such as antipsychotic agents, is contraindicated.
7) Probable Mechanism: additive effect on QT interval
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999d).

3.5.1.CI Tetrabenazine
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Due to the potential for additive effects on the QT interval and increased risk of torsade de pointes, concomitant use of tetrabenazine with drugs that prolong the QT interval should be avoided. However, if concomitant use is required, the patient should be closely monitored for prolongation of the QT interval (Prod Info XENAZINE(R) oral tablets, 2008). In a randomized, double-blind, placebo controlled crossover study of healthy subjects, the effect of a single 25 mg or 50 mg dose of tetrabenazine on the QT interval was studied with moxifloxacin as a positive control. The 50 mg dose of tetrabenazine caused an approximate 8 millisecond mean increase in QT (Prod Info XENAZINE(R) oral tablets, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of tetrabenazine with drugs that prolong the QT interval should be avoided due to the potential for additive effects on the QT interval and increased risk of torsade de pointes. However, if concurrent therapy is required, monitor patient closely for prolongation of the QT interval (Prod Info XENAZINE(R) oral tablets, 2008).
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.CJ Tetrabenazine
1) Interaction Effect: increased risk of QT interval prolongation
2) Summary: Tetrabenazine causes a small increase in the corrected QT interval. As the degree of prolongation increases, QT prolongation can develop into torsade de pointes-type VT. The concomitant use of tetrabenazine with other drugs known for QT prolongation (eg, ziprasidone) should be avoided (Prod Info XENAZINE(R) oral tablets, 2008). In a randomized, double-blind, placebo controlled crossover study of healthy subjects, the effect of a single 25 mg or 50 mg dose of tetrabenazine on the QT interval was studied with moxifloxacin as a positive control. The 50 mg dose of tetrabenazine caused an approximate 8 millisecond mean increase in QT (Prod Info XENAZINE(R) oral tablets, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of tetrabenazine with ziprasidone or other drugs that prolong the QT interval should be avoided due to the potential for additive effects on the QT interval and increased risk of torsade de pointes (Prod Info XENAZINE(R) oral tablets, 2008). However, if concurrent therapy is required, monitor patient closely for prolongation of the QT interval.
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.CK Thioridazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although citing no data, the manufacturer of thioridazine states that concomitant use with other drugs which prolong the QT interval is contraindicated (Prod Info Mellaril(R), 2001). Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), pimozide (Prod Info Orap(R), 2000), quetiapine (Owens, 2001e), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), risperidone (Duenas-Laita et al, 1999d), sertindole (Agelink et al, 2001c), sultopride (Lande et al, 1992d), ziprasidone (Prod Info GEODON (R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2004).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as antipsychotics, and thioridazine, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.CL Trifluoperazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac

arrest)
2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects on the QT interval and is not recommended. Q and T wave distortions have been observed in patients taking phenothiazines (Prod Info Compazine(R), 2002; Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, though no reports are available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999), haloperidol (O'Brien et al, 1999), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001c), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), sultopride (Lande et al, 1992), ziprasidone (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phenothiazines and antipsychotics, is not recommended.
7) Probable Mechanism: additive QT prolongation

3.5.1.CM Trifluoperazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: The manufacturer of ziprasidone states that concomitant use of ziprasidone and phenothiazines is contraindicated (Prod Info Compazine(R), 2002a; Prod Info Geodon(R), 2002w).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone and other drugs that may prolong the QT interval, such as phenothiazines, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.CN Trimipramine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though no formal drug interaction studies have been done, it is recommended that concurrent use with other agents that may prolong QTc interval be avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent administration of ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection, 2007).
7) Probable Mechanism: additive cardiac effects

3.5.1.CO Vasopressin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including vasopressin (Prod Info Geodon(TM), 2002e; Jacoby & Wiegman, 1990).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as vasopressin, is contraindicated.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Ziprasidone prolongs the QTc and an increased risk of potentially fatal ventricular dysrhythmias (Anon, 2000). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002b).

3.5.1.CP Zolmitriptan
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, ziprasidone should not be coadministered with other drugs which are also known to prolong the QTc interval, including zolmitriptan (Prod Info Geodon(R), 2002y; Prod Info Zomig(R), 2001).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that can prolong the QT interval, such as zolmitriptan, is contraindicated.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias ((Anon, 2000)). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more with ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002x).

3.5.1.CQ Zotepine
1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Coadministration of ziprasidone with other drugs that potentially prolong the QTc interval, such as zotepine, is contraindicated (Prod Info Geodon(R), 2002r; Sweetman, 2003).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ziprasidone with other agents that prolong the QT interval, such as zotepine, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Ziprasidone prolongs the QTc in some patients in a dose-related manner. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 milliseconds (msec) at the highest dose (160 milligrams) (Prod Info Geodon(R), 2002q).
b) Since zotepine can prolong the QT interval it is recommended that an ECG is performed before starting treatment. Patients with pre-existing prolongation of the QT interval should not be given zotepine (Sweetman, 2003).

4.0 Clinical Applications

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters
A) Ziprasidone Hydrochloride
1) Therapeutic
a) Physical Findings
1) Improvement of psychotic symptomatology (positive, negative symptoms) (Prod Info GEODON(R) oral capsules, IM injection, 2007).
2) Toxic
a) Laboratory Parameters
1) Torsade de Pointes
a) Ziprasidone may prolong the QT interval in some patients; ECG changes, blood pressure and heart rate monitoring may be warranted (Prod Info GEODON(R) oral capsules, IM injection, 2007).
b) Patients with hypokalemia or hypomagnesemia have an increased risk of the occurrence of torsade de pointes. Serum potassium and magnesium levels, at baseline and during ziprasidone

therapy, should be monitored for patients on concomitant diuretics or at risk for electrolyte disturbances (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) Further evaluation, such as Holter monitoring, should be initiated for any patient who experiences symptoms during ziprasidone therapy that may indicate the development of torsade de pointes (eg dizziness, palpitations, syncope) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

2) Diabetes Mellitus

a) Atypical antipsychotics, such as ziprasidone, have been linked with the development of hyperglycemia, some cases extreme and associated with ketoacidosis or hyperosmolar coma or death. Patients diagnosed with or at risk of diabetes mellitus should be monitored regularly for worsening of glucose control (eg fasting blood glucose, polydipsia, polyuria, polyphagia, weakness) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

b) Physical Findings

1) Tardive Dyskinesia

a) Patients being treated with antipsychotics, such as ziprasidone, may develop tardive dyskinesia. Severity and reversibility appear to be related to the duration of treatment and total cumulative dose administered, but may occur after brief treatment periods at low doses. The development of signs and symptoms of tardive dyskinesia should be monitored (Prod Info GEODON(R) oral capsules, IM injection, 2007).

2) Neuroleptic Malignant Syndrome

a) The development of Neuroleptic Malignant Syndrome (NMS) has been associated with antipsychotic therapy. Patients taking ziprasidone should be monitored for signs and symptoms of NMS (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3) Body Temperature Dysregulation

a) Antipsychotics have been associated with disrupting the body's ability to regulate core body temperature. Patients taking ziprasidone should be monitored for changes in body temperature and dehydration (Prod Info GEODON(R) oral capsules, IM injection, 2007).

B) Ziprasidone Mesylate

1) Therapeutic

a) Physical Findings

1) Improvement of psychotic symptomatology (positive, negative symptoms) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

2) Toxic

a) Laboratory Parameters

1) Torsade de Pointes

a) Ziprasidone may prolong the QT interval in some patients; ECG changes, blood pressure and heart rate monitoring may be warranted (Prod Info GEODON(R) oral capsules, IM injection, 2007).

b) Patients with hypokalemia or hypomagnesemia have an increased risk of the occurrence of torsade de pointes. Serum potassium and magnesium levels, at baseline and during ziprasidone therapy, should be monitored for patients on concomitant diuretics or at risk for electrolyte disturbances (Prod Info GEODON(R) oral capsules, IM injection, 2007).

c) Further evaluation, such as Holter monitoring, should be initiated for any patient who experiences symptoms during ziprasidone therapy that may indicate the development of torsade de pointes (eg dizziness, palpitations, syncope) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

2) Diabetes Mellitus

a) Atypical antipsychotics, such as ziprasidone, have been linked with the development of hyperglycemia, some cases extreme and associated with ketoacidosis or hyperosmolar coma or death. Patients diagnosed with or at risk of diabetes mellitus should be monitored regularly for worsening of glucose control (eg fasting blood glucose, polydipsia, polyuria, polyphagia, weakness) (Prod Info GEODON(R) oral capsules, IM injection, 2007).

b) Physical Findings

1) Tardive Dyskinesia

a) Patients being treated with antipsychotics, such as ziprasidone, may develop tardive dyskinesia. Severity and reversibility appear to be related to the duration of treatment and total cumulative dose administered, but may occur after brief treatment periods at low doses. The development of signs and symptoms of tardive dyskinesia should be monitored (Prod Info GEODON(R) oral capsules, IM injection, 2007).

2) Neuroleptic Malignant Syndrome

a) The development of Neuroleptic Malignant Syndrome (NMS) has been associated with antipsychotic therapy. Patients taking ziprasidone should be monitored for signs and symptoms of NMS (Prod Info GEODON(R) oral capsules, IM injection, 2007).

3) Body Temperature Dysregulation

a) Antipsychotics have been associated with disrupting the body's ability to regulate core body temperature. Patients taking ziprasidone should be monitored for changes in body temperature and dehydration (Prod Info GEODON(R) oral capsules, IM injection, 2007).

4.2 Patient Instructions

A) Ziprasidone (By mouth)
Ziprasidone

Treats schizophrenia and certain problems caused by bipolar disorder.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to ziprasidone, or if you have severe heart failure or have recently had a heart attack. You should not use this medicine if you have a history of heart rhythm problems such as QT prolongation (including congenital long QT syndrome) or if you are using certain medicines that prolong the QT interval in the heart (such as dofetilide, sotalol, quinidine, disopyramide, procainamide, amiodarone, mesoridazine, thioridazine, chlorpromazine, droperidol, pimozide, sparfloxacin, gatifloxacin, moxifloxacin, halofantrine, mefloquine, pentamidine, arsenic trioxide, levomethadyl acetate, dolasetron mesylate, probucol, or tacrolimus). This medicine should not be used in elderly patients who have a mental illness called dementia-related psychosis.

How to Use This Medicine:
Capsule
Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed several times in order to find out what works best for you. Do not use more medicine or use it more often than your doctor tells you to.
It is best to take this medicine with food or milk at the same time every day. Swallow the capsule whole. Do not break, crush, or chew it.
Keep using this medicine for the full treatment time, even if you feel better after the first few doses.

If a Dose is Missed:
If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next dose, wait until then to use the medicine and skip the missed dose. Do not use extra medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:
Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after you have finished your treatment. You will also need to throw away old medicine after the expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, and herbal products.
Make sure your doctor knows if you are using medicines to lower blood pressure, such as atenolol, lisinopril, metoprolol, quinapril, Accupril®, Cozaar®, Diovan®, Lotrel®, Norvasc®, Toprol®, or Zestril®. Tell your doctor if you are using diuretics or water pills (such as furosemide, Aldactazide®, Aldactone®, Dyazide®, Lasix®, Moduretic®, or Maxzide®), levodopa, carbamazepine (Carbatrol®, Tegretol®), or ketoconazole (Nizoral®).
Tell your doctor if you are also using levodopa (such as Dopart® or Larodopa®) or medicines such as bromocriptine (Parlodel®), Pramipexole (Mirapex®), ropinirole (Requip®), cabergoline (Dostinex®), or apomorphine (Apokyn®).
Tell your doctor if you are using any medicines that make you sleepy. These include sleeping pills, cold and allergy medicine, narcotic pain relievers, and sedatives.
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:
Make sure your doctor knows if you are pregnant or breastfeeding, or if you have heart problems, liver disease, Alzheimer's disease, trouble with swallowing, or dizziness or fainting problems. Tell your doctor if you have a history of stroke, seizures, breast cancer, or low potassium or magnesium levels in your blood.
Make sure your doctor knows if you have thoughts of hurting yourself. Tell your doctor if you or anyone in your family has a history of diabetes.
Make sure your doctor knows if you have a family history of a heart condition called congenital long QT syndrome. Tell your doctor if you have ever had Neuroleptic Malignant Syndrome (NMS) caused by other antipsychotic medicines.
Tardive dyskinesia (a movement disorder) may occur and may not go away after you stop using the medicine. Call your doctor if you are having signs of tardive dyskinesia such as rapid, worm-like movements of the tongue, or other uncontrolled movements of the mouth, tongue, cheeks, jaw, or arms and legs.
This medicine may cause an increase in your blood sugar. If you have diabetes, you may need to check your blood sugar more often. If you are using medicine for diabetes, your doctor may need to change your dose.
This medicine is not approved to treat behavior disorders in older people who have dementia. Using this medicine to treat this problem could increase the risk of death. This risk has not been shown for the

approved uses of this medicine.
This medicine may make you dizzy or drowsy. Avoid driving, using machines, or doing anything else that could be dangerous if you are not alert. This medicine may also make you feel lightheaded when you get up suddenly from a lying or sitting position, so get up slowly.
This medicine might reduce how much you sweat. Your body could get too hot if you do not sweat enough. If your body gets too hot, you might feel dizzy, weak, tired, or confused. You might vomit or have an upset stomach. Do not get too hot while you are exercising. Avoid places that are very hot. Call your doctor if you are too hot and cannot cool down.
Your doctor will need to check your progress at regular visits while you are using this medicine. Be sure to keep all appointments.
Some side effects are more likely to happen in elderly people who have memory problems or other reduced mental skills. Make sure the doctor knows if the person who will be using this medicine has Alzheimer's disease or similar problems (often called "dementia").

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, chest tightness, trouble breathing.
Chest pain.
Fast, slow, irregular (uneven), or pounding heartbeat.
Fever, sweating, confusion, muscle stiffness.
In males: Painful, prolonged erection of your penis.
Increase in thirst, hunger, or urination.
Lightheadedness, dizziness, or fainting.
Problems with balance or walking.
Seizures.
Severe diarrhea, nausea, vomiting, or stomach pain.
Skin rash.
Trouble swallowing or talking, sticking out of the tongue, or spasm of neck muscles.
Twitching or muscle movements you cannot control (often in your face, tongue, or jaw).

If you notice these less serious side effects, talk with your doctor:
Anxiety or restlessness.
Changes in vision.
Constipation or upset stomach.
Dry mouth.
Headache.
Sleepiness or unusual drowsiness.
Sneezing, cough, or runny or stuffy nose.
Tiredness.
Weight gain.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

B) Ziprasidone (Injection)
Ziprasidone

Treats agitation (excessive movement, tension, or anxiety) in a person who has schizophrenia.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to ziprasidone, or if you have severe heart failure or have recently had a heart attack. You should not use this medicine if you have a history of heart rhythm problems such as QT prolongation (including congenital long QT syndrome) or if you are using certain medicines that prolong the QT interval in the heart (such as dofetilide, sotalol, quinidine, disopyramide, procainamide, amiodarone, mesoridazine, thioridazine, chlorpromazine, droperidol, pimozide, sparfloxacin, gatifloxacin, moxifloxacin, halofantrine, mefloquine, pentamidine, arsenic trioxide, levomethadyl acetate, dolasetron mesylate, probucol, or tacrolimus). This medicine should not be used in elderly patients who have a mental illness called dementia-related psychosis.

How to Use This Medicine:
Injectable
Your doctor will prescribe your exact dose and tell you how often it should be given. This medicine is given as a shot into one of your muscles.
A nurse or other trained health professional will give you this medicine.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, and herbal products.
Make sure your doctor knows if you are using medicines to lower blood pressure, such as atenolol, lisinopril,

metoprolol, quinapril, Accupril®, Cozaar®, Diovan®, Lotrel®, Norvasc®, Toprol®, or Zestril®. Tell your doctor if you are using diuretics or water pills (such as furosemide, Aldactazide®, Aldactone®, Dyazide®, Lasix®, Moduretic®, or Maxzide®), levodopa, carbamazepine (Carbatrol®, Tegretol®), or ketoconazole (Nizoral®).
Tell your doctor if you are using levodopa (such as Dopart® or Larodopa®) or medicines such as bromocriptine (Parlodel®), Pramipexole (Mirapex®), ropinirole (Requip®), cabergoline (Dostinex®), or apomorphine (Apokyn®).
Tell your doctor if you are using any medicines that make you sleepy. These include sleeping pills, cold and allergy medicine, narcotic pain relievers, and sedatives.
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:
Make sure your doctor knows if you are pregnant or breastfeeding, or if you have heart problems, liver disease, Alzheimer's disease, trouble with swallowing, or dizziness or fainting problems. Tell your doctor if you have a history of stroke, seizures, breast cancer, or low potassium or magnesium levels in your blood.
Tell your doctor if you or anyone in your family has a history of diabetes.
Make sure your doctor knows if you have a family history of a heart condition called congenital long QT syndrome. Tell your doctor if you have ever had Neuroleptic Malignant Syndrome (NMS) caused by other antipsychotic medicines.
Tardive dyskinesia (a movement disorder) may occur and may not go away after you stop using the medicine. Call your doctor if you are having signs of tardive dyskinesia such as rapid, worm-like movements of the tongue, or other uncontrolled movements of the mouth, tongue, cheeks, jaw, or arms and legs.
This medicine is not approved to treat behavior disorders in older people who have dementia. Using this medicine to treat this problem could increase the risk of death. This risk has not been shown for the approved uses of this medicine.
This medicine may make you dizzy or drowsy. Avoid driving, using machines, or doing anything else that could be dangerous if you are not alert. This medicine may also make you feel lightheaded when you get up suddenly from a lying or sitting position, so get up slowly.
This medicine may cause an increase in your blood sugar. If you have diabetes, you may need to check your blood sugar more often. If you are taking medicine for diabetes, your doctor may need to change your dose.
This medicine may cause you to become overheated more easily than usual. Be careful when exercising, or when you are outdoors in hot or humid weather.
Your doctor will need to check your blood at regular visits while you are using this medicine. Be sure to keep all appointments.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, chest tightness, trouble breathing.
Anxiety, agitation, trouble sleeping, or changes in mood or behavior.
Fast, slow, uneven, or pounding heartbeat.
Fever, sweating, confusion, muscle stiffness.
In males: painful, prolonged erection of your penis.
Increase in thirst, hunger, or urination.
Lightheadedness, dizziness, or fainting.
Numbness, tingling, or burning pain in your hands, arms, legs, or feet.
Problems with balance or walking.
Red or black stools.
Seizures.
Severe diarrhea, nausea, vomiting, or stomach pain.
Skin rash.
Trouble swallowing or talking, sticking out of the tongue, or spasm of neck muscles.
Twitching or muscle movements you cannot control (often in your face, tongue, or jaw).

If you notice these less serious side effects, talk with your doctor:
Headache.
Pain where the shot was given.
Sleepiness or unusual drowsiness.
Sneezing, cough, or stuffy nose.
Tiredness.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Ziprasidone

1) Current users of atypical antipsychotic drugs (including ziprasidone) and typical antipsychotic drugs had a similar dose-dependent risk of sudden cardiac death, according to a retrospective cohort of 93,300 adult users of

antipsychotic drugs and 186,600 matched controls. The study included patients age 30 to 74 years (mean 45.7 +/- 11.8 years) with similar cardiovascular risk at baseline who had at least one filled prescription and had 1 outpatient visit in each of the 2 preceding years. Sudden cardiac death was defined as occurring in the community and excluded deaths of patients admitted to the hospital, non-sudden deaths, deaths due to extrinsic causes, or causes not related to ventricular tachyarrhythmia. Current use was defined as the interval between the time the prescription was filled and the end of the day's supply. Low and high doses was defined as comparable to less than 100 milligrams (mg) of chlorpromazine, and doses comparable to chlorpromazine 300 mg or greater, respectively. The adjusted rate of sudden cardiac death (incidence-rate ratio) in current users of atypical antipsychotic drugs in 79,589 person-years was 2.26 (95% CI, 1.88 to 2.72, p less than 0.001) which was similar to the risk in current users of typical antipsychotic drugs in 86,735 person-years which was 1.99 (95% CI, 1.68 to 2.34, p less than 0.001). The risk of sudden cardiac death significantly increased with increasing dose in both the typical and atypical antipsychotic drug groups. In atypical antipsychotic use, the incidence rate ratio increased from 1.59 (95% CI, 1.03 to 2.46) in low-dose use to 2.86 (95% CI, 2.25 to 3.65) in high-dose use. To limit the effects of confounding of the study results, there was a secondary analysis performed in a cohort of patients matched by propensity score, which resulted in a similar risk of sudden death as the primary cohort analysis (Ray et al, 2009). In an editorial in The New England Journal of Medicine, it has been suggested that antipsychotic drugs continue to be used in patients with clear evidence of benefit, but in vulnerable populations with cardiac risk profiles (eg, elderly patients), there should be an age-dependent justification required prior to administration. It has also been suggested (although not formally tested) that ECGs be performed before and shortly after initiation of antipsychotic therapy to screen for existing or emergent QT interval prolongation (Schneeweiss & Avorn, 2009).

2) General (atypical agents): patients resistant to standard antipsychotic agents; patients with therapy-limiting extrapyramidal symptoms, other adverse effects.

3) Specific: comparisons of ziprasidone with clozapine, risperidone, olanzapine, and sertindole in refractory patients are needed to determine potential advantages. Disadvantages of ziprasidone: prolongation of QT/QTc interval, shorter half-life, twice-daily dosing usually required (olanzapine, sertindole may be given once daily).

B) Ziprasidone Hydrochloride

See Drug Consult reference: FIRST- VS SECOND-GENERATION ANTIPSYCHOTIC AGENTS FOR SCHIZOPHRENIA

C) Ziprasidone Mesylate

See Drug Consult reference: FIRST- VS SECOND-GENERATION ANTIPSYCHOTIC AGENTS FOR SCHIZOPHRENIA

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) Atypical antipsychotic (benzisothiazoyl piperazine derivative); serotonin (5HT)-2A/dopamine D2 antagonist. Also a 5HT-1A agonist (property may confer greater protection against adverse extrapyramidal effects) (Kerwin & Taylor, 1996; Bench et al, 1993; Fischman et al, 1996; Owens, 1996; Lieberman, 1993; Pickar, 1995; Anon, 1996a; Schotte et al, 1996).

2) Modest-to-low affinity for alpha-1, H1 receptors (Kerwin & Taylor, 1996). Inhibits norepinephrine reuptake (Pickar, 1995; Seeger et al, 1995).

3) In vitro: ratio of 5HT-2A/dopamine D2 receptor affinity greater than clozapine (2-fold), haloperidol (680-fold) (Seeger et al, 1995).

B) REVIEW ARTICLES

1) Focus on Ziprasidone (Green B, 2001).

2) Treatment of schizophrenia (includes use of atypical agents) (Marder, 1996; Fleischhacker, 1995; Meltzer et al, 1994; Lieberman, 1996; Weiden et al, 1996; Jeste et al, 1996).

3) Psychosis in mania (use of atypical agents) (McElroy et al, 1996).

4) Mechanism of action with respect to neurotransmitter pathways in the brain utilized by atypical antipsychotics, including ZIPRASIDONE (Kendrick, 1999).

5) A brief introductory review of ziprasidone is available (Tandon, 2000).

4.5 Therapeutic Uses

Ziprasidone

Ziprasidone Hydrochloride

Ziprasidone Mesylate

4.5.A Ziprasidone

4.5.A.1 Dementia

See Drug Consult reference: BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA

4.5.B Ziprasidone Hydrochloride

Bipolar I disorder, acute manic or mixed episodes

Major depressive disorder, Treatment-resistant; Adjunct

Schizoaffective disorder

Schizophrenia

4.5.B.1 Bipolar I disorder, acute manic or mixed episodes

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated for the treatment of acute manic or mixed episodes in patients with bipolar disorder, with or without psychotic features (Prod Info GEODON(R) oral capsules, IM injection, 2007)

c) Adult:

1) Ziprasidone was more effective than placebo for treating acute bipolar mania. In a randomized, double-blind, multicenter, placebo-controlled trial, 210 bipolar inpatients, currently in a manic or mixed episode, underwent single-blind placebo treatment for a one-week washout and were then randomized 2:1 to receive ziprasidone (n=140) or placebo (n=70) for 3 weeks. Ziprasidone, given with meals, was started at 40 milligrams (mg) twice daily on day 1, raised to 80 mg twice daily on day 2, and then adjusted if necessary during the trial to a final range of 80 to 160 mg/day. Data from 131 ziprasidone-treated patients and 66 placebo-treated patients were used for determining efficacy. On the 11-item Mania Rating Scale, a significantly greater improvement with ziprasidone compared to placebo was evident by day 2 (p less than 0.003) and remained apparent throughout the study (p less than 0.001 at the end of weeks 1, 2, and 3). By the end of the study, significant differences between the groups, favoring ziprasidone over placebo, were evident on the Clinical Global Impressions (CGI) severity scale, the CGI improvement scale, the Positive and Negative Syndrome Scale, and the Global Assessment of Functioning Scale. Fifty percent of patients receiving ziprasidone and 35% receiving placebo were classified as responders (p less than 0.05). In the ziprasidone group, 6.4% of patients (9 of 140) withdrew because of adverse events, compared to 4.3% (3 of 70) of the placebo group. None of the treatment-related adverse events in either group was serious. The most commonly occurring adverse events were somnolence (ziprasidone vs placebo: 37% vs 13%), headache (21% vs 19%), dizziness (22% vs 10%), and akathisia (11% vs 6%). Movement disorders were uncommon. No change in weight was associated with ziprasidone treatment. Ziprasidone treatment showed a mean prolongation in QT (c) interval of 11 milliseconds (msec). No patient had a QT(c) interval of 500 msec or higher (Keck et al, 2003).

4.5.B.2 Major depressive disorder, Treatment-resistant; Adjunct

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Ziprasidone augmentation may be effective in the treatment of major depression resistant to SSRI therapy

c) Adult:

1) Ziprasidone augmentation of selective serotonin reuptake inhibitor (SSRI) therapy may be an effective option for patients with treatment- resistant major depression. In a prospective, open-label trial (n=20), patients with major depressive disorder resistant to SSRI therapy and a Hamilton Rating Scale for Depression (HAM-D) score of at least 14 received ziprasidone (initial, 20 milligrams (mg) twice daily, titrated in 20 mg/week increments to a maximum of 80 mg twice daily; mean dose, 82.1 mg/day) in addition to continued SSRI therapy with citalopram, fluoxetine, paroxetine, or sertraline for 6 weeks. At endpoint, 10 (50%) patients achieved response (defined as at least a 50% reduction in the HAM-D score from baseline to endpoint) and 5 (25%) patients achieved remission (defined as a HAM-D score of 7 or less at endpoint). Overall, the mean HAM-D score was reduced from 21.8 to approximately 12

from baseline to week 6, respectively. The most common adverse events included fatigue (50%), sleep disturbance (30%), restlessness (15%), tremor (15%), bruxism (15%), headache (10%), dry mouth (20%), gastrointestinal distress (20%), and urinary frequency (10%). No patient had a QTc interval greater than 500 milliseconds; however, a QTc interval increase of 30 milliseconds was observed in two patients. Placebo-controlled trials are needed to clarify the efficacy of ziprasidone augmentation therapy in SSRI-resistant depression (Papakostas et al, 2004).

4.5.B.3 Schizoaffective disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Oral ziprasidone has been shown to be effective in the short term treatment of patients with an acute episode of schizoaffective disorder.

c) Adult:

1) Significant dose-related improvements on all primary efficacy variables (BPRS total, BPRS Core, CGI-S and BPRS Manic scores) were observed in patients receiving ziprasidone compared to placebo in 2 multicenter double-blind placebo-controlled clinical trials (n=115). Inclusion criteria consisted of hospitalized patients with an acute exacerbation of schizoaffective disorder, bipolar or depressive subtype. Patients were required to have a minimum duration of illness of at least 6 months or 1 year. In one study patients were randomized to receive ziprasidone 20 milligrams (mg) twice daily or placebo for 4 weeks. In the second study, patients were randomized to receive ziprasidone 40 mg twice daily, 80 mg twice daily or placebo for 6 weeks. The incidence of individual adverse events was generally low in all treatment groups (Keck et al, 2001).

4.5.B.4 Schizophrenia

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class I
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Positive/negative symptom improvement (Reeves & Harrigan, 1996; Harrigan et al, 1996a; Citrome, 1997a; Kerwin & Taylor, 1996b; Anon, 1996b)
Relatively low incidence of extrapyramidal symptoms (Reeves & Harrigan, 1996; Harrigan et al, 1996a; Citrome, 1997a; Kerwin & Taylor, 1996b; Anon, 1996b)
Causes more QT/QTc prolongation than risperidone, olanzapine, quetiapine, and haloperidol (Prod Info GEODON(R) oral capsules, IM injection, 2007)
Decreased the rate of relapse in patients with chronic, stable schizophrenia (Arato et al, 2002; Prod Info GEODON(R) oral capsules, IM injection, 2007)

c) Adult:

1) Results of the Ziprasidone Extended Use in Schizophrenia (ZEUS) study indicate that ziprasidone treatment decreased the rate of relapse in patients with chronic, stable schizophrenia. In this randomized, double-blind, placebo-controlled study, markedly ill (score of 5 or lower on the Clinical Global Impression Severity scale) patients with chronic, stable schizophrenia in extended-stay, inpatient settings received twice daily doses of ziprasidone 40 milligrams (mg)/day (n=72), ziprasidone 80 mg/day (n=68), ziprasidone 160 mg/day (n=67) or placebo (n=71) for up to 1 year. Patients were allowed to receive anticholinergics, lorazepam, and temazepam, but no other psychotropic medications were permitted during the study. The likelihood of relapse at 1 year was significantly lower in patients treated with ziprasidone 40 mg/day (43%), 80 mg/day (35%) or 160 mg/day (36%) as compared with placebo (77%) (p=0.002, p less than 0.001, p less than 0.001, respectively). Of the ziprasidone-treated patients who relapsed during the study, most (61/71) did so in the first 6 months. However, of patients who stayed in the study for at least 6 months only 9% (10/110) of patients in the ziprasidone groups eventually relapsed, as compared with 42% (8/19) of placebo-treated patients (p=0.001). Patients in all three ziprasidone treatment groups showed significantly better improvements in negative symptoms as compared with placebo beginning at week 16 and continuing until the end of the study. Ziprasidone was generally well tolerated, however, one patient had a grand mal seizure and another experienced extrapyramidal symptoms during treatment (Arato et al, 2002).

2) Placebo-controlled, double-blind studies of patients with acute exacerbation of schizophrenia or schizophreniform disorder found 80 to 160 milligrams (mg) daily to be effective in significantly improving positive and negative symptoms with a relatively low incidence of extrapyramidal symptoms (Reeves & Harrigan, 1996; Harrigan et al, 1996a; Citrome, 1997a; Kerwin & Taylor, 1996b; Anon, 1996b).

3) With 80/160 milligrams (mg) daily (6 weeks): reduction in Positive and Negative Syndrome Scale

(PANSS) total scores by 12.4/17.1 (-5.4 with placebo), negative subscale scores by 3.2/3.9 (-0.9 with placebo); significant improvement in BPRSd total score (18-item Brief Psychiatric Rating Scale derived from PANSS) (Reeves & Harrigan, 1996).
4) Ziprasidone was significantly superior to placebo in both time to relapse and rate of relapse, with no significant difference between the 2 dose groups in a 52-week, placebo-controlled trial (n = 294). Inpatients were randomized to receive ziprasidone 20 milligrams (mg) twice daily, 40 mg twice daily, 80 mg twice daily or placebo (Prod Info GEODON(R) oral capsules, IM injection, 2007).

4.5.C Ziprasidone Mesylate

4.5.C.1 Agitation, acute - Schizophrenia

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class I
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Intramuscular ziprasidone mesylate is effective for the treatment of acute agitation in schizophrenic patients (Prod Info GEODON(R) oral capsules, IM injection, 2007)

c) Adult:

1) The efficacy of intramuscular ziprasidone mesylate for the treatment of acute agitation in schizophrenia was established in two double-blind, randomized, single-day trials. Acutely agitated schizophrenic patients with a score of 3 or higher on at least three Positive and Negative Syndrome Scale (PANSS) items (anxiety, tension, hostility, and excitement) received either a control dose (2 milligrams) or a higher dose of ziprasidone. In the first study, patients (n=79) received 20 mg or 2 mg of intramuscular ziprasidone up to four times in 24 hours at intervals of at least 4 hours. The higher dose of ziprasidone was statistically superior to the control dose as assessed by the area under the curve (AUC) of the Behavioral Activity Rating Scale (BARS) at 0 to 4 hours and by the Clinical Global Impression (CGI) severity rating at 4 hours and at endpoint. In the second study, patients (n=117) received 10 mg or 2 mg of intramuscular ziprasidone up to four times in 24 hours at intervals of at least 2 hours. The 10 mg dose of ziprasidone was statistically superior to the 2 mg dose as assessed by the AUC of the BARS at 0 to 2 hours , but not by the CGI severity rating (Prod Info GEODON(R) oral capsules, IM injection, 2007).

4.6 Comparative Efficacy / Evaluation With Other Therapies

Chlorpromazine

Haloperidol

Olanzapine

Perphenazine

Quetiapine

Risperidone

4.6.A Chlorpromazine

4.6.A.1 Schizophrenia

a) Based upon comparisons of minimum effective dosages identified in placebo- controlled, fixed-dose and fixed-dose-ranging drug development trials, the minimum effective dose of ziprasidone was 120 milligrams/day (equivalent to chlorpromazine 200 milligrams/day) (Woods SW, 2003).

4.6.B Haloperidol

Chronic schizophrenia

Schizophrenic episode, acute

4.6.B.1 Chronic schizophrenia

a) Ziprasidone was as effective as haloperidol in treating overall symptomatology, was more effective in the treatment of negative symptoms, and was better tolerated, in the long-term treatment of outpatients with stable schizophrenia. In a 28-week, double-blind, flexible-dose, parallel-group clinical trial, ziprasidone and haloperidol both improved overall symptomatology in 227 patients with chronic or subchronic schizophrenia. Patients who received ziprasidone had a significantly higher rate of improvement in the treatment of negative symptoms (48% of patients showed improvement) compared to patients who received haloperidol (33% of patients showed improvement). For patient assessment, the Positive and Negative Syndrome Scale (PANSS), the Clinical Global Impressions-Severity of Illness scale (CGI-S), and the Montgomery-Asberg Depression Rating Scale (MADRS) were used at baseline and weeks 3, 6, 16, and 28. In the ziprasidone group, patients received a starting dose of 40 milligrams per day (mg/d) on the first 2 days and 80 mg/d on day 3. The ziprasidone dose could be increased to a maximum of 120 mg/d in the second week and up to 160 mg/d in the third week. For the haloperidol group, patients received a starting dose of 5 mg/d, which could be increased to a maximum of 10 mg/d during the second week and 15 mg/d during the third week of treatment. At week 28, the mean doses of ziprasidone and haloperidol were 116.5 mg/d and 8.6 mg/d, respectively. Adverse events were evaluated using the Simpson-Angus scale, the Barnes Akathisia scale, and the Abnormal Involuntary Movement Scale (AIMS). Adverse events were reported in 85% of patients in the haloperidol group and 77% in the ziprasidone group; twice as many patients receiving haloperidol (16%) compared to ziprasidone (8%) discontinued the study due to treatment-related adverse events. There was also a distinct difference in the percentage of patients who developed movement disorders; 41% in the haloperidol group compared to 15% in the ziprasidone group, although this difference was not statistically significant (Hirsch et al, 2002).

4.6.B.2 Schizophrenic episode, acute

a) Acute exacerbations: ziprasidone 160 mg daily, haloperidol 15 mg daily comparable in efficacy (reduction of BPRS scores). Ziprasidone 4 to 40 mg/day less effective (Anon, 1996).

b) Ziprasidone 160 milligrams (mg) and haloperidol 15 mg were both effective in improving overall psychopathology in patients with an acute exacerbation of schizophrenia or schizoaffective disorder (Goff et al, 1998). In a double-blind, dose-ranging study, patients received either haloperidol 15 mg/day (n=17), or ziprasidone 4 mg (n=19), ziprasidone 10 mg (n=17), ziprasidone 40 mg (n=17), or ziprasidone 160 mg (n=20). Despite 46 patients failing to complete the study, intention-to-treat analysis showed a trend toward significance for the ziprasidone dose response on the Brief Psychiatric Rating scale (p=0.08) and a statistically significant dose response for the Clinical Global Impression (CGI) scale (p less than 0.001). Changes in the CGI severity score were significantly changed from baseline as compared to the ziprasidone 4 mg group for both the haloperidol group (p less than 0.01) and the ziprasidone 160 mg group (p=0.001). Study termination was due to 18 patients having a lack of efficacy (4 in the haloperidol group), 7 due to liver transaminase elevations in ziprasidone groups, and 23 for unrelated reasons.

c) In hospitalized patients, the mean reductions in BPRS total, BPRS agitation items, and CGI were statistically greater after INTRAMUSCULAR (IM) ziprasidone than IM haloperidol, and this continued following conversion to oral treatment. The study was a multicenter, 7-day, randomized, open-label, parallel-group study in 7 countries (n=132). Patients received either an initial dose of ziprasidone 10 milligrams (mg) IM, followed by up to 3 days of flexible-dose IM ziprasidone (5 mg to 20 mg every 4 to 6 hours prn) and continued with oral treatment (80 mg to 200 mg/day) to day 7 (n = 90), or haloperidol IM (2.5 mg to 10 mg) on entry, followed by 2.5 mg to 10 mg IM every 4 to 6 hours prn up to 3 days followed by oral haloperidol 10 mg/day to 80 mg/day to day 7 (n = 32). Ziprasidone was associated iwth a lower incidence of movement disorders compared to haloperidol (Brook et al, 2000).

4.6.C Olanzapine

Chronic schizophrenia

Schizophrenia

4.6.C.1 Chronic schizophrenia

a) When newer antipsychotic medications (olanzapine, quetiapine, risperidone, and ziprasidone) were compared with the first-generation antipsychotic, perphenazine, the majority of patients in each group discontinued their antipsychotic study medication before 18 months. Patients (n=1493) with chronic schizophrenia were randomized to receive olanzapine 7.5 to 30 milligrams/day (mg/day), perphenazine 8 to 32 mg/day, quetiapine 200 to 800 mg/day, risperidone 1.5 to 6.0 mg/day, or ziprasidone 40 to 160 mg/day for up to 19 months. Overall, 74% of patients discontinued treatment for any cause before 18 months; discontinuation rates ranged from 64 to 82%. Time to discontinuation ranged from 3.5 months for ziprasidone to 9.2 months with olanzapine. The time to discontinuation was significantly longer in the olanzapine group as compared with the quetiapine (hazard ratio (HR), 0.63; 95% confidence interval (CI), 0.52 to 0.76; p less than 0.001) or risperidone groups (HR, 0.75; 95% CI, 0.62 to 0.90; p=0.002). Time to

discontinuation due to adverse events were similar between all groups, but the rates ranged from 10% for risperidone to 19% for olanzapine (p=0.04). More patients discontinued olanzapine due to greater weight gain (average of 0.9 kilograms/month) and greater increases in glycosylated hemoglobin, total cholesterol, and triglycerides (Lieberman et al, 2005).

4.6.C.2 Schizophrenia

a) In a randomized, double-blind trial (n=269), six-week courses of OLANZAPINE and ZIPRASIDONE had comparable efficacy for treatment of schizophrenia or schizoaffective disorder (DSM-IV), while the side effects profile of ziprasidone appeared to be more favorable with respect to metabolic indicators but less favorable related to QT interval prolongation. Enrollees were acutely ill, recently admitted inpatients. During the first week, subjects received fixed doses of study drugs: olanzapine 5 milligrams (mg) on days 1 and 2 and 10 mg/day on days 3 to 7 (n=133); ziprasidone 40 mg twice daily on days 1 and 2 and 80 mg twice daily on days 3 to 7 (n=136). Dosing was flexible over weeks 2-6 (olanzapine 5 to 15 mg/day; ziprasidone 40 to 80 mg twice daily); overall median daily doses were 12.4 mg for olanzapine and 138.6 mg for ziprasidone (the latter in 2 divided doses daily). Efficacy measures included the Brief Psychiatric Rating Scale (BPRS), Clinical Global Impression (CGI) severity and improvement scales, Positive and Negative Syndrome Scale, and the Calgary Depression Scale for Schizophrenia. At study end, there were no significant differences on any rating scale between improvements in the olanzapine group and those in the ziprasidone group. At endpoint, 36.8% of the olanzapine group and 48.5% of the ziprasidone group had discontinued. Overall, 39.8% and 46.3% of the olanzapine and ziprasidone groups, respectively, had experienced adverse events that were considered treatment related. No between-group differences were seen related to dyskinesia, dystonia, or extrapyramidal symptoms. Weight gain amounted to approximately 3.5 kilograms (kg) and 1 kg for olanzapine- and ziprasidone-treated patients, respectively (p less than 0.0001). Total cholesterol, low-density lipoprotein cholesterol, and triglycerides increased by approximately 10%, 13%, and 25%, respectively, in the group receiving olanzapine; all the same measures decreased slightly in the ziprasidone group (p less than 0.0001; p=0.0004; p less than 0.003, respectively). Fasting serum insulin increased by median 3.3 and 0.25 micro- units/milliliter in the olanzapine and ziprasidone groups, respectively (p=0.051). Prolongation of the QTc interval amounted to 0.52 and 6.08 milliseconds for the same 2 groups, respectively (p less than 0.05) (Simpson et al, 2004).

b) A multicenter, randomized, double-blind, parallel-group, 28 week study (n=548) found that olanzapine therapy resulted in significantly greater psychopathology improvement and higher response and completion rates compared to ziprasidone, while ziprasidone therapy was superior for weight change and lipid profile. Patients with schizophrenia were randomized to receive olanzapine (n=277) 10 to 20 mg/day or ziprasidone (n=271) 80 to 160 mg/day. The primary efficacy measure, the Positive and Negative Syndrome Scale total score, showed that the olanzapine group had significantly greater improvement than the ziprasidone group (p less than 0.001). The olanzapine group also showed significant improvement from baseline to endpoint compared to ziprasidone in the Positive and Negative Syndrome subscales: positive symptoms, negative symptoms, general psychopathology, cognition, and excitability (all p less than 0.0001 except for negative symptoms p=0.003). Patients were allowed to take benzodiazepines or hypnotic monotherapy during the study, but were removed from the study if they required more than two concurrent benzodiazepine hypnotic medications. Significantly more patients in the ziprasidone group required at least one dose of a benzodiazepine compared to the olanzapine group (53.5% versus 40.4%; p=0.003). Response was defined as a 30% improvement in the Positive and Negative Syndrome Scale total score at endpoint, and the rate was significantly higher for the olanzapine group compared to the ziprasidone group (58.6% versus 42.5%) (p less than 0.001). There was no significant difference in exacerbation of symptoms between the two groups, which was defined as a decrease in the Positive and Negative Syndrome Scale total score by 20% or more and a decrease in the Clinical Global Impression severity of illness score of 1 point or more after week 8 (14.6% olanzapine and 25.3% ziprasidone; p=0.06). Significantly more patients in the olanzapine group (59.6%) than in the ziprasidone group (42.4%) completed the study (p less than 0.001). Reasons for discontinuation were only significant for lack of efficacy (olanzapine 7.2% versus ziprasidone 13.7%; p=0.02) and aggravation of psychosis (olanzapine 1.4% versus ziprasidone 4.4%; p=0.05). There were significantly greater increases in body weight and levels of total cholesterol, low-density lipoprotein cholesterol, and triglycerides (all p less than 0.001) and a significantly greater decrease in high-density lipoprotein cholesterol (p=0.001) in the olanzapine group than in the ziprasidone group (Breier et al, 2005).

4.6.D Perphenazine

4.6.D.1 Chronic schizophrenia

a) When newer antipsychotic medications (olanzapine, quetiapine, risperidone, and ziprasidone) were compared with the first-generation antipsychotic, perphenazine, the majority of patients in each group discontinued their antipsychotic study medication before 18 months. Patients (n=1493) with chronic schizophrenia were randomized to receive olanzapine 7.5 to 30 milligrams/day (mg/day), perphenazine 8 to 32 mg/day, quetiapine 200 to 800 mg/day, risperidone 1.5 to 6.0 mg/day, or ziprasidone 40 to 160 mg/day for up to 19 months. Overall, 74% of patients discontinued treatment for any cause before 18 months; discontinuation rates ranged from 64 to 82%. Time to discontinuation ranged from 3.5 months for ziprasidone to 9.2 months with olanzapine. The time to discontinuation was significantly longer in the olanzapine group as compared with the quetiapine (hazard ratio (HR), 0.63; 95% confidence interval (CI), 0.52 to 0.76; p less than 0.001) or risperidone groups (HR, 0.75; 95% CI, 0.62 to 0.90; p=0.002). Time to

discontinuation due to adverse events were similar between all groups, but the rates ranged from 10% for risperidone to 19% for olanzapine (p=0.04). More patients discontinued olanzapine due to greater weight gain (average of 0.9 kilograms/month) and greater increases in glycosylated hemoglobin, total cholesterol, and triglycerides (Lieberman et al, 2005).

4.6.E Quetiapine

4.6.E.1 Chronic schizophrenia

a) When newer antipsychotic medications (olanzapine, quetiapine, risperidone, and ziprasidone) were compared with the first-generation antipsychotic, perphenazine, the majority of patients in each group discontinued their antipsychotic study medication before 18 months. Patients (n=1493) with chronic schizophrenia were randomized to receive olanzapine 7.5 to 30 milligrams/day (mg/day), perphenazine 8 to 32 mg/day, quetiapine 200 to 800 mg/day, risperidone 1.5 to 6.0 mg/day, or ziprasidone 40 to 160 mg/day for up to 19 months. Overall, 74% of patients discontinued treatment for any cause before 18 months; discontinuation rates ranged from 64 to 82%. Time to discontinuation ranged from 3.5 months for ziprasidone to 9.2 months with olanzapine. The time to discontinuation was significantly longer in the olanzapine group as compared with the quetiapine (hazard ratio (HR), 0.63; 95% confidence interval (CI), 0.52 to 0.76; p less than 0.001) or risperidone groups (HR, 0.75; 95% CI, 0.62 to 0.90; p=0.002). Time to discontinuation due to adverse events were similar between all groups, but the rates ranged from 10% for risperidone to 19% for olanzapine (p=0.04). More patients discontinued olanzapine due to greater weight gain (average of 0.9 kilograms/month) and greater increases in glycosylated hemoglobin, total cholesterol, and triglycerides (Lieberman et al, 2005).

4.6.F Risperidone

4.6.F.1 Chronic schizophrenia

a) When newer antipsychotic medications (olanzapine, quetiapine, risperidone, and ziprasidone) were compared with the first-generation antipsychotic, perphenazine, the majority of patients in each group discontinued their antipsychotic study medication before 18 months. Patients (n=1493) with chronic schizophrenia were randomized to receive olanzapine 7.5 to 30 milligrams/day (mg/day), perphenazine 8 to 32 mg/day, quetiapine 200 to 800 mg/day, risperidone 1.5 to 6.0 mg/day, or ziprasidone 40 to 160 mg/day for up to 19 months. Overall, 74% of patients discontinued treatment for any cause before 18 months; discontinuation rates ranged from 64 to 82%. Time to discontinuation ranged from 3.5 months for ziprasidone to 9.2 months with olanzapine. The time to discontinuation was significantly longer in the olanzapine group as compared with the quetiapine (hazard ratio (HR), 0.63; 95% confidence interval (CI), 0.52 to 0.76; p less than 0.001) or risperidone groups (HR, 0.75; 95% CI, 0.62 to 0.90; p=0.002). Time to discontinuation due to adverse events were similar between all groups, but the rates ranged from 10% for risperidone to 19% for olanzapine (p=0.04). More patients discontinued olanzapine due to greater weight gain (average of 0.9 kilograms/month) and greater increases in glycosylated hemoglobin, total cholesterol, and triglycerides (Lieberman et al, 2005).

215. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002n.
216. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002o.
217. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002p.
218. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002q.
219. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002r.
220. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002s.
221. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002t.
222. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002u.
223. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002v.
224. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002w.
225. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002x.
226. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002y.
227. Product Information: Geodon(TM), ziprasidone. Pfizer Inc., NY, NY, 2002z.
228. Product Information: Geodon™, ziprasidone, Pfizer Inc, New York, NY. PI issued 2/2001, 2001.
229. Product Information: Haldol(R), haloperidol decanoate for injection. Ortho-McNeil Pharmaceutical Corp., Raritan, NJ, 2001.
230. Product Information: Haldol(R), haloperidol decanoate. McNeil Pharmaceutical, Inc., Raritan, NJ, 1998.
231. Product Information: Halfan(R), halofantrine hydrochloride. Research Triangle Park, NC, 1998.
232. Product Information: INVEGA(TM) extended-release oral tablets, paliperidone extended-release oral tablets. Alza Corporation, Mountain View, CA, 2006.
233. Product Information: Inapsine(R), droperidol. Akorn, Inc., Decatur, IL, 2001.
234. Product Information: Levaquin, levofloxacin. Ortho-McNeil Pharmaceutical, Inc, Raritan, NJ, 2004.
235. Product Information: Lorelco(R), probucol. Marion Merrell Dow, Kansas City, MO, 1991.
236. Product Information: Mellaril(R), thioridazine. Mylan Pharmaceuticals Inc., Morgantown, WV, 2001.
237. Product Information: Norpace(R), disopyramide. G.D. Searle & Co., Chicago, IL, 1997.
238. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 1999.
239. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 1999a.
240. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 1999b.
241. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 1999c.
242. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 1999d.
243. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 1999e.
244. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 2000.
245. Product Information: Orlaam(R), levomethadyl. Roxane Laboratories, Inc., 2001.
246. Product Information: PCE(R), erythromycin particles in tablets. Abbott Laboratories, North Chicago, IL, 1997.
247. Product Information: Propulsid(R), cisapride. Janssen Pharmaceutica, Titusville, NJ, 2000.
248. Product Information: Prozac(R), fluoxetine. Eli Lilly and Company, Indianapolis, IN, 2001.
249. Product Information: Quinaglute(R), quinidine gluconate. Berlex Laboratories, Wayne, NJ, 1999.
250. Product Information: RANEXA(R) extended-release oral tablets, ranolazine extended-release oral tablets. CV Therapeutics Inc, Palo Alto, CA, 2008.
251. Product Information: SUTENT(R) oral capsules, sunitinib malate oral capsules. Pfizer Labs, New York, NY, 2008.
252. Product Information: Sandostatin(R), octreotide. Novartis Pharmaceuticals, East Hanover, NJ, 1999.
253. Product Information: Serentil(R), mesoridazine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 2001.
254. Product Information: Solian(R), amisulpride tablets. Lorex Synthelabo, Maidenhead, Berkshire, UK, 1999.
255. Product Information: Solian(R), amisulpride tablets. Lorex Synthelabo, Maidenhead, Berkshire, UK, 1999a.
256. Product Information: Solian(R), amisulpride tablets. Lorex Synthelabo, Maidenhead, Berkshire, UK, 1999b.
257. Product Information: Solian(R), amisulpride tablets. Lorex Synthelabo, Maidenhead, Berkshire, UK, 1999c.
258. Product Information: Solian(R), amisulpride tablets. Lorex Synthelabo, Maidenhead, Berkshire, UK, 1999d.
259. Product Information: Solian(R), amisulpride tablets. Lorex Synthelabo, Maidenhead, Berkshire, UK, 1999e.
260. Product Information: Stelazine(R), trifluoperazine hydrochloride. GlaxoSmithKline, Research Triangle Park, NC, 2002.
261. Product Information: TASIGNA(R) oral capsules, nilotinib oral capsules. Novartis Pharmaceuticals Corporation, East Hanover, NJ;, 2007.
262. Product Information: TYKERB oral tablets, lapatinib oral tablets. GlaxoSmithKline, Research Triangle Park, NC, 2008.
263. Product Information: Tambocor(R) flecainide acetate. 3M Pharmaceuticals, Northridge, CA, 1998.
264. Product Information: Thorazine(R), chlorpromazine. Smithkline Beecham Pharmaceuticals, Philadelphia, PA, 2002.
265. Product Information: Trisenox(R), aresenic trioxide injection. Cell Therapeutics Inc., Seattle, WA, 2000.

266. Product Information: Trisenox(R), arsenic trioxide injection. Cell Therapeutics, Inc., Seattle, WA, 2001a.
267. Product Information: Trisenox(R), arsenic trioxide injection. Cell Therapeutics, Inc., Seattle, WA, 2001b.
268. Product Information: Trisenox(R), arsenic trioxide. Cell Therapeutics, Inc., Seattle, WA, 2001.
269. Product Information: Vascor(R), bepridil. McNeil Pharmaceutical, Spring House, PA, 1997.
270. Product Information: XENAZINE(R) oral tablets, tetrabenazine oral tablets. Prestwick Pharmaceuticals,Inc, Washington, DC, 2008.
271. Product Information: Zomig(R), zolmitriptan tablets. AstraZeneca Pharmaceuticals, Wilmington, DE, 2001.

DRUGDEX® Evaluations

HALOPERIDOL

0.0 Overview

1) Class

a) This drug is a member of the following class(es):

Antipsychotic
Butyrophenone
Dopamine Antagonist

2) Dosing Information

a) Haloperidol

1) Adult

a) Gilles de la Tourette's syndrome

1) 0.5 to 2 mg (moderate symptoms) OR 3 to 5 mg (severe symptoms) ORALLY 2 to 3 times daily (Proc Info haloperidol oral tablets, 2008; Prod Info haloperidol oral solution, 2008)

b) Psychotic disorder

1) 0.5 to 2 mg (moderate symptoms) OR 3 to 5 mg (severe symptoms) ORALLY 2 to 3 times daily (Proc Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

c) Schizophrenia

1) 0.5 to 2 mg (moderate symptoms) OR 3 to 5 mg (severe symptoms) ORALLY 2 to 3 times daily (Proc Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

2) Pediatric

a) Not FDA approved in children less than 3 years of age (Prod Info haloperidol oral tablets, 2008; Prod Info haloperidol oral solution, 2008)

1) Gilles de la Tourette's syndrome

a) age 3 to 12 yr (weight range 15 to 40 kg), begin with the lowest possible dose (0.5 mg per day) c weight-based dose (0.05 to 0.075 mg/kg/day) ORALLY in 2 to 3 divided doses, whichever is less; increase by 0.5 mg at 5 to 7 day intervals to therapeutic effect (Prod Info haloperidol oral tablets, 20 Prod Info haloperidol oral solution, 2008)

b) over age 12 years, 0.5 to 2 mg (moderate symptoms) or 3 to 5 mg (severe symptoms) orally 2 to times daily (Prod Info haloperidol oral tablets, 2008; Prod Info haloperidol oral solution, 2008)

2) Hyperactive behavior, (Short-term treatment) after failure to respond to non-antipsychotic medication and psychotherapy

a) 3 to 12 yr (weight range 15 to 40 kg), 0.05 to 0.075 mg/kg/day ORALLY in 2 to 3 divided doses, increase by 0.5 mg at 5 to 7 day intervals to therapeutic effect; MAX daily dose 0.075 mg/kg/day (Pr Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

3) Psychotic disorder

a) 3 to 12 yr (weight range 15 to 40 kg), 0.05 mg/kg/day ORALLY in 2 to 3 divided doses, may increase by 0.5 mg/day at 5 to 7 day intervals to therapeutic effect; MAX daily dose 0.15 mg/kg/day (Prod Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

b) 12 yr and older, 0.5 to 2 mg (moderate symptoms) OR 3 to 5 mg (severe symptoms) ORALLY 2 3 times daily (Prod Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

4) Schizophrenia

a) 3 to 12 yr (weight range 15 to 40 kg), 0.05 mg/kg/day ORALLY in 2 to 3 divided doses, may increase by 0.5 mg/day at 5 to 7 day intervals to therapeutic effect; MAX daily dose 0.15 mg/kg/day (Prod Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

b) 12 yr and older, 0.5 to 2 mg (moderate symptoms) OR 3 to 5 mg (severe symptoms) ORALLY 2 3 times daily (Prod Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

b) Haloperidol Decanoate

1) Adult

a) Chronic schizophrenia

1) stabilized on low daily oral doses (up to 10 mg/day), 10 to 15 times previous daily oral dose IM month or every 4 wks; MAX initial dose 100 mg (Prod Info haloperidol decanoate injection, 2005)

2) stabilized on high daily oral doses, 20 times previous daily oral dose IM for the first month, then 10 to times previous daily oral dose IM monthly or every 4 wks; MAX initial dose 100 mg (Prod Info haloperido decanoate injection, 2005)

2) Pediatric

a) Safety and effectiveness have not been established in children

c) Haloperidol Lactate

1) Adult

a) Gilles de la Tourette's syndrome

1) 2 to 5 mg IM, may repeat every 4 to 8 hr depending on patient response; increase to every 1 hr if needed (Prod Info haloperidol lactate IM injection, 2005)

b) Schizophrenia

1) 2 to 5 mg IM, may repeat every 4 to 8 hr depending on patient response; increase to every 1 hr if needed (Prod Info HALDOL(R) immediate release IM injection, 2008)

2) Pediatric

a) safety and effectiveness have not been established in pediatric patients (Prod Info HALDOL(R) immediate release IM injection, 2008)

3) Contraindications

a) Haloperidol

1) comatose state from any cause (Prod Info haloperidol oral tablets, 2008)
2) hypersensitivity to haloperidol (Prod Info haloperidol oral tablets, 2008)
3) Parkinson's disease (Prod Info haloperidol oral tablets, 2008)
4) toxic central nervous system depression, severe (Prod Info haloperidol oral tablets, 2008)

b) Haloperidol Decanoate

1) comatose state from any cause (Prod Info HALDOL(R) Decanoate IM injection, 2008)
2) hypersensitivity to haloperidol (Prod Info HALDOL(R) Decanoate IM injection, 2008)
3) Parkinson's disease (Prod Info HALDOL(R) Decanoate IM injection, 2008)
4) toxic CNS depression, severe (Prod Info HALDOL(R) Decanoate IM injection, 2008)

c) Haloperidol Lactate

1) comatose state from any cause (Prod Info HALDOL(R) immediate release IM injection, 2008)
2) hypersensitivity to haloperidol lactate (Prod Info HALDOL(R) immediate release IM injection, 2008)
3) Parkinson's disease (Prod Info HALDOL(R) immediate release IM injection, 2008)
4) toxic CNS depression, severe (Prod Info HALDOL(R) immediate release IM injection, 2008)

4) Serious Adverse Effects

a) Haloperidol

1) Agranulocytosis
2) Dead - sudden death
3) Death
4) Neuroleptic malignant syndrome
5) Paralytic ileus
6) Priapism
7) Prolonged QT interval
8) Seizure
9) Sudden cardiac death
10) Tardive dyskinesia
11) Torsades de pointes

b) Haloperidol Decanoate

1) Agranulocytosis
2) Neuroleptic malignant syndrome
3) Paralytic ileus
4) Priapism
5) Prolonged QT interval
6) Seizure
7) Tardive dyskinesia
8) Torsades de pointes

5) Clinical Applications

a) Haloperidol

1) FDA Approved Indications

a) Gilles de la Tourette's syndrome
b) Hyperactive behavior, (Short-term treatment) after failure to respond to non-antipsychotic medication and psychotherapy
c) Psychotic disorder
d) Schizophrenia

b) Haloperidol Decanoate

1) FDA Approved Indications

a) Chronic schizophrenia

c) Haloperidol Lactate

1) FDA Approved Indications

a) Gilles de la Tourette's syndrome
b) Schizophrenia

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product Index)

B) Synonyms
Haloperidol
Haloperidol Decanoate
Haloperidol Lactate

C) Physicochemical Properties

1) Molecular Weight

a) Haloperidol: 375.87 (Prod Info haloperidol oral tablets, 2008); haloperidol decanoate: 530.13 (Prod Info haloperidol decanoate injection, 2005)

2) pH

a) Haloperidol lactate: 3 to 3.6 (Prod Info HALDOL(R) immediate release IM injection, 2008)

3) Solubility

a) Haloperidol decanoate is soluble in most organic solvents and almost insoluble in water (0.01 mg/mL) (Pr Info haloperidol decanoate injection, 2005).

1.2 Storage and Stability

A) Haloperidol Decanoate

1) Preparation

a) Intramuscular route

1) Do not administer haloperidol decanoate intravenously (Prod Info haloperidol decanoate injection, 2005).

2) Haloperidol decanoate should be administered by deep intramuscular injection (21G needle) into the gluteal region. The maximum recommended volume is 3 milliliters per injection site (Prod Info haloperido decanoate injection, 2005).

B) Haloperidol Lactate

1) Preparation

a) General Information

1) Do NOT administer haloperidol lactate intravenously (Prod Info HALDOL(R) immediate release IM injection, 2008).

C) Haloperidol

1) Oral route

a) Tablet

1) Store at controlled room temperature, between 20 and 25 degrees C (68 and 77 degrees F), in a tigh light-resistant container (Prod Info haloperidol oral tablets, 2008).

D) Haloperidol Decanoate

1) Intramuscular route

a) Solution

1) Store at controlled room temperature, between 15 and 30 degrees C (59 and 86 degrees F). Protect from light. Do not refrigerate or freeze (Prod Info HALDOL(R) Decanoate IM injection, 2008).

2) Investigations of the stability of haloperidol decanoate when drawn into plastic syringes have not bee conducted. Preparation of individual doses of medication in disposable plastic syringes may be carried o a few hours prior to administration, provided these are protected from light. Because of unknown stability and because of concern for dosage sterility, such storage for longer periods is not recommended. Stabili in other types of syringes is also unknown (Pers Comm, 1987).

E) Haloperidol Lactate

1) Intramuscular route

a) Solution

1) Store at controlled room temperature, between 15 and 30 degrees C (59 and 86 degrees F). Protect from light. Do not freeze (Prod Info HALDOL(R) immediate release IM injection, 2008).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Geriatric Patients

Dosage Adjustment During Dialysis

Dosage in Other Disease States

1.3.1 Normal Dosage

Important Note

Important Note

Important Note

Haloperidol

Haloperidol Decanoate

Haloperidol Lactate

1.3.1.A Important Note

The US Food and Drug Administration (FDA) issued an alert concerning reports of Torsades de Pointes and prolongation, some with fatal outcomes associated with the use of haloperidol, haloperidol decanoate, and haloperidol lactate, especially when administered intravenously (not an approved route of administration) or i higher doses than recommended. At least 28 published case reports exist, and case-control studies have demonstrated a dose-response relationship between intravenous haloperidol and the development of Torsad de Pointes (US Food and Drug Administration, 2007).

1.3.1.B Important Note

Haloperidol decanoate is in a sesame seed oil base and should not be given intravenously (Prod Info haloperidol decanoate injection, 2005).

The US Food and Drug Administration (FDA) issued an alert concerning reports of Torsades de Pointes and prolongation, some with fatal outcomes associated with the use of haloperidol, haloperidol decanoate, and haloperidol lactate, especially when administered intravenously (not an approved route of administration) or i higher doses than recommended. At least 28 published case reports exist, and case-control studies have demonstrated a dose-response relationship between intravenous haloperidol and the development of Torsad de Pointes (US Food and Drug Administration, 2007).

1.3.1.C Important Note

Haloperidol lactate should NOT be given intravenously (Prod Info HALDOL(R) immediate release IM injectior 2008).

The US Food and Drug Administration (FDA) issued an alert concerning reports of Torsades de Pointes and prolongation, some with fatal outcomes associated with the use of haloperidol, haloperidol decanoate, and haloperidol lactate, especially when administered intravenously (not an approved route of administration) or i higher doses than recommended. At least 28 published case reports exist, and case-control studies have demonstrated a dose-response relationship between intravenous haloperidol and the development of Torsad de Pointes (US Food and Drug Administration, 2007).

1.3.1.D Haloperidol

Intravenous route

Oral route

Chemotherapy-induced nausea and vomiting; Treatment and Prophylaxis

Hiccoughs

Ocular hypertension

Opioid withdrawal

1.3.1.D.1 Intravenous route

a) CONTINUOUS INTRAVENOUS DOSING

1) An initial bolus dose of 10 milligrams followed by continuous infusion beginning as 10 milligrams per hour is recommended. If control is not achieved, the bolus is repeated every 30 minutes, as well increasing the infusion rate by 5 milligrams per hour. Adjunctive sedative (benzodiazepines) doses should be adjusted as needed or discontinued if possible. After achieving control, infusion rates sho be titrated downward by 50% at each interval, seeking eventual return to bolus dosing. Continuous infusion haloperidol should be considered for patients receiving 80 mg of haloperidol daily (given in or more bolus doses) or who receive more than 10 mg/hour over 5 or more consecutive hours. Continuous dosing is also warranted in patients not effectively managed on other sedatives and in those in whom attempted reversal of the cause of agitation has been unsuccessful (Riker et al, 199

2) Initial infusion doses of 2 to 25 milligrams per hour haloperidol by continuous infusion have been cited in individual cases (Seneff & Mathews, 1995); (Dixon & Craven, 1993)(Fernandez et al, 1988).

3) Maximum infusion rate cited is 40 milligrams per hour (Riker et al, 1994a).

b) INTERMITTENT INTRAVENOUS DOSING

1) Total daily intermittent intravenous haloperidol doses of 80, 285, 130, 460, and 530 milligrams w generally well tolerated (Tesar et al, 1985).

c) SWITCHING FROM INJECTABLE TO ORAL HALOPERIDOL

1) For an initial approximation of the total daily dose required, the parenteral dose administered in t preceding 24 hours may be used; the first oral dose should be given within 12 to 24 hours following last parenteral dose (Prod Info HALDOL(R) injection, 2007).

1.3.1.D.2 Oral route

Behavioral syndrome - Dementia

Gilles de la Tourette's syndrome

Schizophrenia

1.3.1.D.2.a Behavioral syndrome - Dementia

1) A randomized, double-blind, placebo controlled crossover study demonstrated that standard-dos (2 to 3 milligrams (mg) daily) haloperidol was effective and superior to low-dose (0.05 to 0.75 mg da for treating psychosis and disruptive behaviors in patients with Alzheimer's disease. Seventy-one patients were treated with either standard-dose or low-dose haloperidol or placebo for 6 weeks. The patients taking placebo then crossed over to either standard or low- dose haloperidol while the haloperidol patients crossed over to placebo for another 6 weeks. Standard-dose haloperidol was efficacious and superior to low- dose haloperidol and placebo for the 60 patients who completed the first phase of the study. The same results were demonstrated in the second phase. Extrapyramidal side effects were greater with the standard dose however, low- dose haloperidol did not differ from placebo with regard to efficacy (Devanand et al, 1998).

1.3.1.D.2.b Gilles de la Tourette's syndrome

1) Manufacturer dose

a) The recommended dose in adults with moderate symptoms is haloperidol 0.5 to 2 milligrams (mg) orally 2 to 3 times daily, or with severe symptoms 3 to 5 mg orally 2 to 3 times daily (Prod Info haloperidol oral tablets, 2008; Prod Info haloperidol oral solution, 2008).

2) Tourette's syndrome is initially treated with haloperidol 6 to 15 mg/day orally in divided doses. Dosage is gradually increased in 2 mg increments until adverse effects are disabling. When sympto are controlled the dose is tapered to approximately 9 mg/day for maintenance (AMA Department of Drugs, 1980).

1.3.1.D.2.c Schizophrenia

1) SUMMARY

a) The usual daily oral dose range is from 1 to 15 milligrams; doses exceeding 100 milligrams have been used in severely resistant patients. Moderate doses of neuroleptic drugs, defined as between 165 and 375 milligram equivalent of chlorpromazine, were preferred in the maintenanc therapy of chronic psychosis in a meta-analysis of 22 randomized control trials (Bollini et al, 19 The association between dose and clinical effectiveness and side effects was assessed. At dos greater than 375 milligram equivalent of chlorpromazine, there was no incremental clinical improvement seen, and adverse reactions occurred at a significantly higher rate.

2) There is significant variation between patients in the amount of medication required; dosage mus be individualized. The normal dosage range for initiation of therapy for psychiatric indications is 1 to milligrams/day for moderate symptomatology and 6 to 15 milligrams/day for severe symptomatology divided into 2 to 3 doses. Adjustment of the dose up to 100 milligrams/day may be necessary for

severely resistant patients. When switching from parenteral to oral therapy, the first oral dose shoulc be given within 12 to 24 hours. The same oral as parenteral dose may be used with dosage adjustments made based on patient's response (Prod Info Haldol(R), 97a).

3) A 4-week prospective trial demonstrated that patients experiencing first-episode psychosis responded to haloperidol doses that were well below doses commonly prescribed. Patients (n=36) diagnosed with nonaffective psychosis began haloperidol treatment with 2 milligrams (mg) daily. The dose was increased weekly until either significant improvement or the onset of extrapyramidal symptoms occurred. The optimal dose for 42 percent of the patients was 2 mg daily and on average these patients exhibited the greatest improvement (Zhang- Wong et al, 1999).

4) Low dosage (16 milligrams/day) was compared with high dosage (80 milligrams/day) of haloperic in 40 newly admitted schizophrenia patients for 21 days. Upon evaluation on five occasions, the low dosage group showed significantly greater improvement (Winter et al, 1984). Similar results were found in another study (Rifkin et al, 1991).

5) A double-blind study was conducted in 42 patients treated with 10 milligrams, 30 milligrams, and milligrams per day of haloperidol. The researchers found no relationship between neuroleptic dose a outcome of mania, and no differences in side effects. These results suggest that there is no advanta to using more than 10 milligrams per day of haloperidol (Rifkin et al, 1990).

6) Haloperidol doses of 5, 10, and 20 milligrams per day were compared for 4 weeks in 80 newly admitted schizophrenic patients. The results after two weeks showed the 20 milligrams dose to be more effective than the 5 milligrams dose and the same as the 10 milligrams dose. Over the last two week period, the 20 milligrams dose per day did not control the patients. The researchers referred to this as "psychotoxic" side-effects. The researchers recommended 20 milligrams per day for short-ter therapy of psychotic disorders (Van Putten et al, 1990).

1.3.1.D.2.d Mania

1) In a double-blind, randomized study lasting six weeks, three dosage levels of haloperidol (10, 30 80 mg/day) were compared in 47 newly-diagnosed manic inpatients. All patients also received benztropine (2 mg three times per day). There were no significant differences in treatment outcomes side effects among patients at the three dosage levels. The authors concluded that haloperidol dose in excess of 10 mg/day offered no advantage in controlling symptoms of mania (Rifkin et al, 1994).

1.3.1.D.2.e SWITCHING FROM INJECTABLE TO ORAL HALOPERIDOL

1) For an initial approximation of the total daily dose required, the parenteral dose administered in t preceding 24 hours may be used; the first oral dose should be given within 12 to 24 hours following last parenteral dose (Prod Info HALDOL(R) injection, 2007).

1.3.1.D.3 Chemotherapy-induced nausea and vomiting; Treatment and Prophylaxis

See Drug Consult reference: CHEMOTHERAPY AND RADIOTHERAPY TREATMENT GUIDELINES FO NAUSEA AND VOMITING

1.3.1.D.4 Hiccoughs

See Drug Consult reference: HICCUPS - ETIOLOGY AND TREATMENT

1.3.1.D.5 Ocular hypertension

a) Topical administration of the haloperidol ophthalmic solution (0.125% and 1%) produced modest reductions in intraocular pressure in healthy volunteers, however, reductions were not considered statistically significant (Lavin & Andrews, 1986). These data do not suggest the role for topical haloperido in the treatment of glaucoma.

1.3.1.D.6 Opioid withdrawal

See Drug Consult reference: DRUG THERAPY OF OPIOID WITHDRAWAL

1.3.1.D.7 HIGH DOSE THERAPY

a) A randomized, double-blind study demonstrated that high-dose, long-term treatment with haloperidol may not be justified regardless if supported by clinical judgment (Volavka et al, 2000). Hospitalized patie (n=23) with the diagnosis of schizophrenia or schizoaffective disorder and with haloperidol plasma levels at least 15 nanograms per milliliter (ng/mL) were assigned to an experimental group (n=11) or a control group (n=12). The plasma level for the experimental group was reduced to 10 ng/mL via a gradual dose reduction while the control group was maintained at the original level. Over a period of 16 weeks, both groups demonstrated a slight reduction in symptoms and there were no significant differences in sympto severity. Additionally, the reduction in dose did not result in any apparent side effects. The authors conclude that high-dose therapy may be cautiously questioned since this study was small and biased.

b) Two studies failed to establish that a dosage of 100 milligrams/day was more effective than a dosage 10 milligrams/day in 63 acutely schizophrenic patients (Donlon et al, 1980; Ericksen et al, 1978). Howeve another study concluded that previously nonresponsive chronic schizophrenics may benefit from adequa high doses (median 100 milligrams/day) of haloperidol (Psaras et al, 1980).

c) Intravenous haloperidol ranging from 100 to 480 milligrams over 24 hours plus 36 to 480 milligrams o lorazepam has been shown to be effective in treatment of delirium in the critically ill cancer patient; the combination of haloperidol and lorazepam intravenously in a wide range of doses appears to be safe and effective (Adams et al, 1986).

d) The need for high-dose therapy was demonstrated in some chronic patients. By evaluating 100 patie

it was found that eight patients required more than 15 milligrams per day of haloperidol. When the streng was reduced, the eight patients lapsed back into their original psychiatric state. These authors conclude that dose-responsive patients should be examined on an individual basis (Brotman & McCormick, 1990).
e) High-dose therapy was used in a patient receiving treatment via an intra-aortic balloon pump. The patient was given a 50 milligrams bolus dose of haloperidol and 50 milligrams intravenously every hour thereafter. The patient received a total of 1200 milligrams of haloperidol in the first 24 hour period, and 1100 milligrams during the next 24 hour period. The doses were then decreased daily until day ten, when the pump was removed. No signs of extrapyramidal symptoms were exhibited (Sanders et al, 1991).

1.3.1.E Haloperidol Decanoate

1) ORAL TO DEPOT CONVERSION

a) The recommended initial dose of Haldol(R) decanoate is 10 to 20 times the previous daily dose in oral haloperidol equivalents but no more than a maximum initial dose of 100 milligrams given at monthly intervals. However, if initial conversion doses are more than 100 milligrams, the dose should be administered in 2 injections (ie, a maximum of 100 mg followed by the remaining balance in 3 to 7 days) (Prod Info haloperidol decanoate injection, 2005).
b) Clinical experience with depot injections greater than 450 milligrams/month is limited (Prod Info haloperidol decanoate injection, 2005).
c) The pharmacokinetic properties and therapeutic efficacy of haloperidol decanoate were studied in 21 chronic psychotic inpatients stabilized on oral haloperidol. The intramuscular dose was calculated from the oral dose, using standard equivalencies for those neuroleptics other than haloperidol. The depot form was administered for 4 months, the last 3 months given at one-half the original calculated loading dose. The depot form resulted in less fluctuation in blood levels, with levels approximating those on oral therapy. One third of the patients deteriorated, and there was no significant change in the incidence or severity of side effects. The authors concluded that there was no clinical advantage to the use of haloperidol decanoate over oral forms of therapy (de Cuyper et al, 1986).
d) Intramuscular haloperidol decanoate was compared with oral haloperidol in 30 chronic schizophrenic patients (Nair et al, 1986). Patients were stabilized for 2 weeks on an oral dose, which was then maintained for 2 weeks. Patients were then transferred to an intramuscular dose, stabilized, then continued on the dose for 5 months. Side effects were comparable and minimal. Therapeutic responses were also comparable. The monthly dose of haloperidol decanoate needed to achieve an equivalent therapeutic response was 15 times the daily dose of haloperidol in 17 patients, 10 times the daily oral dose of haloperidol in 7 patients, and ranged from 9.4 to 15 times the daily oral haloperidol dose in all patients. The authors concluded that intramuscular haloperidol decanoate is comparable to oral haloperidol in safety and efficacy and produces lower blood levels with less fluctuation.
e) Oral haloperidol given daily was compared with intramuscular haloperidol decanoate given every 28 days to establish pharmacokinetically and therapeutically equivalent dosages (Nayak et al, 1987). The study involved 20 patients and was of an open design. Results showed that haloperidol decanoate every 28 days required dosages 21.4 times higher than haloperidol given daily to achieve similar blood concentrations, but required dosages only 14.1 times higher to achieve similar clinical results. The authors recommended that dosages of haloperidol decanoate should be lower than what is calculated to achieve therapeutic blood levels. The dose is subsequently titrated upwards to achieve the desired therapeutic response.
f) Eighteen patients who were taking oral haloperidol and then switched to depot haloperidol were studied. The first month's mean haloperidol decanoate dose was 23.1 times the oral haloperidol dose, with a mean plasma concentration level of 3 +/- 1.9 mg/mL. The second month's dosing level regimen was decreased by 27.6 percent, giving a mean plasma concentration of 6.5 +/- 2.6 mg/mL. The patients improved during the conversion. The researchers concluded that haloperidol decanoate has less fluctuation than oral haloperidol because of constant absorption (Ereshefsky et al, 1990).
g) A method was described to convert from oral to depot intramuscular forms of haloperidol using a loading dose strategy (Ereshefsky et al, 1993). The method consisted of using a total dose of 20 times the oral dose, administered in consecutive divided doses of 100 to 200 milligrams every three to seven days. Oral haloperidol was discontinued prior to the first injection, except in cases where the daily haloperidol dose was 40 milligrams or greater where the dose was gradually reduced over two months. The depot dose was reduced, typically by 25% in both the second and third months to avoid excessive accumulation. The long-term maintenance dose was adjusted based on clinical response.

1.3.1.F Haloperidol Lactate

1.3.1.F.1 Intramuscular route

Gilles de la Tourette's syndrome

Schizophrenia

1.3.1.F.1.a Gilles de la Tourette's syndrome

1) The recommended dose for the control of tics and vocal utterances of Tourette's disorder is haloperidol lactate 2 to 5 milligrams intramuscularly. Depending on the clinical effect, the dose may repeated every 1 hour, although a 4- to 8-hour interval may be sufficient (Prod Info haloperidol lacta IM injection, 2005).

1.3.1.F.1.b Schizophrenia

1) In schizophrenic adults who are acutely agitated with moderately severe to very severe symptom the recommended dose is haloperidol lactate 2 to 5 milligrams intramuscularly. Depending on the clinical effect, the dose may be repeated every 1 hour, although a 4- to 8-hour interval may be sufficient (Prod Info HALDOL(R) immediate release IM injection, 2008).

1.3.2 Dosage in Renal Failure

A) Haloperidol

1) No specific dosage adjustment is necessary in patients with renal impairment (Bennett et al, 1994).

B) Haloperidol Decanoate

1) No specific dosage adjustment is necessary in patients with renal impairment (Bennett et al, 1994).

C) Haloperidol Lactate

1) No specific dosage adjustment is necessary in patients with renal impairment (Bennett et al, 1994).

1.3.4 Dosage in Geriatric Patients

A) Haloperidol

1) ORAL

a) Geriatric or debilitated patients may require a higher doses (0.5 to 2 milligrams 2 to 3 times daily) to achieve prompt response in some cases (Prod Info haloperidol oral tablets, 2006; Prod Info haloperidol c solution, 2001).

b) Elderly patients with chronic refractory schizophrenia should be initially treated with 0.5 to 1.5 milligram/day orally. Dosage may be gradually increased to a usual maintenance dose of 2 to 8 milligrams/day (AMA Department of Drugs, 1980).

c) Results of a double-blind, crossover study in 58 nursing-home residents suggest that the efficacy of long-term haloperidol, thioridazine, and lorazepam should be closely monitored and routine attempts at drug withdrawal should be considered (Cohen-Mansfield et al, 1999). The residents participating in the study were older than 70 years and had received haloperidol, thioridazine, or lorazepam for agitation for least 4 weeks. Half of the residents had their medication dose tapered over 3 weeks and then received placebo while the other half continued their usual medication dosage. After 7 weeks, the residents cross over and either titrated back on their medication or titrated off and began placebo for another 7 weeks. Analyses exhibited no effect of drug therapy discontinuation on behavior and withdrawal of medication h no impact on psychiatric symptom scores or agitation levels. More research is warranted to identify effective treatment for agitation and the appropriate duration of effectiveness.

d) Mentally retarded elderly patients with hyperkinesia are initially treated with 1.5 to 6 milligrams/day orally in divided doses. Doses may be gradually increased to a maximum of 15 milligrams/day to achieve control. Doses are then tapered to a minimally effective maintenance dose (AMA Department of Drugs, 1980).

B) Haloperidol Decanoate

1) INTRAMUSCULAR - DEPOT

a) Initial conversion from oral therapy for elderly patients, debilitated patients, or those on stable low dos of oral haloperidol, consists of a dose 10 to 15 times the previous oral daily dose. The dose is given at monthly intervals (Prod Info haloperidol decanoate injection, 2005).

C) Haloperidol Lactate

1) A lower dose may be required in the elderly, and titrated to clinical effect. In elderly women there has bee prevalence of tardive dyskinesia (Prod Info HALDOL(R) immediate release IM injection, 2008).

1.3.5 Dosage Adjustment During Dialysis

A) Haloperidol

1) It is unlikely that dosage adjustment is required during dialysis. Its large volume of distribution and low plasma levels suggest that little drug would be removed by dialysis (Anderson et al, 1976; Bennett et al, 1994

B) Haloperidol Decanoate

1) It is unlikely that dosage adjustment is required during dialysis. Its large volume of distribution and low plasma levels suggest that little drug would be removed by dialysis (Anderson et al, 1976; Bennett et al, 1994

C) Haloperidol Lactate

1) It is unlikely that dosage adjustment is required during dialysis. Its large volume of distribution and low plasma levels suggest that little drug would be removed by dialysis (Anderson et al, 1976; Bennett et al, 1994

1.3.6 Dosage in Other Disease States

A) Haloperidol Decanoate

1) DEBILITATED PATIENTS

a) Initial conversion from oral to depot injection in debilitated patients consists of a dose 10 to 15 times t previous oral daily dose. The dose is given at monthly intervals (Prod Info haloperidol decanoate injectio

2005).

B) Haloperidol Lactate

1) A lower dose may be required in debilitated patients or those with a history of adverse reactions to antipsychotic drugs, and titrated to clinical effect (Prod Info HALDOL(R) immediate release IM injection, 2008

1.4.1.D Haloperidol

Oral route

Anorexia nervosa

1.4.1.D.1 Oral route

1.4.1.D.1.a Gilles de la Tourette's syndrome

1) The recommended dose in pediatric patients age 3 to 12 years (weight range 15 to 40 kilograms for the treatment of Tourette's disorder is haloperidol 0.05 to 0.075 milligrams/kilogram/day (mg/kg/day) orally in 2 to 3 divided doses. Begin with the lowest possible dose (0.5 mg per day) or weight-based dose (0.05 to 0.075 mg/kg/day) ORALLY in 2 to 3 divided dose, whichever is less. Increases in dose are recommended at 0.5 mg increments at 5 to 7 day intervals to therapeutic effe to a maximum daily dose of 0.075 mg/kg/day (Prod Info haloperidol oral tablets, 2008; Prod Info haloperidol oral solution, 2008).

2) In children over age 12 years the recommended dose is haloperidol 0.5 to 2 mg (moderate symptoms) or 3 to 5 mg (severe symptoms) orally 2 to 3 times daily (Prod Info haloperidol oral table 2008; Prod Info haloperidol oral solution, 2008).

b) Haloperidol is not recommended for use in children under 3 years old (Prod Info haloperidol oral table 2008; Prod Info haloperidol oral solution, 2008).

1.4.1.D.2 Anorexia nervosa

See Drug Consult reference: ANOREXIA NERVOSA - DRUG THERAPY

1.4.1.E Haloperidol Decanoate

1.4.1.F Haloperidol Lactate

1) Safety and effectiveness have not been established in pediatric patients (Prod Info HALDOL(R) immediate release IM injection, 2008).

1.4.2 Dosage in Renal Failure

A) Haloperidol

1) No specific dosage adjustment is necessary in patients with renal impairment (Bennett et al, 1994).

B) Haloperidol Decanoate

1) No specific dosage adjustment is necessary in patients with renal impairment (Bennett et al, 1994).

1.4.4 Dosage Adjustment During Dialysis

A) Haloperidol

1) It is unlikely that dosage adjustment is required during dialysis. Its large volume of distribution and lov plasma levels suggest that little drug would be removed by dialysis (Anderson et al, 1976; Bennett et al, 1994).

B) Haloperidol Decanoate

1) It is unlikely that dosage adjustment is required during dialysis. Its large volume of distribution and lov plasma levels suggest that little drug would be removed by dialysis (Anderson et al, 1976; Bennett et al, 1994).

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Initial Response

a) Sedation, oral: greater than 1 hour (Forsman & Ohman, 1976).

b) Sedation, intravenous: 1 hour (Forsman & Ohman, 1976).

2.2 Drug Concentration Levels

A) Therapeutic Drug Concentration

1) Schizophrenic, schizoaffective and schizophreniform disorders, 5 to 15 ng/mL (Ulrich et al, 1998); (Van Patten et al, 1992)(Extein et al, 1983; Mavroidis et al, 1983; Morselli et al, 1982; Magliozzi et al, 1981).

a) In a 35-study meta-analysis and review, a lower threshold concentration for therapeutic effect was reported of 5.6 mcg/L (range: 3.1 to 8 mcg/L) and an upper threshold concentration of 16.9 mcg/L (range 11 to 26 mcg/L). A target concentration of 10 mcg/L was recommended (Ulrich et al, 1998).

b) A meta-analysis of 18 studies concluded that there was support for the existence of a therapeutic window between 4 and 26 nanograms/milliliter (de Oliveira et al, 1996a).

c) Increasing the haloperidol dose to achieve plasma levels above 18 ng/mL was not associated with improved response in a study of 66 adult inpatients with schizophrenia (Coryell et al, 1998). These result were supported by a study of 95 adults with acute psychosis (schizophrenia and schizoaffective disorder The probability of improvement among initial non-responders was significantly increased among patients titrated to plasma levels of 5 to 18 ng/mL, as opposed to those at lower or higher haloperidol levels (Janicak et al, 1997).

B) Time to Peak Concentration

1) Oral: 2 to 6 hours (Prod Info Haldol(R), 97).

a) The steady-state pharmacokinetics of oral haloperidol varies widely among different patients (Kudo & Ishizaki, 1999).

b) The steady state plasma concentrations of haloperidol and reduced haloperidol were not significantly different among 4 patient subgroups (n= 101) in a study designed to measure the effect of genetic polymorphism of CYP1A2 inducibility on the steady state plasma concentrations of oral haloperidol. Ther were no significant differences between the 4 subgroups, including age and weight, and smoking status not affect the steady state concentrations in the study. This suggests that CYP1A2 activity does not play key role in the steady state pharmacokinetics of haloperidol or reduced haloperidol (Mihara et al, 2000).

2) Intramuscular, haloperidol: 20 minutes (Prod Info Haldol(R), 97).

3) Intramuscular, haloperidol decanoate: 6 days (Prod Info Haldol(R) Decanoate, 2000).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Bioavailability

1) Oral: 60 to 70% (Prod Info Haldol(R), 97; Cheng et al, 1987; Holley et al, 1983a).

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding

a) greater than 90% (Tedeschi, 1981; Forsman & Ohman, 1977).

2) OTHER DISTRIBUTION SITES

a) Hair, less than 0.1% (Matsuno et al, 1990; Sato et al, 1989; Uematsu et al, 1989).

b) Saliva, levels are higher than serum levels and there is a significant correlation (Yamazumi & Muira, 1981).

B) Distribution Kinetics

1) Volume of Distribution

a) 9.5 to 21.7 liters/kilogram (Kudo & Ishizaki, 1999) or 1300 liters (Forsman & Ohman, 1976).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) Liver (Forsman et al, 1977; Forsman & Ohman, 1976).

a) Some evidence indicates extrahepatic metabolism (Forsman & Ohman, 1976; Forsman et al, 1977).

B) Metabolites

1) Hydroxy metabolite of HALOPERIDOL, active (Shostak et al, 1987) (Midha et al, 1989).

a) A significant correlation exists between the percent improvement and the plasma levels of the hydroxymetabolite reduced HALOPERIDOL (Shostak et al, 1987).

2) 4-fluorobenzol-propionic acid (Forsman et al, 1977).

3) 4-fluoro-phenylaceturic acid (Forsman et al, 1977).

4) Reduced haloperidol (Kudo & Ishizaki, 1999).

5) Pyridinium metabolites (Kudo & Ishizaki, 1999).

6) Haloperidol glucuronide (Kudo & Ishizaki, 1999).

2.3.4 Excretion

A) Kidney

1) Renal Excretion (%)
a) 33 to 40% (Prod Info Haldol(R), 97; Anderson et al, 1976a).
B) Other
1) Feces, 15% (Johnson et al, 1967).

2.3.5 Elimination Half-life
A) Parent Compound
1) ELIMINATION HALF-LIFE
a) 21 hours (range: 10 to 38 hours) (Forsman & Ohman, 1976; Cressman et al, 1974a).
1) HALOPERIDOL DECANOATE administered intramuscularly has a half-life of approximately weeks (Reyntjens et al, 1982).

3.0 Cautions

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING
1) Haloperidol
a) Oral (Tablet)
1) Increased Mortality in Elderly Patients with Dementia-Related Psychosis: Elderly patients with demen related psychosis treated with atypical antipsychotic drugs are at an increased risk of death. Analyses of seventeen placebo-controlled trials (modal duration of 10 weeks), largely in patients taking atypical antipsychotic drugs, revealed a risk of death in drug-treated patients of between 1.6 to 1.7 times the risk death in placebo-treated patients. Over the course of a typical 10-week controlled trial, the rate of death drug-treated patients was about 4.5%, compared to a rate of about 2.6% in the placebo group. Although the causes of death were varied, most of the deaths appeared to be either cardiovascular (eg, heart failu sudden death) or infectious (eg, pneumonia) in nature. Observational studies suggest that, similar to atypical antipsychotic drugs, treatment with conventional antipsychotic drugs may increase mortality. The extent to which the findings of increased mortality in observational studies may be attributed to the antipsychotic drug as opposed to some characteristic(s) of the patients is not clear. Haloperidol is not approved for the treatment of patients with dementia-related psychosis (Prod Info haloperidol oral tablets 2008).
2) Haloperidol Decanoate
a) Intramuscular (Injectable)
1) Increased Mortality in Elderly Patients with Dementia-Related Psychosis: Elderly patients with demen related psychosis treated with antipsychotic drugs are at an increased risk of death. Analyses of sevente placebo-controlled trials (modal duration of 10 weeks), largely in patients taking atypical antipsychotic drugs, revealed a risk of death in drug-treated patients of between 1.6 to 1.7 times the risk of death in placebo-treated patients. Over the course of a typical 10-week controlled trial, the rate of death in drug-treated patients was about 4.5%, compared to a rate of about 2.6% in the placebo group. Although the causes of death were varied, most of the deaths appeared to be either cardiovascular (eg, heart failure, sudden death) or infectious (eg, pneumonia) in nature. Observational studies suggest that, similar to atypical antipsychotic drugs, treatment with conventional antipsychotic drugs may increase mortality. The extent to which the findings of increased mortality in observational studies may be attributed to the antipsychotic drug as opposed to some characteristic(s) of the patients is not clear. Haloperidol decanoa is not approved for the treatment of patients with dementia-related psychosis (Prod Info HALDOL(R) Decanoate IM injection, 2008).
3) Haloperidol Lactate
a) Intramuscular (Solution)
Increased Mortality in Elderly Patients with Dementia-Related Psychosis:
Elderly patients with dementia-related psychosis treated with antipsychotic drugs are at an increase risk of death. Analyses of seventeen placebo-controlled trials (modal duration of 10 weeks), largely i patients taking atypical antipsychotic drugs, revealed a risk of death in drug-treated patients of between 1.6 to 1.7 times the risk of death in placebo-treated patients. Over the course of a typical 1 week controlled trial, the rate of death in drug-treated patients was about 4.5%, compared to a rate about 2.6% in the placebo group. Although the causes of death were varied, most of the deaths appeared to be either cardiovascular (eg, heart failure, sudden death) or infectious (eg, pneumonia)

nature. Observational studies suggest that, similar to atypical antipsychotic drugs, treatment with conventional antipsychotic drugs may increase mortality. The extent to which the findings of increas mortality in observational studies may be attributed to the antipsychotic drug as opposed to some characteristic(s) of the patients is not clear. Haloperidol injection is not approved for the treatment of patients with dementia-related psychosis (Prod Info HALDOL(R) immediate release IM injection, 20(

3.1 Contraindications

A) Haloperidol

1) comatose state from any cause (Prod Info haloperidol oral tablets, 2008)
2) hypersensitivity to haloperidol (Prod Info haloperidol oral tablets, 2008)
3) Parkinson's disease (Prod Info haloperidol oral tablets, 2008)
4) toxic central nervous system depression, severe (Prod Info haloperidol oral tablets, 2008)

B) Haloperidol Decanoate

1) comatose state from any cause (Prod Info HALDOL(R) Decanoate IM injection, 2008)
2) hypersensitivity to haloperidol (Prod Info HALDOL(R) Decanoate IM injection, 2008)
3) Parkinson's disease (Prod Info HALDOL(R) Decanoate IM injection, 2008)
4) toxic CNS depression, severe (Prod Info HALDOL(R) Decanoate IM injection, 2008)

C) Haloperidol Lactate

1) comatose state from any cause (Prod Info HALDOL(R) immediate release IM injection, 2008)
2) hypersensitivity to haloperidol lactate (Prod Info HALDOL(R) immediate release IM injection, 2008)
3) Parkinson's disease (Prod Info HALDOL(R) immediate release IM injection, 2008)
4) toxic CNS depression, severe (Prod Info HALDOL(R) immediate release IM injection, 2008)

3.2 Precautions

A) Haloperidol

1) elderly patients with dementia-related psychosis (unapproved use); increased risk of death; most deaths were attributed to cardiovascular events (eg, heart failure or sudden death) or infections (eg, pneumonia) (Pr Info haloperidol oral tablets, 2008)
2) allergies or allergic reactions to drugs, known (Prod Info haloperidol oral tablets, 2008)
3) bronchopneumonia, some fatal, have been reported (Prod Info haloperidol oral tablets, 2008)
4) cardiac abnormalities, underlying; increased risk of QT prolongation and torsades de pointes (Prod Info haloperidol oral tablets, 2008)
5) cardiovascular disorders, severe, preexisting; potential for transient hypotension and/or onset of anginal p (Prod Info haloperidol oral tablets, 2008)
6) concomitant lithium use; a few patients have experienced encephalopathic syndrome followed by irreversi brain damage; causality not established (Prod Info haloperidol oral tablets, 2008)
7) concomitant use with anticoagulants, anticholinergics (including antiparkinson drugs), anticonvulsants, an drugs known to prolong the QT interval (Prod Info haloperidol oral tablets, 2008)
8) EEG abnormalities; may increase risk of seizures due to possible lowered convulsive threshold (Prod Info haloperidol oral tablets, 2008)
9) elderly patients, especially elderly women are at increased risk of tardive dyskinesia (Prod Info haloperido oral tablets, 2008)
10) electrolyte imbalance, especially hypokalemia and hypomagnesemia; increased risk of QT prolongation and torsades de pointes (Prod Info haloperidol oral tablets, 2008)
11) hypothyroidism; increased risk of QT prolongation and torsades de pointes (Prod Info haloperidol oral tablets, 2008)
12) increased duration of therapy and/or higher cumulative doses; increased risk of tardive dyskinesia (Prod Info haloperidol oral tablets, 2008)
13) long QT syndrome, family history; increased risk of QT prolongation and torsades de pointes (Prod Info haloperidol oral tablets, 2008)
14) neuroleptic malignant syndrome, potentially fatal, has been reported; immediately discontinue (Prod Info haloperidol oral tablets, 2008)
15) QT prolongation, history; increased risk of QT prolongation and torsades de pointes (Prod Info haloperid oral tablets, 2008)
16) QT prolongation and torsades de pointes have been reported (Prod Info haloperidol oral tablets, 2008)
17) rapid mood fluctuation toward depression may occur when haloperidol is used for mania in bipolar disorders (Prod Info haloperidol oral tablets, 2008)
18) seizure disorder, history; may increase risk of seizures due to possible lowered convulsive threshold (Pr Info haloperidol oral tablets, 2008)
19) tardive dyskinesia, potentially irreversible, may occur (Prod Info haloperidol oral tablets, 2008)
20) thyrotoxicosis; severe neurotoxicity may occur (Prod Info haloperidol oral tablets, 2008)

B) Haloperidol Decanoate

1) elderly patients with dementia-related psychosis (unapproved use); increased risk of death; most deaths were attributed to cardiovascular events (eg, heart failure or sudden death) or infections (eg, pneumonia) (Pr Info HALDOL(R) Decanoate IM injection, 2008)
2) allergies or allergic reactions to drugs, known (Prod Info HALDOL(R) Decanoate IM injection, 2008)
3) bronchopneumonia, some fatal, have been reported (Prod Info HALDOL(R) Decanoate IM injection, 2008
4) cardiac abnormalities, underlying; increased risk of QT prolongation and torsades de pointes(Prod Info

HALDOL(R) Decanoate IM injection, 2008)
5) cardiovascular disorders, severe; potential for transient hypotension and/or onset of anginal pain(Prod Inf
HALDOL(R) Decanoate IM injection, 2008)
6) concomitant use with anticoagulants, anticholinergics (including antiparkinson drugs), anticonvulsants, an
drugs known to prolong the QT interval (Prod Info HALDOL(R) Decanoate IM injection, 2008)
7) EEG abnormalities; may increase risk of seizures due to possible lowered convulsive threshold(Prod Info
HALDOL(R) Decanoate IM injection, 2008)
8) elderly patients, especially elderly women are at increased risk of tardive dyskinesia (Prod Info HALDOL(
Decanoate IM injection, 2008)
9) electrolyte imbalance, especially hypokalemia and hypomagnesemia; increased risk of QT prolongation a
torsades de pointes(Prod Info HALDOL(R) Decanoate IM injection, 2008)
10) hypothyroidism; increased risk of QT prolongation and torsades de pointes(Prod Info HALDOL(R)
Decanoate IM injection, 2008)
11) increased duration of therapy and/or higher cumulative doses; increased risk of tardive dyskinesia (Prod
Info HALDOL(R) Decanoate IM injection, 2008)
12) long QT syndrome, family history; increased risk of QT prolongation and torsades de pointes (Prod Info
HALDOL(R) Decanoate IM injection, 2008)
13) neuroleptic malignant syndrome, potentially fatal, has been reported in association with antipsychotic
drugs; immediately discontinue drug (Prod Info HALDOL(R) Decanoate IM injection, 2008)
14) QT prolongation, history; increased risk of QT prolongation and torsades de pointes(Prod Info HALDOL(
Decanoate IM injection, 2008)
15) QT prolongation and torsades de pointes have been reported, especially when administered intravenous
or at doses higher than recommended (Prod Info HALDOL(R) Decanoate IM injection, 2008)
16) rapid mood fluctuation toward depression may occur when risperidone is used for mania in bipolar
disorders (Prod Info HALDOL(R) Decanoate IM injection, 2008)
17) seizure disorder, history; may increase risk of seizures due to possible lowered convulsive threshold(Pro
Info HALDOL(R) Decanoate IM injection, 2008)
18) tardive dyskinesia, potentially irreversible, may occur (Prod Info HALDOL(R) Decanoate IM injection, 20
19) thyrotoxicosis; severe neurotoxicity may occur (Prod Info HALDOL(R) Decanoate IM injection, 2008)

C) Haloperidol Lactate
1) elderly patients with dementia-related psychosis (unapproved use); increased risk of death; most deaths
were attributed to cardiovascular events (eg, heart failure or sudden death) or infections (eg, pneumonia) (Pr
Info HALDOL(R) immediate release IM injection, 2008)
2) allergies, known, or with a history of allergic reactions to drugs (Prod Info HALDOL(R) immediate release
injection, 2008)
3) bronchopneumonia, some cases fatal, has been reported (Prod Info HALDOL(R) immediate release IM
injection, 2008)
4) cardiovascular disorders, severe; potential for transient hypotension and/or onset of anginal pain (Prod In
HALDOL(R) immediate release IM injection, 2008)
5) concomitant use with anticoagulants, anticholinergics (including antiparkinson drugs), anticonvulsants, or
lithium (Prod Info HALDOL(R) immediate release IM injection, 2008)
6) EEG abnormalities; may increase risk of seizures due to lowered convulsive threshold (Prod Info HALDO
(R) immediate release IM injection, 2008)
7) elderly patients, especially elderly women, are at increased risk of tardive dyskinesia (Prod Info HALDOL(
immediate release IM injection, 2008)
8) increased duration of therapy and/or higher cumulative doses; increased risk of tardive dyskinesia (Prod I
HALDOL(R) immediate release IM injection, 2008)
9) neuroleptic malignant syndrome, potentially fatal, has been reported; immediately discontinue if
signs/symptoms develop (Prod Info HALDOL(R) immediate release IM injection, 2008)
10) QT prolongation and torsades de pointes have been reported; increased risk in patients with underlying
cardiac abnormalities, familial long QT syndrome, hypothyroidism, electrolyte imbalance (especially
hypokalemia and hypomagnesemia), and with other drugs that prolong the QT interval (Prod Info HALDOL(R
immediate release IM injection, 2008)
11) rapid mood swing toward depression may occur when haloperidol is used for mania in cyclic disorders
(Prod Info HALDOL(R) immediate release IM injection, 2008)
12) seizure, history of; may increase risk of seizures due to lowered convulsive threshold (Prod Info HALDO
(R) immediate release IM injection, 2008)
13) tardive dyskinesia, potentially irreversible, may occur (Prod Info HALDOL(R) immediate release IM
injection, 2008)
14) thyrotoxicosis; severe neurotoxicity may occur (Prod Info HALDOL(R) immediate release IM injection,
2008)

Cardiac arrest

Heart block, third degree

Hypertension

Hypotension

Prolonged QT interval

Sudden cardiac death

Tachycardia

Torsades de pointes

Ventricular premature beats

3.3.1.A Cardiac arrest

1) Cases of cardiac arrest secondary to haloperidol administration have been reported. A 49-year-old female with normal vital signs was brought to the emergency department in an acute confusional state a was given 5 milligrams (mg) haloperidol intramuscularly upon admission. She was given 10 mg haloperic intramuscularly 5 hours later due to complaints of feeling sick and anxious. The patient remained disoriented and confused and received another dose of haloperidol 10 mg the next morning. Forty-five minutes later, the patient was found unresponsive, cyanotic, and in asystolic arrest. Electrocardiogram a resuscitation showed no evidence of ischemia or prolongation of corrected QT interval. The patient remained comatose and died one month after being transferred to a long-term care facility. Information l received from her treating psychiatrist revealed the patient had previous admissions for similar incidents confusion and had experienced severe reactions to neuroleptic agents. The authors suggest such patien are candidates for medical alert bracelets (Westlake & Rastegar, 1973). In addition, a 65-year-old male patient twice suffered asystolic cardiac arrest after separate intravenous injections of haloperidol 7.5 mg confusion. The authors suggest that extreme (greater than 50 mg) or intermittent intravenous doses nee to be restricted to those patients in intensive care units with cardiac monitoring facilities (Huyse & Van

Schijndel, 1988).

3.3.1.B Heart block, third degree

1) Intermittent third degree heart block occurred during the highest rate of infusion (40 mg/hour) (Riker e al, 1994).

2) Two patients experienced adverse reactions attributed to continuous infusion haloperidol. Intermittent third-degree heart block and prolonged qt interval with torsade de pointes occurred during the highest ra of infusion (40 mg/hour). Hemodynamically compromising tachycardia requiring cardioversion and lidoca occurred during infusion of 10 mg/hour over 5 days. Finally, extrapyramidal side effects appeared after abrupt discontinuation of benzodiazepine treatment, requiring its reinstatement for resolution (Riker et al 1994).

3.3.1.C Hypertension

1) Hypertension has been reported with haloperidol use, especially if excessive doses are ingested. Haloperidol in therapeutic doses rarely has an effect on blood pressure. Many neuroleptics cause hypotension. In overdosage, patients normally remain normotensive. However, a 22-month-old girl accidentally ingesting 15 to 20 mg haloperidol developed significant hypertension of 146/100 at 8 hours and 164/134 at 10 hours after a baseline level of 136/66 taken on admission. IV hydralazine was require to reduce pressures reaching as high as 180 systolic over the subsequent 5 days. This report substantia 2 other reports of hypertension recently received by the manufacturer (Cummingham & Challapalli, 1979

3.3.1.D Hypotension

1) Transient hypotension may occur. A vasopressor may be necessary to treat the hypotension. Epinephrine should not be the vasopressor selected because haloperidol blocks the vasopressor effects and paradoxical lowering of the blood pressure may occur (Prod Info HALDOL(R) injection, 2007).

3.3.1.E Prolonged QT interval

1) Summary

a) Torsades de Pointes and QT prolongation, including sudden death, have been reported especial when haloperidol is administered intravenously or at doses higher than recommended. Risk factors Torsades de Pointes or QT prolongation include QT-prolonging conditions such as electrolyte imbalance (especially, hypokalemia and hypomagnesemia); underlying cardiac abnormalities; hypothyroidism; familial long QT syndrome; and concomitant drugs that prolong the QT interval. Electrocardiogram monitoring is recommended in patients on intravenous haloperidol (US Food and Drug Administration, 2007).

b) The incidence of long QTc interval syndrome or torsade de pointes with haloperidol is small (Lawrence & Nasraway, 1997). The majority of cases occurred in critically ill patients with a history c cardiovascular disease prescribed more than 50 mg/day. It is recommended that before initiating therapy with haloperidol in critically ill patients that a baseline QTc interval and serum magnesium a potassium concentrations be measured. In cases where the baseline QTc interval is 440 millisecond or longer and they are receiving other drugs that may prolong the QTc interval, or they have an electrolyte disturbance, haloperidol or similar drugs should be used with caution. Electrocardiogram monitoring should be done in critically ill patients once haloperidol is initiated. If the QTc interval lengthens by 25% or more, the haloperidol should be discontinued or the dosage should be reduced

2) The medical literature includes 28 case reports of QT prolongation and Torsades de Pointes, includin cases of death when haloperidol was administered intravenously. Furthermore, a dose-response relationship between intravenous doses and subsequent Torsades de Pointes was demonstrated in case control studies (US Food and Drug Administration, 2007).

3) There were 229 cases of QT prolongation in patients administered injectable or oral haloperidol, including 73 cases of Torsades de Pointes of which 11 were fatal, reported in the manufacturer's worldw safety database received through June 30, 2005. Various doses of intravenous haloperidol were used in of the 11 fatal cases. QT-prolonging or medical conditions may have contributed to the events. A second postmarketing investigation, submitted to the Food and Drug Administration in March 2007, reported 13 Torsades de Points, QT prolongation, ventricular arrhythmias and/or sudden death (US Food and Drug Administration, 2007).

4) QT prolongation has been reported in clinical trials. Predisposed patients (long QT-syndrome, hypokalemia, electrolyte imbalance, drugs known to prolong QT, cardiovascular disease, family history c QT prolongation) or those being treated with high doses may have an increased risk of QT prolongation (Prod Info HALDOL(R) injection, 2007).

5) Two patients experienced adverse reactions attributed to continuous infusion haloperidol. Intermittent third-degree heart block and prolonged qt interval with Torsade de Pointes occurred during the highest ra of infusion (40 mg/hour). Hemodynamically compromising tachycardia requiring cardioversion and lidoca occurred during infusion of 10 mg/hour over 5 days (Riker et al, 1994).

6) Intermittent prolonged QT interval with torsades de pointes occurred during the highest rate of infusio (40 mg/hour) (Riker et al, 1994).

3.3.1.F Sudden cardiac death

1) In a large, retrospective, cohort study that included a primary cohort of 93,300 users of antipsychotic

drugs and 186,600 non-users of antipsychotic drugs, there was an increased risk of sudden cardiac deat in adult participants 30 to 74 years of age (mean age of 45.7 years) who were using haloperidol compare to those who were not using antipsychotic drugs (incidence-rate ratio, 1.61; 95% confidence interval (CI) 1.16 to 2.24; p=0.005). In participants being treated with typical antidepressants (haloperidol, thioridazine the incidence-rate ratio for sudden cardiac death increased from 1.31 (95% CI, 0.91 to 1.39) for those us low doses to 2.42 (95% CI, 1.91 to 3.06) for those using high doses (p less than 0.001) (Ray et al, 2009)

3.3.1.G Tachycardia

1) Hemodynamically compromising tachycardia requiring cardioversion and lidocaine occurred during infusion of 10 mg/hour over 5 days (Riker et al, 1994).

3.3.1.H Torsades de pointes

1) Summary

a) Torsades de Pointes and QT prolongation, including sudden death, have been reported especial when haloperidol is administered intravenously or at doses higher than recommended. Risk factors Torsades de Pointes or QT prolongation include QT-prolonging conditions such as electrolyte imbalance (especially, hypokalemia and hypomagnesemia); underlying cardiac abnormalities; hypothyroidism; familial long QT syndrome; and concomitant drugs that prolong the QT interval. Electrocardiogram monitoring is recommended in patients on intravenous haloperidol (US Food and Drug Administration, 2007).

b) The incidence of long QTc interval syndrome or torsade de pointes with haloperidol is small (Lawrence & Nasraway, 1997). The majority of cases occurred in critically ill patients with a history c cardiovascular disease prescribed more than 50 mg/day. It is recommended that before initiating therapy with haloperidol in critically ill patients that a baseline QTc interval and serum magnesium a potassium concentrations be measured. In cases where the baseline QTc interval is 440 millisecond or longer and they are receiving other drugs that may prolong the QTc interval, or they have an electrolyte disturbance, haloperidol or similar drugs should be used with caution. Electrocardiogram monitoring should be done in critically ill patients once haloperidol is initiated. If the QTc interval lengthens by 25% or more, the haloperidol should be discontinued or the dosage should be reduced

2) The medical literature includes 28 case reports of QT prolongation and Torsades de Pointes, includin cases of death when haloperidol was administered intravenously. Furthermore, a dose-response relationship between intravenous doses and subsequent Torsades de Pointes was demonstrated in case control studies (US Food and Drug Administration, 2007).

3) There were 229 cases of QT prolongation in patients administered injectable or oral haloperidol, including 73 cases of Torsades de Pointes of which 11 were fatal, reported in the manufacturer's worldw safety database received through June 30, 2005. Various doses of intravenous haloperidol were used in of the 11 fatal cases. QT-prolonging or medical conditions may have contributed to the events. A second postmarketing investigation, submitted to the Food and Drug Administration in March 2007, reported 13 Torsades de Points, QT prolongation, ventricular arrhythmias and/or sudden death (US Food and Drug Administration, 2007).

4) A case of haloperidol-induced torsade de pointes was reported in a 41-year-old woman with no predisposing factors. The patient developed torsade de pointes 55 minutes after receiving 80 milligrams (mg) of intravenous haloperidol. The patient was treated and the arrhythmia was controlled. She receive one more 80-mg dose of haloperidol without incident and then it was discontinued. The patient experienc no further arrhythmias (O'Brien et al, 1999t).

5) A total of 7 patients developed torsade de pointes after therapeutic use of haloperidol in high doses (Metzger & Friedman, 1993l; Wilt et al, 1993j). Three patients developed the dysrhythmia after administration of 211 to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episodes, but 1 patient subsequently died of cardiac arrest upon readministrati of haloperidol. Four patients developed the dysrhythmia after administration of 170 to 580 mg over 1 to 4 days for delirium associated with bacterial meningitis (1), status asthmaticus (2) or respiratory insufficien (1). All 4 patients recovered with no adverse sequelae.

6) A case of torsade de pointes was reported in a 48-year-old woman who ingested 210 mg of haloperic and 1400 mg of orphenadrine. It was concluded that the haloperidol caused this reaction. The patient wa given gastric lavage, 50 grams of activated charcoal and a constant infusion of lidocaine administered at rate of 4 mg per minute. Later, the lidocaine was stopped and replaced by a pacing electrode. The patie was released eight days later in normal condition (Henderson et al, 1991).

7) A case of torsade de pointes caused by haloperidol was reported in a 36-year-old male chronic schizophrenic patient. The patient had been treated with oral haloperidol 20 mg/day for five days, and th 50 mg/day for two more days during hospitalization in a closed psychiatric department. The torsade de pointes was treated with an isoproterenol infusion 2 to 3 mg/minute until the electrocardiogram returned normal (Kriwisky et al, 1990).

8) In another report, the incidence of torsade de pointes was substantial, developing in 8 of 223 critically patients in intensive care units (Sharma et al, 1998f). Patients who received intravenous haloperidol grea than 35 mg/day or had a QTc interval prolongation of greater than 500 ms were at greatest risk.

3.3.1.I Ventricular premature beats

1) A patient who received 90 mg the first day and 60 mg the second day of this procedure developed

multifocal, premature ventricular beats after a 10 mg dose on the third day. The frequency of these beats decreased from one half to one tenth over a 3 day drug-free period. When the patient then received thiothixene over a 4 day course, the ECG was normal (Mehta et al, 1979).
2) Rapid neuroleptization with high dose haloperidol has been associated with few serious cardiovascul side effects. A patient who received 90 mg the first day and 60 mg the second day of this procedure developed multifocal, premature ventricular beats after a 10 mg dose on the third day. The frequency of these beats decreased from one half to one tenth over a 3 day drug-free period. When the patient then received thiothixene over a 4 day course, the ECG was normal (Mehta et al, 1979).

3.3.2 Dermatologic Effects

Dermatological finding

Hair finding

Photosensitivity

3.3.2.A Dermatological finding

1) The relationship between haloperidol-induced parkinsonism and development of SEBORRHEIC DERMATITIS was studied. In 42 patients with haloperidol-induced parkinsonism, 59.5% developed seborrheic dermatitis, while in 47 patients without the extrapyramidal reaction, only 15% had seborrheic dermatitis (Binder & Jonelis, 1983).
2) Haloperidol has also been reported to cause maculopapular and acneiform SKIN ERUPTIONS (Prod Info Haldol(R), 97a).
3) Four cases of injection site reactions after using haloperidol decanoate 100 mg/mL were reported. Ea of the four patients had been given 50 mg/mL strength and had no reaction. The researchers first though that the vehicle used in the 100 mg/mL strength was the problem, but the same vehicle is used in the 50 mg/mL injection. The conclusion was the concentration of 100 mg/mL created much local intolerance (Hamann et al, 1990).
4) Eight of 9 patients injected with haloperidol decanoate 100 mg/mL developed raised, firm, warm, erythematous nodules of 3.5 cm. Symptoms dissipated over three weeks, but nodules persisted for two months. The authors noted no similar reactions in patients receiving the 50 mg/mL strength (Reinke & Wiesert, 1992).

3.3.2.B Hair finding

1) A case of ALOPECIA areata was reported, possibly secondary to haloperidol therapy. The patient wa 56-year-old man who had taken haloperidol for one month (5 mg twice daily for one week, then 3 mg dai and began to experience hair loss on the back of his head. Haloperidol was discontinued and the patient switched to perphenazine. After one week, hair loss stopped and after one month hair growth was norma The patient was also receiving amoxapine and biperiden which may have contributed to the alopecia (Kubota et al, 1994).

3.3.2.C Photosensitivity

1) Isolated cases of photosensitivity has been reported (Prod Info HALDOL(R) injection, 2007).

3.3.3 Endocrine/Metabolic Effects

Gynecomastia

Hyperprolactinemia

Hypoglycemia

Metabolic syndrome

Syndrome of inappropriate antidiuretic hormone secretion

3.3.3.A Gynecomastia

1) Gynecomastia has been reported with haloperidol treatment (Prod Info HALDOL(R) Decanoate IM injection, 2008; Prod Info HALDOL(R) immediate release IM injection, 2008).

3.3.3.B Hyperprolactinemia

1) Overview

a) Antipsychotic-induced hyperprolactinemia was reported in 65.6%, 45.1%, and 42.4% of women c childbearing potential, postmenopausal women, and men, respectively, in an open-label, clinical tria patients treated with first-generation antipsychotics or risperidone at average doses of 4.2 to 5.2 mg/day. Compared to baseline, prolactin levels were significantly elevated (p less than 0.05) followir use of first-generation antipsychotics (ie, chlorpromazine, droperidol, flupenthixol, fluphenazine, haloperidol, paliperidone, perazine, perphenazine, pimozide, trifluoperazine, and zuclopenthixol) or risperidone in several clinical trials of patients with schizophrenia. Younger patients and women of childbearing potential have a greater risk for hyperprolactinemia following treatment with higher dos of these antipsychotics. Hyperprolactinemia may potentially result in menstrual disturbances, sexual dysfunction, bone mineral density (ie, osteopenia and osteoporosis), and breast and pituitary tumors (Bostwick et al, 2009).

2) Hyperprolactinemia has been reported with antipsychotic drugs; the elevation in prolactin persists dur chronic administration (Prod Info HALDOL(R) Decanoate IM injection, 2008; Prod Info HALDOL(R) immediate release IM injection, 2008).

3) Haloperidol use has been associated with an increased prolactin secretion. It appears that a correlati exists between haloperidol-induced prolactin secretion and antipsychotic effect, blood levels, and extrapyramidal side effects of haloperidol (Rao et al, 1980). However, there is a large intersubject variab in the timing and amount of prolactin secreted with a specific dose (Rubin & Forster, 1980). Furthermore other factors may influence prolactin secretion, the effect is blunted in cases of idiopathic hyperprolactinemia (Falaschi et al, 1980), and the effect may be diminished with high doses of haloperid (Bjorndal et al, 1980). Length of therapy apparently does not diminish the effect (Ohman, 1980).

4) In 15 subjects, with normal prolactin levels and beginning haloperidol therapy 1 to 10 mg twice daily, prolactin levels rapidly increased during the first 6 to 9 days. Thereafter, the level plateaued and in most subjects remained between 30 and 50 ng/mL for the 18 days that prolactin was measured. The level did not exceed 77 ng/mL (Spitzer et al, 1998).

5) Prolactin blood levels resulting from varying doses of haloperidol were studied. In their study, involvin 37 patients who received haloperidol 0.2 to 20 mg/day, the following findings were made; doses less tha mg did not produce elevation, doses of 5 to 20 mg produced increasing elevations of prolactin, and lithiu did not enhance the prolactin response (Mielke & Gallant, 1982).

6) The prolactin response to intramuscular haloperidol (0.5 mg, 1 mg, and 1.5 mg) was studied in 6 norr premenopausal women during the follicular and luteal phases of their menstrual cycles. These were compared to the prolactin response in normal young men at the same doses of haloperidol. The women had significantly greater prolactin responses to haloperidol 1 mg and 1.5 mg doses than the men. This w most likely due to a potentiating effect of estrogen. However, the prolactin response to haloperidol at the lower dose of 0.5 mg was significantly smaller in women than men. The women did not differ in their prolactin response to haloperidol during the early and late phase of their menstrual cycle, showing that a increase in endogenous estrogen did not augment the prolactin response to haloperidol (Asnis et al, 198

a) Management

1) Appropriate drug selection, monitoring and management are all important when prescribing antipsychotics that have the potential for inducing hyperprolactinemia. Prior to treatment with ar antipsychotic, question patients regarding changes in libido or galactorrhea. Female patients should be assessed for menstrual abnormalities and male patients, for erectile or ejaculatory dysfunction. In the event that any of these symptoms are present, consider obtaining baseline prolactin levels. Patients should be informed of the potential for sexual dysfunction with antipsychotic use. Several weeks after an antipsychotic is initiated, obtain a prolactin level measurement. In cases where the patient experiences troublesome adverse effects related to elevated prolactin levels and discontinuing the antipsychotic is not an option, treatment with a dopamine agonist (eg, bromocriptine or cabergoline) should be considered (Bostwick et al, 200

3.3.3.C Hypoglycemia

1) Hypoglycemia has been reported with haloperidol treatment (Prod Info HALDOL(R) Decanoate IM injection, 2008; Prod Info HALDOL(R) immediate release IM injection, 2008).

3.3.3.D Metabolic syndrome

See Drug Consult reference: ANTIPSYCHOTIC AGENTS - METABOLIC SYNDROME

3.3.3.E Syndrome of inappropriate antidiuretic hormone secretion

1) Syndrome of inappropriate antidiuretic hormone secretion (SIADH) developed in a lethargic 54-year-c patient following the administration of haloperidol 10 mg/day orally for 1 month. Serum sodium was 111 mEq/L and plasma and urine osmolalities were 225 and 325 mOsm/L, respectively. Renal, liver, and thyr function tests were normal. The response from an adrenocorticotropic hormone stimulation test was alsc normal. Discontinuation of haloperidol and water restriction resolved symptoms and improved serum sodium concentration. After several weeks had lapsed, haloperidol was reinitiated and after 5 days of therapy, the patient became lethargic and serum sodium was 115 mEq/L. The SIADH resolved following water restriction and discontinuation of haloperidol. The authors postulated two possible mechanisms for SIADH induced by haloperidol. Haloperidol may alter the central osmotic threshold for ADH (antidiuretic

hormone) levels, or haloperidol may act on the kidneys directly to increase their sensitivity to ADH (Peck Shenkman, 1979).
2) A 77-year-old female, receiving haloperidol 6 mg daily for 5 days, then 10 mg per day, developed SIADH on the eighth day. While she was taking digoxin and hydrochlorothiazide/triamterene, the tempor relationship to haloperidol suggested it as the cause (Husband et al, 1981).
3) A 25-year-old patient with a history of schizophrenia and mental retardation developed syndrome of inappropriate antidiuretic hormone secretion (SIADH). Prior to admission, the patient received haloperidc 30 mg/day for 4 months. Upon admission, serum sodium was 118 mEq/L, serum and urine osmolality we 254 and 299 mOsm/kg, respectively, and urine sodium was 23 mEq/L. To rule out other causes of SIADI serum calcium, magnesium, and phosphorus levels were determined, a hemogram, and renal, liver, adrenal, and thyroid function tests were performed, and all were normal. Roentgenograms of the chest a skull, an EEG, and CT and brain scan were also normal. The patient was treated with fluid restriction anc discharged 12 days following admission. The authors failed to state if haloperidol was discontinued or if t dose reduced, nor was a rechallenge with haloperidol performed, so the possibility of psychogenic water intake does exist for the etiology of SIADH in this case (Matuk & Kalyanaraman, 1977).

3.3.4 Gastrointestinal Effects

Constipation

Dysphagia

Gastrointestinal tract finding

Paralytic ileus

Xerostomia

3.3.4.A Constipation
1) Haloperidol has been reported to cause constipation (Prod Info Haldol(R), 97a).

3.3.4.B Dysphagia
See Drug Consult reference: ANTIPSYCHOTIC-INDUCED DYSPHAGIA

3.3.4.C Gastrointestinal tract finding
1) Haloperidol has been reported to cause ANOREXIA, DYSPEPSIA, NAUSEA and VOMITING, CONSTIPATION, DIARRHEA, and hypersalivation (Prod Info Haldol(R), 97a).
2) In one study of reported cases (n=192) of antipsychotic-induced PANCREATITIS, 12% of the cases were associated with the use of haloperidol at a mean daily dose of 8.2 milligrams. In most patients, time onset of pancreatitis was within 6 months after initiation of treatment (Koller et al, 2003c).

3.3.4.D Paralytic ileus
1) Incidence: rare
2) A case of ileus was reported in a 52-year-old female who received a mean dose of 41.4 mg haloperidol/day, raised to a mean dose of 53 mg/day the 5 days prior to onset. The resulting fecal impaction resolved over 6 days with discontinuation of haloperidol, IV fluids, and continuous nasogastric suction (Maltbie et al, 1981).

3.3.4.E Xerostomia
1) Dry mouth has been reported (Prod Info HALDOL(R) injection, 2007).

3.3.5 Hematologic Effects

Agranulocytosis

Leukopenia

3.3.5.A Agranulocytosis
1) Incidence: rare (Prod Info HALDOL(R) injection, 2007)
2) Agranulocytosis has occurred, rarely, in association with haloperidol and other medications (Prod Info HALDOL(R) injection, 2007).

3.3.5.B Leukopenia

1) Moderate doses of haloperidol have been associated with the development of mild and usually transi leukopenia (Prod Info Haldol(R), 97a).

2) A case of leukopenia (from 13,000 cu/mm to 3,200 cu/mm) 15 days after starting haloperidol 10 mg/d was reported. This followed a similar occurrence with thiothixene. The mechanism for this rare adverse effect could not be established, but the white count returned to normal within a few days after discontinuation of the drug, and subsequent treatment with fluphenazine has not caused a recurrence (Cutler & Heiser, 1979).

3.3.6 Hepatic Effects

3.3.6.A Hepatotoxicity

1) Chronic cholestatic LIVER DISEASE occurred in a 15-year-old black male following treatment with haloperidol (6 mg daily) and benztropine (8 mg daily) for 4 weeks. The patient was treated for an acute psychotic episode. At this time, the patient presented with jaundice to his psychiatrist and was admitted t the hospital approximately 2 months later. JAUNDICE and pruritus continued for over 7 months. Twenty- eight months after the occurrence of jaundice, the patient is asymptomatic but had mildly elevated alkalir phosphatase and transaminase levels (Dincsoy & Saelinger, 1982).

3.3.8 Musculoskeletal Effects

Musculoskeletal finding

Myasthenia gravis

Rhabdomyolysis

3.3.8.A Musculoskeletal finding

1) An increased incidence of hip fracture was reported in elderly patients receiving psychotropic agents (Ray et al, 1987). This study was a case-control evaluation of 1021 patients with hip fractures and 5606 controls, and indicated that an increased risk of hip fracture was observed with the use of hypnotic/anxiolytic agents with a long elimination half-life (greater than 24 hours), tricyclic antidepressant and antipsychotic agents. Current users were defined as subjects who had received a prescription in the day period prior to the admission date for index hospitalization. The long half-life hypnotic/anxiolytic ager studied were lorazepam, diazepam, chlordiazepoxide and barbiturates, excluding phenobarbital. The tricyclic antidepressants included amitriptyline, doxepin and imipramine; antipsychotic agents evaluated were thioridazine, haloperidol, chlorpromazine and perphenazine/amitriptyline. In contrast, shorter-acting hypnotic-anxiolytic agents (half-life of 24 hours or less) were not associated with an increased risk of hip fracture in these patients. The most frequently used agents in this category were diphenhydramine, hydroxyzine and chloral hydrate. The increased risk of hip fracture observed in this study was directly related to the doses of the drugs. Analysis for confounding by dementia did not alter the results. Addition studies are needed to confirm these results in this and other populations and to evaluate the effects of other psychotropic drugs that have less sedative effects.

3.3.8.B Myasthenia gravis

See Drug Consult reference: DRUG-INDUCED MYASTHENIA GRAVIS

3.3.8.C Rhabdomyolysis

1) A case of haloperidol-induced rhabdomyolysis in the absence of neuroleptic malignant syndrome was reported in a 6-year-old handicapped boy. Oral haloperidol (0.3 milligrams daily) was initiated to treat involuntary movements. The haloperidol was effective and the dose was increased to 0.8 milligrams twic daily. After haloperidol was begun, the patient's urine became dark brown on occasion and the myoglobi level in his urine increased. Mild rhabdomyolysis was suspected and haloperidol was discontinued. Subsequently, the myoglobin in the urine decreased, creatinine kinase decreased to normal, and the urir no longer become dark brown (Yoshikawa et al, 2000).

2) In a 23-year-old male a dystonic reaction occurred complicated by the occurrence of rhabdomyolysis. Ten hours following administration of haloperidol 5 mg PO TID, the patient experienced a dystonic reacti which was mistaken for psychotic behavior. Tonic activity continued into the second day and Benadryl 5(mg IV had minimal effect; the reaction was finally controlled with benztropine IV. On the third day, rhabdomyolysis was observed, and urinary myoglobin on minimal effect; the reaction was finally controlle with benztropine IV. On the third day, rhabdomyolysis was observed, and urinary myoglobin on day 4 wa 67 mcg/mL. Patient recovered following urinary alkalinization and IV fluid therapy (Cavanaugh & Finlays(1984).

3.3.9 Neurologic Effects

Akathisia

Dementia

Dysphoric mood

Dystonia

Encephalopathy

Extrapyramidal disease

Neuroleptic malignant syndrome

Parkinsonism

Phobia

Seizure

Tardive dyskinesia

Tic

3.3.9.A Akathisia

1) A study compared akathisia induced by haloperidol or thiothixene. The haloperidol group (5 mg as tes dose followed by 10 mg/day) experienced akathisia in 75% of cases. The thiothixene group (0.22 mg/kg test dose followed by 0.44 mg/kg/day) experienced akathisia in 46% of cases (Van Putten et al, 1984a; V Putten et al, 1984b).

3.3.9.B Dementia

1) Dementia, characterized by symptoms of confusion, memory impairment, disorientation, and slowing motor performance, has been reported (Thornton, 1976b; Cohen & Cohen, 1974a).

3.3.9.C Dysphoric mood

1) Dysphoria has been reported in patients treated with haloperidol for Gilles de la Tourette syndrome. C 72 patients being treated for Gilles de la Tourette syndrome, 3 patients developed pronounced and 3 patients developed mild dysphoria. The change in mood was not related to akinesia or other extrapyrami side effects, drowsiness, or cognitive impairment. Improvement was seen when dosage was reduced. Th report confirms 2 other case studies of similar nature (Caine & Polinsky, 1979).

2) Twenty-six cases of dysphoria, 13 of which were severe, were reported in patients being treated with haloperidol for Tourette syndrome. All appeared to have a threshold dose, above which dysphoria occur and below which symptoms subsided. The threshold dose was individualized and ranged from 1 to 30 mg/day (Bruun, 1982).

3.3.9.D Dystonia

1) During the first few days after initiating treatment with an antipsychotic medication, symptoms of dystonia may occur in susceptible individuals. Symptoms may include spasm of neck muscles, which ma progress to tightening of the throat, swallowing difficulty, breathing difficulty, and/or protrusion of the tongue. These symptoms can occur at low doses but most often occur (and occur with a greater severity with high potency and at higher doses of first generation antipsychotic medications. Males and younger a groups appear to be at greater risk for developing acute dystonia (Prod Info HALDOL(R) IM injection, 2008).

2) Extrapyramidal and dystonic reactions have occurred following usual therapeutic doses of haloperido The incidence of dystonias following haloperidol is reported to be as high as 16% (Swett, 1975) and for extrapyramidal symptoms as high as 25% (Anon, 1973a).

3) Laryngeal-pharyngeal dystonia was reported in a patient 16 hours after being treated with a single do of haloperidol 5 mg IM. The reaction was treated with benztropine 2 mg IV, repeated after 2 minutes, whereupon recovery without sequelae occurred in 5 minutes (Menuck, 1981).

4) Sudden death was reported in a woman receiving haloperidol 230 mg over less than 48 hours. The proposed mechanism was laryngeal-pharyngeal dystonia, followed by laryngospasm and cardiac arrest (Modestin et al, 1981). A similar case was reported after a patient received 340 mg over less than 96 hou

(Ketai et al, 1979).
5) Dystonic reactions were reported to persist for several weeks after a single dose of haloperidol in two patients (Anderson et al, 1981).
6) A high incidence of dystonic reactions was reported in cocaine abusers. Of 7 chronic heavy cocaine users, administration of intramuscular haloperidol (8 mg on 2 consecutive days) resulted in the occurrenc of acute dystonic reactions in 6; the onset of dystonia was approximately 22 hours following the first dos 4 patients and 3 hours following the second dose in 2 others. Diphenhydramine or benztropine was effective in alleviating dystonia in all patients. These data suggest a higher incidence of dystonic reactior in cocaine abusers treated with neuroleptic agents. However, controlled studies are required to confirm these findings, using a cocaine naive control group (Kumor et al, 1986).

3.3.9.E Encephalopathy
1) A case of post-surgical toxic encephalopathy has been attributed to high-dose haloperidol in a 54-yea old African-American male. The patient had a history of bipolar disorder, hypertension and a cerebrovascular accident. Despite increasing doses of haloperidol (up to 270 milligrams intravenously ov 24 hours) to treat agitation, mental status continued to worsen to the point of obtundation, with toxic encephalopathy diagnosed on day 14 after surgery. After haloperidol discontinuation, encephalopathy completely resolved within 8 days (Maxa et al, 1997).
2) An encephalopathic syndrome with irreversible brain syndrome has been reported (Thornton, 1976b; Cohen & Cohen, 1974a).

3.3.9.F Extrapyramidal disease
1) Incidence: frequent (Prod Info HALDOL(R) injection, 2007)
2) Extrapyramidal symptoms occur frequently. Parkinson-like symptoms, akathisia or dystonia may occu typically within the first few days of starting haloperidol. There is a greater association with higher doses. Dose reductions may alleviate symptoms. Antiparkinson drugs (such as benztropine mesylate or trihexyphenidyl hydrochloride) may be useful. Discontinuation of haloperidol may be necessary in patient with persistent extrapyramidal symptoms (Prod Info HALDOL(R) injection, 2007).
3) Extrapyramidal and dystonic reactions have occurred following usual therapeutic doses of haloperido The incidence of dystonias following haloperidol is reported to be as high as 16% (Swett, 1975) and for extrapyramidal symptoms as high as 25% (Anon, 1973a).
4) Extrapyramidal disturbances can present as mild to severe dyskinetic and dystonic reactions includin oculogyric crises, forced opening of the mouth, protrusion of tongue, spasm of facial muscles, opisthotor and scoliotic positioning, general muscle rigidity, cogwheel phenomenon, coarse tremors, oral dyskinesia restlessness, dystonic spasms and posturings of the neck, trunk, and limbs, aphonia and dysphagia (Ge et al, 1972; Walinder & Carlsson, 1973; Simpson, 1973; Lake & Fann, 1973; Yosselson & Kaplan, 1975; Shields & Bray, 1976; Loudon & Waring, 1976; Rice, 1977). Although a number of agents have been reported to be effective in treating these extrapyramidal disturbances including apomorphine, biperiden, procyclidine, and propranolol, conventional agents such as diphenhydramine, trihexyphenidyl, or benztropine may not always result in improvement of the dystonic reactions (Shields & Bray, 1976). Thes neurotoxic reactions have been reported in patients with thyrotoxicosis (Lake & Fann, 1973; Yosselson & Kaplan, 1975) as well as pediatric patients (Shields & Bray, 1976). Some reports indicate that concomita drug therapy such as with lithium may aggravate extrapyramidal reactions (Loudon & Waring, 1976). Son data suggests that, particularly in elderly patients, parkinsonism reactions induced by haloperidol may persist for up to 2 weeks (Rice, 1977). Parkinsonism-like symptoms (sialorrhea, dystonia, torticollis, and trismus) have occurred following discontinuation of haloperidol therapy (De Maio, 1973). Rigidity occurre in association with dyspnea, cyanosis, and dehydration in a thyrotoxic, 74-year-old female (Hamadah & Teggin, 1974).
5) The extrapyramidal side effects of haloperidol were shown to be lessened by joint administration of imipramine-like drugs (Butterworth, 1972).
6) The incidence of extrapyramidal reactions was lower in patients receiving intravenous as opposed to oral haloperidol (Menza et al, 1987). More studies are required to fully evaluate the potential mechanism for a lower incidence of EPS with the intravenous route. In addition, this study only involved 10 patients (received intravenous haloperidol, 6 received oral haloperidol) and more studies involving larger patient populations are necessary to confirm significant differences.
7) Four cases of severe muscle rigidity were reported in burn patients receiving haloperidol for the neuropsychiatric complications of thermal injury. The authors postulated that the seemingly high incidenc (greater than 30%) of this reaction could have resulted from an increased sensitivity of the neuromuscula receptors to acetylcholine, which is present in greater concentrations after haloperidol treatment (Huang al, 1987).
8) A 5-year-old female with Sydenham's chorea treated with doses of 0.5 to 0.7 mg orally 4 times daily c haloperidol developed side effects of dysphagia, aphonia, and dystonic posturing(Shields & Bray, 1976). Seven weeks later the patient was hospitalized and was noted to have abnormal head posture, left arm extension with fist clinched, inability to walk without falling frequently, and placement of her right thumb in the roof of her mouth causing pressure against the gingiva resulting in the exposure of 2 teeth's roots. Th haloperidol was discontinued and various drugs including diphenhydramine, benztropine, and levodopa were given without effect. The patient's condition deteriorated requiring frequent tube feeding with the patient being unable to walk and often assuming a fixed extensor posture. Due to circumstantial evidenc

the choreiform movements and dystonias were believed to be resulted to the haloperidol ingestion.
9) A 23-year-old woman receiving Lugol's solution, propylthiouracil (PTU), trihexyphenidyl, and haloperi developed facial rigidity, a fixed grin, aphasia, an inability to walk, severe weakness, diarrhea, and dryne of the lips and tongue. Four days prior to hospital admission when diarrhea developed, all drugs were discontinued except haloperidol. After 4 days, some improvement in her symptoms were noted. The authors suggested that this type of reaction is not necessarily idiosyncratic but expected in thyrotoxic patients (Yosselson & Kaplan, 1975).
10) A 32-year-old woman developed haloperidol toxicity because of manganese toxicity. The Parkinsonism-like neurotoxicity may be due to the free-radical formation in the presence of ionic manganese in the neuromelanin-containing regions of the brain (Mehta & Reilly, 1990).
11) The incidence and severity of tardive dyskinesia and extrapyramidal side effects was evaluated in 5 outpatients receiving either fluphenazine decanoate or haloperidol decanoate. Twenty-one patients had probable movement disorders based on the Involuntary Movement Scale and the Simpson-Angus Extrapyramidal symptoms (EPS) Rating Scale. Of these, only six had been previously identified by standard observational means. Frequency was higher with haloperidol decanoate, but these patients we also receiving higher doses (Bransgrove & Kelly, 1994).

See Drug Consult reference: NEUROLEPTIC-INDUCED EXTRAPYRAMIDAL REACTIONS

3.3.9.G Neuroleptic malignant syndrome

1) Incidence: rare
2) Neuroleptic malignant syndrome occurred in a 26-year-old male receiving 20 mg haloperidol TID for hypomania (Town, 1982). This patient developed profound rigidity and dystonia, tachycardia, hypertensi sweating, fever, confusion, depressed level of consciousness, incontinence, elevated CPK and leucocytosis. Withdrawal of the drug and treatment with anti-Parkinsonism drugs resulted in improvemer
3) Neuroleptic malignant syndrome was reported in 3 adults during haloperidol therapy of psychotic stat Discontinuation of haloperidol and institution of antiparkinson medications reversed the adverse effect (Cruz et al, 1983; Dosani, 1983; Henderson & Wooten, 1981). One proposed mechanism attributed dopamine receptor blockade in the striatum increasing thermogenesis and in the hypothalamus impairin heat dissipation (Henderson & Wooten, 1981).
4) Two cases of adverse reactions resembling neuroleptic malignant syndrome were reported in childre treated with haloperidol for psychiatric disorders. Therapy consisted of discontinuing haloperidol and administering fluids and antiparkinson medication (Geller & Greydanus, 1979).
5) Amantadine was used successfully to treat a case of neuroleptic malignant syndrome in a 19-year-ol female patient treated with haloperidol. The proposed mechanism for amantadine was dopaminergic agonist activity (Amdurski et al, 1983).
6) Neuroleptic malignant syndrome (NMS) was reported in a head injury patient treated with haloperidol control agitation. NMS began to develop by the third day and haloperidol was discontinued on the elever day. Improvement began to occur by the fourth day after discontinuation of haloperidol (Vincent et al, 1986).
7) Neuroleptic malignant syndrome (NMS) occurred in a chronic schizophrenic treated with haloperidol. The patient, having been treated with haloperidol for 10 years, was given 2 intramuscular doses to contr an abrupt increase in agitation accompanied by other mental changes. Characteristic signs and sympton of NMS occurred. These improved by the fourth day after haloperidol was discontinued, but recurred wh haloperidol was reinstituted on the twelfth day (Matthews & Cersosimo, 1986).
8) A fatal case of neuroleptic malignant syndrome was reported in an 84-year-old male being treated wi haloperidol for agitation associated with dementia. The patient had been taking haloperidol 6 mg/day, bu the dosage was rapidly increased by the family of the patient without informing the physician. Within 8 da the patient developed neuroleptic malignant syndrome. The authors postulated that the rapid increase in haloperidol dosage may have contributed to the severity of the case (Osser & Stewart, 1988).
9) Neuroleptic malignant syndrome (NMS) was reported in a 67-year-old female with parkinsonism bein treated with haloperidol for agitation. The patient having been treated with haloperidol 1 mg at bedtime fo five months was given a total of 12 mg haloperidol intramuscularly, with an additional 13 mg over the ensuing 48 hours. Within 2 days characteristic signs and symptoms of NMS occurred. Withdrawal of haloperidol and treatment with anti-Parkinsonism drugs resulted in improvement (Ryken & Merrell, 1989)
10) Neuroleptic malignant syndrome was reported in a 25-year-old male head injury patient being treate with haloperidol for agitation. Withdrawal of the haloperidol and treatment with dantrolene and bromocriptine resulted in improvement (Heird et al, 1989).
11) Neuroleptic malignant syndrome (NMS) secondary to haloperidol and subsequent to amantadine withdrawal occurred in a 75-year-old male with "senile" dementia and Parkinsonian symptoms (Hermesh al, 1984). The patient developed NMS approximately 2 days after initiation of therapy with haloperidol 0.5 mg orally 3 times daily to control delusions and aggressive behavior. Haloperidol was discontinued and therapy with amantadine 200 mg twice daily was initiated due to suspected NMS, resulting in subsidence NMS symptoms. Amantadine was withdrawn after approximately 1 month of treatment due to exacerbati of delusions, and NMS symptoms recurred approximately 2 days later. Amantadine and levodopa were given, resulting in abatement of NMS symptoms within several days. It is suggested that NMS occurred i this patient secondary to amantadine withdrawal as a result of decreased central dopamine activity, the same mechanism was implicated in the haloperidol induced NMS. It is speculated that Parkinson's disea may have increased this patient's vulnerability to further diminution of dopamine activity.

3.3.9.H Parkinsonism

1) Summary

a) Contrary to common belief, the results of a retrospective cohort study suggest that atypical antipsychotics may not be safer than typical antipsychotics when dose and potency are considered (Rochon et al, 2005).

2) The results of a cohort study indicate that high-dose atypical antipsychotic therapy carries a similar ris for the development of parkinsonism as does typical antipsychotic therapy. In a population-based, retrospective cohort study, adults (aged 66 years and older) with evidence of dementia were followed for to 1 year for the development of parkinsonism symptoms associated with typical or atypical antipsychotic use. As compared with older adults receiving atypical antipsychotic therapy (ie, olanzapine, risperidone, quetiapine), incident parkinsonism was 30% more likely to occur in those taking typical antipsychotics (ie chlorpromazine, haloperidol, perphenazine) (adjusted HR, 1.3; 95% (CI), 1.04 to 1.58), and 60% less like to occur in patient who did not receive either therapy (HR), 0.4; 95% CI, 0.29 to 0.43). Older adults using higher potency typical antipsychotics had almost a 50% greater risk of experiencing parkinsonism as compared with patients prescribed atypical antipsychotics (all were considered lower potency) (HR, 1.44 95% CI, 1.13 to 1.84); however, in patients receiving lower potency typical antipsychotics, the risk of developing parkinsonism was no different from that in adults taking atypical antipsychotics (HR, 0.75; 95 CI. 0.48 to 1.15). In addition, a positive dose-related relationship was observed between the occurrence incident parkinsonism and the use of atypical antipsychotics. The risk for developing parkinsonism was more than twice as great in patients using a high-dose atypical antipsychotic agent as compared with thc prescribed a low-dose atypical antipsychotic agent (HR, 2.07; 95% CI, 1.42 to 3.02). Furthermore, patier taking a typical antipsychotic were found to have a similar risk for the development of parkinsonism as patients receiving high-dose atypical antipsychotic therapy (p=ns). The authors conclude that atypical antipsychotics may not be safer than typical antipsychotics when dose and potency are considered (Rochon et al, 2005).

3.3.9.I Phobia

1) Phobia was triggered by use of haloperidol. After a psychotic depressive episode successfully treatec with haloperidol, the patient experienced severe anxiety when placed in stressful driving circumstances. Her symptoms resulted in her taking unusual precautions to avoid these situations. After five years of thi phobic situation, the symptoms gradually disappeared after haloperidol was discontinued (Bristol, 1982). Other similar cases have been reported (Mikkelson et al, 1981).

3.3.9.J Seizure

1) Incidence: rare

2) Convulsions, in association with parkinsonism symptoms, have occurred in pediatric patients treated with 1.5 to 2.5 mg of haloperidol or following a 6 mg overdose. Treatment with or without antiparkinsonis drugs was reported to result in complete recovery within a few days in all patients (Debray & Galland, 1970).

See Drug Consult reference: ANTIPSYCHOTICS - EFFECT ON SEIZURE THRESHOLD

3.3.9.K Tardive dyskinesia

1) Several cases of tardive dyskinesia or worsening of tardive dyskinesia have been reported, at doses ranging from 3 to 18 mg/day. Although features of the dyskinesias were different in each case, including onset, manifestations, concurrent therapy, and duration, all authors described a causal relationship with haloperidol (Kiloh et al, 1973; Moline, 1975); (Petty, 1980)(Faheem et al, 1982; Peabody et al, 1987).

2) The incidence of dyskinesias induced by neuroleptic agents was studied in 58 autistic children. Daily doses of haloperidol ranged from 0.02 to 0.22 mg/kg. Thirteen (22%) developed dyskinesias. There appeared to be no relationship between onset of symptoms and dose or administration schedule (Perry al, 1985).

3) Molindone was compared with haloperidol with regard to their ability to mask neuroleptic withdrawal-exacerbated tardive dyskinesia, using the theoretical proposition that agents less able to mask are less dyskinetogenic. In a parallel, double-blind study, 11 patients were given either molindone or haloperidol following discontinuation of previous neuroleptic therapy and at a point where involuntary movements showed a significant increase. Doses were based on standard relative potency assignments calculated from previous neuroleptic medications and ranged from 50% to 200% dose equivalency as compared to previous neuroleptics. Molindone was shown to be less effective than haloperidol in masking tardive dyskinesia, thereby suggesting lower dyskinetogenic potential (Glazer et al, 1985a).

3.3.9.L Tic

1) Nondystonic, nonakathisic TICs were reported in a hyperactive child. The reaction was similar to that seen when the boy was treated with amphetamine on one occasion and carbamazepine on another (Gualtieri & Patterson, 1986).

3.3.10 Ophthalmic Effects

Blurred vision

Eye / vision finding

3.3.10.A Blurred vision

1) Blurred vision has been reported (Prod Info HALDOL(R) injection, 2007).

3.3.10.B Eye / vision finding

1) A study was conducted in cooperation with Group Health Cooperative of Puget Sound using men and women born before 1931 to evaluate the risk of cataracts from exposure to phenothiazine drugs. A total 45,301 individuals were identified as potential patients in an effort to study a large population. A list of criteria was used to evaluate these patients, and the group was then whittled to 4,674 individuals. The results of the study showed there is no significant increase in risk of cataract extraction in patients who used haloperidol in either short or long-term cases (Isaac et al, 1991).

2) OCULOGYRIC CRISIS has been reported following the use of haloperidol (Dukes, 1975).

3.3.12 Psychiatric Effects

3.3.12.A Psychotic disorder

1) Psychotic exacerbation has been reported. Deterioration was correlated with dosage increase. An acutely psychotic patient, treated with haloperidol 30 mg/day for 10 days with no improvement, deteriora further over a 3 day period when the dose of haloperidol was increased to 60 mg/day. Upon reduction of the haloperidol dose, the patient gradually improved. When fluphenazine replaced haloperidol, the patier showed a gradual but dramatic recovery (Tornatore et al, 1981).

3.3.14 Reproductive Effects

3.3.14.A Priapism

1) Incidence: rare

2) PRIAPISM has been reported (Greenberg & Lee, 1987; Gomez, 1985).

3.3.15 Respiratory Effects

Pulmonary embolism

Respiratory finding

3.3.15.A Pulmonary embolism

1) The use of psychotropic medications has been linked to an increased risk of fatal pulmonary embolis In a case-control study including 62 cases of fatal pulmonary embolism and 243 matched controls, researchers found that compared to non-use, the current use of conventional antipsychotic medications (thioridazine and haloperidol) was associated with an increased risk of fatal pulmonary embolism (adjuste odds ratio, 13.3; 95% CI, 2.3 to 76.3). In addition, low potency antipsychotics, such as thioridazine, were associated with the highest risk, with an odds ratio of 20.8 (95% CI, 1.7 to 259). The current use of antidepressants was also associated with an increased risk of fatal pulmonary embolism (adjusted odds ratio, 4.9; 95% CI, 1.1 to 22.5); however, current or past use of other psychotropic drugs was not associated with an increased risk (adjusted odds ratio, 1.4; 95% CI, 0.3 to 5.8). (Parkin et al, 2003).

3.3.15.B Respiratory finding

1) A case of acute laryngeal dystonia was reported in a 26-year-old woman receiving haloperidol (no do reported) for management of schizophrenia. The patient received both diphenhydramine and lorazepam intravenously with subsequent resolution of symptoms. Haloperidol was discontinued and the patient wa discharged on oral diphenhydramine 24 hours later (Fines et al, 1999).

2) A 53-year-old female with a 25 year history of psychiatric illness was admitted to the ER after having discontinued all of her medications three weeks earlier. She had been taking trifluoperazine 5 mg daily, benztropine 2 mg daily and lithium in alternating daily doses of 600 and 900 mg. She had no known allergies. She was subsequently admitted to the psychiatric crisis unit where she was put on haloperidol mg every 8 hours. Two hours after the second dose, she experienced shortness of breath with audible wheezing. Physical examination findings included sinus tachycardia and auscultation of the chest reveal poor air entry with diffuse high pitched wheezing. There were no other adverse effects detected and she remained afebrile. The bronchospasm was treated and her breathing returned to normal within 30 minute Two hours later, she developed laryngeal stridor for which she was treated with benztropine. The haloperidol was discontinued and the patient was restarted on trifluoperazine. Allergy tests were done, b

skin testing revealed no significant wheal and flare responses. A tartrazine test was also done, but the results were negative. The cause and mechanism of the haloperidol induced bronchospasm remained unclear (Sethna et al, 1991).

3.3.16 Other

Dead - sudden death

Death

Drug dependence

Extrapyramidal disease

Hyperpyrexia

Withdrawal sign or symptom

3.3.16.A Dead - sudden death

1) Cases of sudden death have been reported in association with haloperidol treatment. Causality has n been determined; however, haloperidol cannot be ruled out. Sudden and unexpected death can occur in psychotic patients who may or may not be receiving treatment with other antipsychotic drugs (Prod Info HALDOL(R) injection, 2007).

2) A 59-year-old man admitted for an acute recurrence of a paranoid disorder died after admission (Turbott, 1984). Prior to admission, the patient had not received any neuroleptic medication. The patient was taking pindolol, hydrochlorothiazide, and amiloride for hypertension. The patient was also taking chlordiazepoxide and allopurinol. Physical examination was normal on admission. The patient received t 10-milligram doses of haloperidol orally three hours apart. Following the second dose, an ECG revealed normal sinus rhythm with a rate of 100 beats/minute, a QT interval of 0.42 seconds, and slight T-wave flattening. Shortly after the ECG, the patient was found cyanotic on the floor. A repeat ECG showed asystole, resuscitation efforts were unsuccessful. Autopsy revealed moderate left ventricular hypertrophy and 80% blockage of the right coronary artery and 70% blockage of the anterior descending left coronary artery. No other abnormalities were noted.

3) A 30-year-old male with a long history of multiple drug abuse died after receiving haloperidol (Mahutte 1982). Upon hospital admission, physical examination, routine laboratories and ECG were normal. Multip drug screens were negative. The patient's course over the next three weeks was varied. The patient was taking desipramine 100 milligrams (mg) each day and haloperidol 10 mg orally as needed for agitation. C the three days prior to his death, the patient received haloperidol 50 mg/day, 50 mg/day and 40 mg/day, respectively. After the last haloperidol dose, he was noted to be in respiratory distress, and bloody sputu was suctioned from the patient. The blood pressure at this time was 56/24 mmHg. Cardiac arrest followe and the patient expired. Autopsy revealed grossly congested lungs with diffuse alveolar hemorrhages. There was no evidence of pulmonary emboli, aspiration, or pneumonia. There was no evidence of significant cardiac disease or injury. The cause of death was thought to be transient pulmonary hypertension.

4) A 44-year-old woman with chronic paranoid schizophrenia, myopia, and obesity died 2 hours after a haloperidol dose (Modestin et al, 1981). All previous laboratories and ECGs were normal. The patient ha taken no medications for 6 weeks prior to admission. During the next two days the patient received 60 milligrams (mg) haloperidol intramuscularly and 160 mg orally. The patient experienced two dyskinetic episodes which were successfully treated by biperiden 2 mg. The patient's last dose of biperiden was tak the morning of the second day. Two hours after the patient's last dose of haloperidol (90 mg), vital signs were pulse regular at 84 beats/minute, blood pressure 120/80 mmHg, and respirations normal. Shortly thereafter, the patient cried out and was found unresponsive. The patient's pulse was not palpable and h breathing was labored, but she was not cyanotic. Her mouth was distorted and she bit her lower lip. Cardiopulmonary resuscitation was unsuccessful. Significant findings at autopsy were mild congestion of pulmonary and systemic circulation and large amounts of viscous mucus just above and below the epiglottis. The proposed mechanism was laryngeal-pharyngeal dystonia, followed by laryngospasm and cardiac arrest.

5) A 35-year-old woman with no prior psychiatric problems or significant medical history died in her slee hours after a total oral dose of haloperidol 80 milligrams (mg) (Ketai et al, 1979). In the previous 65 hours she had received haloperidol 260 mg orally. In response to a dystonic reaction 8 hours prior to her death the patient was given 2 mg of benztropine and started on 1 mg twice daily. The only significant finding or autopsy was mild, nonspecific edema of the lungs, brain and liver. This was thought due to attempts at cardiopulmonary resuscitation.

3.3.16.B Death

1) Results of a population-based, retrospective cohort study demonstrated that the use of conventional antipsychotics was associated with an even greater risk for death than atypical antipsychotics when administered to elderly patients (aged 66 years and older) with dementia. Atypical versus no antipsychot use and conventional versus atypical antipsychotic use pair-wise comparisons were made. A total of 27,259 matched pairs were identified and the dementia cohort was stratified based on place of residence (community versus long-term care facilities). In order to adjust for difference in baseline health status, propensity score matching was used. The primary outcome of the study was all-cause mortality. The risk for death was evaluated at 30, 60, 120, and 180 days after the antipsychotic medications were initially dispensed. There was a statistically significant increase in the risk for death at 30 days associated with n use of atypical antipsychotic medications compared with nonuse in both the community-dwelling cohort (adjusted hazard ratio (HR), 1.31 (95% confidence interval (CI), 1.02 to 1.70); absolute risk difference, 0. percentage point) and long-term care cohort (adjusted HR, 1.55 (95% CI, 1.15 to 2.07); absolute risk difference, 1.2 percentage points). For both cohorts, the risk associated with atypical antipsychotics appeared to persist to 180 days. The risk for death associated with conventional antipsychotics was ever greater than the risk identified with atypical antipsychotics. At 30 days, the adjusted HR for the communit dwelling cohort was 1.55 (95% CI, 1.19 to 2.02) and 1.26 (95% CI, 1.04 to 1.53) for the long-term care cohort (adjusted risk difference for both was 1.1 percentage points). The risk appeared to persist to 180 days for both groups. Some important limitations to the study include unknown or unmeasured confound may influence the results and cause of death could not be examined (Gill et al, 2007).

2) Results of a population-based, retrospective cohort study demonstrated comparable to possibly great risk of death associated with the use of conventional antipsychotic medications in the elderly (aged 65 years and older) compared with atypical antipsychotic medications. The analysis excluded patients with cancer and included only new users of antipsychotic medications. The primary study outcome was 180-c all-cause mortality. A set of potential confounders was measured based on healthcare utilization data wit 6 months before the initiation of antipsychotic medications. Of the 37,241 elderly patients identified, 12,8 and 24,359 received conventional and atypical antipsychotic medications, respectively. The risk of death the conventional drug group within the first 180 days was 14.1% compared with 9.6% in the atypical drug group (unadjusted mortality ratio, 1.47; 95% confidence interval (CI), 1.39 to 1.56). In the multi-variable analysis which controlled for potential confounders, the adjusted mortality ratio for the risk of death within 180 days for conventional versus atypical drug therapy was 1.32 (95% CI, 1.23 to 1.42). When the most frequently prescribed conventional antipsychotic drugs were compared with risperidone, the mortality rat associated with haloperidol was 2.14 (95% CI, 1.86 to 2.45) and loxapine was 1.29 (95% CI, 1.19 to 1.40 while there was no difference associated with olanzapine. The increased mortality risk for conventional versus atypical drug therapy was greatest when doses higher (above median) doses were used (mortalit ratio 1.67; 95% CI, 1.5 to 1.86) and also during the first 40 days of therapy (mortality ratio 1.6; 95% CI, 1 to 1.8). Confirmatory analyses consisting of multi-variable Cox regression, propensity score, and instrumental variable estimation confirmed the results of the study (Schneeweiss et al, 2007).

3) The results of a retrospective cohort study indicate that conventional antipsychotic agents are at leas likely as atypical antipsychotic agents to increase the risk of death among elderly patients 65 years of ag or older. The study included 9,142 new users of conventional agents (mean age, 83.2 years) and 13,748 new users of atypical agents (mean age, 83.5 years). A higher adjusted relative risk of death was associated with the use of conventional antipsychotics as compared with atypical antipsychotics at all tim points studied after beginning therapy (within 180 days: RR, 1.37; 95% CI, 1.27 to 1.49; less than 40 day RR, 1.56; 95% CI, 1.37 to 1.78; 40 to 79 days: RR, 1.37; 95% CI, 1.19 to 1.59; 80 to 180 days: RR, 1.27 95% CI, 1.14 to 1.41). In addition, the adjusted risks of death observed in patients with dementia (RR, 1. 95% CI, 1.15 to 1.45), without dementia (RR, 1.45; 95% CI, 1.3 to 1.63), in a nursing home (RR, 1.26; 95 CI, 1.08 to 1.47), or not in a nursing home (RR, 1.42; 95% CI, 1.29 to 1.56) were also higher with the use conventional antipsychotic therapy as compared with atypical antipsychotic use. This risk appeared to be dose-related and was greater with the use of higher dose (ie, greater than the median) conventional antipsychotics (RR, 1.73; 95% CI, 1.57 to 1.90). Additional studies which specifically investigate the optimum care of elderly patients requiring antipsychotic therapy are needed so that appropriate guidance regarding therapeutic intervention can be provided (Wang et al, 2005).

3.3.16.C Drug dependence

1) Several cases of intentional haloperidol ABUSE have been reported. Five patients treated for haloperidol toxicity had taken the drug for recreational purposes. All experienced severe extrapyramidal side effects. No reason was given for the choice of this agent for recreational use (Doenecke & Heuermann, 1980).

3.3.16.D Extrapyramidal disease

See Drug Consult reference: NEUROLEPTIC-INDUCED EXTRAPYRAMIDAL REACTIONS

3.3.16.E Hyperpyrexia

1) Hyperpyrexia has been reported with haloperidol treatment (Prod Info HALDOL(R) Decanoate IM injection, 2008; Prod Info HALDOL(R) immediate release IM injection, 2008). A case report described hyperpyrexia in a patient treated with haloperidol 2 mg four times daily. The patient was also receiving benztropine concomitantly (Westlake & Rastegar, 1973). The incidence of hyperthermia (37 to 37.9 C)

ranged from 3 to 13% following haloperidol doses of 10 to 15 mg/day (Harder et al, 1971).

3.3.16.F Withdrawal sign or symptom

1) Sudden discontinuation of haloperidol has been associated with a withdrawal syndrome. Tachycardia hypertension, restlessness, and abdominal distress occurred in a patient upon sudden discontinuation of haloperidol 40 mg/day and doxepin 150 mg/day (Pary et al, 1980). This was postulated to be due either cholinergic rebound or a hyperdopaminergic state (Gardos, 1980).

2) Physical agitation, epigastric distress with vomiting, pallor, diaphoresis, and other symptoms occurred days after discontinuation of haloperidol and benztropine. These symptoms persisted until the fifth day, when benztropine alleviated them (Lieberman, 1981).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info HALDOL(R) injection, 2007) (All Trimesters)

a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other) and there are no controlled studies in women or studies in women and animals are not available. Drugs should be given only if the potential benefit justifies the potential risk to the fetus.

2) Australian Drug Evaluation Committee's (ADEC) Category: C(Australian Drug Evaluation Committee, 199

a) Drugs which, owing to their pharmacological effects, have caused or may be suspected of causing harmful effects on the human fetus or neonate without causing malformations. These effects may be reversible. Accompanying texts should be consulted for further details.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

3) Crosses Placenta: Unknown

4) Clinical Management

a) Although the teratogenicity of haloperidol has not been proven, its use during pregnancy is discourag It is suggested that haloperidol use during pregnancy be limited to psychotic patients requiring long-term therapy (Berkowitz et al, 1981). If use during pregnancy cannot be avoided, ultrasound with particular attention to limb formation should be considered in first trimester exposures (Diav-Citrin et al, 2005).

5) Literature Reports

a) A prospective, observational study of 54 women (mean age, 30.7 years), recruited from the Emory Women's Mental Health program exposed to antipsychotic medication during pregnancy, showed permeability of the placental barrier. Outcomes were determined by maternal and umbilical cord blood samples taken at delivery and through data collected from maternal reports and medical records. Placen passage ratios (defined as the ratio of umbilical cord to maternal plasma concentrations) showed a significant difference between antipsychotic medications, with olanzapine 72.1% (95% CI, 46.8%-97.5%) being the highest, followed by haloperidol 65.5% (95% CI, 40.3%-90.7%), risperidone 49.2% (95% CI, 13.6%-84.8%), and quetiapine 24.1% (95% CI, 18.7%-29.5%), showing the lowest placental passage rat There was a greater frequency of pre-term deliveries (21.4%, p=less than 0.23), low birth weights (30.8% p=less than 0.07), and neonatal intensive care admission (30.8%, p=less than 0.09) in infants exposed t olanzapine (Newport et al, 2007).

b) A multicenter, prospective, controlled study found no difference in the rate of congenital abnormalities the drug-exposed group and the control group. Haloperidol exposure occurred in 188 pregnancies and penfluridol in 27, with 161 of these known to be in the first trimester. The control group consisted of 631 pregnancies exposed to nonteratogens from 4 participating ENTIS (European Network of Teratology Information Services) centers. Other results include a higher rate of elective pregnancy terminations, hig rate of preterm birth, lower median birth rate and lower median birth weight of full-term infants in the drug exposed group. There were no significant differences in the rate of miscarriages, ectopic pregnancies or stillbirths between the control and haloperidol- or penfluridol-exposed groups(Diav-Citrin et al, 2005).

c) One case report describes a full-term, 3880 gram infant exposed to haloperidol in utero, who experienced "jitteriness" at birth. The mother, a 35-year-old woman with schizoaffective disorder, was maintained on haloperidol decanoate 200 mg every two weeks throughout pregnancy. The last dose was administered 3 weeks prior to delivery. By day 8 of life, the infant became increasingly irritable and experienced an episode of tonic-clonic movements in all extremities with tongue thrusting and torticollis. These episodes continued, but with treatment of clonazepam 0.02mg/kg/day, the tonic-clonic movement began to resolve by day 12. The infant was discharged following resolution of movement disorders and weaning of the clonazepam (Collins & Comer, 2003).

d) A 34-year-old pregnant woman ingested 300 mg haloperidol at 34 weeks gestation and presented CN depression, hypotonia, and involuntary spasms of the extremities. A biophysical profile of the fetus on admission was 2 of 10 (two points for amniotic fluid, no evidence of fetal movement, flexion-extension or fetal breathing, fetal heart rate 150 beats/minute, nonreactive with minimal long-term and short-term variability). The mother appeared fully recovered by 48 hours after admission, but a biophysical profile of was not achieved for the fetus until 5 days after admission. A healthy girl was delivered at 39 weeks gestation and she had normal developmental milestones and growth at 18 months of age (Hansen et al, 1997).

e) Although there are isolated cases of teratogenicity associated with haloperidol (McCullar & Heggenes 1975), no cause-effect relationship has been established. Haloperidol is transferred to the fetus via the placenta (Uematsu et al, 1991). Two cases of limb malformations have occurred in infants born to wome

given haloperidol with other potentially teratogenic drugs during the first trimester of pregnancy (Kopelma et al, 1975). Haloperidol has been used in the second and third trimesters, and during labor, without causing neonatal depression or other effects on the newborn (Ayd, 1976).

B) Breastfeeding

1) American Academy of Pediatrics Rating: Drugs for which the effect on nursing infants is unknown but may be of concern. (Anon, 2001)

2) World Health Organization Rating: Avoid breastfeeding if possible. Monitor infant for side effects. (Anon, 2002)

3) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant ris when used during breastfeeding. Weigh the potential benefits of drug treatment against potential risks before prescribing this drug during breastfeeding.

4) Clinical Management

a) Haloperidol is excreted into human breastmilk, with a milk to plasma ratio estimated at 0.6 to 0.7 (Whalley et al, 1981). One group reported that the nursing infant receives a dose approximately equivale to 3% of the maternal dose (Yoshida et al, 1998). It is suggested that when the maternal dose is high, th infant's exposure to the drug may be minimized by limiting the number of feeds per day. There has been clear association between the small quantities of haloperidol in breastmilk and adverse effects in the exposed newborns (Whalley et al, 1981; Stewart et al, 1980), although a decline in developmental score has been reported (Anon, 2001).

5) Literature Reports

a) Animal studies have demonstrated that offspring exposed to haloperidol through breast milk experien drowsiness and impairment of motor activity (Iqbal et al, 2001).

b) A wide variation of haloperidol excretion into breast milk has been reported. This is most likely due to the different maternal doses and inter-individual variation in drug metabolism (Chisholm & Kuller, 1997). One study reported a breast milk concentration of 23.5 ng/mL following the administration of haloperidol milligrams twice daily (Whalley et al, 1981). The antipsychotic dose of haloperidol in children ranges from 0.02 to 0.07 milligrams/kilogram/day (Serrano, 1981). Assuming a newborn infant (3 kg) ingests 150 mL/kg/day of breast milk, the maximum dose received would be 0.01 milligram or one-sixth the therapeu dose. Another author reported a breast milk concentration of only 2 to 5 ng/mL following a maternal haloperidol dose of 12 to 30 mg/day (Stewart et al, 1980).

3.5.1.A Acecainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Concurrent use of acecainide and haloperidol is not recommended due to the risk of additi effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitorin is advised (Yamreudeewong et al, 2003a).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of acecainide and haloperidol is not recommend due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant use o Class III antiarrhythmic agents such as acecainide and haloperidol may have additive effects on the QT interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.B Ajmaline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999z; O'Brien et al, 1999r; Pro Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001z; Duenas-Laita et al, 1999y; Agelin et al, 2001x; Lande et al, 1992z; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increas the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychoti not recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT

(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also show an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and tir to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that tissue binding mechanism is more likely responsible for the plasma level changes than an eliminatio alteration (Young et al, 1993).

3.5.1.C Amiodarone
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concurrent use of amiodarone and haloperidol is not recommended due to the risk of additive effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yamreudeewong et al, 2003a).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of amiodarone and haloperidol is not recommended due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Patients who received concurrent administration of amiodarone and haloperidol experienced a potentially significant QTc interval prolongation. All adult patients admitted to a tertiary teaching hospital between January 2005 and December 2006 who received both amiodarone and haloperido were included in a retrospective analysis of data collected to assess patients' risk, cardiac effects, a baseline statistics to determine change in QT interval. Of the 49 patients (age, 68 +/- 10 years) who met inclusion criteria, there were 381 amiodarone and haloperidol distinct exposures, of which 36.2 (138 of 381) exposures included at least one additional QT-interval prolonging drug. Duration of concomitant amiodarone-haloperidol exposure per patient averaged 3 days (range, 1 to 17 days), a the daily dose of haloperidol was 11 +/- 12 mg (range, 1 to 65 mg). There was no apparent affiliatior between longer QTc intervals and the increased number of concomitant QT-interval prolonging drug but QTc intervals were longer with higher daily doses on average. Nearly 55% of patients receiving amiodarone alone had a QTc interval greater than 450 msec and 38% patients had a QTc interval greater than 500 msec. The mean increase in QTc interval following exposure to haloperidol was 9.8 msec (95% CI, 0.6 to 19 msec). Notably, no ventricular arrhythmia was observed (Bush et al, 2008).
b) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant use o Class III antiarrhythmic agents such as amiodarone and haloperidol may have additive effects on th QT interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.D Amisulpride
1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003c; Prod Info Haldol(R), 2001a). Amisulpride has rarely caused QT prolongation (Prod Info Solian(R) 1999e). Caution is advised with coadministration of drugs that potentially prolong the QTc interval.
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if haloperidol and amisulpride are used concomitantly. Scre patients for conditions that may predispose to QT prolongation and torsade de pointes (i.e. cardiomyopathy, alcohol abuse, hypothyroidism). Monitor the ECG and electrolytes at baseline and throughout therapy.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre

patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003b).

b) Seven patients developed torsade de pointes after therapeutic use of haloperidol in high doses. Three patients developed the dysrhythmia after administration of 211 milligrams (mg) to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episode but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol (Metzger & Friedman, 1993b; Wilt et al, 1993a). Torsades de pointes developed in 8 of 223 critically ill patients i intensive care units. Patients who received intravenous haloperidol greater than 35 mg/day or had a QTc interval prolongation of greater than 500 milliseconds were at greatest risk (Sharma et al, 1998

3.5.1.E Amitriptyline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministratio a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsh & Forker, 1982).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychoti not recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.F Amoxapine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministratio a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsh & Forker, 1982).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychoti not recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.G Aprindine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Coadministration of haloperidol with other drugs that potentially prolong the QTc interval, such as aprindine, should be approached with caution. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Owens, 2001f; Prod Info Haldol(R), 1998b; Larochelle et al, 1984).

3) Severity: major

4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of aprindine and haloperidol is not recommende due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio dosing and telemetric monitoring is advised.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.H Arsenic Trioxide

1) Interaction Effect: prolongation of the QTc interval and/or torsades de pointes
2) Summary: Arsenic trioxide can prolong the QT interval in some patients, which may result in ventricul tachycardia, ventricular fibrillation, and torsades de pointes and should not be administered with other drugs that may prolong the QT interval (Prod Info Trisenox(R), 2001a). Several antipsychotic agents hav demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999o), haloperidol (O'Brien e al, 1999j), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), risperidone (Duena Laita et al, 1999p), sertindole (Agelink et al, 2001m), quetiapine (Owens, 2001p), sultopride (Lande et al 1992o), ziprasidone (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of arsenic trioxide and antipsychotics is not recommended.
7) Probable Mechanism: additive effects on QTc prolongation
8) Literature Reports
a) QT/QTc prolongation should be expected during treatment with arsenic trioxide and torsade de pointes as well as complete heart block has been reported. Over 460 ECG tracings from 40 patients with refractory or relapsed APL treated with arsenic trioxide were evaluated for QTc prolongation. Sixteen of 40 patients (40%) had at least one ECG tracing with a QTc interval greater than 500 mse Prolongation of the QTc was observed between 1 and 5 weeks after arsenic trioxide infusion, and th returned towards baseline by the end of 8 weeks after arsenic trioxide infusion. In these ECG evaluations, women did not experience more pronounced QT prolongation than men, and there was no correlation with age (Prod Info Trisenox(R), 2001).

3.5.1.I Astemizole

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999n), haloperidol (O'Brien et al, 1999i), quetiapine (Owens, 2001o), risperidone (Duenas-Laita et al, 1999m; Prod Info Risperdal(R) risperidone, 2002a), sertindole (Agelink et al, 2001l), sultopride (Lande et al, 1992l), and zotepine (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministration of astemizole and other drugs known to prolong the QTc interval, including antipsychotics, is not recommended (Prod Info Hismanal(R), 1996).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of astemizole and agents that prolong the QT interval, such as antipsychotics, is not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) A total of 7 patients developed torsade de pointes after therapeutic use of haloperidol in high dos (Metzger & Friedman, 1993g; Wilt et al, 1993e). Three patients developed the dysrhythmia after administration of 211 to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episodes, but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol. Four patients developed the dysrhythmia after administration of 170 580 mg over 1 to 4 days for delirium associated with bacterial meningitis (1), status asthmaticus (2) respiratory insufficiency (1). All 4 patients recovered with no adverse sequelae.

3.5.1.J Azimilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concurrent use of azimilide and haloperidol is not recommended due to the risk of additive effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitorin is advised (Yamreudeewong et al, 2003a).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of azimilide and haloperidol is not recommende due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio

dosing and telemetric monitoring is advised.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant use o Class III antiarrhythmic agents such as azimilide and haloperidol may have additive effects on the Q interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.K Belladonna
1) Interaction Effect: excessive anticholinergic activity (severe dry mouth, constipation, decreased urination, excessive sedation, blurred vision)
2) Summary: The anticholinergic activity of the active alkaloids present in belladonna may predispose th patient to excessive anticholinergic activity if taken with haloperidol. Belladonna contains L-hyoscyamine atropine, and scopolamine with a total alkaloid content of at least 0.3% in the leaves and 0.5% in the roo (Blumenthal et al, 1998). Because belladonna is typically available as a homeopathic preparation, the clinical severity of the interaction with haloperidol is unknown. Caution is advised.
3) Severity: minor
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Excessive anticholinergic activity may be manifested by dry mouth, constipatio urinary retention, tachycardia, decreased sweating, mydriasis, blurred vision, elevated temperature, muscular weakness, and sedation. If such effects are noted, belladonna should be discontinued immediately. In severe cases, paralytic ileus, confusion, psychoses, agitation, delusions, delirium, and paranoia may be encountered as well as tachycardia, dysrhythmia, and hypertension. In severe cases, immediate medical attention should be obtained.
7) Probable Mechanism: additive anticholinergic effect

3.5.1.L Belladonna Alkaloids
1) Interaction Effect: excessive anticholinergic activity (severe dry mouth, constipation, decreased urination, excessive sedation, blurred vision)
2) Summary: The anticholinergic activity of the active alkaloids present in belladonna may predispose th patient to excessive anticholinergic activity if taken with haloperidol. Belladonna contains L-hyoscyamine atropine, and scopolamine with a total alkaloid content of at least 0.3% in the leaves and 0.5% in the roo (Blumenthal et al, 1998). Because belladonna is typically available as a homeopathic preparation, the clinical severity of the interaction with haloperidol is unknown. Caution is advised.
3) Severity: minor
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Excessive anticholinergic activity may be manifested by dry mouth, constipatio urinary retention, tachycardia, decreased sweating, mydriasis, blurred vision, elevated temperature, muscular weakness, and sedation. If such effects are noted, belladonna should be discontinued immediately. In severe cases, paralytic ileus, confusion, psychoses, agitation, delusions, delirium, and paranoia may be encountered as well as tachycardia, dysrhythmia, and hypertension. In severe cases, immediate medical attention should be obtained.
7) Probable Mechanism: additive anticholinergic effect

3.5.1.M Benztropine
1) Interaction Effect: excessive anticholinergic effects (sedation, constipation, dry mouth)
2) Summary: Combined use of haloperidol and anticholinergics may result in excessive anticholinergic effects (Prod Info Haldol(R), 2000a). In a number of case reports, the use of haloperidol with benztropine trihexyphenidyl, or procyclidine, has resulted in a worsening of schizophrenic symptoms. In addition, whe anticholinergics are used with phenothiazines or haloperidol, there may be an increased incidence of tardive dyskinesia (Linnoila et al, 1980a; Singh & Kay, 1979a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor signs of excessive anticholinergic effects. Adjust the doses or discontir the medications as needed.
7) Probable Mechanism: additive anticholinergic effects
8) Literature Reports
a) Concomitant haloperidol and benztropine therapy has been reported to result in inhibition of antipsychotic effects of haloperidol and increased "social avoidance" behavior in several schizophre patients (Singh & Smith, 1973; Prod Info Cogentin(R), 1994).
b) Routine use of antiparkinson medication with neuroleptic agents is controversial and there is evidence that these agents should only be administered at the occurrence of extrapyramidal symptoms, and then only for a short period of time thereafter. This interaction, although not well-documented, supports recommendations by many investigators that routine use of anticholinergic

medications with phenothiazines and haloperidol is not warranted and may be deleterious (Perry et 1991).

c) In a study to evaluate the prophylactic use of benztropine in haloperidol-induced dystonic reactio 29 psychotic patients were treated with haloperidol and either benztropine or a placebo. The results showed no significant difference in side-effects between benztropine or the placebo, except increas dry mouth with benztropine. The occurrence of dystonic reactions with the use of benztropine dropp from 33% to 14%. The researchers conclude that the increased side-effects of benztropine are of litt consequence when compared to the positive effects of the drug (Goff et al, 1991b).

d) Acute intestinal pseudo-obstruction may occur in patients receiving benztropine and haloperidol concomitantly. A 68-year-old female with mild multi-infarct dementia developed acute intestinal pseudo-obstruction after receiving 2 doses of benztropine to treat extrapyramidal symptoms associated with haloperidol therapy. Treatment with haloperidol 0.5 mg 3 times daily was initiated af the patient developed psychotic behavior and agitation. She was hospitalized three days later with extrapyramidal symptoms and was treated with intravenous benztropine. Her abdomen became significantly distended within 3-4 hours. Upon examination, she was dehydrated and had reduced bowel sounds. Dilation of her large bowel and some distention of her small bowel loops were appare on x-ray. Haloperidol and benztropine were discontinued and supportive therapy was initiated. Her abdominal distention had resolved within 24 hours. Benztropine may acutely potentiate the effect of haloperidol, causing acute pseudo-obstruction (Sheikh, 2001).

3.5.1.N Bepridil

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Some antipsychotic agents prolong the QT interval and an additive effect would be anticipated if administered with other agents which lengthen the QT interval (Prod Info Geodon(TM), 200 Agelink et al, 2001c; Owens, 2001d; Prod Info Orap(R), 1999b; Prod Info Haldol(R), 1998a). In U.S. clini trials, bepridil increased QT and QTc intervals which was associated with torsades de pointes in approximately 1% of patients. Other drugs that increase the QT interval may exaggerate the prolongatio the QT interval observed with bepridil (Prod Info Vascor(R), 1997). Pimozide is contraindicated in patient taking other drugs which may prolong the QT interval (Prod Info Orap(R), 1999b).

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of antipsychotics and agents that prolong the QT interval, such as bepridil, is contraindicated. In particular, pimozide is contraindicated in individuals with congenital QT syndrome, patients with a history of cardiac arrhythmias, or patients taking other drugs wh may prolong the QT interval.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999a).

b) Sometimes fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone therapeutically (Duenas-Laita et al, 1999c; Ravin & Levenson, 1997).

3.5.1.O Betel Nut

1) Interaction Effect: increased extrapyramidal side effects of haloperidol (difficulty with movement or abnormal movement of muscles)

2) Summary: Case reports have described increased extrapyramidal side effects when betel nut was chewed by patients taking fluphenazine and fluphenthixol for schizophrenia (Deahl, 1989a). The extrapyramidal effects were not improved with anticholinergic therapy with procyclidine, and resolved wit betel nut discontinuation (Deahl, 1989a). A similar effect may occur if betel nut is chewed with concomita haloperidol therapy. The cholinergic activity of betel nut has been attributed to the arecoline content. Wh given with peripheral anticholinergics, arecoline increased the heart rate due to central muscarinic agoni activity (Nutt et al, 1978a). Case reports suggest the onset of betel nut activity to be within 3 weeks with resolution within 4 to 7 days after discontinuation (Deahl, 1989a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: It is unclear to what extent the cholinergic effect of betel nut may increase the incidence of extrapyramidal side effects of haloperidol, especially if patients are treated with anticholiner agents to control these side effects. Deterioration in symptoms of patients with Parkinson's disease or ot extrapyramidal movement disorders may be expected. Persons who have been chewing betel nut have characteristic red stain on the teeth which may help the clinician discover betel nut use.

7) Probable Mechanism: cholinergic effect of betel nut

8) Literature Reports

a) Within 3 weeks of initiating betel nut chewing, a 51-year-old Indian man experienced marked rigidity, bradykinesia, and jaw tremor. This patient had been stabilized for the previous 2 years on fluphenazine decanoate depot 50 milligrams (mg) every 3 weeks for schizophrenia and procyclidine mg twice daily for a mild Parkinsonian tremor. Within one week of discontinuation of betel nut chewi the patient's condition returned to baseline. This report appears to demonstrate decreased anticholinergic effects of procyclidine when coadministered with betel nut (Deahl, 1989).

b) Following betel nut ingestion, a 45-year-old Indian man developed akathisia, tremor and stiffness which was not affected by dosage escalations of up to 20 mg daily of procyclidine. This patient had been previously stabilized on fluphenthixol 60 mg depot every two weeks for the previous year for schizoaffective disorder without extrapyramidal side effects. His symptoms resolved over 4 days afte discontinuing betel nut. It appears that the anticholinergic effects of procyclidine were diminished wh betel nut was chewed concomitantly (Deahl, 1989).

c) High doses (5 mg, 10 mg, and 20 mg) of subcutaneous (SC) arecoline given one hour after SC administration of 0.5 mg of the peripheral anticholinergic agent methscopolamine increased the hea rate and blood pressure of six patients with Huntington's disease. Significant increases in blood pressure occurred at doses of 5 mg, 10 mg (p less than 0.01) and 20 mg (p less than 0.05). Heart ra increased at doses of 5 mg and 20 mg (p less than 0.01), and 10 mg (p less than 0.05). Subjective effects in some patients included tremor, flushing or pallor at the time of peak drug effect and nause weakness, and mental changes at the higher doses. No peripheral cholinergic effects were noted. T results indicated a central muscarinic effect for arecoline (Nutt et al, 1978).

d) A low dose (0.5 mg) of arecoline given intravenously 3 minutes after the peripheral anticholinergi agent glycopyrrolate 0.15 mg to 8 patients with major depressive disorder increased their heart rates The peak heart rate increase in a non-REM portion of the sleep cycle during the 10 minute post-infusion period was 6.75 +/- 12.9 beats per minute for placebo and 25 +/- 10.3 beats per minute for arecoline. The peak heart rates all began 1 to 8 minutes after the arecoline infusion, and the mean heart rate was significantly elevated over placebo from 2 to 10 minutes after arecoline infusion (p les than 0.05) (Abramson et al, 1985).

e) Though chewing betel nut alone does not significantly increase catecholamine levels, a popular betel nut preparation does. Six to eight minutes after chewing betel nut, 4 subjects had only a moderate increase in plasma noradrenaline from 266.2 +/- 105.7 picograms/milliliter (pg/mL) to 313. +/- 92.9 pg/mL (p equal to 0.0607). Combining betel nut with lime, catechu and Piper betel flower as commonly done caused significant elevation of norepinephrine in nine subjects from 292.2 +/- 59.5 pg/mL to 375.1 +/- 130.0 pg/mL (p equal to 0.0244) and epinephrine from 62.5 +/- 23.9 pg/mL to 10 +/- 45.0 pg/mL (p equal to 0.0226). In this group dopamine was also elevated in 8 of 9 subjects, but mean was not significant (Chu, 1995).

3.5.1.P Bretylium

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Concurrent use of bretylium and haloperidol is not recommended due to the risk of additive effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitorin is advised (Yamreudeewong et al, 2003a).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of bretylium and haloperidol is not recommende due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant use o Class III antiarrhythmic agents such as bretylium and haloperidol may have additive effects on the C interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.Q Bupropion

1) Interaction Effect: increased plasma levels of haloperidol

2) Summary: It is recommended that haloperidol, an antipsychotic metabolized by the cytochrome P450 2D6 isoenzyme, be initiated at the lower end of the dose range when administered concomitantly with bupropion (Prod Info Wellbutrin XL(TM), 2003; Prod Info Zyban(R), 2000).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Coadministration of bupropion and haloperidol should be approached with caution and should be initiated at the lower end of the dose range of haloperidol. If bupropion is added tc the treatment regimen of a patient already receiving haloperidol, consider decreasing the dose of

haloperidol.
7) Probable Mechanism: inhibition of cytochrome P450 2D6-mediated haloperidol metabolism

3.5.1.R Cabergoline
1) Interaction Effect: the decreased therapeutic effect of both drugs
2) Summary: Cabergoline is a long-acting dopamine receptor agonist with a high affinity for dopamine-2 receptors. It should not be administered concomitantly with dopamine-2 antagonists, such as phenothiazines, butyrophenones, thioxanthines, and metoclopramide (Prod Info Dostinex(R), 1996).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Cabergoline, a dopamine-2 receptor agonist, should not be used concurrently with a dopamine-2 antagonist, such as haloperidol.
7) Probable Mechanism: antagonistic pharmacologic effects

3.5.1.S Carbamazepine
1) Interaction Effect: decreased haloperidol effectiveness
2) Summary: In a case report, the addition of carbamazepine to patients stabilized with haloperidol resulted in mean reductions of haloperidol levels by 60%. Two other case reports and a clinical study supported this finding, while a third case report did not (Kahn et al, 1990a; Arana et al, 1986a; Fast et al, 1986; Klein et al, 1984; Hesslinger et al, 1999a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor for the therapeutic efficacy of haloperidol following the addition of carbamazepine; higher haloperidol dosage may be required in some clinical situations.
7) Probable Mechanism: increased cytochrome P450 2D6 and 3A4-mediated haloperidol metabolism
8) Literature Reports
a) Serum haloperidol levels of 14 schizophrenic patients dropped an average of 50% when carbamazepine was added to their therapy. Haloperidol doses ranged from 2 mg to 20 mg daily and the carbamazepine dose was adjusted to yield levels of 8 to 12 mcg/mL. The drop in haloperidol lev resulted in the worsening of one patient's condition. Two patients had significant symptom reduction while on carbamazepine, despite the decrease in the haloperidol levels. Their improvement may hav been due to direct effects of the carbamazepine, or as a secondary effect due to the lowering of the haloperidol levels. The authors recommend monitoring serum medication levels when administering haloperidol in combination with carbamazepine (Kahn et al, 1990).
b) Serum haloperidol levels of seven patients treated for psychosis fell when carbamazepine was added to their therapy. Haloperidol doses ranged from 10 mg to 40 mg daily and carbamazepine do ranged from 400 mg to 1000 mg daily. After carbamazepine was added, haloperidol levels decrease by 19% to 100%. The two patients whose blood levels fell to undetectable levels had a marked worsening of symptoms. Careful monitoring should take place if carbamazepine is added to haloper therapy (Arana et al, 1986).
c) Concomitant administration of haloperidol and carbamazepine as reported to result in neurotoxic (drowsiness, slurred speech, concentration difficulties) in a 37-year-old woman with cerebral palsy a dipolar disorder (Brayley & Yellowlees, 1987). Withdrawal of carbamazepine resulted in subsidence symptoms on this second occasion. It is speculated that the interaction occurred at the level of the CNS, as opposed to toxic effects of either drug alone, as carbamazepine serum levels were subtherapeutic during the toxic episodes and due to the fact that carbamazepine is reported to enhance haloperidol metabolism. In addition, the patient received higher doses of carbamazepine following withdrawal of haloperidol without the occurrence of toxic effects. Cerebral palsy may have been a predisposing factor to the interaction.
d) Twenty-seven schizophrenic patients enrolled in a study to determine the effects of carbamazepi and valproic acid on the plasma levels of haloperidol and the psychopathologic outcome. Following four-day washout period, patients were assigned to receive treatment for four weeks with haloperidc monotherapy, haloperidol with carbamazepine, or haloperidol with valproic acid. Doses of haloperidc remained stable throughout the study, and the doses of carbamazepine and valproic acid were titrat to a plasma level of 6 to 12 mg/L and 50 to 100 mg/L, respectively. When administered with carbamazepine, haloperidol plasma levels decreased by 45% (from 7.6 ng/mL to 4.6 ng/mL) over th 28-day period. Decreases in the rating scores on the Positive subscale of the Positive and Negative Syndrome Scale (pPANSS) were significant during the carbamazepine phase of the study, indicatin that the coadministration of carbamazepine and haloperidol may worsen the clinical outcome compared to haloperidol monotherapy (Hesslinger et al, 1999).

3.5.1.T Chloral Hydrate
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Chloral hydrate has been shown to prolong the QTc interval at the recommended therapeu dose (Young et al, 1986). Even though no formal drug interaction studies have been done, the

administration of drugs known to prolong the QTc interval, such as antipsychotics and chloral hydrate is recommended. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999m), haloperidol (O'Brien et al, 1999h), quetiapine (Owens, 2001n), risperidone (Duenas-Laita et al, 1999l), sertindole (Agelink et al, 2001k), sultopride (Lande et al, 1992k), and zotepin (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of chloral hydrate and antipsychotics is not recommended.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) The overall incidence of QT interval prolongation with sertindole is estimated at 1.9% to 4%, and the potential risk of developing torsades de pointes has been estimated at 0.13% to 0.21% (Brown & Levin, 1998b). Periodic electrocardiographic monitoring is required in the United Kingdom per sertindole's official labeling (Cardoni & Myer, 1997).
b) A total of 7 patients developed torsade de pointes after therapeutic use of haloperidol in high dos (Metzger & Friedman, 1993f; Wilt et al, 1993d). Three patients developed the dysrhythmia after administration of 211 to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episodes, but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol.

3.5.1.U Chloroquine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Chloroquine has been shown to prolong the QTc interval at the recommended therapeutic dose and an additive effect would be anticipated if administered with other agents which lengthen the QT interval (Prod Info Aralen(R), 2001). Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999w), haloperidol (O'Brien et al, 1999p), quetiapine (Owens 2001x), risperidone (Duenas-Laita et al, 1999w), sertindole (Agelink et al, 2001u), sultopride (Lande et a 1992w), and zotepine (Sweetman, 2004).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of antipsychotics and agents that prolong the QT interval, such as chloroquine is not recommended.
7) Probable Mechanism: additive effect on QT prolongation
8) Literature Reports
a) Sometimes fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone therapeutically (Duenas-Laita et al, 1999v; Ravin & Levenson, 1997e).

3.5.1.V Chlorpromazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects o the QT interval and is not recommended. Q and T wave distortions have been observed in patients takin phenothiazines (Prod Info Compazine(R), 2002; Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, though no reports are available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999k), haloperidol (O'Brien et al, 1999g), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001m), risperidone (Duenas-Laita et al, 1999k), sertindole (Agelink e al, 2001j), sultopride (Lande et al, 1992i), ziprasidone (Prod Info GEODON(R) intramuscular injection, or capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phenothiazines and antipsychotics, is not recommended.
7) Probable Mechanism: additive QT prolongation

3.5.1.W Cisapride

1) Interaction Effect: worsening of psychotic symptoms and/or an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concomitant therapy of cisapride with any drug that prolongs the QT interval, such as haloperidol, is contraindicated (Prod Info Propulsid(R), 2000a). Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Balk, 2003n; Prod Info Haldol(R), 2001h). No pharmacokinetic interaction was observed in a study of 15 schizophrenic patients taking cisapride with haloperidol, though psychiatric symptoms worsened (Mihara et al, 1999a).

3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: The concurrent administration of cisapride and agents that prolong the QT interval, such as haloperidol, is contraindicated.
7) Probable Mechanism: inhibition of haloperidol metabolism by cisapride; accelerated haloperidol absorption; additive effect on QT interval
8) Literature Reports
a) Psychiatric symptoms significantly increased with concomitant cisapride therapy in 15 schizophrenic patients receiving haloperidol, although no pharmacokinetic interaction was observed Patients received cisapride 5 milligrams (mg) twice daily along with haloperidol 12 mg to 36 mg daily for one week. No significant changes in the mean plasma concentrations of haloperidol or reduced haloperidol were observed during cisapride coadministration. Side effects, measured by the UKU rating scale, were not significantly affected. The authors noted that higher doses of cisapride may affect haloperidol concentrations (Mihara et al, 1999).
b) Prolonged QT interval, ventricular arrhythmias, and torsades de pointes have been reported in 2 cases from July 1993 through May 1999. Of these cases, 70 have resulted in death. A majority (85% of patients experiencing cardiotoxicity had risk factors that predisposed them to arrhythmias (Prod Ir Propulsid(R), 2000).
c) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003m).

3.5.1.X Clarithromycin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999d), haloperidol (O'Brien et al, 1999c), quetiapine (Owens, 2001e), risperidone (Duenas-Laita et al, 1999d), sertindole (Agelink et al, 2001d), sultopride (Lande et al, 1992c), and zotepi (Sweetman, 2004). Even though no formal drug interaction studies have been done, concomitant use of clarithromycin and antipsychotic agents may cause additive effects on the QT interval and is not recommended (Prod Info Biaxin(R), 2002).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of clarithromycin and agents that prolong the QT interval, such as antipsychotics, is not recommended.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) A 32-year-old male with schizoaffective disorder and metabolic syndrome experienced a significa increase in plasma concentration following administration of quetiapine. The patient, hospitalized for acute psychotic symptoms was treated with 50 mg quetiapine daily, with a gradual increase in dosag to 700 mg over 10 days. Psychotic symptoms dissipated within 3 weeks. On day 28, the patient developed a lower airway infection, and was orally treated with 750 mg sultamicillin, 500 mg clarithromycin along with his evening dose of quetiapine 400 mg. The following morning, 750 mg sultamicillin, 500 mg clarithromycin, and the morning 300-mg quetiapine dose were given. Within ho the patient became somnolent, and plasma sample testing resulted in 826.8 microgram/L (normal range, 70 to 170 microgram/L). The patient developed severe impaired consciousness and respirato depression. Quetiapine overdose was suspected and treatment was discontinued. Plasma levels we continually measured over the course of a week until complete recovery was achieved (Schulz-Du E et al, 2008).
b) A total of 7 patients developed torsade de pointes after therapeutic use of haloperidol in high dos (Metzger & Friedman, 1993a; Wilt et al, 1993). Three patients developed the dysrhythmia after administration of 211 to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episodes, but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol. Four patients developed the dysrhythmia after administration of 170 580 mg over 1 to 4 days for delirium associated with bacterial meningitis (1), status asthmaticus (2) respiratory insufficiency (1). All 4 patients recovered with no adverse sequelae.
c) Prolongation of the QTc interval was reported in 8 patients receiving risperidone (Prod Info

Risperdal(R) risperidone, 2002).

3.5.1.Y Dalfopristin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Quinupristin/dalfopristin is a major inhibitor of cytochrome P450 3A4 (CYP3A4) isoenzyme and haloperidol is a CYP3A4 substrate. Coadministration of these two agents may likely result in increas plasma concentrations of haloperidol, which may lead to QTc interval prolongation and risk of torsades d pointes (Prod Info SYNERCID(R) intravenous injection, 2003; Prod Info Haldol(R) Injection, 2001).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of quinupristin/dalfopristin and haloperidol shoul be avoided. Monitor ECG if used concomitantly.

7) Probable Mechanism: inhibition of cytochrome P450 3A4-mediated haloperidol metabolism

3.5.1.Z Dehydroepiandrosterone

1) Interaction Effect: reduced effectiveness of haloperidol

2) Summary: Dehydroepiandrosterone (DHEA) levels within the normal range of 100 to 400 microgram/deciliter (mcg/dL) are conducive to optimal treatment of patients with psychosis (Howard, 1992a). In case reports, patients have been resistant to antipsychotics when DHEA levels were elevated (Howard, 1992a). Patient being treated with haloperidol should avoid DHEA supplementation.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Avoid concomitant use of dehydroepiandrosterone (DHEA) and haloperidol. If DHEA is elevated, treatment with dexamethasone 1 mg orally per day may be used to normalize DHEA levels.

7) Probable Mechanism: elevated dehydroepiandrosterone (DHEA) blood levels may reduce responsiveness to haloperidol

8) Literature Reports

a) A 24-year-old female diagnosed with schizophrenia was resistant to daily doses of haloperidol 20 milligrams (mg), fluphenazine 40 mg, lithium carbonate 1200 mg, and lithium carbonate 900 mg plus thioridazine 300 mg. The patient appeared Cushinoid with moon face, acne, facial hair, abdominal h and a 40 pound weight gain in the previous 8 months. Dehydroepiandrosterone (DHEA) measured a part of an endocrine panel was 725 micrograms/deciliter (mcg/dL) (normal: 100 to 400 mcg/dL). Dexamethasone 1 mg orally at bedtime resulted in substantial improvement within one week. The patient appeared calmer, more alert with improved psychotic symptoms and ability to concentrate. A two weeks, a repeated DHEA level was within normal range (328 mcg/dL). The author concluded th elevated DHEA levels were associated with severe psychosis resistant to conventional antipsychotic therapy (Howard, 1992).

b) A 13-year-old male decompensated with a subsequent two-year period of emotional problems accompanied by heavy use of LSD, hashish, barbiturates, and alcohol. His mental status included bizarre, disorganized, delusional thinking, auditory and visual hallucinations, paranoia, lack of attent to personal hygiene, agitation, and combativeness. He was diagnosed with chronic paranoid schizophrenia; schizophrenia, chronic undifferentiated type, and schizoaffective disorder, excited typ He was resistant to daily doses of trifluoperazine 40 mg, chlorpromazine 400 mg, and imipramine 10 mg. He was also resistant to combination therapy with chlorpromazine 400 mg with thiothixene 80 m thioridazine 1000 mg, perphenazine 48 mg with lithium carbonate 1200 mg, clonazepam 4 mg, and carbamazepine 1200 mg daily. Baseline DHEA level exceeded 900 mcg/dL. A seven-day suppressi test with dexamethasone 1 mg orally at bedtime resulted in a normal DHEA level of 200 mcg/dL. By day 5, psychosis improved and the patient was well-oriented, conversational, and was making good eye contact. Once dexamethasone was discontinued, rapid decompensation and florid psychosis ensued despite "substantial amounts of psychotropic medications." DHEA increased to 536 mcg/dL. The author concluded that elevated DHEA levels were associated with florid psychosis resistant to conventional antipsychotic therapy (Howard, 1992).

3.5.1.AA Desipramine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministration a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsha & Forker, 1982).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.AB Dextromethorphan
1) Interaction Effect: exacerbation of dextromethorphan adverse effects (CNS excitement, mental confusion, respiratory depression, nervousness, tremors, insomnia, diarrhea)
2) Summary: Dextromethorphan is metabolized by the cytochrome P450IID6 isoenzyme in humans. Haloperidol is an inhibitor of CYP2D6 (Shen, 1995; Slaughter & Edwards, 1995). Coadministration of dextromethorphan and haloperidol may result in elevated concentrations of dextromethorphan and increased adverse effects.
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Monitor patient for signs and symptoms of dextromethorphan toxicity (CNS excitement, mental confusion, respiratory depression, nervousness, tremors, insomnia, diarrhea). A reduction of dextromethorphan doses may reduce or resolve adverse effects.
7) Probable Mechanism: inhibition of dextromethorphan metabolism

3.5.1.AC Dibenzepin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministratio a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsh & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.AD Dicumarol
1) Interaction Effect: decreased anticoagulant effectiveness
2) Summary: Haloperidol may increase the metabolism of dicumarol and reduce the hypoprothrombine effect of oral anticoagulants (Prod Info Dicumarol, 1995).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: In patients receiving oral anticoagulant therapy, the prothrombin time ratio or I (international normalized ratio) should be closely monitored with the addition and withdrawal of treatmen with haloperidol, and should be reassessed periodically during concurrent therapy. Adjustments of the dicumarol dose may be necessary in order to maintain the desired level of anticoagulation.
7) Probable Mechanism: increased dicumarol metabolism

3.5.1.AE Disopyramide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and

zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999z; O'Brien et al, 1999r; Pro Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001z; Duenas-Laita et al, 1999y; Agelin et al, 2001x; Lande et al, 1992z; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increas the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychoti not recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT (TM) oral tablets, 2009).

b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).

c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also show an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and tir to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that tissue binding mechanism is more likely responsible for the plasma level changes than an eliminatio alteration (Young et al, 1993).

3.5.1.AF Dofetilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Concurrent use of dofetilide and haloperidol is not recommended due to the risk of additive effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitorin is advised. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated (Yamreudeewong et al, 2003a).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of dofetilide and haloperidol is not recommende due to the potential for inducing life-threatening arrhythmias. Dofetilide should be stopped for at least 2 days before any interacting drug is initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have also demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant u of Class III antiarrhythmic agents such as dofetilide and haloperidol may have additive effects on the QT interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.AG Dolasetron

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999i), haloperidol (O'Brien et al, 1999f), quetiapine (Owens, 2001k), risperidone (Duenas-Laita et al, 1999i), sertindole (Agelink et al, 2001h), sultopride (Lande et al, 1992g), and zotepir (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministration dolasetron and other drugs known to prolong the QTc interval, including antipsychotics, is not recommended (Prod Info Anzemet(R), 1997a).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of dolasetron and agents that prolong the QT interval, such as antipsychotics, is not recommended.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) In several studies, dolasetron resulted in significant, dose-related increases in mean PR, QRS, a

QTc intervals compared to baseline values. Measured changes in ECG parameters were transient, reversible, and asymptomatic. Increases in PR and QRS intervals may be due to prolongation of maximum upstroke velocity (Vmax) due to binding of dolasetron to fast sodium channels. The cause QTc interval prolongation appears to be due to prolongation of the QRS interval, increases in heart rate, or both (Prod Info Anzemet(R), 1997; Hunt et al, 1995; Kris et al, 1994).
b) A total of 7 patients developed torsade de pointes after therapeutic use of haloperidol in high dos (Metzger & Friedman, 1993e; Wilt et al, 1993c). Three patients developed the dysrhythmia after administration of 211 to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episodes, but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol. Four patients developed the dysrhythmia after administration of 170 580 mg over 1 to 4 days for delirium associated with bacterial meningitis (1), status asthmaticus (2) respiratory insufficiency (1). All 4 patients recovered with no adverse sequelae.
c) Prolongation of the QTc interval was reported in 8 patients receiving risperidone (Prod Info Risperdal(R) risperidone, 1999).

3.5.1.AH Doxepin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministratio a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsh & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychoti not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.AI Droperidol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999t), haloperidol (O'Brien et al, 1999m), quetiapine (Owens, 2001u), risperidone (Duenas-Laita et al, 1999s), sertindole (Agelink et al, 2001p), sultopride (Lande et al, 1992t), and zotepir (Sweetman, 2003). Droperidol has been shown to prolong the QTc interval at the recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadministration droperidol and other drugs known to prolong the QTc interval, including antipsychotics is not recommend (Prod Info Inapsine(R), 2002).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of droperidol and antipsychotics is not recommended.
7) Probable Mechanism: additive cardiac effects

3.5.1.AJ Encainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Coadministration of haloperidol with other drugs that potentially prolong the QTc interval, such as encainide, should be approached with caution. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Owens, 2001f; Prod Info Haldol(R), 1998b; Larochelle et al, 1984).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of encainide and haloperidol is not recommende due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AK Enflurane

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Some antipsychotic agents prolong the QT interval and an additive effect would be anticipated if administered with other agents which lengthen the QT interval (Agelink et al, 2001aa; Owe 2001ad; Prod Info Haldol(R), 1998j; Lande et al, 1992ac). Even though no formal drug interaction studie have been done, antipsychotic agents should not be coadministered with other drugs which are also kno to prolong the QTc interval, including enflurane (Owens, 2001ad).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of enflurane and agents that prolong the QT interval, such as antispychotics, is not recommended.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Sometimes fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone therapeutically (Duenas-Laita et al, 1999ab; Ravin & Levenson, 1997h).

3.5.1.AL Erythromycin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Erythromycin significantly increased the mean QTc interval versus baseline in a retrospect study of 49 patients (Oberg & Bauman, 1995a). Erythromycin has demonstrated QTc prolongation in combination with other drugs that prolong the QT interval (Prod Info PCE(R), 1997). Several antipsychot agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999x), haloperic (O'Brien et al, 1999q), risperidone (Duenas-Laita et al, 1999x), sertindole (Agelink et al, 2001v), sultopric (Lande et al, 1992x), and zotepine (Sweetman, 2003). Caution is advised with coadministration of drugs that potentially prolong the QTc interval.

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Caution is advised if erythromycin and antipsychotics are used concomitantly. Monitor QT interval at baseline and periodically during treatment.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Erythromycin significantly increased the QTc interval compared with baseline in a retrospective study of 49 patients. The erythromycin dose was 500 milligrams or 1 gram four times daily, with a mean of 15 doses received. Patients (n equal to 9) who received 60 mg/kg/day or more all develope increases in QT interval of 15% or greater. For all patients, the mean QTc interval increased from 4 milliseconds (msec) at baseline to 483 msec (p less than 0.01). In patients with delayed repolarizatic at baseline (n equal to 9), the QTc interval increased from 473 msec to 525 msec (p less than 0.01). patients with heart disease (n equal to 30), all experienced an increase in QTc interval (mean of 15% compared with an increase of 8% in patients without heart disease (p less than 0.05). In 5 patients (10%), the QTc interval was severely prolonged. One patient developed torsades de pointes attribut to erythromycin. Of 16 patients receiving cotrimoxazole concomitantly, 8 developed QT prolongatior 15% or greater (Oberg & Bauman, 1995).

3.5.1.AM Flecainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Coadministration of haloperidol with other drugs that potentially prolong the QTc interval, such as flecainide, should be approached with caution. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Owens, 2001f; Prod Info Haldol(R), 1998b; Prod Info Tambocor(R), 1998; Larochelle et al, 1984).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of flecainide and haloperidol is not recommende due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AN Fluconazole

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Case reports have described QT prolongation and torsades de points associated with

fluconazole (Khazan & Mathis, 2002; Wassmann et al, 1999). Haloperidol (Prod Info Haldol(R), 1998e), risperidone (Prod Info Risperdal(R) risperidone, 2000), amisulpride (Prod Info Solian(R), 1999l), sertindo (Brown & Levin, 1998a); sultopride (Lande et al, 1992j), and zotepine (Sweetman, 2004) have been shov to prolong the QT interval at therapeutic doses. Even though no formal drug interaction studies have bee done, caution is advised if drugs known to prolong the QT interval are used concomitantly.
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if fluconazole and antipsychotics are used concomitantly.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AO Fluoxetine
1) Interaction Effect: haloperidol toxicity (pseudoparkinsonism, akathisia, tongue stiffness) and an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003f; Prod Info Haldol(R), 2001d). Fluoxetine has been shown to prolong the QTc interval at the recommended therapeutic dose (Prod Info Prozac(R), 2001). Caution is advised with coadministration of drugs that potentially prolong the QTc interval. In addition, several case reports describe development of extrapyramidal symptoms when fluoxetine and haloperidol were taken together, possibly due to inhibitior haloperidol metabolism (Benazzi, 1996a; Goff et al, 1991a; Stein, 1991a; Tate, 1989a).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: The concurrent administration of fluoxetine and haloperidol is not recommende
7) Probable Mechanism: inhibition of haloperidol metabolism by fluoxetine; theoretical additive effects or QT prolongation
8) Literature Reports
a) Fluoxetine increased plasma concentrations of haloperidol in 8 outpatients. Patients received fluoxetine 20 mg daily for 10 days with maintenance doses of haloperidol (average dose, 14 mg per day). After ten days, mean plasma concentrations of haloperidol had increased by 20%. Extrapyramidal symptom scores did not change appreciably after the addition of fluoxetine although one patient developed mild akathisia and another developed tremors. Extrapyramidal symptoms we expected to increase because of indirect inhibition of dopamine synthesis by fluoxetine (Goff et al, 1991).
b) A 39-year-old male experienced tardive dyskinesia with concomitant fluoxetine and haloperidol therapy. He was taking fluoxetine 20 mg daily for 2 months, then haloperidol 2 mg twice daily was started and later lowered to 1 mg per day. Five months later during a routine examination, tardive dyskinesia was diagnosed. The suggested mechanism was the down-regulation of dopamine activit (Stein, 1991).
c) A 39-year-old female developed tardive dyskinesia associated with concomitant fluoxetine and haloperidol therapy. She had been taking haloperidol 2 to 5 mg a day for two years (both with and without benztropine) with occasional mild, reversible extrapyramidal symptoms. Five days before stopping haloperidol, she started taking fluoxetine, which was increased over several days to 40 mg twice a day. After two weeks of fluoxetine she took haloperidol 5 mg each on two consecutive days (along with continuation of fluoxetine). She then experienced severe tongue stiffness, parkinsonism, and akathisia. Both fluoxetine and haloperidol were withdrawn. During the next seven days her extrapyramidal symptoms gradually disappeared (Tate, 1989).
d) A 40-year-old male developed urinary retention while taking fluoxetine and haloperidol. During a recurrence of depression, the patient was treated with fluoxetine 20 mg per day, alprazolam 1.5 mg day, and haloperidol 1 mg per day. The patient had previously taken fluoxetine and alprazolam with incident. Approximately one week after beginning therapy, the patient developed difficulty in voiding urine, dilated pupils, dry mouth, palpitations, restlessness, hand tremors, and insomnia. After discontinuation of haloperidol and alprazolam, side effects ceased within one week. The authors postulated that the interaction was due to fluoxetine inhibition of cytochrome CYP2D6, which metabolizes haloperidol (Benazzi, 1996).

3.5.1.AP Fluvoxamine
1) Interaction Effect: an increased risk of haloperidol toxicity
2) Summary: Haloperidol serum concentrations were increased by the coadministration of fluvoxamine i small double blind, randomized, placebo controlled, crossover study (Daniel et al, 1994a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Caution should be used when fluvoxamine is administered with haloperidol. Monitor serum concentrations of haloperidol and adjust the dose accordingly. Also monitor the patient fo signs and symptoms of worsening clinical and cognitive assessments.
7) Probable Mechanism: inhibition of cytochrome P450-mediated metabolism of haloperidol
8) Literature Reports

a) Four inpatient males with chronic schizophrenia were stabilized on haloperidol and benztropine orally. In randomized order, the patients were then placed on fluvoxamine for six weeks or identicall appearing placebo. Results showed that the addition of fluvoxamine to haloperidol therapy significar elevated serum concentrations of haloperidol. In addition, haloperidol concentrations did not plateau during the six-week period of fluvoxamine treatment, indicating that the haloperidol concentrations n have continued to increase at a constant dose of fluvoxamine. The coadministration of haloperidol a fluvoxamine also worsened all measures of clinical and cognitive function assessments, including delayed recall memory and attentional function. It is possible that haloperidol may require the cytochrome P450 1A2 system for metabolism, and fluvoxamine is known to be a potent inhibitor of t enzyme pathway (Daniel et al, 1994).

3.5.1.AQ Foscarnet

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Foscarnet can prolong the QT interval in some patients, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999ab), haloperidol (O'Brien al, 1999s), quetiapine (Owens, 2001ac), risperidone (Duenas-Laita et al, 1999aa), sertindole (Agelink et 2001z), sultopride (Lande et al, 1992ab), and zotepine (Sweetman, 2003). Because antipsychotics may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of foscar and antipsychotics is not recommended (Prod Info Foscavir(R), 1998; Ravin & Levenson, 1997g).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of foscarnet and antipsychotics is not recommended.
7) Probable Mechanism: additive cardiac effects

3.5.1.AR Gemifloxacin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although pharmacokinetic studies between gemifloxacin and drugs that prolong the QT interval, such as antipsychotics, have not been performed, gemifloxacin should be used cautiously in patients receiving antipsychotic medications (Prod Info Factive(R), 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of two drugs that prolong the QT interval, such a gemifloxacin and antipsychotics, is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AS Halofantrine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Halofantrine can prolong the QT interval in some patients, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Some antipsychotic agents prolong the QT interval and an additive effect would be anticipated if administered with other agents which lengthen the interval (Agelink et al, 2001b; Owens, 2001c; Prod Info Solian(R), 1999c; Prod Info Haldol(R), 1998; Lan et al, 1992b). The concurrent administration of halofantrine with antipsychotics is not recommended (Pro Info Halfan(R), 1998).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of halofantrine and an antipsychotic is not recommended.
7) Probable Mechanism: additive cardiac effects

3.5.1.AT Halothane

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Some antipsychotic agents prolong the QT interval and an additive effect would be anticipated if administered with other agents which lengthen the QT interval (Agelink et al, 2001i; Owens 2001l; Prod Info Solian(R), 1999j; Prod Info Haldol(R), 1998d; Lande et al, 1992h). Even though no form drug interaction studies have been done, antipsychotic agents should not be coadministered with other drugs which may also prolong the QTc interval, including halothane (Owens, 2001l).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of halothane and agents that prolong the QT interval, such as antispychotics, is not recommended.
7) Probable Mechanism: additive effect on QT interval
8) Literature Reports
a) Sometimes fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone therapeutically (Duenas-Laita et al, 1999j; Ravin & Levenson, 1997b).

3.5.1.AU Hydroquinidine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999z; O'Brien et al, 1999r; Prc Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001z; Duenas-Laita et al, 1999y; Agelin et al, 2001x; Lande et al, 1992z; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increas the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychoti not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT (TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also show an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and tir to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that tissue binding mechanism is more likely responsible for the plasma level changes than an eliminatio alteration (Young et al, 1993).

3.5.1.AV Ibutilide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concurrent use of ibutilide and haloperidol is not recommended due to the risk of additive effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitorin is advised (Yamreudeewong et al, 2003a).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of ibutilide and haloperidol is not recommended due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio dosing and telemetric monitoring is advised.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant use o Class III antiarrhythmic agents such as ibutilide and haloperidol may have additive effects on the QT interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.AW Imipramine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministratior

a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsha & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.AX Isoflurane
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Some antipsychotic agents prolong the QT interval and an additive effect would be anticipated if administered with other agents which lengthen the QT interval (Agelink et al, 2001y; Owens 2001aa; Prod Info Solian(R), 1999aa; Prod Info Haldol(R), 1998i; Lande et al, 1992aa). Even though no formal drug interaction studies have been done, antipsychotic agents should not be coadministered with other drugs which are also known to prolong the QTc interval, including isoflurane (Owens, 2001aa).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of isoflurane and agents that prolong the QT interval, such as antipsychotics, is not recommended.
7) Probable Mechanism: additive effect on QT interval
8) Literature Reports
a) Sometimes fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone therapeutically (Duenas-Laita et al, 1999z; Ravin & Levenson, 1997f).

3.5.1.AY Isradipine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Isradipine can prolong the QT interval in some patients, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes, and its use with other drugs known to cause QT prolongation is not recommended (Prod Info DynaCirc(R), 2000). Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999g), haloperidol (O'Brien et al, 1999d), quetiapine (Owens, 2001h), risperidone (Duenas-Laita et al, 1999f), sertindole (Agelink et al, 2001b), and zotepine (Sweetman, 2004).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of isradipine and an antipsychotic is not recommended.
7) Probable Mechanism: additive cardiac effects

3.5.1.AZ Kava
1) Interaction Effect: additive dopamine antagonist effects
2) Summary: Theoretically, kava may add to the effect of dopamine antagonists, increasing the risk for adverse effects. Case reports describe what appears to be dopamine-blocking activity of kava manifested in patients as dystonia, dyskinesias, and Parkinsonism (Spillane et al, 1997a; Schelosky et al, 1995a). Kava extracts antagonized apomorphine-induced hyperreactivity to external stimuli in mice, suggesting dopamine blockade activity (Jamieson et al, 1989).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Avoid concomitant use of kava with dopamine antagonists. The desired effect and/or adverse effects of the dopamine antagonist may be increased or may be variable depending on the time of administration of kava and the quality of the kava product (i.e., whether it contains a standardized amount of kava).
7) Probable Mechanism: dopamine antagonist effect of kava
8) Literature Reports
a) A 27-year-old Aboriginal Australian male presented three times following heavy kava use with symptoms of severe choreoathetosis of the limbs, trunk, neck, and facial musculature, and athetosis

the tongue. Level of consciousness was not impaired. Symptoms resolved within 12 hours of intravenous diazepam on each occasion. Acute rheumatic fever was excluded, cerebrospinal fluid a computed tomography of the brain was normal, and urinary drug screen was negative. The only abnormalities found in hematological and biochemical tests were a serum alkaline phosphatase of 1 international units/liter (IU/L) (normal: 35-135 IU/L) and serum gamma-glutamyltransferase of 426 IU (normal less than 60 IU/L). These were attributed to kava use. The patient did not drink alcohol (Spillane et al, 1997).

b) A 76-year-old female with idiopathic Parkinson's disease of 17 years' duration treated for 8 years with levodopa 500 milligrams (mg) and benserazide 125 mg was prescribed kava extract (Kavaspor Forte(R)) 150 mg twice daily for complaints of inner tension. Within 10 days, she noted a pronounce increase in her daily "off" periods both in terms of duration and number. Within 2 days of discontinui the kava product, symptoms had returned to her normal baseline (Schelosky et al, 1995).

c) A 63-year-old female experienced sudden and acute forceful involuntary oral and lingual dyskinesias on the fourth day of self-initiated therapy with kava extract (Kavasporal Forte(R)) 150 m three times daily. She was treated successfully in the emergency room with biperiden 5 mg intravenously. She denied taking any other medications in the months preceding this event (Schelos et al, 1995).

d) A 22-year-old female took kava extract (Laitan(R)) 100 mg once for anxiety and nervousness. Within four hours she experienced oral and lingual dyskinesias, tonic rotation of the head, and painf twisting trunk movements. She was treated successfully with biperiden 2.5 mg intravenously. She denied taking any other medications in the months preceding this event (Schelosky et al, 1995).

e) A 28-year-old male experienced acute involuntary neck extension with forceful upward deviation the eyes within 90 minutes of taking kava extract (Laitan(R)) 100 mg. Symptoms resolved spontaneously within 40 minutes. This man had a history of acute dystonic reactions following exposure to promethacin (50 mg) and fluspirilene (1.5 mg), which had responded biperiden 5 mg intravenously 9 and 12 years previously (Schelosky et al, 1995).

3.5.1.BA Levodopa

1) Interaction Effect: decreased levodopa effectiveness

2) Summary: The therapeutic effects of levodopa may be reduced when coadministered with haloperido (Prod Info Stalevo(TM), 2003).

3) Severity: moderate

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: Monitor for clinical response to levodopa. The therapeutic effects of levodopa may be reduced with concomitant administration of haloperidol.

7) Probable Mechanism: antagonistic pharmacologic effect

3.5.1.BB Levomethadyl

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003a; Prod Info Haldol(R), 2001). Coadministration of levomethadyl with drugs that potentially prolong t QTc interval, such as haloperidol, is contraindicated (Prod Info Orlaam(R), 2001).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of levomethadyl with agents that prolong the QT interval, such as haloperidol, is contraindicated.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003).

3.5.1.BC Lidoflazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Lidoflazine has been shown to prolong the QTc interval at the recommended therapeutic

dose (Hanley & Hampton, 1983). Even though no formal drug interaction studies have been done, the coadministration of antipsychotics and other drugs known to prolong the QTc interval is not recommende Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Soliar (R), 1999), haloperidol (O'Brien et al, 1999), quetiapine (Owens, 2001), risperidone (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001), sultopride (Lande et al, 1992), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of lidoflazine and antipsychotics is not recommended.
7) Probable Mechanism: additive cardiac effects

3.5.1.BD Lithium
1) Interaction Effect: weakness, dyskinesias, increased extrapyramidal symptoms, encephalopathy, and brain damage
2) Summary: An encephalopathic syndrome followed by irreversible brain damage has occurred in a fev patients treated with lithium plus a dopamine-2 antagonist, particularly haloperidol. A causal relationship between these events and the concomitant administration of a dopamine-2 antagonist and lithium has nc been established (Prod Info LITHOBID(R) slow-release oral tablets, 2005). Coadministration of lithium ar a number of antipsychotic drugs has caused a wide variety of encephalopathic symptoms, brain damage extrapyramidal symptoms, and dyskinesias in isolated case reports. In most cases, these effects have occurred with therapeutic lithium levels (Amdisen, 1982; Prakash, 1982; Addonizio et al, 1988a). Howeve many series and trials have reported using such combinations with no severe adverse consequences (Goldney & Spence, 1986). The mechanism is not fully understood, but chronic lithium treatment decreas neostriatal dopaminergic activity, probably through a direct action on the G protein and the capacity of th G proteins, once activated, to stimulate adenyl cyclase (Carli et al, 1994). Hyperglycemic reactions have also occurred during combined phenothiazine and lithium use (Zall et al, 1968).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients closely for any signs of toxicity or extrapyramidal symptoms, especially if high doses of dopamine-2 antagonists, particularly haloperidol, and lithium are used. Serum lithium levels should be monitored periodically. Some clinicians advocate maintaining levels in the low therapeutic range.
7) Probable Mechanism: unknown
8) Literature Reports
a) Concomitant haloperidol and lithium therapy has resulted in symptoms of encephalopathy, confusion, extrapyramidal symptoms, and fever in several patients with mania (Cohen & Cohen, 197 Loudon & Waring, 1976; Thomas, 1979). Irreversible neurological injuries have been reported (Sanc & Hurwitz, 1983; Keitner & Rahman, 1984).
b) Seizures, encephalopathy, delirium, and abnormal EEG occurred in four patients during combine lithium and thioridazine therapy (Spring, 1979). Serum lithium levels were below 1 mEq/L at the time the toxic reaction in all cases. All patients had previously tolerated lithium in combination with anothe phenothiazine. Three of these patients developed symptoms within eight days of initiating combinati therapy.
c) The addition of lithium to neuroleptic therapy exacerbated extrapyramidal symptoms (EPS) in a small study (Addonizio et al, 1988). The patients had received at least five days of treatment with eit oral thiothixene, haloperidol, or fluphenazine in mean doses of 607.5 chlorpromazine equivalents pri to initiation of the lithium and were experiencing drug-induced extrapyramidal symptoms. Oral lithiun was added when clinically indicated in sufficient doses to achieve a therapeutic serum concentration The maximum levels attained were 0.65 to 1.27 mEq/L. The EPS ratings increased in all ten patients following the addition of lithium. However, only three patients developed marked symptoms and no patient developed lithium toxicity. Significantly increased symptoms included gait, shoulder shaking, elbow rigidity, and tremor.
d) Ten patients treated with clozapine and lithium were studied (Blake et al, 1992). Of the ten patier four experienced significant neurologic effects, including jerking of limbs, facial spasms and tics, trer of hands and arms, tongue twitching, and stumbling gait. One of these also experienced delirium. These effects reversed when lithium was discontinued or given at a lower dose. On rechallenge, one two patients suffered recurrence of symptoms. By keeping serum lithium no greater than 0.5 mEq/L, clozapine could be safely coadministered.
e) Chlorpromazine serum levels can be significantly reduced in the presence of lithium treatment. If used concurrently, abrupt cessation of lithium may result in rebound elevation of chlorpromazine levels, resulting in chlorpromazine toxicity. In patients on a lithium-chlorpromazine combination, abru withdrawal of the lithium may precipitate chlorpromazine cardiotoxicity. In this report, such toxicity w manifested as sudden ventricular fibrillation associated with prolongation of the QTc interval. Hypotension and EPS are also possible in this situation (Stevenson et al, 1989).
f) However, other data do not support that such adverse events are frequent or indeed causally related to combination therapy. Combination of dopamine antagonist antipsychotic drugs and lithium

have been used successfully in many patients with manic-depressive illness. It has been proposed t the interaction may only become significant with very high doses of one or both drugs or with failure discontinue dosing in the presence of toxic symptoms (Miller & Menninger, 1987).

g) A 69-year-old patient with oxygen-dependent chronic obstructive pulmonary disorder and a 25-y history of bipolar disorder was started on risperidone 3 mg for the treatment of new-onset auditory a visual hallucinations. She had also been maintained on a regimen of lithium (450 mg daily) for more than 10 years. In addition, she was given amantadine (100 mg twice daily) for tremor. Three weeks after the start of risperidone, the patient experienced a decline in mental status in addition to dizzine worsening tremors, nausea and vomiting, polyuria, depression, and visual and auditory hallucinatior She was then admitted to the hospital for delirium. Her lithium serum level was 1.36 mEq/L at the tir of the admission. All medications were discontinued. Although her lithium level decreased to 0.41 mEq/L, she continued to experience profound delirium, tremors, lethargy, and hallucinations for alm one week. After she started to respond to commands, she was restarted on lithium (300 mg at bedtime) because of the onset of mild hypomania. Five days later, she was discharged with a regim of lithium and low-dose lorazepam for treatment of insomnia. It is suggested that delirium could have been caused by the concurrent use of lithium and risperidone. Other factors could also have caused delirium, such as the patient's serum lithium level and the underlying pulmonary pathology. In additi amantadine, which facilitates the release of presynaptic dopamine and has a mild anticholinergic effect, may have contributed (Chen & Cardasis, 1996).

3.5.1.BE Lithospermum

1) Interaction Effect: decreased effectiveness of dopamine antagonists

2) Summary: Theoretically, the dopamine agonist activity of lithospermum may oppose that of dopamine antagonists, decreasing their effectiveness. Lithospermum likely decreases prolactin secretion via dopamine stimulation (Sourgens et al, 1982a). Animal data suggest that the effect occurs rapidly within 3 hours after injection, subsiding within 6 to 9 hours (Sourgens et al, 1980a). The magnitude and clinical significance of this phenomenon has yet to be determined in humans. Furthermore, it is not known if the ability to stimulate dopamine receptors is limited to the hypothalamic region or if such an effect will be nc elsewhere (i.e., if patients with psychosis will experience worsening of their condition due to dopamine stimulation secondary to lithospermum). Caution is recommended until the effects on humans and possil implications of a drug-herb interaction with dopamine antagonists can be fully determined.

3) Severity: minor

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: If therapy is initiated with lithospermum and a dopamine antagonist, monitor closely for return of symptoms previously controlled by the dopamine antagonist.

7) Probable Mechanism: dopamine agonism of lithospermum may counteract dopamine antagonists

8) Literature Reports

a) Administration of freeze dried extracts (FDE) of Lithospermum officinale (Boraginaceae) by intravenous injection to rats resulted in reduced prolactin serum levels and hypophyseal stores. Whe administered diluent, prolactin levels decreased from 36 +/- 8 nanograms/milliliter (ng/mL) serum to +/- 4 ng/mL serum (p less than 0.005) when administered Lithospermum officinale FDE (40 milligrar (mg)/100 grams body weight) within 3 hours post intravenous administration. The authors concluded that Lithospermum officinale possibly impacted prolactin secretion at the hypothalamic site via dopamine stimulation (Sourgens et al, 1982).

b) Prolactin levels decreased rapidly below basal values in rats within the first 3 hours following a single intravenous injection of Lithospermum officinale. Prolactin levels returned to control levels wit 6 to 9 hours after the injection (Sourgens et al, 1980).

3.5.1.BF Lorcainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Coadministration of haloperidol with other drugs that potentially prolong the QTc interval, such as lorcainide, should be approached with caution. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Owens, 2001f; Prod Info Haldol(R), 1998b; Larochelle et al, 1984).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of lorcainide and haloperidol is not recommende due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.BG Mefloquine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, caution is advised if

mefloquine is used with other drugs which can prolong the QTc interval (Prod Info Lariam(R), 1999). Mefloquine was associated with significant QT prolongation in a study of 46 healthy subjects (Davis et al 1996). Antipsychotics including haloperidol (Prod Info Haldol(R), 1998g), quetiapine (Owens, 2001s), risperidone (Prod Info Risperdal(R) risperidone, 2000b), amisulpride (Prod Info Solian(R), 1999r), sertinc (Agelink et al, 2001o); sultopride (Lande et al, 1992r), and zotepine (Sweetman, 2004) have been showr prolong the QT interval at therapeutic doses.
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if mefloquine and antipsychotics are used concomitantly.
7) Probable Mechanism: additive effect on QT interval

3.5.1.BH Mesoridazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although citing no data, the manufacturer of mesoridazine states that concomitant use witl other drugs which prolong the QT interval is contraindicated (Prod Info Serentil(R), 2001). Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999s), haloperidol (O'Brien et al, 1999l), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001t), risperidone (Duenas-Laita et al, 1999r), sertindole (Agelink et 2001n), sultopride (Lande et al, 1992s), ziprasidone (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2004).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as antipsychotics and mesoridazine, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.BI Methyldopa
1) Interaction Effect: CNS toxicity (dementia) or reversible parkinsonism
2) Summary: Cases of marked increases of psychotic behavior or newly developed bizarre behavior hav developed within one week after the addition of haloperidol to an established methyldopa regimen. The abnormal behavior dramatically improved within days upon discontinuation of either agent. The few case reported do not establish a cause-effect relationship, but the combination should be used with caution ar the patient observed closely for several days (Thornton, 1976a; Nadel & Wallach, 1979a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: Monitor psychiatric symptoms. Discontinue haloperidol if necessary.
7) Probable Mechanism: increased dopamine inhibition
8) Literature Reports
a) Two male patients experienced adverse mental effects resulting from combined methyldopa and haloperidol therapy (Thornton, 1976). The first case was a 48-year-old male with hypertension treate with 1 gram per day of methyldopa for three years. Following initiation of 8 milligrams per day of haloperidol for anxiety, the patient developed symptoms of psychomotor retardation, memory impairment, ideas of reference with accompanying inappropriate suspiciousness, and inability to do mathematical calculations. Discontinuing the haloperidol resulted in resolution of these symptoms within 48 hours. The second case was a 43-year-old male with hypertension treated with 1.5 grams day of methyldopa for 18 months who developed symptoms of disorientation, inability to recognize c handwriting, inability to concentrate and marked slowing of both motor and muscle performance with three days after starting 6 milligrams per day of haloperidol for anxiety. Following discontinuation of haloperidol, the symptoms disappeared completely within 72 hours.
b) A patient became irritable, aggressive, assaultive and unmanageable several days after receivin combination therapy with haloperidol and methyldopa (Nadel & Wallach, 1979). Improvement in symptoms occurred as soon as methyldopa was discontinued.
c) The potentiation of haloperidol by methyldopa was studied in schizophrenic patients (Chouinard al, 1973). Ten patients were maintained on haloperidol 10 milligrams and methyldopa 500 milligram daily from day 2 until the end of the 4-week trial. Among the ten patients, 20 incidences of extrapyramidal side effects were reported, which exceeds the expected incidence of extrapyramidal side effects of 25% following therapeutic doses of haloperidol (Anon, 1973). Antiparkinsonian medication was needed in eight out of 10 patients to control these drug-induced extrapyramidal effe Somnolence was noted in eight patients and considered severe in two.

3.5.1.BJ Nefazodone
1) Interaction Effect: an increased risk of extrapyramidal effects, hypotension, and sedation
2) Summary: A single dose of haloperidol administered with steady-state nefazodone decreased haloperidol clearance. Pharmacodynamic effects of haloperidol were not significantly altered (Prod Info

Serzone(R), 1998; DeVane, 1995).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Patients receiving combined haloperidol with nefazodone should be monitored closely for signs of excessive haloperidol side effects. Reductions in haloperidol dosage may be necessa
7) Probable Mechanism: decreased haloperidol metabolism and clearance
8) Literature Reports
a) The effect of nefazodone on the pharmacokinetics and pharmacodynamics of haloperidol was studied in 12 healthy males. Nefazodone 200 mg every 12 hours had a slight effect on the pharmacokinetics of a single dose of haloperidol 5 mg. The average area under the plasma concentration curve (AUC), highest concentration, and 12-hour concentration of haloperidol were increased 36%, 13%, and 37%, respectively. Only the effect on the AUC reached statistical significance. The pharmacodynamics of haloperidol were not effected by nefazodone consistently (Barbhaiya et al, 1996).

3.5.1.BK Nortriptyline
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministratio a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsh & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychoti not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.BL Octreotide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Octreotide has been shown to prolong the QTc interval at the recommended therapeutic dose (Prod Info Sandostatin(R), 1999). Even though no formal drug interaction studies have been done, the coadministration of antipsychotics and other drugs known to prolong the QTc interval, including octreotide, is not recommended. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999u), haloperidol (O'Brien et al, 1999n), risperidone (Duen Laita et al, 1999t), sertindole (Agelink et al, 2001q), quetiapine (Owens, 2001v), sultopride (Lande et al, 1992u), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of octreotide and antipsychotics is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.BM Olanzapine
1) Interaction Effect: an increased risk of parkinsonism (cogwheeling rigidity, unstable gait)
2) Summary: A patient receiving haloperidol experienced extreme parkinsonism following the addition o olanzapine therapy. Possible explanations include a pharmacokinetic interaction between olanzapine, a weak cytochrome P450 2D6 (CYP2D6) inhibitor, and haloperidol, a CYP2D6 substrate. Pharmacodynamically, the small amount of dopamine (D2) blockade from olanzapine may have been enough to increase the patient's parkinsonism (Gomberg, 1999a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Patients should be closely monitored for signs and symptoms of increased parkinsonian adverse effects when olanzapine is added to haloperidol therapy. Doses of haloperidol ma

need to be decreased.
7) Probable Mechanism: competitive inhibition of cytochrome P450 2D6-mediated haloperidol metabolis increased dopamine D2 blockade
8) Literature Reports
a) A 67-year-old hospitalized male with bipolar disorder who had stopped taking his medications wa restarted on haloperidol 10 mg nightly, benztropine 1 mg nightly, and valproate 750 mg twice daily. H had been experiencing some mild parkinsonian symptoms at baseline, but these symptoms did not worsen when haloperidol was reinstituted. Following stabilization on this regimen, it was decided to change his antipsychotic medication to olanzapine to minimize any parkinsonism that was a result o his medications. While tapering the haloperidol and initiating olanzapine, the patient experienced extreme parkinsonism that resulted in an inability to walk. His mental status remained unchanged. Haloperidol was discontinued on day 7 of combination therapy, and two days later the patient's parkinsonism side effects had resolved back to baseline. Benztropine was then discontinued, and th parkinsonian symptoms did not reoccur while on olanzapine (Gomberg, 1999).

3.5.1.BN Pentamidine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Pentamidine has been shown to prolong the QTc interval at the recommended therapeutic dose (Lindsay et al, 1990). Even though no formal drug interaction studies have been done, the coadministration of antipsychotics and other drugs known to prolong the QTc interval, including pentamidine, is not recommended (Agelink et al, 2001e; Owens, 2001g; Prod Info Haldol(R), 2001b; Pro Info Solian(R), 1999f; Duenas-Laita et al, 1999e; Duenas-Laita et al, 1999e; Prod Info Nipolept(R), 1996 Metzger & Friedman, 1993c; Lande et al, 1992d).
3) Severity: major
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of pentamidine and antipsychotics is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.BO Phenylalanine
1) Interaction Effect: increased incidence of tardive dyskinesia
2) Summary: Taking phenylalanine concomitantly with certain neuroleptic drugs may exacerbate tardive dyskinesia (Gardos et al, 1992a). Abnormal phenylalanine metabolism in certain patients may lead to phenylalanine accumulation in the brain and in turn, reduced brain availability of other large neutral amin acids. This may interfere with the synthesis of catecholamines (Gardos et al, 1992a).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if phenylalanine is administered with a neuroleptic agent. Monitor the patient closely for signs of tardive dyskinesia.
7) Probable Mechanism: reduced brain availability of other large neutral amino acids and interference w catecholamine synthesis
8) Literature Reports
a) Phenylalanine tended to increase the incidence of tardive dyskinesia in patients taking neurolept in an open study. Three groups of patients were studied: (1) patients with unipolar depression with tardive dyskinesia (n=11), (2) patients with no tardive dyskinesia with current or past exposure to greater than or equal to 100 milligrams (mg) of a chlorpromazine equivalent for at least 3 months (n=10), and (3) patients with no tardive dyskinesia not previously exposed to a neuroleptic drug (n=1 Neuroleptic agents were taken during the study by 6 patients in group 1, and 5 patients in group 2. Patients received powdered phenylalanine 100 mg/kilogram dissolved in orange juice after an overnight fast. Blood samples were obtained just prior to phenylalanine administration and 2 hours after administration. Three patients in group 1 (with tardive dyskinesia) had the highest postloading phenylalanine plasma levels, this group as a whole had higher (though nonsignificant) mean phenylalanine levels than the other groups. Tardive dyskinesia score (measured using the Abnorma Involuntary Movements Scale (AIMS)) nonsignificantly increased in group 1. Postloading phenylalar level and postloading AIMS scores were significantly positively correlated in group 1 (rs=0.347, p les than 0.05; Spearman correlation coefficient 0.543, p less than 0.05). Postloading phenylalanine leve and baseline AIMS scores demonstrated a trend toward correlation (rs=0.246, p=0.092; Spearman correlation coefficient 0.679, p less than 0.05). In all patients, phenylalanine loading increased plasn phenylalanine levels approximately eight-fold, and plasma tyrosine increased 2.5 times as a result o conversion of phenylalanine to tyrosine. Plasma levels of competing large neutral amino acids such tryptophan decreased slightly (Gardos et al, 1992).

3.5.1.BP Pimozide
1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal

2003x; Prod Info Haldol(R), 2001m). According to the manufacturer, coadministration of pimozide with drugs that potentially prolong the QTc interval, such as haloperidol, is contraindicated (Prod Info Orap(R) 1999e).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as haloperidol and pimozide, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003w).
b) Seven patients developed torsade de pointes after therapeutic use of haloperidol in high doses. Three patients developed the dysrhythmia after administration of 211 milligrams (mg) to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episode but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol (Metzger & Friedman, 1993k; Wilt et al, 1993i). Torsades de pointes developed in 8 of 223 critically ill patients ir intensive care units. Patients who received intravenous haloperidol greater than 35 mg/day or had a QTc interval prolongation of greater than 500 milliseconds were at greatest risk (Sharma et al, 1998
c) In experimental studies of conditions other than Tourette's Disorder, sudden, unexpected deaths have occurred. The patients were receiving pimozide dosages of approximately 1 mg/kg. One possi mechanism for such deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmia. The manufacturer recommends that an electrocardiogram be performed before pimozid treatment is initiated and periodically thereafter, especially during the period of dose adjustment (Pro Info Orap(R) pimozide, 1999).

3.5.1.BQ Pirmenol
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999z; O'Brien et al, 1999r; Pro Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001z; Duenas-Laita et al, 1999y; Agelin et al, 2001x; Lande et al, 1992z; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increas the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychoti not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT (TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also show an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and ti to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that tissue binding mechanism is more likely responsible for the plasma level changes than an eliminatio

alteration (Young et al, 1993).

3.5.1.BR Prajmaline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999z; O'Brien et al, 1999r; Prc Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001z; Duenas-Laita et al, 1999y; Agelin et al, 2001x; Lande et al, 1992z; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increas the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychoti not recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT (TM) oral tablets, 2009).

b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).

c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also show an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and tir to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that tissue binding mechanism is more likely responsible for the plasma level changes than an eliminatio alteration (Young et al, 1993).

3.5.1.BS Probucol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Even though no formal drug interaction studies have been done, the coadministration of drugs known to prolong the QTc interval is not recommended. Probucol has been shown to prolong the QTc interval (Gohn & Simmons, 1992; Prod Info Lorelco(R), 1991). Antipsychotics including haloperidol (Prod Info Haldol(R), 1998f), quetiapine (Owens, 2001q), risperidone (Prod Info Risperdal(R) risperidone 2000a), amisulpride (Prod Info Solian(R), 1999p), sertindole (Brown & Levin, 1998c); sultopride (Lande e al, 1992p), and zotepine (Sweetman, 2004) have been shown to prolong the QT interval at therapeutic doses.

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Caution is advised if probucol and antipsychotics are used concomitantly.

7) Probable Mechanism: additive effect on QT interval

3.5.1.BT Procainamide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, haloperidol, iloperidone, paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Solian(R), 1999z; O'Brien et al, 1999r; Prc Info INVEGA(TM) extended-release oral tablets, 2006; Owens, 2001z; Duenas-Laita et al, 1999y; Agelin et al, 2001x; Lande et al, 1992z; Prod Info GEODON(R) intramuscular injection, oral capsule, 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and increas the risk of arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended (Prod Info FANAPT(TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychoti not recommended.

7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperidone 12 mg twice a day was associated with QTc prolongation of 9 msec (Prod Info FANAPT (TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide therapy (Prod Info Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antipsychotic agent) were studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. The study demonstrated significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine versus haloperidol treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL on haloperidol alone to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also show an increase from 1.9 ng/mL on haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and tir to peak concentration (Tmax) were not significantly changed, thereby suggesting to the authors that tissue binding mechanism is more likely responsible for the plasma level changes than an eliminatio alteration (Young et al, 1993).

3.5.1.BU Prochlorperazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects o the QT interval and is not recommended. Q and T wave distortions have been observed in patients takin phenothiazines (Prod Info Compazine(R), 2002; Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, though no reports are available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999k), haloperidol (O'Brien et al, 1999g), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001m), risperidone (Duenas-Laita et al, 1999k), sertindole (Agelink e al, 2001j), sultopride (Lande et al, 1992i), ziprasidone (Prod Info GEODON(R) intramuscular injection, or capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phenothiazines and antipsychotics, is not recommended.
7) Probable Mechanism: additive QT prolongation

3.5.1.BV Procyclidine
1) Interaction Effect: excessive anticholinergic effects (sedation, constipation, dry mouth)
2) Summary: Use of haloperidol in combination with anticholinergics may result in excessive anticholinergic effects (Prod Info Haldol(R), 2000). A significant reduction in haloperidol serum levels occurred following the addition of procyclidine in patients who were previously well stabilized. Following discontinuation of procyclidine haloperidol serum levels returned to baseline (Bamrah et al, 1986). In a number of case reports, the use of haloperidol with benztropine, trihexyphenidyl, or procyclidine has resulted in a worsening of schizophrenic symptoms. In addition, when anticholinergics are used with phenothiazines or haloperidol, there may be an increased incidence of tardive dyskinesia (Singh & Kay, 1979; Linnoila et al, 1980).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Use this combination only when clearly indicated. Monitor for excessive anticholinergic effects. A dosage adjustment for haloperidol may be required in order to maintain or achie a therapeutic effect.
7) Probable Mechanism: additive anticholinergic effects

3.5.1.BW Propafenone
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Coadministration of haloperidol with other drugs that potentially prolong the QTc interval, such as propafenone, should be approached with caution. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Owens, 2001f; Prod Info Haldol(R), 1998b; Larochelle et al, 1984).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of haloperidol and propafenone is not recommended due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.BX Propranolol

1) Interaction Effect: an increased risk of hypotension and cardiac arrest

2) Summary: A case report described 3 hypotensive episodes and 2 cardiopulmonary arrests in a patier who received haloperidol and propranolol concomitantly on 3 separate occasions. Alpha-receptor bindin by haloperidol and an additive relaxant effect on peripheral blood vessels by haloperidol and propranolol possibly blunting sympathetic heart stimulation is a postulated mechanism for this interaction. The autho advise caution in coadministering haloperidol and propranolol or other beta blockers (Alexander et al, 1984). Monitoring the patient for signs of hypotension is warranted.

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Concomitant use of haloperidol and propranolol may increase the risk of hypotension and cardiac arrest. Caution is advised when coadministering haloperidol and propranolol or other beta blockers (Prod Info INDERAL(R) LA oral capsules, 2007; Alexander et al, 1984). Monitor the patient for signs of hypotension.

7) Probable Mechanism: unknown

8) Literature Reports

a) A case report described 3 hypotensive episodes and 2 cardiopulmonary arrests with concomitan haloperidol and propranolol use in a 48-year-old woman with schizophrenia and hypertension. Two years after starting haloperidol 20 mg/day and trichlormethiazide 4 mg/day, the patient was admitte with psychosis due to discontinuing haloperidol. Her blood pressure (BP) was 205/100 mmHg. Propranolol 80 mg was initiated followed by haloperidol 10 mg nine hours later. Ninety minutes later she was unresponsive with shallow breathing and a BP of 80/0 mmHg. The patient recovered and w discharged with haloperidol 30 mg/day and trichlormethiazide 4 mg/day. Ten months later, the patie was admitted with agitation after stopping her medicine. Haloperidol 10 mg was administered. Ten hours later, she was given haloperidol 10 mg and propranolol 40 mg. Hypotension and cardiopulmonary arrest occurred 2.5 hours later. She was discharged the next day with loxapine 25 mg/day, trichlormethiazide 4 mg/day, and propranolol 80 mg twice per day. Five months later, the patient presented with acute psychosis and a BP of 210/110 mmHg. Because her chart could not be located to assess prior treatment, she was given propranolol 80 mg and 15 minutes later, haloperido 10 mg. Hypotension and cardiac arrest occurred 30 minutes later. After discharge, she continued to successfully maintained on trichlormethiazide 4 mg/day, propranolol 80 mg twice daily, and loxapine 30 mg/day. A postulated mechanism is alpha-receptor binding by haloperidol and an additive relaxa effect on peripheral blood vessels by haloperidol and propranolol that may blunt sympathetic heart stimulation (Alexander et al, 1984).

3.5.1.BY Protriptyline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministratio a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsh & Forker, 1982).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychoti not recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.BZ Quetiapine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003h; Prod Info Haldol(R), 2001e). Quetiapine may prolong the QT interval at therapeutic and toxic dos Coadministration of haloperidol 7.5 mg twice daily with quetiapine 300 mg twice daily did not alter the steady-state pharmacokinetics of quetiapine (Prod Info Seroquel(R), 2003). Caution is advised with

coadministration of drugs that potentially prolong the QTc interval.
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Caution is advised if haloperidol and quetiapine are used concomitantly. Scree patients for conditions that may predispose to QT prolongation and torsade de pointes (i.e. cardiomyopathy, alcohol abuse, hypothyroidism). Monitor the ECG and electrolytes at baseline and throughout therapy.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, though TdP has been associated with a dose low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, screen patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003g).

3.5.1.CA Quinupristin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Quinupristin/dalfopristin is a major inhibitor of cytochrome P450 3A4 (CYP3A4) isoenzyme and haloperidol is a CYP3A4 substrate. Coadministration of these two agents may likely result in increas plasma concentrations of haloperidol, which may lead to QTc interval prolongation and risk of torsades d pointes (Prod Info SYNERCID(R) intravenous injection, 2003; Prod Info Haldol(R) Injection, 2001).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of quinupristin/dalfopristin and haloperidol shoul be avoided. Monitor ECG if used concomitantly.
7) Probable Mechanism: inhibition of cytochrome P450 3A4-mediated haloperidol metabolism

3.5.1.CB Rifampin
1) Interaction Effect: decreased haloperidol effectiveness
2) Summary: Haloperidol blood levels and half-life were examined in 7 patients treated concurrently with haloperidol and rifampin(Takeda et al, 1986). Blood levels and half-lives of haloperidol were significantly decreased compared to controls.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor the patient for a decreased clinical response to haloperidol when rifam is added to the drug therapy. The haloperidol dose may need to be increased while receiving rifampin ar decreased when rifampin is discontinued.
7) Probable Mechanism: increased hepatic metabolism

3.5.1.CC Rifapentine
1) Interaction Effect: decreased haloperidol effectiveness
2) Summary: Rifapentine is known to induce hepatic enzymes involved in the metabolism of haloperidol When haloperidol and rifapentine are administered together, it may be necessary to increase the dose o haloperidol used (Prod Info Priftin(R), 2000).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor the patient for a decreased clinical response to haloperidol when rifapentine is added to the drug therapy. The haloperidol dose may need to be increased while receiving rifapentine and decreased when rifapentine is discontinued.
7) Probable Mechanism: increased hepatic metabolism

3.5.1.CD Risperidone
1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003j; Prod Info Haldol(R), 2001f). Sometimes fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone therapeutically (Duenas-Laita et al, 1999o; Ravin & Levenson,

1997d; Gesell & Stephen, 1997a) and in overdose situations (Lo Vecchio et al, 1996a; Brown et al, 1993
Caution is advised with coadministration of drugs that potentially prolong the QTc interval.
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if haloperidol and risperidone are used concomitantly. Scree
patients for conditions that may predispose to QT prolongation and torsade de pointes (i.e.
cardiomyopathy, alcohol abuse, hypothyroidism). Monitor the ECG and electrolytes at baseline and
throughout therapy.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Sometimes fatal QRS prolongation and QTc prolongation have been reported in patients taking
risperidone therapeutically (Duenas-Laita et al, 1999n; Ravin & Levenson, 1997c; Gesell & Stephen
1997) and in overdose situations (Lo Vecchio et al, 1996; Brown et al, 1993).
b) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc
associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular
fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with
intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with
doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos
as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre
patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before
therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring
potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds
(msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue
haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or
development of U-waves occurs (Hassaballa & Balk, 2003i).

3.5.1.CE Sematilide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac
arrest)
2) Summary: Concurrent use of sematilide and haloperidol is not recommended due to the risk of additiv
effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitorin
is advised (Yamreudeewong et al, 2003a).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of sematilide and haloperidol is not recommende
due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio
dosing and telemetric monitoring is advised.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in
ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents
have demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant use o
Class III antiarrhythmic agents such as sematilide and haloperidol may have additive effects on the
interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.CF Sertindole
1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal
2003r; Prod Info Haldol(R), 2001j). Sertindole has demonstrated QTc prolongation (Agelink et al, 2001t;
Brown & Levin, 1998e; Cardoni & Myer, 1997b). Caution is advised with coadministration of drugs that
potentially prolong the QTc interval.
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if haloperidol and sertindole are used concomitantly. Screer
patients for conditions that may predispose to QT prolongation and torsade de pointes (i.e.
cardiomyopathy, alcohol abuse, hypothyroidism). Monitor the ECG and electrolytes at baseline and
throughout therapy.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Seven patients developed torsade de pointes after therapeutic use of haloperidol in high doses.
Three patients developed the dysrhythmia after administration of 211 milligrams (mg) to 825 mg
haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episode
but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol (Metzger &
Friedman, 1993i; Wilt et al, 1993g). Torsades de pointes developed in 8 of 223 critically ill patients ir
intensive care units. Patients who received intravenous haloperidol greater than 35 mg/day or had a

QTc interval prolongation of greater than 500 milliseconds were at greatest risk (Sharma et al, 1998

b) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003q).

c) The overall incidence of QT interval prolongation with sertindole is estimated at 1.9% to 4%, and the potential risk of developing torsade de pointes has been estimated at 0.13% to 0.21% (Brown & Levin, 1998d). Periodic electrocardiographic monitoring is required in the United Kingdom per sertindole's official labeling (Cardoni & Myer, 1997a).

d) Thirty, otherwise healthy, schizophrenic patients participated in an open, dose titration (4 to 16 mg/day) study to determine the cardiovascular effects of sertindole. At the end of the 3-week study i was concluded that resting heart rate and frequency corrected QT intervals increased in a dose-rela manner, while there was no change in PQ-conduction times, autonomic parasympathetic tone, or blood pressure. Conduction times increased an average 3.5% to 6.5% over the dosing range (Agelir et al, 2001s).

3.5.1.CG Sotalol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Concurrent use of sotalol and haloperidol is not recommended due to the risk of additive effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitorin is advised (Yamreudeewong et al, 2003a).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of sotalol and haloperidol is not recommended d to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant use o Class III antiarrhythmic agents such as sotalol and haloperidol may have additive effects on the QT interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.CH Sparfloxacin

1) Interaction Effect: prolongation of the QTc interval and/or torsades de pointes

2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003v; Prod Info Haldol(R), 2001l). Coadministration of sparfloxacin with drugs that potentially prolong th QTc interval, such as haloperidol, is contraindicated (Prod Info Zagam(R), 1998a).

3) Severity: contraindicated

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of sparfloxacin with agents that prolong the QT interval, such as haloperidol, is contraindicated.

7) Probable Mechanism: additive effects on QTc prolongation

8) Literature Reports

a) In clinical trials involving 1489 patients with a baseline QTc measurement, the mean prolongation the QTc interval at sparfloxacin steady-state was 10 msec (2.5%). Of these subjects, 0.7% had a QT interval greater than 500 msec at steady-state. However, no arrhythmic effects were seen in any of t patients. The magnitude of the QTc effect does not increase with repeated administration of sparfloxacin, and the QTc interval returns to baseline within 48 hours after discontinuation of sparfloxacin (Prod Info Zagam(R), 1998).

b) A 47-year-old woman treated with sparfloxacin went into cardiac arrest as a result of torsade de pointes and required cardiopulmonary resuscitation. dizziness and lost consciousness. Her pre-treatment electrocardiogram showed QT and QTc intervals of 0.34 and 0.46 seconds, respectively. A electrocardiogram post-arrest revealed QT and QTc intervals of 0.35 and 0.60 seconds, respectively Continuous electrocardiography confirmed numerous episodes of torsade de pointes. Sparfloxacin w discontinued and the QTc returned to baseline within a week. Upon further testing, it was determine

that the patient suffered from a mild idiopathic long QT syndrome. Due to the onset of symptoms wit administration of sparfloxacin and the relief of symptoms following discontinuation of the drug, it is highly probable that sparfloxacin contributed to the torsades de pointes (Dupont et al, 1996).
c) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003u).

3.5.1.CI Spiramycin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Spiramycin has been shown to prolong the QTc interval at the recommended therapeutic dose (Stramba-Badiale et al, 1997). Even though no formal drug interaction studies have been done, the coadministration of antipsychotics and other drugs known to prolong the QTc interval, including spiramyc is not recommended. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999v), haloperidol (O'Brien et al, 1999o), quetiapine (Owens, 2001w), risperidone (Duenas-Laita et al, 1999u), sertindole (Agelink et al, 2001r), sultopride (Lande et al, 1992v), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of spiramycin and antipsychotics is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.CJ Sulfamethoxazole

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Cotrimoxazole has been shown to prolong the QTc interval at the recommended therapeu dose (Lopez et al, 1987). Even though no formal drug interaction studies have been done, the coadministration of antipsychotics and other drugs known to prolong the QTc interval, including cotrimoxazole, is not recommended. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999h), haloperidol (O'Brien et al, 1999e), quetiapine (Owens 2001i), risperidone (Duenas-Laita et al, 1999g), sertindole (Agelink et al, 2001f), sultopride (Lande et al, 1992e), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of cotrimoxazole and antipsychotics is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.CK Sultopride

1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003l; Prod Info Haldol(R), 2001g). Sultopride may induce prolongation of the QT interval and ventricula arrhythmias including torsades de pointes following therapeutic or toxic doses (Harry, 1997b; Lande et a 1992n; Montaz et al, 1992a). Caution is advised with coadministration of drugs that potentially prolong th QTc interval.
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Caution is advised if haloperidol and sultopride are used concomitantly. Screer patients for conditions that may predispose to QT prolongation and torsade de pointes (i.e. cardiomyopathy, alcohol abuse, hypothyroidism). Monitor the ECG and electrolytes at baseline and throughout therapy.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) Seven patients developed torsade de pointes after therapeutic use of haloperidol in high doses. Three patients developed the dysrhythmia after administration of 211 milligrams (mg) to 825 mg

haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episode but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol (Metzger & Friedman, 1993h; Wilt et al, 1993f). Torsades de pointes developed in 8 of 223 critically ill patients i intensive care units. Patients who received intravenous haloperidol greater than 35 mg/day or had a QTc interval prolongation of greater than 500 milliseconds were at greatest risk (Sharma et al, 1998

b) Numerous case reports have described significant QTc prolongation and torsades de pointes (T associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003k).

c) Sultopride may induce prolongation of the QT interval and ventricular arrhythmias including torsades de pointes following therapeutic or toxic doses (Harry, 1997a; Lande et al, 1992m; Montaz al, 1992).

3.5.1.CL Tacrine

1) Interaction Effect: Parkinsonian syndrome (akinesia, shuffling gait, masked facies, slurred speech, lea pipe rigidity, cogwheel signs)

2) Summary: Parkinsonian syndrome with concomitant use of tacrine and haloperidol has been reportec two separate case reports. Both patients were able to tolerate one of the drugs when the other was discontinued. Both of these drugs increase acetylcholine activity in the striatal region of the brain, which may have caused the effects observed (McSwain & Forman, 1995a; Maany, 1996a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Patients should be closely monitored for signs of a Parkinsonian syndrome wh being treated with haloperidol and tacrine. Discontinuation of one agent may be required.

7) Probable Mechanism: increased striatal acetylcholine activity

8) Literature Reports

a) The first case report of tacrine and haloperidol resulting in a parkinsonian syndrome was in an 87 year old male (McSwain & Forman, 1995). Haloperidol doses of 5 mg daily were being administered for agitation and paranoia. When tacrine 10 mg four times daily was added to his regimen, he developed severe parkinsonian symptoms within 72 hours, including akinesia, masked facies, shuffl gait, and lead-pipe rigidity. When both tacrine and haloperidol were discontinued, the symptoms resolved within approximately eight hours. Haloperidol was successfully reinitiated at a dose of 4 mg daily without recurrence of the parkinsonian syndrome.

b) A 72-year old female with agitated paranoid psychosis became controlled on haloperidol 10 mg daily without undue side effects, including extrapyramidal syndrome. When tacrine 10 mg four times daily was added to her regimen for dementia, she developed a disabling parkinsonian syndrome wit a week. Symptoms included severe akinesia, shuffling gait, masked facies, slurred speech, and pronounced rigidity and cogwheel signs. The haloperidol regimen was tapered off and replaced with risperidone 1 mg twice daily, with resolution of the parkinsonian syndrome within a few days. She di not experience further extrapyramidal signs, even after the tacrine dose was increased to 20 mg fou times daily (Maany, 1996).

3.5.1.CM Tedisamil

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Concurrent use of tedisamil and haloperidol is not recommended due to the risk of additive effects on the QT interval. If concurrent use cannot be avoided, cautious dosing and telemetric monitorin is advised (Yamreudeewong et al, 2003a).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of haloperidol and tedisamil is not recommende due to the potential for inducing life-threatening arrhythmias. If concurrent use cannot be avoided, cautio dosing and telemetric monitoring is advised.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventricular tachycardia, ventricular fibrillation, and torsades de pointes. Several antipsychotic agents have demonstrated QT prolongation including haloperidol (O'Brien et al, 1999a). Concomitant use o

Class III antiarrhythmic agents such as tedisamil and haloperidol may have additive effects on the C interval and is not recommended (Yamreudeewong et al, 2003).

3.5.1.CN Telithromycin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Some antipsychotic agents prolong the QT interval and an additive effect would be anticipated if administered with other agents which lengthen the QT interval (Agelink et al, 2001g; Owens 2001j; Prod Info Haldol(R), 1998c; Lande et al, 1992f). Even though no formal drug interaction studies ha been done, antipsychotic agents should not be coadministered with other drugs which are also known to prolong the QTc interval, including telithromycin (Owens, 2001j).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Due to the potential for additive effects on the QT interval, the concurrent administration of telithromycin and an antipsychotic is not recommended.

7) Probable Mechanism: additive effect on QT interval

8) Literature Reports

a) Fatal QRS prolongation and QTc prolongation have been reported in patients taking risperidone therapeutically (Duenas-Laita et al, 1999h; Ravin & Levenson, 1997a).

3.5.1.CO Terfenadine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Some antipsychotics have been shown to prolong the QTc interval at the recommended therapeutic dose (Prod Info Geodon(TM), 2002a; Owens, 2001ab; Prod Info Orap(R), 1999d). Even thou no formal drug interaction studies have been done, the coadministration of terfenadine and other drugs known to prolong the QTc interval, including antipsychotics, is contraindicated (Anon, 1997).

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of terfenadine with any drug that prolongs the Q interval, such as antipsychotic agents, is contraindicated.

7) Probable Mechanism: additive effect on QT interval

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999c).

3.5.1.CP Tetrabenazine

1) Interaction Effect: increased risk of QT interval prolongation, neuroleptic malignant syndrome, extrapyramidal disorders

2) Summary: Tetrabenazine causes a small increase in the correct QT interval. As the degree of prolongation increases, QT prolongation can develop into torsade de pointes-type VT. The concomitant u of tetrabenazine with other drugs known for QT prolongation (eg, haloperidol) should be avoided. In a randomized, double-blind, placebo controlled crossover study of healthy subjects, the effect of a single 2 mg or 50 mg dose of tetrabenazine on the QT interval was studied with moxifloxacin as a positive contro The 50 mg dose of tetrabenazine caused an approximate 8 millisecond mean increase in QT (Prod Info XENAZINE(R) oral tablets, 2008). In addition to QT prolongation, tetrabenazine may also cause adverse reactions such as neuroleptic malignant syndrome and extrapyramidal disorders, which may be exaggerated when coadministered with neuroleptic drugs (eg, haloperidol) (Prod Info XENAZINE(R) oral tablets, 2008)

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Coadministration of tetrabenazine with haloperidol or other neuroleptic drugs m increase tetrabenazine adverse reactions, such as QT interval prolongation and increased risk of torsade de pointes. Other adverse reactions, such as neuroleptic malignant syndrome and extrapyramidal disord may be enhanced when given with a dopamine agonist such as haloperidol (Prod Info XENAZINE(R) ora tablets, 2008).

7) Probable Mechanism: increased dopamine levels; additive effects on QT interval prolongation

3.5.1.CQ Thioridazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Although citing no data, the manufacturer of thioridazine states that concomitant use with other drugs which prolong the QT interval is contraindicated (Prod Info Mellaril(R), 2001). Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999q), haloperidol (O'Brien et al, 1999k), pimozide (Prod Info Orap(R), 2000), quetiapine (Owens, 2001 paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), risperidone (Duenas-Laita et 1999q), sertindole (Agelink et al, 2001n), sultopride (Lande et al, 1992q), ziprasidone (Prod Info GEODC (R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2004).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as antipsychotics, and thioridazine, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.CR Tramadol
1) Interaction Effect: an increased risk of seizures
2) Summary: Seizures have been reported in patients using tramadol. The manufacturer of tramadol sta that combining neuroleptic medications with tramadol may enhance the risk of seizures (Prod Info Ultran (R), 1998).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Caution should be used if tramadol is to be administered to patients receiving neuroleptic therapy. If possible, avoid this combination, especially in patients with underlying conditions t might predispose to seizures.
7) Probable Mechanism: unknown

3.5.1.CS Trifluoperazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects o the QT interval and is not recommended. Q and T wave distortions have been observed in patients takin phenothiazines (Prod Info Compazine(R), 2002; Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, though no reports are available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999k), haloperidol (O'Brien et al, 1999g), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001m), risperidone (Duenas-Laita et al, 1999k), sertindole (Agelink e al, 2001j), sultopride (Lande et al, 1992i), ziprasidone (Prod Info GEODON(R) intramuscular injection, or capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phenothiazines and antipsychotics, is not recommended.
7) Probable Mechanism: additive QT prolongation

3.5.1.CT Trihexyphenidyl
1) Interaction Effect: excessive anticholinergic effects (sedation, constipation, dry mouth)
2) Summary: Use of haloperidol in combination with anticholinergics may result in additive anticholinergi effects (Prod Info Haldol(R), 2000b). In a number of case reports, the use of haloperidol with benztropine trihexyphenidyl, or procyclidine has resulted in a worsening of schizophrenic symptoms. In addition, whe anticholinergics are used with phenothiazines or haloperidol, there may be increased incidence of tardive dyskinesia (Singh & Kay, 1979b; Linnoila et al, 1980b).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Use this combination only when clearly indicated. Monitor for excessive anticholinergic effects. Dosage adjustments may be required.
7) Probable Mechanism: additive anticholinergic effects

3.5.1.CU Trimethoprim
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Cotrimoxazole has been shown to prolong the QTc interval at the recommended therapeu dose (Lopez et al, 1987). Even though no formal drug interaction studies have been done, the coadministration of antipsychotics and other drugs known to prolong the QTc interval, including cotrimoxazole, is not recommended. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999h), haloperidol (O'Brien et al, 1999e), quetiapine (Owens

2001i), risperidone (Duenas-Laita et al, 1999g), sertindole (Agelink et al, 2001f), sultopride (Lande et al, 1992e), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of cotrimoxazole and antipsychotics is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.CV Trimipramine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info Solian(R), 1999b), haloperidol (O'Brien et al, 1999b), risperidone (Duenas-Laita et al, 1999b), sertindole (Agelink et al, 2001a), quetiapine (Owens, 2001b), sultopride (Lande et al, 1992a), and zotepi (Sweetman, 2003). Even though no formal drug interaction studies have been done, the coadministratio a tricyclic antidepressant and an antipsychotic is not recommended (Prod Info Pamelor(R), 2001; Marsh & Forker, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychoti not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have include prolongation of the corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. In experimental studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 mg/kg. The proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmias (Prod Info Orap(R), 1999).

3.5.1.CW Vasopressin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Antipsychotics and vasopressin have been shown to prolong the QTc interval at the recommended therapeutic dose (Owens, 2001a; Prod Info Solian(R), 1999a; Duenas-Laita et al, 1999a; Brown & Levin, 1998; Harry, 1997; Prod Info Nipolept(R), 1996; Metzger & Friedman, 1993; Mauro et al, 1988). Even though no formal drug interaction studies have been done, the coadministration of drugs known to prolong the QTc interval is not recommended.
3) Severity: major
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of drugs that prolong the QT interval, such as antipsychotics and vasopressin, is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.CX Venlafaxine
1) Interaction Effect: increased haloperidol serum concentrations and an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Venlafaxine may inhibit haloperidol metabolism (Prod Info Effexor(R) XR, 2003a). Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Balk, 2003p; Proc Info Haldol(R), 2001i). Venlafaxine has been shown to prolong the QTc interval at the recommended therapeutic dose (Prod Info Effexor(R) XR, 2003a). Concomitant use is not recommended.
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: The concurrent administration of haloperidol and venlafaxine is not recommended.
7) Probable Mechanism: decreased haloperidol metabolism; theoretical additive effect on QT prolongati
8) Literature Reports
a) Under steady-state conditions, venlafaxine 150 mg daily decreased the total oral clearance of a single 2 mg dose of haloperidol by 42% in 24 healthy subjects. This resulted in a 70% increase in th haloperidol area under the concentration-time curve (AUC). The haloperidol maximum concentratio (Cmax) was increased by 88% when venlafaxine was coadministered, but the elimination half-life of haloperidol was not affected. The mechanism behind this interaction is not known (Prod Info Effexor XR, 2003).
b) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc

associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003o).

3.5.1.CY Vitex

1) Interaction Effect: decreased effectiveness of dopamine antagonists

2) Summary: Theoretically, the dopamine agonist activity of Vitex may oppose that of dopamine antagonists, decreasing their effectiveness. Vitex has been effective in alleviating luteal phase defects du to hyperprolactinemia and in relieving symptoms related to premenstrual tension syndrome (Milewicz et a 1993a; Lauritzen et al, 1997a). Vitex reduced prolactin secretion in humans (Milewicz et al, 1993a). In vit Vitex inhibited prolactin release by binding to the D2 receptor (Jarry et al, 1994a).

3) Severity: minor

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: If therapy is initiated with Vitex and a dopamine antagonist, monitor closely for return of symptoms previously controlled by the dopamine antagonist.

7) Probable Mechanism: dopamine agonism of Vitex may counteract dopamine antagonists

8) Literature Reports

a) Vitex agnus castus (Vitex) effectively normalized prolactin release in a randomized double-blind, placebo-controlled trial of 52 women with luteal phase defects due to latent hyperprolactinemia. Administration of Vitex agnus castus 20 mg daily for three months reduced prolactin release (from 2 to 22.5 nanogram (ng)/mL; p equal to 0.23), normalized shortened luteal phases (from 5.5 days to 1 days; p less than 0.005), and eliminated deficits in luteal progesterone synthesis (from 2.46 ng/mL t 9.69 ng/mL; p less than 0.001). No side effects were noted (Milewicz et al, 1993).

b) Vitex agnus castus and pyridoxine caused a similar reduction on the premenstrual tension scale (PMTS) in a randomized, controlled trial of 127 women with PMTS. Patients taking Vitex agnus cast (Agnolyt(R)) experienced more relief from breast tenderness, inner tension, headache, edema, constipation, and depression than those taking pyridoxine. Patients in the Vitex agnus castus group receive one capsule of Agnolyt(R) and one placebo capsule daily for 3 menstrual cycles. Patients in the pyridoxine group received one placebo capsule twice daily on days 1-15 of the menstrual cycle a pyridoxine 100 mg twice daily on days 16 to 35 of the menstrual cycle for 3 menstrual cycles. Unspecified gastrointestinal disturbances occurred in the treatment group along with two cases of sk reaction and one transient headache (Lauritzen et al, 1997).

c) In vitro, Vitex (Agnus castus) was found to bind to the D2 receptor in rat pituitary cell cultures. Ba prolactin release was significantly inhibited by 0.5 milligram (mg) and 1 mg of vitex extract/mL cultur medium (p less than 0.05). Agnus castus extract doses from 0.125 mg/mL to 1 mg/mL significantly suppressed prolactin release in cells stimulated by thyrothropin releasing hormone (TRH) (p less tha 0.05). Dopaminergic action was demonstrated in the rat corpus striatum membrane dopamine recep assay. Agnus castus extract did not affect basal luteinizing hormone (LH) or follicle-stimulating hormone (FSH), indicating selectivity for prolactin secretion, and not generalized inhibition of pituitar hormone secretion. The effect was not due to a cytotoxic effect as demonstrated by the lack of effec on the MTT-conversion test. The authors concluded that Agnus castus exerted its prolactin inhibiting effect via stimulation of D2 receptors in the pituitary (Jarry et al, 1994).

3.5.1.CZ Ziprasidone

1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003e; Prod Info Haldol(R), 2001c). Coadministration of ziprasidone with drugs that potentially prolong th QTc interval, such as haloperidol, is contraindicated (Prod Info Geodon(R), 2002a).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of ziprasidone with agents that prolong the QT interval, such as haloperidol, is contraindicated.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Seven patients developed torsade de pointes after therapeutic use of haloperidol in high doses. Three patients developed the dysrhythmia after administration of 211 milligrams (mg) to 825 mg haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episode but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol (Metzger &

Friedman, 1993d; Wilt et al, 1993b). Torsades de pointes developed in 8 of 223 critically ill patients i intensive care units. Patients who received intravenous haloperidol greater than 35 mg/day or had a QTc interval prolongation of greater than 500 milliseconds were at greatest risk (Sharma et al, 1998

b) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003d).

c) It has been shown that ziprasidone prolongs the QTc and that this represents a risk of potentially fatal ventricular dysrhythmias ((Anon, 2000)). QT prolongation is dose-related. It is not yet known whether ziprasidone will cause torsades de pointes or increase the rate of sudden death. In clinical trials ziprasidone increased the QTc interval, compared to placebo, by approximately 10 millisecond (msec) at the highest dose (160 milligrams). Baseline QTc interval increased 9 to 14 msec more wit ziprasidone than with risperidone, olanzapine, quetiapine, and haloperidol, but QTc interval was 14 msec less than that observed with thioridazine (Prod Info Geodon(R), 2002).

3.5.1.DA Zolmitriptan

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Zolmitriptan has been shown to prolong the QTc interval at the recommended therapeutic dose (Prod Info Zomig(R), 2001). Antipsychotics including haloperidol (Prod Info Haldol(R), 1998h), quetiapine (Owens, 2001y), risperidone (Prod Info Risperdal(R) risperidone, 2000c), amisulpride (Prod In Solian(R), 1999y), sertindole (Agelink et al, 2001w); sultopride (Lande et al, 1992y), and zotepine (Sweetman, 2004) have been shown to prolong the QT interval at therapeutic doses. Even though no formal drug interaction studies have been done, the coadministration of drugs known to prolong the QT interval is not recommended.

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of zolmitriptan and antipsychotics is not recommended.

7) Probable Mechanism: additive effect on QT interval

3.5.1.DB Zotepine

1) Interaction Effect: increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arres

2) Summary: Haloperidol is associated with QTc prolongation and torsade de pointes (Hassaballa & Bal 2003t; Prod Info Haldol(R), 2001k). Zotepine may cause QT prolongation (Sweetman, 2003). Caution is advised with coadministration of drugs that potentially prolong the QTc interval.

3) Severity: major

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Caution is advised if haloperidol and zotepine are used concomitantly. Screen patients for conditions that may predispose to QT prolongation and torsade de pointes (i.e. cardiomyopathy, alcohol abuse, hypothyroidism). Monitor the ECG and electrolytes at baseline and throughout therapy.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Numerous case reports have described significant QTc prolongation and torsades de pointes (Tc associated with haloperidol. Hemodynamically significant ventricular tachyarrhythmias, ventricular fibrillation, asystole, and death have been reported. The risk of TdP appears to be greater with intravenous haloperidol, but has occurred with oral and intramuscular use. The risk increases with doses greater than 35 milligrams (mg) over 24 hours, although TdP has been associated with a dos as low as 10 mg administered intravenously over 4 hours. To prevent haloperidol-induced TdP, scre patients for a history of dilated cardiomyopathy or alcohol abuse, testing for hypothyroidism before therapy, obtaining an electrocardiogram at baseline and throughout therapy, and monitoring potassium, magnesium, and calcium. In patients with a baseline QTc greater than 450 milliseconds (msec), haloperidol should be used cautiously or an alternative agent should be used. Discontinue haloperidol if the QTc increases more than 25% from baseline or if flattening of T-waves or development of U-waves occurs (Hassaballa & Balk, 2003s).

b) Seven patients developed torsade de pointes after therapeutic use of haloperidol in high doses. Three patients developed the dysrhythmia after administration of 211 milligrams (mg) to 825 mg

haloperidol over 1 to 2 days for agitated delirium. These 3 patients recovered from the initial episode but 1 patient subsequently died of cardiac arrest upon readministration of haloperidol (Metzger & Friedman, 1993j; Wilt et al, 1993h). Torsades de pointes developed in 8 of 223 critically ill patients in intensive care units. Patients who received intravenous haloperidol greater than 35 mg/day or had a QTc interval prolongation of greater than 500 milliseconds were at greatest risk (Sharma et al, 1998
c) Since zotepine can prolong the QT interval it is recommended that an ECG is performed before starting treatment. Patients with pre-existing prolongation of the QT interval should not be given zotepine (Sweetman, 2003).

3.5.5 Intravenous Admixtures

Drugs

Solutions

3.5.5.1 Drugs

Haloperidol

Haloperidol Lactate

3.5.5.1.A Haloperidol

Amitriptyline

Amsacrine

Benztropine

Biperiden

Buprenorphine

Chlorpromazine

Cimetidine

Diacetylmorphine

Diazepam

Dobutamine

Dopamine

Famotidine

Filgrastim

Fluconazole

Fludarabine

Fluphenazine

Foscarnet

Heparin Sodium

Imipramine

Lidocaine

Lorazepam

Mesoridazine

Nitroglycerin

Nitroprusside

Norepinephrine

Ondansetron

Paclitaxel

Phenylephrine

Prochlorperazine

Sargramostim

Tacrolimus

Theophylline

Trifluoperazine

3.5.5.1.A.1 Amitriptyline

a) Compatible

1) Amitriptyline in a 1:1 or 3:1 mixture with haloperidol, visually compatible with no decreas in haloperidol concentration in 4 hours at room temperature; drug concentrations not specif (Pers Comm, 1990)

3.5.5.1.A.2 Amsacrine

a) Compatible

1) Amsacrine 1 mg/mL with haloperidol 0.2 mg/mL visually compatible in Dextrose 5% in water for a 4-hour study period at room temperature under fluorescent lighting (Trissel et al 1990)

3.5.5.1.A.3 Benztropine

a) Incompatible

1) Benztropine in a 1:1 or 2:1 mixture with haloperidol, precipitate formation reported in 1 hour at room temperature and 53% haloperidol decomposition reported in 4 hours; drug concentrations not specified (Pers Comm, 1990)

3.5.5.1.A.4 Biperiden

a) Compatible

1) Biperiden in a 1:1 mixture with haloperidol, visually compatible with no decrease in haloperidol concentration in 4 hours at room temperature; drug concentrations not specifie (Pers Comm, 1990)

3.5.5.1.A.5 Buprenorphine

a) Compatible

1) Buprenorphine in a 1:1 volume ratio with haloperidol, physically and chemically compati for up to 7 hours at room temperature (Pers Comm, 1990)

3.5.5.1.A.6 Chlorpromazine

a) Conflicting Data

1) Incompatible

a) Chlorpromazine in a 2:1 mixture with haloperidol, visually compatible for 4 hours at room temperature, but 44% decrease in haloperidol concentration reported (Pers Com 1990); however, chlorpromazine in a 1:1 mixture with haloperidol, visually compatible with no decrease in haloperidol concentration in 4 hours at room temperature; drug concentrations not specified (Pers Comm, 1990)

2) Compatible

a) Chlorpromazine in a 1:1 mixture with haloperidol, visually compatible with no decrease in haloperidol concentration in 4 hours at room temperature; drug concentrations not specified (Pers Comm, 1990)

b) Chlorpromazine in a 2:1 mixture with haloperidol, visually compatible for 4 hours at room temperature, but 44% decrease in haloperidol concentration reported (Pers Com 1990)

3.5.5.1.A.7 Cimetidine

a) Compatible

1) Cimetidine 6 mg/mL with haloperidol 5 or 0.5 mg/mL visually compatible in Dextrose 5% water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991b)

3.5.5.1.A.8 Diacetylmorphine

a) Conflicting Data

1) Incompatible

a) Diacetylmorphine in high concentration incompatible with haloperidol; drug concentrations and conditions not specified (Allwood, 1991)

2) Compatible

a) Diacetylmorphine (up to 1 g with haloperidol 7.5 mg compatible in a 10-mL syringe; conditions not specified) (Allwood, 1991a)

3.5.5.1.A.9 Diazepam

a) Incompatible

1) Diazepam in a 1:1 or 2:1 mixture with haloperidol, precipitate formation reported within 2 hours at room temperature; drug concentrations not specified (Pers Comm, 1990)

3.5.5.1.A.10 Dobutamine

a) Compatible

1) Dobutamine 4 mg/mL with haloperidol 5 or 0.5 mg/mL visually compatible in Dextrose 5 in water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991e)

3.5.5.1.A.11 Dopamine

a) Compatible

1) Dopamine 1.6 mg/mL with haloperidol 5 or 0.5 mg/mL visually compatible in Dextrose 5 in water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991a)

3.5.5.1.A.12 Famotidine

a) Compatible

1) Famotidine 0.267 mg/mL with haloperidol 5 or 0.5 mg/mL visually compatible in Dextros 5% in water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991g)

3.5.5.1.A.13 Filgrastim

a) Compatible

1) Filgrastim 30 mcg/mL in Dextrose 5% in water with haloperidol 0.2 mg/mL in Dextrose 5 in water, compatible for up to 4 hours at 22 degrees C (Trissel & Martinez, 1994)

3.5.5.1.A.14 Fluconazole

a) Incompatible

1) Fluconazole 2 milligrams/milliliter (mg/mL) with haloperidol 5 mg/mL, visually incompatil delayed precipitation reported (Lor et al, 1991)

3.5.5.1.A.15 Fludarabine

a) Compatible

1) Fludarabine 1 mg/mL with haloperidol 0.2 mg/mL, both in Dextrose 5% in water, visually compatible for a 4-hour study period at room temperature under fluorescent light (Trissel et 1991a)

3.5.5.1.A.16 Fluphenazine

a) Incompatible

1) Fluphenazine in a 1:1 mixture with haloperidol, immediate precipitate formation reported with 65% haloperidol decomposition in 4 hours at room temperature; drug concentrations n specified (Pers Comm, 1990)

3.5.5.1.A.17 Foscarnet

a) Incompatible

1) Foscarnet 24 mg/mL with haloperidol 5 mg/mL, delayed formation of a fine white precipitated reported (Lor & Takagi, 1990)

3.5.5.1.A.18 Heparin Sodium

a) Incompatible

1) Heparin sodium 100 or 200 U/mL in a Dextrose 5% in water or Sodium chloride 0.9% infusion running at 1000 U/hr, with haloperidol 5 mg/1 mL injected over 1 minute, formation a white precipitate reported immediately; the authors recommend that heparin infusions be stopped and the line flushed with Dextrose 5% in water or Sodium chloride 0.9% before an after the injection of haloperidol and that a similar flushing procedure be followed for administration of haloperidol through a heparin lock (Solomon & Nasinnyk, 1982)

2) Heparin sodium 50 U/mL in a Sodium chloride 0.9% infusion running at 1 mL/min with haloperidol 5 mg/1 mL given over 3 minutes, formation of white turbidity reported (Trissel, 1990)

3) Heparin sodium 2500 U/1 mL with haloperidol 5 mg/1 mL, turbidity or precipitate formati reported within 5 minutes in syringe (Trissel, 1990)

3.5.5.1.A.19 Imipramine

a) Conflicting Data

1) Incompatible

a) Haloperidol in a 1:1 or 1:2 mixture with imipramine, compatibility is questionable because the mixture exhibited no visual changes in 1 hour, was slightly cloudy and viscous in 2 hours, was clear and very viscous in 4 hours at room temperature, but no haloperidol decomposition was observed in a 4 hour study period; drug concentrations not specified (Pers Comm, 1990)

2) Compatible

a) Haloperidol in a 1:1 or 1:2 mixture with imipramine, compatibility is questionable because the mixture exhibited no visual changes in 1 hour, was slightly cloudy and viscous in 2 hours, was clear and very viscous in 4 hours at room temperature, but no haloperidol decomposition was observed in a 4 hour study period; drug concentrations not specified (Pers Comm, 1990)

3.5.5.1.A.20 Lidocaine

a) Compatible

1) Haloperidol 5 or 0.5 mg/mL with lidocaine 4 mg/mL visually compatible in Dextrose 5% water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991f)

3.5.5.1.A.21 Lorazepam

a) Compatible

1) Haloperidol 5 mg/1 mL with lorazepam 2 or 4 mg/1 mL, physically compatible for 4 hour in syringe; temperature not specified (Prod Info Ativan(R) Injection compatibility charts, 198

2) Haloperidol in a 1:1 mixture with lorazepam, physically compatible for 16 hours at room temperature; drug concentrations not specified (Pers Comm, 1990)

3.5.5.1.A.22 Mesoridazine

a) Incompatible

1) Haloperidol in a 1:1 mixture with mesoridazine, immediate precipitate formation reported drug concentrations not specified (Pers Comm, 1990)

3.5.5.1.A.23 Nitroglycerin

a) Compatible

1) Haloperidol 5 or 0.5 mg/mL with nitroglycerin 0.4 mg/mL visually compatible in Dextrose 5% in water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991h)

3.5.5.1.A.24 Nitroprusside

a) Conflicting Data

1) Incompatible

a) Haloperidol 5 mg/mL with nitroprusside 0.2 mg/mL, immediate formation of cloudy solution reported in Dextrose 5% in water; however, nitroprusside 0.2 mg/mL has beer

reported to be compatible with haloperidol 0.5 mg/mL in Dextrose 5% (Outman & Monolakis, 1991i)

2) Compatible

a) Haloperidol 0.5 mg/mL with nitroprusside 0.2 mg/mL visually compatible in Dextros 5% in water for 24 hours at 21 degrees C under fluorescent light; however, nitroprussi 0.2 mg/mL has been reported to be incompatible with haloperidol 5 mg/mL in Dextrose 5% (Outman & Monolakis, 1991)

3.5.5.1.A.25 Norepinephrine

a) Compatible

1) Haloperidol 5 or 0.5 mg/mL with norepinephrine 0.032 mg/mL visually compatible in Dextrose 5% in water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991j)

3.5.5.1.A.26 Ondansetron

a) Compatible

1) Haloperidol 0.2 mg/mL in Dextrose 5% in water with ondansetron 1 mg/mL in Sodium chloride 0.9% was physically compatible for 4 hours at 22 degrees C under ambient lightin (Trissel et al, 1991b; Prod Info Zofran(R), 1999)

3.5.5.1.A.27 Paclitaxel

a) Compatible

1) Haloperidol 0.2 mg/mL in Dextrose 5% injection with paclitaxel 1.2 mg/mL in Dextrose 5 injection in glass container, no visual or turbidimetric evidence of incompatibility in simulate Y-site injection for a 4-hour study period, admixture stored at room temperature under fluorescent light (Trissel & Bready, 1992). However, this admixture was not tested for chemical stability.

3.5.5.1.A.28 Phenylephrine

a) Compatible

1) Haloperidol 5 or 0.5 mg/mL with phenylephrine 0.02 mg/mL visually compatible in Dextrose 5% in water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991d)

3.5.5.1.A.29 Prochlorperazine

a) Incompatible

1) Haloperidol in a 1:1 or 1:2 mixture with prochlorperazine, immediate formation of cloudy solution reported with precipitate formation reported in 1 to 2 hours at room temperature; d concentrations not specified (Pers Comm, 1990)

3.5.5.1.A.30 Sargramostim

a) Incompatible

1) Haloperidol lactate 0.2 mg/mL with sargramostim 10 mcg/mL, both in sodium chloride 0.9%, formation of small particles reported in 1 of 2 samples within 4 hours at 22 degrees C under fluorescent light (Trissel et al, 1992)

3.5.5.1.A.31 Tacrolimus

a) Compatible

1) Haloperidol 2.5 mg/mL in 5% Dextrose injection with tacrolimus 1 mg/mL in 0.9% Sodiu chloride injection, visually compatible for 24 hours at room temperature under fluorescent li (Min et al, 1992)

3.5.5.1.A.32 Theophylline

a) Compatible

1) Haloperidol 5 or 0.5 mg/mL with theophylline, premixed 1.6 mg/mL visually compatible i Dextrose 5% in water for 24 hours at 21 degrees C under fluorescent light (Outman & Monolakis, 1991c)

3.5.5.1.A.33 Trifluoperazine

a) Incompatible

1) Haloperidol in a 1:1 mixture with trifluoperazine, immediate formation of a cloudy solutio reported; drug concentrations not specified (Pers Comm, 1990)

3.5.5.1.B Haloperidol Lactate

Allopurinol Sodium

Amifostine

Aztreonam

Cyclizine Lactate

Fenoldopam Mesylate

Gallium Nitrate

Granisetron Hydrochloride

Piperacillin Sodium/Tazobactam

Propofol

Vinorelbine

3.5.5.1.B.1 Allopurinol Sodium

a) Incompatible

1) Haloperidol lactate is physically incompatible in solution with allopurinol sodium for injection; conditions not specified; do not mix with or administer through the same intravenc port (Prod Info Aloprim(TM), 1999).

2) Allopurinol sodium 3 mg/mL in Sodium chloride 0.9% injection with haloperidol lactate 0 mg/mL in Sodium chloride 0.9% injection, heavy turbidity formed immediately and develope into crystalline particles within 1 hour (Trissel & Martinez, 1994a)

3.5.5.1.B.2 Amifostine

a) Compatible

1) Amifostine 10 mg/mL in Dextrose 5% in water with haloperidol lactate 0.2 mg/mL in 5% Dextrose injection, compatible during simulated Y-site administration (Trissel & Martinez, 1995a)

3.5.5.1.B.3 Aztreonam

a) Compatible

1) Aztreonam 40 mg/mL in 5% Dextrose in water with haloperidol lactate 0.2 mg/mL in Dextrose 5% in water, compatible for up to 4 hours at 23 degrees C (Trissel & Martinez, 1995)

3.5.5.1.B.4 Cyclizine Lactate

a) Incompatible

1) Cyclizine lactate 50 mg/mL (3 mL) with haloperidol lactate 5 mg/mL (0.3 mL) in 0.9% Sodium chloride injection (17 mL), crystals were seen within 24 hours when mixed in syring driver; however, no crystals were noted when water for injection or Dextrose 5% injection were used and stored at 25 degrees C for 24 hours (Fawcett et al, 1994).

3.5.5.1.B.5 Fenoldopam Mesylate

a) Compatible

1) Fenoldopam mesylate 80 mcg/mL in Sodium chloride 0.9% injection with haloperidol lactate 0.2 mg/mL in Sodium chloride 0.9% injection, visually and physically compatible for to 4 hours at 23 degrees C in a clear glass tube under constant fluorescent light during simulated Y- site administration (Trissel et al, 2003).

3.5.5.1.B.6 Gallium Nitrate

a) Incompatible

1) Gallium nitrate (Ganite(R)) 1 mg/mL in Sodium chloride 0.9% admixed from a plastic syringe in a 1:1 ratio simulating Y-site administration with haloperidol lactate (undiluted) 5 mg/mL, immediate white haze that adhered to test tube after centrifugation, leaving a clear liquid at 15 minutes which remained clear for 24-hour study period, stored at room temperature under fluorescent light in a glass container; chemical stability not tested (Lobe Dollard, 1993)

3.5.5.1.B.7 Granisetron Hydrochloride

a) Compatible

1) Granisetron hydrochloride diluted with 5% dextrose injection to a concentration of 50 mcg/mL is compatible with haloperidol lactate at a concentration of 0.2 mg/mL (D5W) durin simulated Y-site injection. Compatibility was measured using visual examinations in fluorescent light and in high-intensity monodirectional light. Turbidity, particle size and parti counts were completed for certain solutions. The mixtures were assessed at 1 and 4 hours (Trissel, 1997).

3.5.5.1.B.8 Piperacillin Sodium/Tazobactam

a) Incompatible

1) Piperacillin sodium 40 mg/mL plus tazobactam 5 mg/mL in Dextrose 5% in water with haloperidol lactate 0.2 mg/mL in Dextrose 5% in water, white turbidity and numerous white particles formed immediately (Trissel & Martinez, 1994b)

3.5.5.1.B.9 Propofol

a) Compatible

1) Propofol 1% injectable emulsion and haloperidol lactate 0.2 milligrams/milliliter in a 1:1 volume mixture (simulated Y-site administration) are visually compatible in polycarbonate t tubes at 15 minutes and 1 hour at approximately 23 degrees Celsius as determined by visualization with fluorescent light and a high-intensity, mono-directional light source (Tynd beam) (Trissel et al, 1997).

3.5.5.1.B.10 Vinorelbine

a) Compatible

1) Haloperidol lactate 0.2 mg/mL in Sodium chloride 0.9% with vinorelbine 1 mg/mL in Sodium chloride 0.9%, compatible for up to 4 hours at 22 degrees C (Trissel & Martinez, 1994c)

3.5.5.2 Solutions

Haloperidol

Haloperidol Lactate

3.5.5.2.A Haloperidol

Dextrose 5% in water

Total Parenteral Nutrition

3.5.5.2.A.1 Dextrose 5% in water

a) Compatible

1) Dextrose 5% in water with haloperidol 100 mg/L stable for 38 days at 24 degrees C in a amber glass bottle or a plastic container (Das Gupta & Stewart, 1982)

3.5.5.2.A.2 Total Parenteral Nutrition

a) Compatible

1) Haloperidol 0.2 mg/mL in Dextrose 5% in water added to total parenteral nutrition soluti compatible in simulated Y-site administration for 4 hours at 23 degrees C; specific composition of total parenteral nutrition solution listed below (Trissel et al, 1997a):

Amino acids 10% (Aminosyn(R) II)	3.5%
Dextrose	5%
Sterile water for injection	516.8 mL
Potassium phosphates	3.5 mM
Sodium chloride	25 mEq
Potassium chloride	35 mEq
Magnesium sulfate	8 mEq
Multivitamins	10 mL
Trace elements	1 mL
Calcium gluconate	9.3 mEq

2) Haloperidol 0.2 mg/mL in Dextrose 5% in water added to total parenteral nutrition soluti compatible in simulated Y-site administration for 4 hours at 23 degrees C; specific composition of total parenteral nutrition solution listed below (Trissel et al, 1997a):

Amino acids 10% (FreAmine(R) III)	3.5%
Dextrose	5%
Sterile water for injection	516.75 mL
Sodium chloride	37.5 mEq
Potassium chloride	40 mEq
Magnesium sulfate	8 mEq
Multivitamins	10 mL
Trace elements	1 mL
Calcium gluconate	5 mEq

3) Haloperidol 0.2 mg/mL in Dextrose 5% in water added to total parenteral nutrition soluti compatible in simulated Y-site administration for 4 hours at 23 degrees C; specific composition of total parenteral nutrition solution listed below (Trissel et al, 1997a):

Amino acids 10% (Aminosyn(R) II)	4.25%
Dextrose	25%
Sterile water for injection	161 mL
Potassium phosphates	15 mM
Sodium chloride	25 mEq
Potassium chloride	18 mEq
Magnesium sulfate	8 mEq
Multivitamins	10 mL
Trace elements	1 mL
Calcium gluconate	9.15 mEq

4) Haloperidol 0.2 mg/mL in Dextrose 5% in water added to total parenteral nutrition soluti compatible in simulated Y-site administration for 4 hours at 23 degrees C; specific composition of total parenteral nutrition solution listed below (Trissel et al, 1997a):

Amino acids 10% (FreAmine(R) III)	4.25%
Dextrose	25%
Sterile water for injection	158.6 mL
Potassium phosphates	5.75 mM
Sodium chloride	40 mEq
Potassium chloride	25 mEq
Magnesium sulfate	8 mEq
Multivitamins	10 mL
Trace elements	1 mL
Calcium gluconate	7.5 mEq

3.5.5.2.B Haloperidol Lactate

Dextrose 5% and Sodium chloride 0.225%

Dextrose 5% in water

lactated Ringer's injection

Lactated Ringer's injection

Sodium chloride 0.45%

Sodium chloride 0.9%

3.5.5.2.B.1 Dextrose 5% and Sodium chloride 0.225%

a) Conflicting Data

1) Incompatible

a) Haloperidol 3 mg/mL (as the lactate salt) in 10 mL of Dextrose 5% and Sodium chloride 0.225%, precipitated by 0.5 hour (Fraser & Riker, 1994a)
b) Haloperidol 2 mg/mL (as the lactate salt) in 10 mL of Dextrose 5% and Sodium chloride 0.225%, precipitated by 1 hour (Fraser & Riker, 1994a)

2) Compatible
a) Haloperidol 0.1, 0.5, 0.75, 1 mg/mL (as the lactate salt) in 10 mL of Dextrose 5% a Sodium chloride 0.225%, visually compatible for up to 7 days at 21 degrees C (Fraser Riker, 1994)

3.5.5.2.B.2 Dextrose 5% in water

a) Compatible
1) Haloperidol 0.1, 0.5, 0.75, 1, 2, 3 mg/mL (as the lactate salt) in 10 mL of Dextrose 5% i water, visually compatible for up to 7 days at 21 degrees C (Fraser & Riker, 1994)

3.5.5.2.B.3 lactated Ringer's injection

a) Incompatible
1) Haloperidol 3 mg/mL (as the lactate salt) in 10 mL of lactated Ringer's injection, precipitated immediately (Fraser & Riker, 1994c)
2) Haloperidol 2 mg/mL (as the lactate salt) in 10 mL of lactated Ringer's injection, precipitated by 0.25 hour (Fraser & Riker, 1994c)

3.5.5.2.B.4 Lactated Ringer's injection

a) Compatible
1) Haloperidol 0.1, 0.5, 0.75, 1 mg/mL (as the lactate salt) of 10 mL of lactated Ringer's injection, visually compatible for up to 7 days at 21 degrees C (Fraser & Riker, 1994b).

3.5.5.2.B.5 Sodium chloride 0.45%

a) Conflicting Data
1) Incompatible
a) Haloperidol 3 mg/mL (as the lactate salt) in 10 mL Sodium chloride 0.45%, precipitated immediately, and haloperidol 2 mg/mL, precipitated by 0.25 hour (Fraser & Riker, 1994e)

2) Compatible
a) Haloperidol 0.1, 0.5, 0.75, 1 mg/mL (as the lactate salt) in 10 mL of Sodium chlorid 0.45%, visually compatible for up to 7 days at 21 degrees C (Fraser & Riker, 1994d)

3.5.5.2.B.6 Sodium chloride 0.9%

a) Conflicting Data
1) Incompatible
a) Haloperidol 1,2,3 mg/mL (as the lactate salt) in 10mL of Sodium chloride 0.9% precipitated immediately, and the precipitate became more dense over time (Fraser & Riker, 1994e)
b) Haloperidol 10,20, or 30 mg/mL with sodium chloride 0.9%, slight precipitate formation reported with the precipitate increasing with time in the larger concentrations however, sodium chloride 0.9% has been reported to be compatible with haloperidol 1 5 mg/mL (Outman & Monolakis, 1991l).

2) Compatible
a) Haloperidol 0.1, 0.5, 0.75 mg/mL (as the lactate salt) in 10 mL of Sodium chloride 0.9%, visually compatible for up to 7 days at 21 degrees C (Fraser & Riker, 1994d)
b) Haloperidol 1 or 5 mg/10mL with sodium chloride 0.9%, visually compatible for an hour study period at 21 degrees C under fluorescent light; however, sodium chloride 0.9% has been reported to be incompatible with haloperidol 10, 20 or 30 mg/10 mL (Outman & Monolakis, 1991k)

1) Therapeutic

a) Physical Findings

1) Decrease in severity or elimination of target psychotic symptoms:

a) Positive psychotic symptoms (delusions, auditory hallucinations, racing thoughts)

b) Negative psychotic symptoms (anhedonia, apathy, amotivation, ambivalence).

2) Improvement in socialization, grooming, and attention to activities of daily living.

2) Toxic

a) Laboratory Parameters

1) Complete blood counts (every 6 months)

2) Electrocardiogram at baseline and periodically while on therapy, especially if administered intravenously (US Food and Drug Administration, 2007; Pacher & Kecskemeti, 2004).

a) Torsades de Pointes and QT prolongation, including sudden death, have been reported especially when haloperidol is administered intravenously or at doses higher than recommende (US Food and Drug Administration, 2007; Pacher & Kecskemeti, 2004)

3) Hepatic function tests (every 6 months)

b) Physical Findings

1) Abnormal involuntary movement scale (AIMS) examination or similar test for tardive dyskinesia every 6 months.

2) Assessment for extrapyramidal symptoms (EPS) during dose adjustment and every 3 months.

B) Haloperidol Lactate

1) Therapeutic

a) Physical Findings

1) Control of agitation is indicative of clinical response.

2) Toxic

a) Physical Findings

1) Allergic reactions should be monitored, especially in patients with known allergies, or a history of drug-induced allergic reactions.

2) Bronchopneumonia with symptoms including lethargy, decreased thirst, and reduced pulmonary ventilation should be monitored, especially in the elderly.

3) Electrocardiogram at baseline and periodically while on therapy to monitor for arrhythmias (including Torsades de Pointes) and QT prolongation, especially when haloperidol is administered intravenously (route not approved) or at doses higher than recommended (Prod Info HALDOL(R) immediate release IM injection, 2008; US Food and Drug Administration, 2007; Pacher & Kecskeme 2004).

4) Hypotension and/or anginal pain should be monitored in patients with comorbid cardiovascular disorders.

5) Involuntary dyskinetic movements (including tardive dyskinesia), which are potentially irreversible should be monitored, especially in elderly women or patients receiving longer durations of treatment

6) Neuroleptic malignant syndrome (NMS) should be monitored and includes symptoms of hyperpyrexia, muscle rigidity, altered mental status, irregular pulse or blood pressure, tachycardia, diaphoresis and cardiac dysrhythmias. If confirmed, haloperidol therapy may need to be discontinue and medical management instituted. Following recovery from NMS, if therapy is to be reinstituted, careful monitoring is recommended to prevent recurrences (Prod Info HALDOL(R) immediate releas IM injection, 2008).

7) Seizure monitoring is recommended especially in patients with a history of seizures or EEG abnormalities.

4.2 Patient Instructions

A) Haloperidol (By mouth)

Haloperidol

Treats symptoms of mental and emotional disorders. Helps patients with Tourette's syndrome and children w severe behavior problems, including hyperactivity.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to haloperidol, or if you have Parkinson disease. This medicine should not be given to patients with severe brain disease.

How to Use This Medicine:
Tablet

Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed several times in order to find out what works best for you. Do not use more medicine or use it

more often than your doctor tells you to.

If a Dose is Missed:
If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your r dose, wait until then to use the medicine and skip the missed dose. Do not use extra medicine to make u for a missed dose.

How to Store and Dispose of This Medicine:
Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after you have finished your treatment. You will also need to throw away old medicine after the expiratior date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamii and herbal products.
You must be careful if you are also using other medicine that might cause similar side effects as haloperidol. This includes medicine that might cause low blood pressure, overheating, or liver problems.
Make sure your doctor knows about all other medicines you are using.
Tell you doctor if you are also using lithium, phenindione, medicine for seizures, or medicine to treat Parkinson's disease.
Tell your doctor if you are using any medicines that make you sleepy. These include sleeping pills, cold a allergy medicine, narcotic pain relievers, and sedatives.
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:
Make sure your doctor knows if you are pregnant or breastfeeding, or if you have liver disease, kidney disease, heart or blood vessel disease, blood pressure problems, overactive thyroid, or history of seizure or breast cancer.
Tell your doctor about any other medicine you have used to treat a mental disorder, especially if the medicine caused problems.
This medicine may make you dizzy or drowsy. Avoid driving, using machines, or doing anything else that could be dangerous if you are not alert.
You might get overheated more easily while using this medicine. Be aware of this if you are exercising o the weather is hot. Drinking water might help. If you get too hot and feel dizzy, weak, tired, confused, or sick to your stomach, you need to cool down.
Do not stop using this medicine suddenly without asking your doctor. You may need to slowly decrease your dose before stopping it completely.
Your doctor will need to check your progress at regular visits while you are using this medicine. Be sure keep all appointments.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or thro chest tightness, trouble breathing.
Change in how much or how often you urinate.
Changes in vision.
Fast or pounding heartbeat.
Fever or chills.
Jerky muscle movement you cannot control (often in your face, tongue, or jaw).
Headache, confusion, lightheadedness, or fainting.
Painful, prolonged erection of your penis.
Problems with balance or walking.
Seeing or hearing things which are not there.
Seizures or tremors.
Severe muscle stiffness.
Troubled breathing.
Unusual bleeding, bruising, or weakness.
Yellowing of skin and eyes.

If you notice these less serious side effects, talk with your doctor:
Breast pain or swelling.
Change in menstrual periods.
Decreased thirst or dry mouth.
Loss of appetite.
Nausea, vomiting, diarrhea, or constipation.
Skin rash.

Trouble sleeping, restlessness.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

B) Haloperidol (Injection)

Haloperidol

Treats mental illness (such as schizophrenia), behavior problems, agitation, and symptoms of Tourette's syndrome.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to haloperidol, or if you have Parkinson disease. This medicine should not be given to patients with severe brain disease.

How to Use This Medicine:
Injectable

Your doctor will prescribe your exact dose and tell you how often it should be given. This medicine is giv as a shot into one of your muscles.
A nurse or other trained health professional will give you this medicine.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitami and herbal products.

Make sure your doctor knows if you are also using lithium (Eskalith®, Lithane®, Lithobid®), rifampin (Rimactane®, Rifadin®), a blood thinner (such as phenindione), or medicine for Parkinson's disease (su as carbidopa, levodopa, Sinemet®).
Tell your doctor if you are using any medicines that make you sleepy. These include sleeping pills, cold a allergy medicine, narcotic pain relievers, and sedatives.
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:

Make sure your doctor knows if you are pregnant or breastfeeding, or if you have liver disease, kidney disease, lung disease, glaucoma, an overactive thyroid, or a history of seizures or neuroleptic malignant syndrome (NMS). Your doctor needs to know if you have any kind of heart or blood vessel problems, including blood pressure problems, heart rhythm problems, or mineral imbalance.
Older adults may be more sensitive to the side effects of this medicine, including heart failure or pneumonia. This medicine is not used to treat behavioral problems in older adults with dementia.
Tardive dyskinesia (a movement disorder) may occur and may not go away after you stop using the medicine. Check with your doctor right away if you or your child have any of the following symptoms whil taking this medicine: lip smacking or puckering, puffing of the cheeks, rapid or worm-like movements of t tongue, uncontrolled chewing movements, or uncontrolled movements of the arms and legs.
This medicine may make you more sensitive to sunlight and heat. Avoid sunlamps, hot tubs, tanning bec and saunas. Take care not to get overheated during exercise or outdoor activity. Use a sunscreen when outdoors.
This medicine may make you dizzy or drowsy. Avoid driving, using machines, or doing anything else tha could be dangerous if you are not alert. You may also feel lightheaded when getting up suddenly from a lying or sitting position, so stand up slowly.
Do not stop using this medicine suddenly without asking your doctor. You may need to slowly decrease your dose before stopping it completely.
Your doctor will need to check your progress at regular visits while you are using this medicine. Be sure keep all appointments.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:

Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or thro chest tightness, trouble breathing.
Change in how much or how often you urinate.
Chills, cough, sore throat, and body aches.
Fast, slow, or irregular heartbeat.
Feeling very thirsty or hungry.
Fever, sweating, confusion, uneven heartbeat, or muscle stiffness.
Jerky muscle movement you cannot control (often in your face, tongue, or jaw).
Lightheadedness or fainting.
Painful, prolonged erection of your penis.
Problems with vision, speech, or walking.
Seeing or hearing things which are not there.
Seizures or tremors.
Trouble breathing or swallowing.
Twitching or muscle movements you cannot control.

Unexplained fever or muscle stiffness.
Unusual facial expressions.
Unusual bleeding, bruising, or weakness.
Yellowing of your skin or the whites of your eyes.

If you notice these less serious side effects, talk with your doctor:
Breast pain or swelling.
Drowsiness, depression, or headache.
Dry mouth.
Hair loss.
Irregular menstrual periods.
Loss of appetite.
Nausea, vomiting, constipation, or stomach upset.
Skin rash.
Trouble having sex.
Trouble sleeping, restlessness.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

C) Haloperidol Decanoate (Injection)

Haloperidol Decanoate

Treats mental disorders such as schizophrenia.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to haloperidol decanoate, or if you have Parkinson's disease. This medicine should not be given to patients with severe brain disease.

How to Use This Medicine:
Injectable
Your doctor will prescribe your exact dose and tell you how often it should be given. This medicine is giv as a shot into one of your muscles.
A nurse or other trained health professional will give you this medicine.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamir and herbal products.
Make sure your doctor knows if you are also using lithium (Eskalith®, Lithane®, Lithobid®), rifampin (Rimactane®, Rifadin®), a blood thinner (such as phenindione), or medicine for Parkinson's disease (suc as carbidopa, levodopa, Sinemet®).
Do not drink alcohol while you are using this medicine.
Tell your doctor if you are using any medicines that make you sleepy. These include sleeping pills, cold a allergy medicine, narcotic pain relievers, and sedatives.

Warnings While Using This Medicine:
Make sure your doctor knows if you are pregnant or breastfeeding, or if you have liver disease, kidney disease, lung disease, glaucoma, an overactive thyroid, or a history of seizures or neuroleptic malignant syndrome (NMS). Your doctor needs to know if you have any kind of heart or blood vessel problems, including blood pressure problems, heart rhythm problems, or mineral imbalance.
Older adults may be more sensitive to the side effects of this medicine, including heart failure or pneumonia. This medicine is not used to treat behavioral problems in older adults with dementia.
Tardive dyskinesia (a movement disorder) may occur and may not go away after you stop using the medicine. Check with your doctor right away if you or your child have any of the following symptoms whil taking this medicine: lip smacking or puckering, puffing of the cheeks, rapid or worm-like movements of t tongue, uncontrolled chewing movements, or uncontrolled movements of the arms and legs.
This medicine may make you more sensitive to sunlight and heat. Avoid sunlamps, hot tubs, tanning bec and saunas. Take care not to get overheated during exercise or outdoor activity. Use a sunscreen when outdoors.
This medicine may make you drowsy or dizzy. Avoid driving, using machines, or doing anything else that could be dangerous if you are not alert. You may also feel lightheaded when getting up suddenly from a lying or sitting position, so stand up slowly.
Do not stop using this medicine suddenly without asking your doctor. You may need to slowly decrease your dose before stopping it completely.
Your doctor will need to check your progress at regular visits while you are using this medicine. Be sure keep all appointments.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or thro

chest tightness, trouble breathing.
Blood in your urine.
Chills, sore throat, and body aches.
Decreased thirst.
Fast or uneven heartbeat.
Feeling very thirsty or hungry.
Fever, sweating, confusion, or muscle stiffness.
Lightheadedness or fainting.
Problems with vision, speech, balance, or walking.
Seeing or hearing things which are not there.
Seizures (convulsions).
Tremors or movements that you cannot control in the tongue, face, neck, jaw, or eyes
Trouble breathing or swallowing.
Unusual bleeding, bruising, or weakness.
Unusual facial expressions.
Yellowing of your skin or the whites of your eyes.

If you notice these less serious side effects, talk with your doctor:
Anxiety, drowsiness, or depression.
Decrease in how much or how often you urinate.
Dry mouth, cough, or headache.
Hair loss.
Loss of appetite.
Nausea, vomiting, diarrhea, or stomach upset.
Pain in the breast, irregular menstrual periods.
Skin rash, sunburn, or pain at the injection site.
Trouble having sex, or increased development of breasts (in men).
Trouble sleeping, restlessness.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Current users of atypical antipsychotic drugs and typical antipsychotic drugs (including haloperidol) had a simi dose-dependent risk of sudden cardiac death, according to a retrospective cohort of 93,300 adult users of antipsychotic drugs and 186,600 matched controls. The study included patients age 30 to 74 years (mean 45.7 +/ 11.8 years) with similar cardiovascular risk at baseline who had at least one filled prescription and had 1 outpatier visit in each of the 2 preceding years. Sudden cardiac death was defined as occurring in the community and excluded deaths of patients admitted to the hospital, non-sudden deaths, deaths due to extrinsic causes, or cause not related to ventricular tachyarrhythmia. Current use was defined as the interval between the time the prescripti was filled and the end of the day's supply. Low and high doses was defined as comparable to less than 100 milligrams (mg) of chlorpromazine, and doses comparable to chlorpromazine 300 mg or greater, respectively. The adjusted rate of sudden cardiac death (incidence-rate ratio) in current users of atypical antipsychotic drugs in 79,5 person-years was 2.26 (95% CI, 1.88 to 2.72, p less than 0.001) which was similar to the risk in current users of typical antipsychotic drugs in 86,735 person-years which was 1.99 (95% CI, 1.68 to 2.34, p less than 0.001). The risk of sudden cardiac death in current haloperidol users in 21,728 person-years was 1.61 (95% CI, 1.16 to 2.24, p=0.005). The risk of sudden cardiac death significantly increased with increasing dose in both the typical and atypical antipsychotic drug groups. In typical antipsychotic use, the incidence rate ratio increased from 1.31 (95% 0.97 to 1.77) in low-dose use to 2.42 (95% CI, 1.91 to 3.06) in high-dose use. To limit the effects of confounding c the study results, there was a secondary analysis performed in a cohort of patients matched by propensity score, which resulted in a similar risk of sudden death as the primary cohort analysis (Ray et al, 2009). In an editorial in The New England Journal of Medicine, it has been suggested that antipsychotic drugs continue to be used in patients with clear evidence of benefit, but in vulnerable populations with cardiac risk profiles (eg, elderly patients) there should be an age-dependent justification required prior to administration. It has also been suggested (althou not formally tested) that ECGs be performed before and shortly after initiation of antipsychotic therapy to screen fo existing or emergent QT interval prolongation (Schneeweiss & Avorn, 2009).

B) Haloperidol is a butyrophenone-derivative antipsychotic agent with a very low incidence of sedative, anticholinergic, and cardiovascular adverse effects; however, it may produce a very high incidence of extrapyrami symptoms. The drug is useful in treating a variety of psychiatric disorders including schizophrenia and Tourette's syndrome. Haloperidol decanoate is a long-acting depot dosage form, which may be administered in up to 4-week intervals, which is a potential advantage in noncompliant patients.

C) Clinical evidence demonstrates that all the commonly marketed neuroleptic agents have therapeutic equivaler when adequate doses are utilized (Appleton et al, 1980). When a flexible dosage regimen is used to titrate the chosen agent to maximum effect, all neuroleptics will demonstrate statistical equivalence in a study population. However, one agent may be effective while another will not in any given individual patient. Pharmacokinetic and pharmacodynamic differences as well as possible multiple etiologies of the patient's schizophrenia may be reasor for the individual inequivalence (Young & Koda-Kimble, 1988). The patient's past medication history of neuroleptic agents should play an important role in drug selection. The patient's subjective response to neuroleptics should al be used in deciding on a specific agent. A reduction in symptoms or a pleasurable response following the first

neuroleptic dose will improve patient compliance better than if the patient has a bad experience after the first dose (May, 1978). The last factor in deciding which neuroleptic agent to use is its adverse effect profile. Almost all neuroleptic agents possess similar adverse effects; however, the overall incidence of a particular category of adverse effects varies between the agents.

D) The US Food and Drug Administration (FDA) issued an alert concerning reports of Torsades de Pointes and C prolongation, some with fatal outcomes associated with the use of haloperidol, haloperidol decanoate, and haloperidol lactate, especially when administered intravenously (not an approved route of administration) or in higher doses than recommended. At least 28 published case reports exist, and case-control studies have demonstrated a dose-response relationship between intravenous haloperidol use and the development of Torsad de Pointes. Two post-marketing analyses of the association of QT prolongation or Torsades de Pointes with oral c injectable haloperidol revealed 242 cases, with at least 8 fatalities involving intravenous administration. Risk facto for the development of QT prolongation or Torsades de Pointes include concomitant QT-prolonging conditions, su as electrolyte imbalance; underlying cardiac abnormalities; hypothyroidism; familial long QT syndromes; or concomitant use of drugs known to prolong the QT interval. However, some cases have occurred in patients with predisposing factors. The true incidence of QT prolongation or Torsades de Pointes cannot be determined at this time (US Food and Drug Administration, 2007).

E) Based upon a critical review of the literature, it is suggested that haloperidol decanoate provides no advantage and safety and is more expensive (Hemstrom et al, 1988). It is recommended that haloperidol decanoate be reserved for schizophrenic patients who have responded to oral haloperidol and who may significantly benefit fror long-acting preparation. Haloperidol and haloperidol decanoate are effective agents in the treatment of certain psychiatric disorders and should be included on hospital formularies where these types of patients are routinely treated.

See Drug Consult reference: CHEMOTHERAPY AND RADIOTHERAPY TREATMENT GUIDELINES FOR NAUS AND VOMITING

See Drug Consult reference: FIRST- VS SECOND-GENERATION ANTIPSYCHOTIC AGENTS FOR SCHIZOPHRENIA

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) Haloperidol is pharmacologically related to the piperazine phenothiazines (Ayd, 1978). Similar to other neuroleptics, haloperidol centrally blocks the action of dopamine by binding previously to DA-2 receptors, anc a lesser extent, DA-1 receptors. The potency of all antipsychotic drugs correlates well with their affinity for DA receptors (AMA Department of Drugs, 1983; Snyder, 1981).

2) Haloperidol is relatively non-sedating but is more likely to produce extrapyramidal symptoms as compared other antipsychotic agents; autonomic side effects are less than with other agents (AMA Department of Drugs 1983).

3) Haloperidol 2 mg is approximately equivalent to 100 mg chlorpromazine, 2 mg fluphenazine, 10 mg loxapi and 4 mg thiothixine in antipsychotic potency (AMA Department of Drugs, 1983). The drug is used primarily i schizophrenia and acute psychosis. Other indications are schizoaffective disorders, paranoid syndrome, and Tourette's syndrome (AMA Department of Drugs, 1983).

B) REVIEW ARTICLES

1) A pharmacokinetics update of haloperidol has been reviewed (Kudo & Ishizaki, 1999).

2) The pharmacokinetics and therapeutic use of IM haloperidol decanoate in the treatment of psychosis have been reviewed (Beresford & Ward, 1987a).

3) A comprehensive review of haloperidol pharmacokinetics has been published and included all factors whi have the potential of influencing the serum levels of haloperidol (Froemming et al, 1989a).

4) The use of haloperidol in the treatment of psychotic symptoms in the elderly has been reviewed, including pharmacokinetics, indications and principles for use, side effects, and advantages of haloperidol (Steinhart, 1983).

5) Practice guidelines for the treatment of schizophrenia have been developed by the American Psychiatric Association (Anon, 1997).

4.5 Therapeutic Uses

Haloperidol

Haloperidol Decanoate

Haloperidol Lactate

4.5.A Haloperidol

Agitation

Alcohol withdrawal syndrome

Anorexia nervosa

Behavioral syndrome - Dementia

Chemotherapy-induced nausea and vomiting; Treatment and Prophylaxis

Delirium

Dementia

Flashbacks, LSD

Gilles de la Tourette's syndrome

Hiccoughs

Hiccoughs, Intractable

Hyperactive behavior, (Short-term treatment) after failure to respond to non-antipsychotic medication and psychotherapy

Migraine

Nausea and vomiting; Treatment and Prophylaxis

Obsessive-compulsive disorder; Adjunct

Ocular hypertension

Opioid withdrawal

Pain

Postoperative nausea and vomiting; Prophylaxis

Problematic behavior in children (Severe), With failure to respond non-antipsychotic medication or psychotherapy

Psychotic disorder

Rheumatoid arthritis

Schizophrenia

Severe major depression with psychotic features

Sneezing

4.5.A.1 Agitation

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Effective treatment for agitated, critical care patients (Ziehm, 1991)
Controlled studies are needed to identify the most effective and safe method of haloperidol administration

c) Adult:

1) HALOPERIDOL given intramuscularly (IM), intravenously (IV), or orally has been reported effecti in the management of disruptive patients in the emergency room setting (Clinton et al, 1987). The average total doses of HALOPERIDOL administered were 8 mg, 6 mg, and 9 mg for the IM, IV, and oral routes, respectively.

d) Pediatric:

1) Haloperidol provided effective sedation for a 9-month-old girl during mechanical ventilation after bone marrow transplant. Sedation with fentanyl 18 micrograms/kilogram (mcg/kg) per hour and midazolam 1 milligram (mg) per hour was not adequate. By day 33 of mechanical ventilation, she wa receiving fentanyl 30 mcg/kg/hour, methadone 1.4 mg/kg intravenously (IV) every 6 hours, and lorazepam 1.1 mg/kg IV every 4 hours. Eleven doses of pancuronium over 24 hours were needed to minimize movement. Intravenous haloperidol 0.06 mg/kg was administered, followed 6 hours later b maintenance regimen of 0.015 mg/kg IV every 6 hours. Twelve hours after the loading dose, the patient was reported to be calm, with no thrashing. She required 2 additional doses of haloperidol during the next 8 hours in response to intermittent agitation, and, during the 24 hours after the loadi dose, a dose of pancuronium and 2 extra doses of fentanyl were administered. Two days after initiat of haloperidol, she needed no extra doses of fentanyl, lorazepam, or pancuronium. She was successfully extubated 3 days after starting haloperidol, after which haloperidol was discontinued ar the other sedatives tapered. Similar, successful treatments with haloperidol were reported for 4 othe pediatric cases (ages 11 months, 12 years, 14 years, and 16 years) (Harrison et al, 2002).

4.5.A.2 Alcohol withdrawal syndrome

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
bolus doses of haloperidol and clonidine provided better patient outcome than continuous infusion doses

c) Adult:

1) Severity and duration of alcohol withdrawal syndrome (AWS) was significantly lower in patients receiving bolus rather than infusions of haloperidol and clonidine. In a prospective, randomized, stuc adult patients with AWS who had trauma or gastrointestinal surgery, a history of alcohol abuse (grea than 60 grams per day), and a clinical withdrawal assessment for alcohol score (CIWA-Ar) greater th 20 were randomized to the infusion-titrated group (ITG) or the bolus-titrated group (BTG). All patient received bolus doses of flunitrazepam (for agitation), haloperidol (for hallucinations), and clonidine (autonomic signs) to achieve a CIMA- Ar score less than 20. An infusion of flunitrazepam infusion (25 100 micrograms/kilogram/hour (mg/kg/hr)) was started to prevent convulsions. Patients were then randomized to the ITG (n=21) or the BTG (n=23), in which, haloperidol plus clonidine was administe as infusion or bolus doses to achieve a CIWA-Ar score of less than 10 and Ramsey Sedation Score (RSS) of 2 to 4. Doses were dependent on the initial need for the drug and ranged from 50 to 200 mcg/kg/hr or bolus doses less than 20 milligrams (mg), 20 to 40 mg, or greater than 40 mg for haloperidol and 150 to 300 mcg/kg/hr or bolus doses less than 150 mcg, 150 to 300 mcg, or greater than 300 mcg for clonidine. Propofol 50 to 400 mg was given as a rescue medication. The primary outcome, severity and duration of AWS, favored the BTG. CIWA-Ar scores increased following ITG from approximately 21 to 29, p less than or equal to 0.01, but not in the BTG where scores remained approximately 23 (p less than or equal to 0.01 compared to ITG). The duration of AWS was significantly longer for patients in the ITG (median interquartile range: 4 to 10 days) than patients in BTG (median interquartile range: 2 to 4 days), p less than or equal to 0.01. In addition, the days spe in the intensive care unit (ICU) were significantly longer for ITG patients (median interquartile range: to 25 days) than BTG patients (median interquartile range: 5 to 10 days), p less than or equal to 0.0 Pneumonia developed in 9 of 23 (39%) of BTG patients and 15 of 21 (71%) of ITG patients, p less th or equal to 0.01 (Spies et al, 2003).

4.5.A.3 Anorexia nervosa

See Drug Consult reference: ANOREXIA NERVOSA - DRUG THERAPY

4.5.A.4 Behavioral syndrome - Dementia

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb

Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
May be efficacious for treating behavioral problems associated with Alzheimer's disease
Use may expose the patient to unnecessary adverse reactions

c) Adult:
1) HALOPERIDOL 1 to 5 milligrams orally each day was effective in improving psychotic and behavioral symptoms in patients with probable ALZHEIMER'S DISEASE during a single-blind pilot study (Devanand et al, 1989). However, severe adverse effects were observed during therapy, primarily extrapyramidal symptoms, and no patient could be maintained on the maximum dose of 5 milligrams daily. The average daily dose at the end of the 8-week haloperidol phase (preceded and followed by 4-week placebo phases) was 2.44 milligrams daily. Cognitive function deteriorated durin HALOPERIDOL therapy, with only partial recovery by the end of the subsequent 4-week placebo phase. This small study suggests that HALOPERIDOL is effective in treating psychosis and other behavioral disturbances in Alzheimer's patients, but that severe extrapyramidal adverse effects and adverse effects on cognitive function can compromise efficacy. However, in most cases, benefits of therapy appear to outweigh adverse effects (based upon opinions of physician and family members) Larger controlled studies are required to further evaluate neuroleptic therapy in Alzheimer's disease

4.5.A.5 Chemotherapy-induced nausea and vomiting; Treatment and Prophylaxis
See Drug Consult reference: CHEMOTHERAPY AND RADIOTHERAPY TREATMENT GUIDELINES FC NAUSEA AND VOMITING

4.5.A.6 Delirium

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Effective in controlling patients with delirium and agitation

c) Adult:
1) Haloperidol, administered via continuous infusion, was effective in controlling delirium and agitati in a series of three critically ill intensive care unit patients. In all of the three patients, symptoms wer previously not adequately controlled with high doses of benzodiazepines and narcotics and bolus injections of intravenous haloperidol. Control of delirium was rapidly attained following initiation of continuous intravenous haloperidol (4 to 24 mg/hour) which allowed other sedatives to be discontinu and facilitated weaning from the ventilator. Two of the patients had underlying psychiatric illness (Seneff & Mathews, 1995).
2) Eight critically ill, mechanically ventilated patients with severe agitation unresponsive to benzodiazepines, narcotics, and intermittent bolus haloperidol were eventually controlled with haloperidol by continuous intravenous infusion. Initial infusion rates ranged from 3 to 25 milligrams (mg)/hour (mean 9 mg/hour), with titration as high as 40 mg/hour for control (mean maintenance infusion 18 mg/hour). Control of agitation was demonstrated by a decline in the number of daily supplemental sedative doses (from 23 to 7) and by declines in the Sedation-Agitation Scale. Nursing time per patient decreased from 320 to 96 minutes, although one patient still required 2 nurses and adjunctive sedative doses daily (Riker et al, 1994a).
3) AIDS patients with organic mental disorders were treated for their delirium with high-dose intravenous haloperidol in combination with lorazepam (Fernandez et al, 1989). Although effective ir treating symptoms of delirium, half of the 38 patients treated developed extrapyramidal symptoms. A subsequent study randomized hospitalized AIDS patients with delirium to either haloperidol, chlorpromazine, or lorazepam (Breitbart et al, 1996b). Both neuroleptic agents significantly improvec symptoms of delirium with a low incidence of side effects. Lorazepam, however, was not effective, a the majority of patients treated with this agent developed treatment-limiting adverse effects. The me dose of haloperidol used was 2.8 mg during the first 24 hours of treatment and 1.4 mg for the remainder of the protocol.
4) In a prospective study of 14 delirious, medically ill patients with severe agitation, it was shown th those patients receiving intravenous (IV) HALOPERIDOL 4 milligrams/day plus at least 1 mg of benzodiazepine had fewer extrapyramidal symptoms than those patients receiving intravenous HALOPERIDOL 4 mg/day alone (Menza et al, 1988). DIAZEPAM, LORAZEPAM, OXAZEPAM, and ALPRAZOLAM were used with the dosage reported in milligram equivalents of DIAZEPAM. Doses were oral except four cases of IV LORAZEPAM. The approximate ratio of milligram of HALOPERIDC to milligram equivalents of DIAZEPAM was 4:1. In the HALOPERIDOL plus benzodiazepine treated patients, only one patient suffered very mild parkinsonian-like extrapyramidal symptoms, and there were no cases of akathisia or dystonia. The authors concluded that IV HALOPERIDOL combined wi benzodiazepines may be safely and effectively used to control severe agitation in delirious, medicall patients in critical care areas.

5) Intravenous HALOPERIDOL (100 to 480 milligrams/day) with LORAZEPAM (36 to 480 mg/day) successfully treated delirium in critically ill cancer patients. Mild to moderate levels of sedation were achieved in 24 of 25 patients within 90 minutes; most within 20 minutes. Seven patients died from underlying disease within 1 month of institution of therapy, and 18 patients recovered after correctio of the underlying problem. The longest duration of therapy was 3 months. Only 1 of the 25 patients experienced side effects (a dystonic reaction) serious enough to discontinue therapy (Adams et al, 1986).

4.5.A.7 Dementia

See Drug Consult reference: BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA

4.5.A.8 Flashbacks, LSD

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Useful in decreasing flashbacks associated with LSD

c) Adult:

1) Oral doses of 1 to 2 milligrams 3 times daily were effective in decreasing the frequency, intensity and duration of flashbacks associated with LSD ingestion. In a series of 8 patients, 3 patients were noted to have an increase in the number of flashbacks when HALOPERIDOL was discontinued (Moskowitz, 1971).

4.5.A.9 Gilles de la Tourette's syndrome

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (3 yr and older)
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated for the control of tics and vocal utterances of Tourette's disorder in adults and childrer age 3 years and older (Prod Info haloperidol oral tablets, 2008; Prod Info haloperidol oral soluti 2008).

In pediatric patients (n=22) haloperidol was not significantly more effective on the Tourette Syndrome Global Scale compared with placebo, and was associated with a significantly greate incidence of extrapyramidal symptoms, while pimozide demonstrated effectiveness over placeb according to a 24-week, randomized, crossover study (Sallee et al, 1997a).

More effective than pimozide on the Gilles de la Tourette's syndrome severity scale and more effective than placebo on 4 of 6 measurement scales, according to a randomized, placebo-controlled, double-blind parallel and crossover study (n=57) in adults and children (Shapiro et a 1989a).

.

c) Adult:

1) Haloperidol was more effective than pimozide on the Gilles de la Tourette's syndrome (TS) seve scale and was more effective than placebo on 4 of 6 measurement scales according to a randomize placebo-controlled, double-blind, parallel-group and crossover study (n=57). Patients with DSM-III criteria for TS, aged 8 to 46 years (mean 21.1 +/- 11 years) were randomized to receive haloperidol (n=20), pimozide (n=18), or placebo (n=19) during the 6-week, parallel-phase study (period 1), followed by a 3-week single-blind placebo or drug-free period. The study included previously untreat patients, and patients with inadequate prior response or history of adverse effects from haloperidol, clonidine, or other drugs. In the crossover phase (period 2), patients who received 6 weeks of active treatment (haloperidol or pimozide) were crossed over to the alternate study drug while patients initi assigned to placebo during the parallel phase were randomized to either haloperidol or pimozide an then crossed-over to the alternate drug for an additional 6 weeks. Patients received once daily dosir titrated to clinical effect up to a maximum dose of pimozide 0.3 milligram/kilogram (mg/kg) or 20 mg, whichever was smaller, or haloperidol 10 mg. Haloperidol was more effective than pimozide on the physician-rated TS severity scale (p=0.011). Haloperidol was also more effective than placebo on 1) the physician-rated TS severity scale (p=0.01), 2) total vocal tics (p=0.019), 3) Clinical Global Impression Scale (CGI scale) of therapeutic effects (rated by physician p=0.009, rated by patient p=0.01), and 4) the CGI scale of adverse effects (rated by physician p=0.01, rated by patient p=0.01 There was not a significant difference in the incidence of QTc interval greater than 0.44 sec (pimozi n=9 vs haloperidol n=1). The results of the study may have been limited by the short duration of treatment (Shapiro et al, 1989a).

2) Although haloperidol is the drug of choice in the treatment of Tourette's syndrome, more than on drug has been effective (Shapiro & Shapiro, 1981a). In some cases, combination therapy with haloperidol and nicotine or nifedipine has been effective (McConville et al, 1991); (Sandberg et al, 1989)(Alessi et al, 1989). The goal of treatment is to determine the lowest dosage that results in 70% improvement and the fewest side effects (Erenberg, 1992).

3) Nine out of 10 patients with Tourette's syndrome, not adequately controlled with haloperidol, wer successfully treated with adjunct nicotine gum (McConville et al, 1991). The patients began a therap of a 2 mg nicotine gum in conjunction with a mean dose of 2.8 mg per day of haloperidol. The numb of vocal and motor tics were recorded after chewing the gum 30 and 60 minutes. Nine out of the ten patients experienced reduced tic frequency. The mechanism of action is still under investigation.

d) Pediatric:

1) Haloperidol was not significantly more effective on the Tourette Syndrome (TS) Global Scale compared with placebo, and was associated with a significantly greater incidence of extrapyramidal symptoms, while pimozide demonstrated effectiveness over placebo, according to a 24-week, randomized, crossover study in pediatric patients (n=22). Patients with DSM-III-R criteria for TS, age 7 to 16 years (mean 10.2 +/- 2.5 years) were included in the study. Following an initial 2-week place baseline period, patients were randomized to receive 6 weeks of treatment with either haloperidol 1 milligram (mg), pimozide 1 mg, or placebo with dose titration of 2 mg/week to produce a 70% reduct in tic symptoms. Each 6-week treatment period was followed by a 2-week placebo washout period prior to crossing over to alternate therapy. A 70% tic reduction on the total TS global scale was achieved in 64% (14/22) with equivalent mean effective doses of pimozide 3.4 +/- 1.6 mg or haloperidol 3.5 +/- 2.2 mg/day compared with 23% (5/22) who received placebo (p=0.02 for treatme group effect). In a post hoc analysis, pimozide was significantly more effective than placebo on the total TS global scale , TS global tic subscale, the TS symptom list tic subscale score, Clinical Global Impression (CGI) tic severity scale, and on the clinician-rated Children's Global Assessment Scale (less than 0.05 on all scores). Haloperidol was significantly more effective than placebo on the CGI ti severity scale and on the clinician-rated Children's Global Assessment Scale (p less than 0.05 for bo scores). The number of extrapyramidal symptoms was higher during the haloperidol-treatment perio (mean 4.1 +/- 6.9) compared with the pimozide-treatment period (mean 2 +/- 3) (p less than 0.05), o placebo (mean 1.4 +/- 3) (p less than 0.01). Moderate to severe adverse events including depressio anxiety, or severe dyskinesias occurred in 9 of 22 patients during the haloperidol-treatment phase compared with 3 of 22 patients during the pimozide-treatment phase. There were no significant electrocardiovascular effects on heart rate, rhythm, or waveform in either the pimozide or haloperidc treatment phases compared with placebo (Sallee et al, 1997a).

2) Nicotine potentiated the effects of haloperidol in the treatment of Tourette's syndrome (Sandberg al, 1989). Ten children between the ages of 7 and 17 years (mean 12 years) who were taking haloperidol in doses ranging from 1 to 3 mg/day (mean 1 mg/day) were given nicotine gum 2 mg thr times daily. Eighty percent of the children showed both decreases of tics and improvement of concentration and attention span. This positive effect lasted from 45 to 60 minutes. However, 70% o the children discontinued the gum due to side effects. The side effects included stomach pain, naus decreased appetite, complaints of bitter taste and burning sensation in the mouth, and weight loss. T mechanism of action by which nicotine potentiates haloperidol is not known and more studies are needed. Two cases were reported of children in which NICOTINE gum 2 mg helped control Tourette syndrome that could not be adequately controlled with haloperidol alone (Sandberg et al, 1988).

3) The combination of haloperidol (1 milligram orally twice daily) plus nifedipine (10 milligrams orally times daily) was effective in the treatment of Gilles de la Tourette's syndrome in a 9-year-old boy wh was refractory to both nifedipine and haloperidol when administered as single agent therapy (Alessi al, 1989). The mechanism of apparent synergism in this patient is unclear, however, the authors postulate that the combination results in a relative reduction in D2 receptor-binding sites, causing a relative increase in the site specific potency of haloperidol. More studies are required to investigate t combination in Tourette's patients.

4.5.A.10 Hiccoughs

See Drug Consult reference: HICCUPS - ETIOLOGY AND TREATMENT

4.5.A.11 Hiccoughs, Intractable

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Intramuscular HALOPERIDOL 2 mg successfully treated intractable hiccups in 2 patients (Ives et al, 1985)

4.5.A.12 Hyperactive behavior, (Short-term treatment) after failure to respond to non-antipsychotic medication and psychotherapy

FDA Labeled Indication

a) Overview

FDA Approval: Adult, no; Pediatric, yes (3 yr and older)
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated for short-term treatment of hyperactive children with excessive motor activity and concomitant conduct disorders such as impulsivity, difficulty sustaining attention, aggressivity, mood lability and poor frustration tolerance (Prod Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

4.5.A.13 Migraine

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class III; Pediatric, Class III
Strength of Evidence: Adult, Category C; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

In case reports, intravenous haloperidol has been effective in relieving symptoms of migraine headache

c) Adult:

1) Intravenous haloperidol was effective in relieving symptoms of migraine headache in a series of s cases. Haloperidol was primarily administered for the relief of nausea and vomiting, but was also fou to alleviate headache pain. Following an intravenous bolus of 500 to 1000 milliliters of normal saline haloperidol was given as a dose of 5 mg over 2 to 3 minutes. Headache pain was better after 25 to (minutes, and none of the six patients returned for additional treatment within the next two days (Fish 1995). Randomized prospective trials are needed to validate these findings.

d) Pediatric:

1) HALOPERIDOL 0.05 to 0.1 milligrams/kilogram/day orally has been effective in relieving hemiple episodes of MIGRAINE HEADACHE in children (Salmon & Wilson, 1984).

4.5.A.14 Nausea and vomiting; Treatment and Prophylaxis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Prevents nausea and vomiting due to numerous causes

c) Adult:

1) Numerous studies have indicated that HALOPERIDOL in 1 to 4 milligram doses, intramuscular o oral, is an effective ANTIEMETIC in the prevention or treatment of nausea and vomiting due to varic causes including POSTOPERATIVE NAUSEA and vomiting, CANCER CHEMOTHERAPY, IRRADIATION, and GASTROINTESTINAL DISORDERS (Barton et al, 1975; Robbins & Nagel, 197 Cole & Duffy, 1974; Christman et al, 1974; Plotkin et al, 1973; Tornetta, 1972); (Shields et al, 1971). postoperative nausea, HALOPERIDOL by the intravenous route was more rapid in onset than either DROPERIDOL or PROCHLORPERAZINE (Loeser et al, 1979).

2) Two cases were reported of HALOPERIDOL combined with LORAZEPAM to successfully treat nausea and vomiting associated with the intravenous use of DIHYDROERGOTAMINE for treatment intractable migraine headaches (Backonja et al, 1989). The authors found that the intravenous administration of 0.5 to 1 mg each of HALOPERIDOL and LORAZEPAM 15 minutes prior to the intravenous administration of DIHYDROERGOTAMINE prevents nausea and vomiting. HALOPERIDOL and LORAZEPAM cause marked sedation and the authors therefore recommend th 0.25 mg of each drug be given initially and an additional 0.25 to 0.5 mg be added as needed.

3) HALOPERIDOL gave better results in emesis induced by platinol and NITROGEN MUSTARD; BENZQUINAMIDE gave better results with DOXORUBICIN. This was in a study where BENZQUINAMIDE was compared with HALOPERIDOL for relief of emesis due to specific antineoplastic agents in 64 patients. In patients not being relieved by the first agent, crossover usua resulted in some relief. More PROCHLORPERAZINE resistant patients obtained relief with HALOPERIDOL than with BENZQUINAMIDE (Neidhart et al, 1981b).

4.5.A.15 Obsessive-compulsive disorder; Adjunct

a) Overview

FDA Approval: Adult, no; Pediatric, no

Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Useful as adjunct therapy in treating refractory obsessive compulsive disorder

c) Adult:
1) The addition of haloperidol was useful in treating refractory obsessive compulsive disorder. In a double-blind, randomized, placebo-controlled trial lasting four weeks, 34 patients receiving, but refractory to, fluvoxamine (maximum 300 mg/day) for obsessive compulsive disorder had either haloperidol (maximum 10 mg/day) or placebo added to their regimen (McDougle et al, 1994). Severa scales used to assess obsessive compulsive symptoms, tics, depression, and related symptoms showed that the addition of haloperidol was significantly better than the addition of placebo in reduci the severity of obsessive compulsive symptoms with chronic tic disorders. The only significant adver effect occurring with haloperidol was akathisia in 9 of 31 patients. Haloperidol addition was of limitec benefit in treating obsessive compulsive disorder patients without tics.

4.5.A.16 Ocular hypertension

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Not effective

c) Adult:
1) Topical administration of the HALOPERIDOL ophthalmic solution (0.125% and 1%) produced modest reductions in intraocular pressure in healthy volunteers; however, reductions were not considered statistically significant (Lavin & Andrews, 1986).
2) HALOPERIDOL 3 milligrams orally was reported to produce significant decreases in intraocular pressure in non-glaucomatous volunteers at 3 to 4 hours post-administration (Sheppard & Schaid, 1986). However, significant reductions in intraocular pressure were not observed in glaucomatous patients receiving topical antiglaucoma medications, and more studies are required to determine benefits in glaucomatous patients; the authors suggest that lack of response in this group was relate to use of the concurrent topical medications.

4.5.A.17 Opioid withdrawal

See Drug Consult reference: DRUG THERAPY OF OPIOID WITHDRAWAL

4.5.A.18 Pain

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Questionable effects on pain control

c) Adult:
1) No shift to the left in dosage histograms was found in 424 cancer patients treated with MORPHIN vs MORPHINE plus HALOPERIDOL. The authors concluded that HALOPERIDOL did not potentiate MORPHINE analgesia (Hanks et al, 1983).
2) In a single case report (Daw & Cohen-Cale, 1981), HALOPERIDOL was shown to have an independent analgesic effect as well as a narcotic-potentiating effect in the treatment of severe pelv pain.
3) In intractable pain, HALOPERIDOL has successfully been used as an analgesic. A review of the cases reveals that it has been used for terminal cancer pain, intractable arthritic pain, and severe denervation dysesthesia. Some of these patients have been able to greatly decrease their consumption of narcotics; others have managed on HALOPERIDOL alone. The rationale for use of HALOPERIDOL for this purpose rests with its structural similarity to MEPERIDINE, its effectiveness preventing withdrawal symptoms upon removal of narcotics in addicts, a recognition of an analgesic dose-response seen at doses which, until recently, were rarely used (ie, 20 to 40 mg/day), and the demonstration that HALOPERIDOL binds to the opiate receptor. Further study of the analgesic effec of HALOPERIDOL is warranted (Maltbie et al, 1979a).
4) In chronic facial pain, nonmigranous and nonneuralgiform in nature, HALOPERIDOL along with relaxation therapy was successful in relieving pain in 12 of 12 patients. Although this type of pain ha very high psychogenic component and improvement in the psychiatric well-being of the patient coul

be the rationale of successful therapy, HALOPERIDOL has also been shown to have analgesic properties. The author suggests that further study might elucidate more clearly the use of HALOPERIDOL in these patients (Raft et al, 1979).

4.5.A.19 Postoperative nausea and vomiting; Prophylaxis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

The administration of haloperidol after spinal anesthesia reduced the incidence of postoperative nausea and vomiting

c) Adult:

1) Prophylactic administration of haloperidol after spinal anesthesia reduced the incidence of postoperative nausea and vomiting during the first 24 hours after surgery. In a randomized, double-blind, placebo- controlled study (n=108), patients undergoing lower limb orthopedic or endoscopic urologic surgery under spinal anesthesia received a single intramuscular dose of haloperidol 1 milligram (mg), haloperidol 2 mg, or placebo after spinal anesthesia with local anesthetic and morph 0.3 mg for the prophylaxis of postoperative nausea and vomiting. Treatment failure was defined as a nausea score of 1 (mild) or higher, any episode of vomiting, or a request for rescue antiemetic. Over 60% of patients met criteria for treatment failure within the first 12 hours following surgery, with both haloperidol doses demonstrating a significant dose-related reduction in incidence of postoperative nausea, vomiting, or antiemetic use (treatment failure, placebo 76%, haloperidol 1 mg 56%, haloperidol 2 mg 50%; p=0.012). The total treatment failure rate at 24 hours was 65% (placebo 76% haloperidol 1 mg 64%, haloperidol 2 mg 55%; p=0.03). No difference was found between the two haloperidol doses. No extrapyramidal effects were observed with the use of haloperidol during the study (Parlow et al, 2004).

4.5.A.20 Problematic behavior in children (Severe), With failure to respond non-antipsychotic medication or psychotherapy

FDA Labeled Indication

a) Overview

FDA Approval: Adult, no; Pediatric, yes (3 yr and older)
Efficacy: Pediatric, Effective
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated in the treatment of severe behavior problems in children with combative, explosive hyperexcitability which is not accounted for by immediate provocation
Also effective in the short-term treatment of hyperactive children who show excessive motor activity with accompanying conduct disorders (i.e. impulsivity, difficulty sustaining attention, aggressivity, mood lability and poor frustration tolerance)
Recommended for children unresponsive to psychotherapy or medications other than antipsychotics

c) Pediatric:

1) Symptomatic improvement was seen with HALOPERIDOL in 12 hospitalized patients 7 to 11 yea old who suffered from childhood-onset PERVASIVE DEVELOPMENTAL DISORDER. The average dose of HALOPERIDOL was 0.04 milligrams/kilogram per day. There was remarkable improvement peer interaction, reduction in autistic-like behavior, improved reality testing, and decreased impulsivi and hyperactivity. This low-dose treatment with HALOPERIDOL produced minimal side effects. Thre children exhibited transient drowsiness in the initial phase of treatment, but this decreased over time and did not interfere with their cognitive performance. Two children suffered mild extrapyramidal symptoms with rigidity and cogwheeling. These symptoms were treated with oral DIPHENHYDRAMINE and did not recur when the drug was withdrawn (Joshi et al, 1988).

2) HALOPERIDOL (0.5 to 4 milligrams/kilogram) was more effective than placebo in a double-blind crossover study of 41 patients aged 2.3 to 6.9 years with INFANTILE AUTISM. HALOPERIDOL resulted in a significant decrease in behavioral symptoms and significant increases in facilitation and retention of discrimination (Anderson et al, 1984).

3) HALOPERIDOL 0.5 to 4 milligrams was compared with placebo in a double-blind, crossover stud in nine autistic children, ages 2 to 7 years, confirming the efficacy of HALOPERIDOL in autism (Coh et al, 1980). It was found effective in reducing rates of stereotypy and facilitating low rates of orientir to the rater, while not affecting other behaviors, including motor activity, speech, affect, or irritability. The results of this ongoing study, involving 33 patients, have been updated (Campbell et al, 1982a).

4.5.A.21 Psychotic disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (3 yr and older (oral formulations only))
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated for management of manifestations of psychotic disorders (Prod Info haloperidol oral tablets, 2006; Prod Info haloperidol oral solution, 2001)

4.5.A.22 Rheumatoid arthritis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Improves clinical features and laboratory parameters of RHEUMATOID ARTHRITIS

c) Adult:

1) Patients with rheumatoid arthritis previously treated only with nonsteroidal antiinflammatory drugs were found to have no significant difference in responses to either 150 milligrams (mg)/day indomethacin or 1.5 mg/day HALOPERIDOL. A proposed mechanism for this effect of HALOPERID is membrane-stabilization on platelets (Grimaldi & Bergonzi, 1980). A follow-up study (Grimaldi, 198 suggested a specific antirheumatic activity of HALOPERIDOL, based on increased serum sulfphydry levels and decreased PIP joints technetium index, ESR, and joint count.

4.5.A.23 Schizophrenia

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (3 yr and older (oral formulations only))
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated in the management of schizophrenia

c) Adult:

1) Haloperidol is effective in the treatment of SCHIZOPHRENIA and ACUTE PSYCHOSIS, as well schizoaffective disorders and paranoid syndrome. Usual oral haloperidol doses range from 5 to 20 milligrams/day, but doses of 100 mg/day or more may be indicated (Carter, 1986).

2) Intravenous HALOPERIDOL was used successfully in five severely regressed, nonviolent, psychiatric inpatients with psychotic disorders (Plotnick & Brown, 1991). Five psychiatric patients unable to thrive without intravenous fluids and nutrition and incapable of ingesting oral medications were given intravenous HALOPERIDOL in therapeutic doses to alleviate psychotic symptoms and were studied in retrospect. All five cases showed significant improvement in symptoms shortly following use of intravenous HALOPERIDOL. Four of the five patients were discharged in complete remission of symptoms after brief hospital stays. The authors suggested that HALOPERIDOL given a slow intravenous push was a safe and rapidly effective treatment for severely regressed, nonviole psychotic inpatients.

3) A double-blind study with 20 patients suffering manic or schizomanic psychoses determined that CARBAMAZEPINE and HALOPERIDOL in combination were as effective as HALOPERIDOL alone. The doses were haloperidol 24 mg/day and CARBAMAZEPINE 600 mg/day. No evidence was foun to show that the combination was more effective than HALOPERIDOL alone (Moller et al, 1989). Similarly, the combination of CARBAMAZEPINE plus HALOPERIDOL was compared with HALOPERIDOL plus placebo in a controlled study involving 43 patients with excited psychoses. Combination therapy was reported superior to HALOPERIDOL alone with clinical benefits being as apparent in excited schizophrenia as in mania (Klein et al, 1984a).

4) The positive correlation between early response and clinical outcome in schizophrenic patients treated with HALOPERIDOL was reported. Doses were not reported, but averaged 26 and 32 mg at hours in dysphoric and nondysphoric patients, respectively. Eighty-two percent of patients classified nondysphoric after 24 hours had good clinical results after 3 weeks, while 23% of dysphoric patients after 24 hours had poor clinical results after 3 weeks. The authors concluded that early subjective ar symptom improvement is an indicator of therapeutic outcome (Awad & Hogan, 1985).

5) Amphetamine was beneficial when added to chronic haloperidol therapy in 21 patients with undifferentiated or paranoid schizophrenia (Goldberg et al, 1991). Thirty-two percent reflected negat symptoms, 46% displayed positive symptoms, and 11% had paranoid symptoms. The study assess

changes in neuropsychological function such as positive effects on affect and cognition. A single dos of 0.25 milligrams/kilogram of dextroamphetamine was administered and the patients were evaluate for cognitive function, performance and comprehension. Six patients showed improvement after administration of the amphetamine. Increases in spontaneous eye-blink rate and enlarged cerebral ventricles were associated with improvement. The authors concluded that amphetamine paired with haloperidol had a positive effect on symptoms of schizophrenia; however, no definite conclusions co be drawn because no long term study was done.

4.5.A.24 Severe major depression with psychotic features

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Successfully used in combination with tricyclic antidepressants to treat psychotic depression

c) Adult:

1) Two cases were reported of patients suffering from PSYCHOTIC DEPRESSION successfully be treated with a combination of low dose HALOPERIDOL (1 to 3 mg/day) and DESIPRAMINE (100 mg/day). The HALOPERIDOL serum levels of the patients were 1.5 to 2.4 ng/mL. The authors concluded that the higher doses of neuroleptics commonly used to treat this condition may not be necessary (Lin et al, 1989).

4.5.A.25 Sneezing

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective in 1 case report

c) Adult:

1) A single case of intractable sneezing of 139 days (every 4 to 5 seconds except when sleeping or talking) was slowed to every 30 seconds with a dose of haloperidol 1.5 milligrams (mg) twice daily. T rate continued to slow as the dose was increased and stopped altogether at a dose of 5 mg 3 times daily. The dose was then gradually reduced over 6 months without recurrence (Davison, 1982).

4.5.B Haloperidol Decanoate

Chronic schizophrenia

Gilles de la Tourette's syndrome

4.5.B.1 Chronic schizophrenia

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated for the treatment of schizophrenic patients who require prolonged parenteral antipsychotic therapy (Prod Info haloperidol decanoate injection, 2005)

c) Adult:

1) Monthly intramuscular injections of HALOPERIDOL DECANOATE 50 milligrams for 5 months wa reported effective in the treatment of chronic schizophrenic patients, many of whom showed poor compliance to oral medication (Bucci & Marini, 1985).

4.5.B.2 Gilles de la Tourette's syndrome

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy

Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Effective in treatment of severe, intractable Tourette's syndrome unresponsive to oral haloperid in 1 case report (Clarke & Ford, 1988)

c) Adult:
1) HALOPERIDOL DECANOATE intramuscularly was reported effective in the treatment of severe, intractable Tourette's syndrome unresponsive to oral HALOPERIDOL in a 23-year-old male (Clarke Ford, 1988). The patient had been unresponsive to oral HALOPERIDOL (doses of up to 10 milligran orally four times daily) for several years. Oral HALOPERIDOL was discontinued and a test dose of HALOPERIDOL DECANOATE 100 milligrams intramuscularly was administered, resulting in a reduction in tics, coprolalia, and copropraxic gestures over the ensuing two weeks. HALOPERIDOL DECANOATE was continued in doses of up to 400 milligrams intramuscularly monthly, then was subsequently reduced to 200 milligram maintenance doses. Tourette's symptoms disappeared completely after 4 months of treatment.

4.5.C Haloperidol Lactate

Gilles de la Tourette's syndrome

Schizophrenia

4.5.C.1 Gilles de la Tourette's syndrome

FDA Labeled Indication

a) Overview
FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Indicated for the control of tics and vocal utterances of Tourette's disorder (Prod Info HALDOL(I immediate release IM injection, 2008)

c) Adult:
1) Indicated for the control of tics and vocal utterances of Tourette's disorder (Prod Info HALDOL(R immediate release IM injection, 2008).
2) In some cases, combination therapy with haloperidol and nicotine or nifedipine has been effectiv the treatment of Tourette's syndrome (McConville et al, 1991); (Sandberg et al, 1989)(Alessi et al, 1989). The goal of treatment is to determine the lowest dosage that results in 70% improvement and the fewest side effects (Erenberg, 1992).
3) Nine out of 10 patients with Tourette's syndrome, not adequately controlled with haloperidol, wer successfully treated with adjunct nicotine gum (McConville et al, 1991). The patients began a therap of a 2 mg nicotine gum in conjunction with a mean dose of 2.8 mg per day of haloperidol. The numb of vocal and motor tics were recorded after chewing the gum 30 and 60 minutes. Nine out of the ten patients experienced reduced tic frequency. The mechanism of action is still under investigation.

4.5.C.2 Schizophrenia

FDA Labeled Indication

a) Overview
FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Indicated for the treatment of schizophrenia in adult patients (Prod Info HALDOL(R) immediate release IM injection, 2008).

c) Adult:
1) Haloperidol is effective in the treatment of schizophrenia and acute psychosis, as well as schizoaffective disorders and paranoid syndrome (Carter, 1986).
2) A double-blind study with 20 patients suffering manic or schizomanic psychoses determined that carbamazepine and haloperidol in combination were as effective as haloperidol alone. The doses w haloperidol 24 mg/day and carbamazepine 600 mg/day. No evidence was found to show that the combination was more effective than haloperidol alone (Moller et al, 1989). Similarly, the combinatio

of carbamazepine plus haloperidol was compared with haloperidol plus placebo in a controlled study involving 43 patients with excited psychoses. Combination therapy was reported superior to haloperidol alone with clinical benefits being as apparent in excited schizophrenia as in mania (Kleir al, 1984a).
3) The positive correlation between early response and clinical outcome in schizophrenic patients treated with haloperidol was reported. Doses were not reported, but averaged 26 and 32 mg at 24 hours in dysphoric and nondysphoric patients, respectively. Eighty-two percent of patients classified nondysphoric after 24 hours had good clinical results after 3 weeks, while 23% of dysphoric patients after 24 hours had poor clinical results after 3 weeks. The authors concluded that early subjective ar symptom improvement is an indicator of therapeutic outcome (Awad & Hogan, 1985).
4) Amphetamine was beneficial when added to chronic haloperidol therapy in 21 patients with undifferentiated or paranoid schizophrenia (Goldberg et al, 1991). Thirty-two percent reflected negat symptoms, 46% displayed positive symptoms, and 11% had paranoid symptoms. The study assesse changes in neuropsychological function such as positive effects on affect and cognition. A single dos of 0.25 milligrams/kilogram of dextroamphetamine was administered and the patients were evaluate for cognitive function, performance and comprehension. Six patients showed improvement after administration of the amphetamine. Increases in spontaneous eye-blink rate and enlarged cerebral ventricles were associated with improvement. The authors concluded that amphetamine paired with haloperidol had a positive effect on symptoms of schizophrenia; however, no definite conclusions co be drawn because no long term study was done.

4.6 Comparative Efficacy / Evaluation With Other Therapies

Alizapride

Alprazolam

Amisulpride

Amitriptyline

Amobarbital

Aripiprazole

Ascorbic Acid

Benzquinamide

Bromperidol

Carbamazepine

Chlorpromazine

Chlorprothixene

Zuclopenthixol

4.6.A Alizapride

4.6.A.1 Nausea

a) The combination of tropisetron and haloperidol was compared with alizapride to treat nausea and vomiting in high-dose alkylating agent cancer chemotherapy. Twenty-six patients received only alizapride therapy. In the initial 24-hour period, six patients on tropisetron and haloperidol experienced no nausea o vomiting, opposed to one patient taking alizapride. At the end of the study period (72 hours), six patients taking tropisetron plus haloperidol showed no signs of nausea and vomiting compared with zero patients receiving alizapride (Bregni et al, 1991).

4.6.B Alprazolam

4.6.B.1 Dementia - Problem behavior

a) Alprazolam was as effective as low-dose haloperidol in a double-blind, cross-over trial in elderly, nurs home patients with disruptive behaviors associated with delirium, dementia, amnestic disorders, and oth cognitive disorders (Christensen & Benfield, 1998). Patients (n=48) currently receiving haloperidol 1 milligram (mg) or less on a scheduled basis had behavioral episodes measured at baseline. Thereafter patients either continued haloperidol for 6 weeks or entered a 2-week washout period followed by alprazolam 0.5 mg daily for 4 weeks. Both groups were reassessed and then crossed-over into the other group. There was no significant difference in the number of behavioral episodes for patients taking alprazolam compared to patients receiving haloperidol. There was also no difference in either group as compared to baseline. Since no placebo was used in this study, it is difficult to determine whether the patients actually benefited from either therapy.

4.6.C Amisulpride

4.6.C.1 Schizophrenia

a) Amisulpride was superior to haloperidol for the treatment of acute exacerbations of schizophrenia, in regard to both efficacy and safety. In a randomized, double-blind study, patients aged 18 to 45 years witl paranoid schizophrenia or schizophreniform disorder (by DSM-IV criteria) were treated for 4 months with oral haloperidol 10 to 30 milligrams (mg) per day (n=105) or amisulpride 400 to 1200 mg/day (n=94). Starting doses were 20 mg/day for haloperidol and 800 mg/day for amisulpride. Doses were then adjuste according to the patient's condition. Significantly more patients in the haloperidol group than in the

amisulpride group withdrew from the study, due mainly to adverse effects (21% vs 4%) and lack of effica (9% vs 6%). At the end of the study, scores on the Positive and Negative Syndrome Scale (PANSS) had improved more in the amisulpride group than in the haloperidol group, with the difference reaching significance on the negative PANSS score (p=0.01). The percentage of responders ("much" or "very muc improved on the Clinical Global Impressions (CGI) global improvement scale) was 71% in the amisulprid group and 47% in the haloperidol group (p=0.0006). Five percent of the patients in the amisulpride group were considered "worse" after treatment, compared to 15% of those in the haloperidol group. At the end the study, 40% of the amisulpride group were considered "normal," "borderline," or "mildly ill," vs 25% of the haloperidol group. Half of the patients who received haloperidol reported at least one extrapyramidal adverse event, compared to 33% of those who received amisulpride. At least one serious adverse event (mainly psychotic disorders and extrapyramidal effects) occurred in 16% of patients receiving haloperido and 4% of those receiving amisulpride. Weight gain (increase of 5% or more from baseline) was more frequent in the amisulpride group (33% vs 17%, p=0.051) (Carriere et al, 2000).

b) SUMMARY: AMISULPRIDE has been shown to be as effective as HALOPERIDOL in short-term and long-term treatment of schizophrenia. In some studies, AMISULPRIDE demonstrated greater efficacy related to negative symptomatology and improved tolerability (eg, fewer extrapyramidal effects).

c) In an open-label, randomized, multi-center trial (n=488), a 12-month course of AMISULPRIDE produc a similar incidence of drug-related adverse effects (69%) compared to HALOPERIDOL (70%), with amisulpride inducing lower rates of extrapyramidal side effects than haloperidol (13% vs 28%), in patient with subchronic or chronic schizophrenia with acute exacerbation (DSM-III-R). Amisulpride showed simil efficacy to haloperidol on positive symptoms of schizophrenia and significantly greater effectiveness thar haloperidol on negative symptoms (p=0.0001). Enrollees included patients with at least moderate scores 2 or more of the 4 positive items of the Brief Psychiatric Rating Scale (BPRS). Randomization was in a 3 1 ratio, amisulpride (n=370) to haloperidol (n=118). Scores on the Simpson-Angus extrapyramidal scale, Barnes Akathisia Scale, and the Abnormal Involuntary Movement Scale (AIMS) favored amisulpride ove haloperidol (p=0.0001; p less than 0.0001; and p=0.014, respectively). Serious adverse events (primarily psychiatric, including psychosis, agitation, aggression, and suicide attempts) occurred in 10% and 7%, respectively, of amisulpride- and haloperidol-treated patients. Rates of weight gain and amenorrhea were 11% and 6% for amisulpride compared with 3% and 0, respectively, for haloperidol. Discontinuations due adverse effects were 8% and 10%, respectively (amisulpride vs haloperidol). Withdrawals due to lack of efficacy were significantly less in the amisulpride group (12% vs 22%; p=0.009). At the end of 12 months the rate of change in BPRS scores was 44.8% and 33.7% from baseline in the amisulpride and haloperic groups, respectively. Mean decreases in the Positive and Negative Syndrome Scale (PANSS) positive scores were similar across groups (amisulpride, 48.4%; haloperidol 44.2%), whereas changes in PANSS negative scores were significantly greater for amisulpride (35.1% decrease vs 12% decrease; p=0.0001) Dosing was flexible, based on efficacy and tolerability. Maximum doses permitted during acute episodes were 1200 milligrams/day (mg/d) for amisulpride and 30 mg/d for haloperidol; during stable periods, dose were to fall between 200 and 800 mg for amisulpride and between 5 and 20 mg for haloperidol (mean da doses by study end were amisulpride 605 mg and haloperidol 14.6 mg) (Colonna et al, 2000).

d) In a double-blind, randomized study, AMISULPRIDE 800 milligrams (mg)/day over 6 weeks was shov to be as effective as HALOPERIDOL 20 mg/day for the treatment of subchronic schizophrenia or chronic schizophrenia with an acute exacerbation (DSM-III-R criteria), with AMISULPRIDE showing possibly greater efficacy in improving negative symptoms, as well as greater tolerability (n=191). On the Positive and Negative Symptom Scales (PANSS), negative symptoms were significantly improved in amisulpride-treated patients compared with the haloperidol group (mean change, 7.5 vs 5.1; p=0.038). Results on so parts of the Clinical Global Impression (CGI) rating also favored amisulpride (p=0.01 and p less than 0.0 respectively). Overall, 54 of 95 patients (56.8%) in the amisulpride group had at least one adverse event (mostly extrapyramidal symptoms) compared with 72 of 96 patients (75%) in the haloperidol group; 25 a 39 patients, respectively, dropped out of the study (p=0.04) (Moller et al, 1997).

e) Amisulpride was as effective for relapse prevention as haloperidol over a 1-year period in long-term i patients with predominantly negative symptoms of schizophrenia (Speller et al, 1997). Patients were randomly allocated to receive either amisulpride (n=29) or haloperidol (n=31) at a dose calculated to be equivalent to their previous antipsychotic medication. Amisulpride doses were 800 milligrams (mg), 600 450 mg, 300 mg, 150 mg, and 100 mg daily. For haloperidol doses were 20 mg, 16 mg, 11.5 mg, 8 mg, 4 mg, and 3 mg daily. Dose reductions were undertaken every 3 months with the trial medication reduced the next lowest level, unless the lowest dose had been achieved or there was evidence of psychotic exacerbation. During the year, 18% of the amisulpride group and 35% of the haloperidol group experienc psychotic exacerbations (not statistically significant). At the end of the year, 76% of the amisulpride grou had achieved the lowest dose while 58% of the haloperidol group were on the lowest dose (either 3 mg c 4.5 mg). Amisulpride patients did show a greater reduction of the affective flattening and the avolition-apathy global items on the Scale for the Assessment of Negative Symptoms but it was again not significa

f) In a double-blind study, 41 schizophrenic patients were treated, with flexible doses, of haloperidol (n= and amisulpride (n=21) over a period of 42 days (Delcker et al, 1990). On the basis of the Brief Psychiat Rating Scale subscore for anxiety-depression syndrome, and the Arbeitsgemeinschaft fuer Methodik unc Dokumentation in der Psychiatrie (AMDP) system subscore for the somatic depressive syndrome and th hypochondriac syndrome, the amisulpride group showed better results than the haloperidol group. No difference between the two drugs was found in improvement of psychotic symptoms. Amisulpride showe tendency to cause fewer extrapyramidal adverse effects.

g) In a double-blind study, amisulpride (10 milligrams/kilogram (mg/kg) daily) was compared to haloperic (0.5 mg/kg daily) in treatment over one month of patients with acute schizophrenia. The 9 patients in the amisulpride group completed the study, whereas 5 of 10 patients of haloperidol group dropped out of the trial, 3 because of adverse effects. Both drugs significantly improved the acute psychotic symptomatolog and were tolerated in a comparable manner. Extrapyramidal effects were much more pronounced in the haloperidol group (Ruther et al, 1989).

h) In a comparative, double-blind study, 40 patients hospitalized for acute psychosis were treated with amisulpride (800 to 1200 milligrams (mg)/day, 20 patients) or haloperidol (20 to 30 mg/day, 20 patients) 21 days (Costa & Silva, 1989). No significant difference in efficacy was reported between the two drugs according to the Brief Psychiatric Rating Scale. Amisulpride showed less frequent and less intense extrapyramidal adverse effects. Larger, long-term comparative studies are needed to more clearly asses the efficacy, safety and therapeutic role of amisulpride in schizophrenia.

i) A double-blind trial evaluated the therapeutic effects and tolerance of high doses of amisulpride (800 t 1200 milligrams (mg) daily) (20 patients) versus haloperidol (20 to 30 mg daily) (19 patients) in acute psychotic disorders (acute delusional attacks and positive symptoms of schizophrenia). Both drugs exhibited good antipsychotic activity, but amisulpride had a prompt effect, provided more improvement o symptoms (particularly on the anergy, thought disorder, and activation items of the Brief Psychiatric Rati Scale), and exhibited a better tolerance (Pichot & Boyer, 1988).

4.6.C.2 Adverse Effects

a) AMISULPRIDE appears to have better tolerability compared with HALOPERIDOL in both short-term a long-term regimens.

b) In an open-label, randomized, multi-center trial (n=488), a 12-month course of AMISULPRIDE produc a similar incidence of drug-related adverse effects (69%) compared to HALOPERIDOL (70%), with amisulpride inducing lower rates of extrapyramidal side effects than haloperidol (13% vs 28%), in patient with subchronic or chronic schizophrenia with acute exacerbation (DSM-III-R). Amisulpride showed simil efficacy to haloperidol on positive symptoms of schizophrenia and significantly greater effectiveness thar haloperidol on negative symptoms (p=0.0001). Enrollees included patients with at least moderate scores 2 or more of the 4 positive items of the Brief Psychiatric Rating Scale (BPRS). Randomization was in a 3 1 ratio, amisulpride (n=370) to haloperidol (n=118). Scores on the Simpson-Angus extrapyramidal scale, Barnes Akathisia Scale, and the Abnormal Involuntary Movement Scale (AIMS) favored amisulpride ove haloperidol (p=0.0001; p less than 0.0001; and p=0.014, respectively). Serious adverse events (primarily psychiatric, including psychosis, agitation, aggression, and suicide attempts) occurred in 10% and 7%, respectively, of amisulpride- and haloperidol-treated patients. Rates of weight gain and amenorrhea were 11% and 6% for amisulpride compared with 3% and 0, respectively, for haloperidol. Discontinuations due adverse effects were 8% and 10%, respectively (amisulpride vs haloperidol). Withdrawals due to lack of efficacy were significantly less in the amisulpride group (12% vs 22%; p=0.009). At the end of 12 months the rate of change in BPRS scores was 44.8% and 33.7% from baseline in the amisulpride and haloperic groups, respectively. Mean decreases in the Positive and Negative Syndrome Scale (PANSS) positive scores were similar across groups (amisulpride, 48.4%; haloperidol 44.2%), whereas changes in PANSS negative scores were significantly greater for amisulpride (35.1% decrease vs 12% decrease; p=0.0001) Dosing was flexible, based on efficacy and tolerability. Maximum doses permitted during acute episodes were 1200 milligrams/day (mg/d) for amisulpride and 30 mg/d for haloperidol; during stable periods, dose were to fall between 200 and 800 mg for amisulpride and between 5 and 20 mg for haloperidol (mean da doses by study end were amisulpride 605 mg and haloperidol 14.6 mg) (Colonna et al, 2000).

c) AMISULPRIDE produces fewer disturbances of psychomotor, cognitive, extrapyramidal, and affective functions compared with HALOPERIDOL, according to a double-blind, randomized, cross-over study in healthy volunteers (n=21). Enrollees received 4 different 5-day regimens, with at least 10 days of washo between treatments. On days 1 and 5, subjects ingested 2 capsules in the morning: (1)placebo plus placebo; (2)amisulpride 50 milligrams (mg) plus placebo; (3)amisulpride 200 mg plus amisulpride 200 mg (400 mg/day); or (4)haloperidol 2 mg plus haloperidol 2 mg (4 mg/day). On days 2, 3, and 4, the same dosages were given but divided between morning and evening. Amisulpride 50 mg/day had no effect comparing baseline with post-treatment measurements. Amisulpride 400 mg was associated with a few adverse effects on psychomotor and cognitive performance (on day 5 only). Haloperidol was problematic from day 1; it induced several affective disturbances, including higher ratings for depression on the Hamilton Scale, lower feelings of well-being on the Subjective Well-Being under Neuroleptics Scale, and more negative symptoms on the Positive and Negative Symptoms Scale. With respect to affective measures, only drowsiness was significantly greater after amisulpride 400 mg than after placebo (p=0.01 Mean ratings of extrapyramidal symptoms and akathisia were always significantly higher after haloperidc than amisulpride 400 mg (Simpson-Angus Extrapyramidal Side Effect Scale, p equal or less than 0.01; Barnes Akathisia Scale, p equal or less than 0.02). Five times more patients requested anti-cholinergic agents while receiving haloperidol than during amisulpride 400-mg treatment. Two patients dropped out due to side effects of haloperidol vs no drop-outs for amisulpride (Ramaekers et al, 1999).

4.6.D Amitriptyline

4.6.D.1 Schizoaffective disorder

a) Amitriptyline (mean 148 mg/day, maximum 150 mg/day), haloperidol (mean 7.2 mg/day, maximum 12 mg/day), and placebo were compared in 64 patients with unstable and schizotypal borderline disorders.

a wide variety of psychological tests, haloperidol was shown to be significantly more effective than amitriptyline in these disorders, including disorders with a depressive component (Soloff et al, 1986).

4.6.E Amobarbital

4.6.E.1 Psychotic disorder

a) A single-blind study of 15 healthy male schizophrenic patients showed that intramuscular administrati of sodium amytal 250 mg or midazolam 5 milligrams was significantly more effective than haloperidol 10 mg in controlling motor agitation. They were also more effective than haloperidol in controlling hostility, though this did not reach statistic significance (Wyant et al, 1990).

4.6.F Aripiprazole

4.6.F.1 Schizophrenia

a) SUMMARY: Aripiprazole (up to 30 mg daily) and haloperidol (up to 20 mg daily) appear similarly effective in patients with acutely relapsed schizophrenia or schizoaffective disorder; adverse effects may less with aripiprazole.

b) Haloperidol 5 to 20 mg daily, but not aripiprazole (5 to 30 mg daily), was superior to placebo with respect to improvement in BPRS scores in a 4-week study involving acutely relapsed inpatients with DSI III/IV schizophrenia (n=103). Both haloperidol and aripiprazole were more effective than placebo in responder analysis based on CGI-severity scores (Prod Info Abilify(TM), 2002).

c) In a placebo-controlled, phase III study involving relapsed schizophrenic or schizoaffective patients (n=414), aripiprazole 15 or 30 mg daily and haloperidol 10 mg daily (fixed doses) were each statistically superior to placebo with regard to changes in PANSS-total and BPRS-total scores; based on responder analysis (a 30% reduction in PANSS-total scores from baseline at last visit), each dose of aripiprazole w significantly more effective than placebo, whereas haloperidol was not. There was evidence of better tolerability with aripiprazole compared to haloperidol (eg, benztropine requirements for extrapyramidal effects, prolactin increases, weight increase). Extrapyramidal symptoms were reportedly similar with aripiprazole and placebo, and fewer patients receiving aripiprazole discontinued treatment due to advers events compared to haloperidol and placebo (Kane et al, 2000). However, this study did not report statistical comparisons of aripiprazole and haloperidol for any parameter (efficacy versus baseline or adverse effects); responder-analysis data revealed only a small difference between the two drugs. Overa this study does not provide evidence that aripiprazole is significantly more efficacious than haloperidol.

d) Results of phase II studies also suggested fewer adverse effects with aripiprazole compared to haloperidol (Saha et al, 1999; Anon, 2000). In these studies, lower changes from baseline in Simpson-Angus Scale scores (parkinsonian symptoms) and less requirement for benztropine were observed with doses of aripiprazole (2, 10, or 30 mg daily) than with haloperidol 10 mg daily; prolactin levels were not increased by aripiprazole, compared to significant increases with haloperidol, and significantly less weigl gain was evident in the aripiprazole groups (all doses). Comparative efficacy data were not presented.

4.6.G Ascorbic Acid

4.6.G.1 PCP intoxication

a) Four treatment regimens for phencyclidine intoxication were compared: 10 patients received placebo 10 received 1 gram intramuscular ascorbic acid, 10 received 5 mg intramuscular haloperidol, and 10 received both the haloperidol and ascorbic acid. Treatments were administered at 0 and 30 minutes and assessments were made at 0, 30, and 60 minutes by blinded evaluators. The order of responses, each being significantly better than the previous by statistical analysis, was ascorbic acid, placebo, haloperido and the combination therapy. The authors concluded that ascorbic acid potentiated the action of haloperidol, either by inhibiting the binding of phencyclidine to the dopamine receptor or by interfering wi the metabolism of haloperidol (Giannini et al, 1987).

4.6.H Benzquinamide

4.6.H.1 Vomiting

a) Although benzquinamide may be a useful antiemetic for some conditions, haloperidol appears to be superior. Effectiveness of antiemetic agents may vary in the treatment of nausea and vomiting due to different chemotherapeutic agents. The efficacy of haloperidol was compared with that of benzquinamide 64 patients receiving cancer chemotherapy. In a randomized, cross-over, double-blind study, 36 patients received haloperidol 2 milligrams (mg) or benzquinamide 50 mg intramuscularly, 10 minutes before chemotherapy administration. Patients preferred haloperidol over benzquinamide for control of emesis induced by cisplatin (78% versus 22%) or nitrogen mustard (67% versus 16%). However, patients receiv doxorubicin preferred benzquinamide (46% versus 38%). In patients previously unrelieved by prochlorperazine, haloperidol was more effective than benzquinamide (54% versus 29%). Complete relie of vomiting was achieved in 14 of 45 and 5 of 41 patients receiving haloperidol and benzquinamide, respectively (Neidhart et al, 1981a).

4.6.I Bromperidol

4.6.I.1 Psychotic disorder

a) In a double-blind 4-week study, bromperidol was compared with haloperidol in the initial treatment of psychotic patients (Denijs, 1980). The median daily oral dose was 9 to 12 mg for bromperidol and 12 mg haloperidol. Brief Psychiatric Rating Scale scores showed marked intragroup improvements for both bromperidol and haloperidol. Differences between the drugs were slight at all times. Nurses' Observatior Scale for Inpatient Evaluation-30 scores also showed intragroup improvement without significant intergrc differences. Bromperidol had more of an activating effect, while haloperidol was more antimanic. Most frequent side effects were tremor, parkinsonism, akathisia and increased salivation. For the bromperidol group, paroxysmal dyskinesia, sedation and orthostatic hypotension were also noted. Overall results showed that all bromperidol patients were either improved or unchanged (similar for haloperidol) and 19 20 patients tolerated bromperidol well. Bromperidol is equally effective as haloperidol in treating psychos

b) Bromperidol was compared with haloperidol in a double-blind study with 40 psychotic (mostly schizophrenic) patients (Poeldinger et al, 1977). Initial doses were 5 mg/day orally of either bromperidol haloperidol, with subsequent dosage adjustments At study end, the mean daily dose of each drug was 6 mg/day, with a range of 5 to 12 mg/day for bromperidol and 5 to 9 mg/day for haloperidol. Sixty-five perc of patients showed improvement with bromperidol and 50% with haloperidol, with negligible differences between the two drugs when directly compared. Global evaluation revealed that a majority of patients (1 out of 20 for each drug) had either very good, good, or moderate improvement, with only one bromperidc patient showing no improvement and one haloperidol patient having deteriorated. Parkinsonian side effe were observed in four bromperidol and three haloperidol patients. There were no autonomic or psychic s effects. Bromperidol is at least as effective a treatment for psychic disorders as haloperidol, on the basis its quicker onset of action.

c) The efficacy of bromperidol was compared with that of haloperidol in a 12-week double-blind controlle study involving 164 schizophrenic patients. Dosages were started at 3 to 6 mg daily and individually adjusted for best therapeutic response. Fifty-five percent of the bromperidol patients showed improveme compared to 38% for haloperidol. Bromperidol was judged to be a better form of treatment than the previous neuroleptic in 42.9% of the cases versus 23.8% for haloperidol. General improvement scores showed that bromperidol was more effective and had a quicker onset of action. Specific symptoms on th Brief Psychiatric Rating Scale were improved significantly more with bromperidol. Side effects reported (dystonia, akathisia, parkinsonism) were either less with bromperidol, or equal to haloperidol (Itoh, 1985)

4.6.J Carbamazepine

4.6.J.1 Drug-induced psychosis, Inhalant

a) Carbamazepine demonstrated comparable efficacy to haloperidol in the treatment of inhalant-induced psychotic disorder (Hernandez- Avila et al, 1998). Patients received either 1 capsule of carbamazepine 2 milligrams (mg) 3 times daily (n=20) or 1 capsule of haloperidol 5 mg 3 times daily (n=20) for 5 weeks. Doses were increased at weekly intervals by 1 capsule if the patient failed to show a 25% decrease in th Brief Psychiatric Rating Scale (BPRS). At the end of the study, mean daily doses were carbamazepine 9 mg (serum level of 10.8 micrograms/liter) and haloperidol 21.7 mg. Similar improvements were found in both groups with 48.3% improvement in the carbamazepine group and 52.7% improvement in the haloperidol group.

4.6.K Chlorpromazine

Delirium

Drug-induced psychosis - Phencyclidine-related disorder

Schizophrenia

4.6.K.1 Delirium

a) Chlorpromazine (n=13) and haloperidol (n=11) were effective and had few side effects in the treatmer of delirium in AIDS patients in a double-blind study; lorazepam (n=6) was not effective and was associat with adverse effects (Breitbart et al, 1996a). Average doses for the first 24 hours of treatment were lorazepam 3 mg, chlorpromazine 50 milligrams, and haloperidol 1.4 milligram. There was significant improvement in the 2 neuroleptic-treated groups in the first 24 hours as measured by the Delirium Ratinç Scale scores (p less than 0.001 for both groups). Very little further improvement was seen after day 2. Delirium symptoms did not improve in the lorazepam-treated group. Cognitive status as measured by the Mini-Mental State scale improved in the chlorpromazine group (p less than 0.001) and haloperidol group (NS), but did not improve in the lorazepam group. Few extrapyramidal side effects were associated with either neuroleptic drug, but all lorazepam-treated patients developed adverse effects that led to the remc of this drug from the protocol. The authors recommend further study to confirm their finding that early intervention with low-dose neuroleptics is effective in managing delirium in AIDS patients (Breitbart et al,

1996a).

4.6.K.2 Drug-induced psychosis - Phencyclidine-related disorder

a) Haloperidol was reported more effective than chlorpromazine in treating signs of psychosis secondary phencyclidine in one uncontrolled report (Giannini & Eighan, 1984). Haloperidol 5 milligrams intramuscularly (IM) was given in 2 separate doses 20 minutes apart or chlorpromazine 50 milligrams IM was administered in 2 separate doses according to the same schedule. The authors suspect that the greater benefits of haloperidol were attributable to specificity for DA-2 presynaptic sites.

4.6.K.3 Schizophrenia

a) Based upon comparisons of minimum effective dosages identified in placebo- controlled , fixed-dose and fixed-dose-ranging drug development trials, the minimum effective dose of haloperidol was 4 milligrams/day (equivalent to chlorpromazine 200 milligrams/day) (Woods SW, 2003).

b) Haloperidol was compared with placebo, chlorpromazine, diazepam, and imipramine as prophylactic agents to prevent relapse of schizophrenic patients. At the end of the three year trial, haloperidol and chlorpromazine significantly prolonged remission as compared to the other three treatments. Daily doses haloperidol were 3 milligrams; chlorpromazine doses were 75 milligrams (Nishikawa et al, 1982b).

4.6.K.4 Adverse Effects

a) Haloperidol, chlorpromazine, and sulpiride were compared in normal volunteers to test mood state (McClelland et al, 1990a). The twelve volunteers were assessed using sixteen visual analogue scales su as elapsed time estimation, tapping rate, body sway and tremor. The volunteers were divided into four groups: haloperidol (3 milligrams per day), chlorpromazine (50 milligrams per day), sulpiride (400 milligrams per day) and a placebo group. The results showed chlorpromazine and haloperidol users experienced reduced alertness and contentedness. Haloperidol reduced feelings of "calmness" in the volunteers. Sulpiride did not significantly alter vision in the volunteers. Haloperidol affected the informatic processing function, but did not affect motor ability and speed in the group taking this drug.

4.6.L Chlorprothixene

Schizophrenia

Tardive dyskinesia

4.6.L.1 Schizophrenia

a) Chlorprothixene was compared with (mean dose 251 milligrams/day; dose range 100 to 400 mg/day) haloperidol (mean dose 9 milligrams/day; dose range 5 to 16 mg/day) and placebo in a 3-week randomized, double-blind, crossover study of 34 patients with acute schizophrenia. There were no statistically significant differences in relation to efficacy (Marjerrison et al, 1971).

4.6.L.2 Tardive dyskinesia

a) The Nordic Dyskinesia Study Group (Anon, 1986) compared the effects of several neuroleptic drugs c tardive dyskinesia and parkinsonian symptoms in 33 chronic psychiatric patients in a crossover, randomized, open study. Treatment consisted of 6 months of therapy in each of 4 groups, preceded by a week, placebo-washout period. Treatment groups were chlorprothixene 132 to 142 milligrams/day, haloperidol 5.5 to 5.6 milligrams/day, perphenazine 16.8 to 24.2 mg/day, and haloperidol 11 milligrams/d in combination with biperiden 7 mg/day. Doses were chosen to be relatively equipotent according to established tables. Perphenazine, haloperidol, and haloperidol/biperiden all caused a reduction in tardive dyskinesia and an increase in parkinsonian symptoms. Chlorprothixene reduced tardive dyskinesia sligh and had no effect on parkinsonian symptoms. All drugs were equally effective at controlling psychotic symptoms. The authors concluded that long-term therapy with low-potency drugs presented a minimal ris of potentially irreversible tardive dyskinesia and a lower likelihood of inducing acute parkinsonian symptoms.

4.6.L.3 Adverse Effects

a) The Nordic Dyskinesia Study Group (Anon, 1986) compared the effects of several neuroleptic drugs c tardive dyskinesia and parkinsonian symptoms in 33 chronic psychiatric patients in a crossover, randomized, open study. Treatment consisted of 6 months of therapy in each of 4 groups, preceded by a week, placebo-washout period. Treatment groups were chlorprothixene 132 to 142 milligrams/day, haloperidol 5.5 to 5.6 milligrams/day, perphenazine 16.8 to 24.2 mg/day, and haloperidol 11 milligrams/d in combination with biperiden 7 mg/day. Doses were chosen to be relatively equipotent according to established tables. Perphenazine, haloperidol, and haloperidol/biperiden all caused a reduction in tardive dyskinesia and an increase in parkinsonian symptoms. Chlorprothixene reduced tardive dyskinesia sligh and had no effect on parkinsonian symptoms. All drugs were equally effective at controlling psychotic symptoms. The authors concluded that long-term therapy with low-potency drugs presented a minimal ris of potentially irreversible tardive dyskinesia and a lower likelihood of inducing acute parkinsonian symptoms.

4.6.M Clocapramine

4.6.M.1 Schizophrenia

a) In 26 chronic schizophrenia patients, clocapramine (75 mg/day initially, to a maximum of 700 mg/day) was compared with haloperidol (3 mg/day, to a maximum of 30 mg/day) in a double-blind, crossover stud lasting 28 weeks. There was no significant difference between the 2 drugs. Although no side effects were significant enough to terminate therapy, clocapramine produced fewer and milder side effects. The author concluded that clocapramine was equivalent to haloperidol in antipsychotic efficacy but superior in terms safety (Yamagami, 1985).

4.6.N Clomipramine

4.6.N.1 Autistic disorder

a) Among subjects who completed full therapeutic trials of haloperidol and clomipramine for treatment of autistic disorder, the two drugs were comparable; however, haloperidol was superior to clomipramine on intent-to-treat basis, because of the large proportion of patients who were unable to complete clomipram treatment due to side effects and behavior problems. In a double- blind, placebo-controlled crossover study, 36 subjects with a DSM- IV diagnosis of autism were given placebo, haloperidol, and clomipramin for periods of 7 weeks each. Clomipramine was begun at 25 milligrams (mg) at bedtime for 2 days and increased to 25 mg twice a day for 2 days, 25 mg 3 times a day for 2 days, and finally 50 mg twice a day Haloperidol was begun at 0.25 mg at bedtime for 2 days and increased to 0.25 mg twice a day for 2 days 0.25 mg 3 times a day for 2 days, and finally 0.5 mg twice a day. For both drugs, adjustments of the final dose could be made as clinically indicated. During week 7 of each period, drug dosages were tapered in preparation for the next treatment. Percentages of subjects completing each trial were 70% for haloperid 38% for clomipramine, and 66% for placebo. In the haloperidol trials, 7 of 10 discontinuations were for si effects (fatigue or lethargy, dystonia, depression) and the remainder for behavior problems. With clomipramine, 12 of 20 discontinuations were for side effects (fatigue or lethargy, tremors, tachycardia, insomnia, diaphoresis, nausea or vomiting, and decreased appetite) and the remainder for behavior problems. In the placebo trials, 10 of 11 discontinuations were for behavior problems. On an intent-to-tre basis, significant improvement in irritability (p less than 0.05) and hyperactivity (p less than 0.05) was see with haloperidol only (versus baseline). No differences among treatments were observed for stereotypic behavior, lethargy, or inappropriate speech. When data only from patients completing full therapeutic tria were assessed, both haloperidol and clomipramine were superior to baseline with regard to irritability and stereotypy (Remington et al, 2001).

4.6.O Clonazepam

Gilles de la Tourette's syndrome

Psychotic disorder

4.6.O.1 Gilles de la Tourette's syndrome

a) In a retrospective study, haloperidol, clonazepam, and clonidine were compared in the treatment of 8 patients suffering multifocal tic disorders, either Tourette's syndrome or chronic motor tics. The most effective drug for treating Tourette's syndrome was haloperidol, mean dose of 5.8 milligrams/day. The m effective drug for treating chronic motor tics was clonazepam, mean dose of 4.8 milligrams/day. Clonidin was effective in six patients, but only in combination with either haloperidol or clonazepam. The authors recommend treatment with clonazepam first, due to the risk of tardive dyskinesia associated with haloperidol. Then clonazepam in combination with clonidine, if clonazepam alone is not effective. Then in nonresponsive patients haloperidol should be used (Troung et al, 1988a).

4.6.O.2 Psychotic disorder

a) Clonazepam and haloperidol (both given by the intramuscular route) were compared for tranquilizatio of agitated psychotic patients with manic symptoms. Fifteen patients received three doses of either clonazepam 1 to 2 milligrams or haloperidol 5 to 10 milligrams at 30 minute intervals. Both drugs successfully controlled the agitation, but haloperidol gave a more rapid response (Chouinard et al, 1993a Better results may have been obtained by administering single higher doses of intramuscular (IM) clonazepam: 4 to 5 milligrams of IM clonazepam every 30 to 60 minutes seems to be effective, safe and rapid for the control of acute psychotic agitation and onset of action may be similar to IM haloperidol (Benazzi & Mazzoli, 1994).

4.6.P Clonidine

4.6.P.1 Gilles de la Tourette's syndrome

a) In a retrospective study, haloperidol, clonazepam, and clonidine were compared in the treatment of 8 patients suffering multifocal tic disorders, either Tourette's syndrome or chronic motor tics. The most effective drug for treating Tourette's syndrome was haloperidol, mean dose of 5.8 mg/day. The most effective drug for treating chronic motor tics was clonazepam, mean dose of 4.8 mg/day. Clonidine was effective in six patients, but only in combination with either haloperidol or clonazepam. The authors recommend treatment with clonazepam first, due to the risk of tardive dyskinesia associated with haloperidol. Then clonazepam in combination with clonidine, if clonazepam alone is not effective. Then i nonresponsive patients haloperidol should be used (Troung et al, 1988).

4.6.Q Clozapine

Hostile behavior

Schizophrenia, Refractory

4.6.Q.1 Hostile behavior

a) Clozapine reduced hostility in patients with schizophrenia and was superior to haloperidol and risperidone in that regard. One hundred fifty seven patients with a diagnosis of schizophrenia or schizoaffective disorder and a history of poor response to drug treatment were randomly assigned to receive clozapine, olanzapine, risperidone, or haloperidol in cross-titration with the antipsychotic drug us prior to the start of the study. Concomitant mood stabilizers and antidepressants had been phased out earlier. Daily doses of olanzapine, risperidone, and haloperidol were escalated within the first week to th target doses of 20, 8, and 20 milligrams (mg), respectively. Patients receiving clozapine were scheduled achieve the target daily dose of 500 mg on day 24. Doses remained fixed for the remainder of the initial 8 week period. In a second (6-week) period, doses were allowed to vary: 200 to 800 mg for clozapine, 10 t 40 mg for olanzapine, 4 to 16 mg for risperidone, and 10 to 30 mg for haloperidol. Hostility, measured by the hostility item of the Positive and Negative Syndrome Scale (PANSS), improved significantly (in comparison to baseline) in the clozapine group only (p=0.019). This effect was independent of effects on psychotic symptoms (delusional thinking, hallucinations) or on sedation. The effect of clozapine on hostil was superior to that of haloperidol (p=0.021) or risperidone (p=0.012) but not to that of olanzapine (Citro et al, 2001).

4.6.Q.2 Schizophrenia, Refractory

a) Olanzapine and risperidone improved neurocognitive deficits more than did haloperidol or clozapine i patients with schizophrenia or schizoaffective disorder that was refractory to treatment with typical antipsychotics. In a randomized, double-blind study, inpatients were given clozapine (n=24) 200 to 800 milligrams (mg) per day, olanzapine (n=26) 10 to 40 mg/day, risperidone (n=26) 4 to 16 mg day, or haloperidol (n=25) 10 to 30 mg/day. Dose escalation and fixed-dose treatment (target doses: olanzapine mg/day, risperidone 8 mg/day, haloperidol 20 mg/day, clozapine 500 mg/day) occurred during the first 8 weeks of the 14-week study; during the last 6 weeks, dosages were adjusted individually (generally increased if response was insufficient, but sometimes reduced because of adverse effects). Improvemer over time in global neurocognitive score was seen for olanzapine and risperidone. In general executive a perceptual organization and in processing speed and attention, improvement was seen with olanzapine. simple motor function, there was improvement with clozapine. Changes in global neurocognitive performance with olanzapine and risperidone were of medium magnitude (approximately 8 to 9 "IQ equivalents") but large enough to be clinically significant. Beneficial changes with clozapine were modes Despite cognitive gains, patients still had significant impairments of cognitive ability and social/vocationa functioning. Improvements in neurocognitive deficits were associated with improvements in negative symptoms (Bilder et al, 2002b).

b) Schizophrenic patients treated with clozapine were more likely to be rated as improved and less likel discontinue treatment due to lack of efficacy than a matched group treated with haloperidol. Seventy-one patients between the ages of 20 to 55 years with a diagnosis of schizophrenic or schizoaffective disorde were enrolled in this 6-month, double-blind, prospective, randomized trial. These outpatients, were documented as poor or partial responders to antipsychotic therapy and had a rating of at least moderate 1 of 4 Brief Psychiatric Rating Scale (BSRS) items (conceptual disorganization, suspiciousness, hallucinatory behavior, or unusual thought content). The two major outcome measures for this study wer time to discontinuation of study medication due to lack of clinical response and 20% improvement in the item BPRS cluster during two consecutive rating periods. The haloperidol group (n=34) was targeted to receive 10 milligrams (mg)/day, along with 2 mg/day of benztropine, while the clozapine group was to receive 500 mg/day (n=37). Doses could be adjusted in either group to a range of 4 to 16 mg/day for the haloperidol group and 200 to 800 mg/day for the clozapine group depending upon the patient's clinical course. At the end of 29 weeks, 50.5% of the haloperidol-treated group (mean dose 18.9 mg/day) and 11.6% of the clozapine group (mean dose 523 mg/day) had discontinued treatment due to lack of efficac (p=0.02). The mean BPRS ratings at the end of the study were 3.2 and 4.2 for the clozapine and haloperidol groups respectively (p less than 0.001). There was no difference found between the groups a

measured by the Schedule for Assessment of Negative Symptoms (SANS) score using the sum of the 4 global ratings. Haloperidol-treated patients experienced more dry mouth and decreased appetite, while t clozapine-treated group reported more salivation, sweating, and dizziness. Three haloperidol and 2 clozapine-treated patients dropped-out of the study due to adverse drug effects (Kane et al, 2001).

c) Clozapine exhibited improved efficacy with fewer adverse effects as compared to haloperidol in a randomized, double-blind, 12-month study conducted at Veterans Affairs medical centers (n=423 with refractory schizophrenia). Using intention-to-treat analysis, schizophrenia symptom scores were significantly improved with clozapine over haloperidol at 6 weeks (p equals 0.008) and 6 months (p equa 0.001), with no statistical difference in quality of life measures. When crossover cases were excluded, quality of life measures were significantly better in the clozapine group at 3 months and 1 year (p equals 0.02). Clozapine also reduced scores for tardive dyskinesia, akathisia and extrapyramidal syndrome. Clozapine's higher costs for drug acquisition and laboratory monitoring were offset by decreased inpatie hospital stays (Rosenheck et al, 1997).

d) These investigators later evaluated compliance with clozapine versus haloperidol. The results confirm that clozapine established better medication continuation and regimen compliance. Patients taking clozapine continued taking the study drug for a mean of 35.5 weeks as compared with on 27.2 weeks among haloperidol patients (p=0.0001). No differences were found between the groups in the proportion prescribed pills that were returned at any time point. Continuation with medication is greater with clozapi than haloperidol and is partly explained by greater symptom improvement and reduced side effects. No differences were discovered in regimen compliance (Rosenheck et al, 2000).

4.6.Q.3 Adverse Effects

a) The results of one study suggest that patients receiving atypical antipsychotics have a higher inciden of PANCREATITIS than patients receiving a conventional antipsychotic medication. In a retrospective, pharmacovigilance study, 192 cases of pancreatitis were identified in patients taking clozapine (mean do 306.7 milligrams (mg)/day), olanzapine (mean dose, 15 mg/day), risperidone, (mean dose, 4 mg/day) or haloperidol (mean dose, 8.2 mg/day). Of the identified cases, 40%, 33%, and 16% were related to treatment with the atypical antipsychotic medications clozapine, olanzapine, or risperidone, respectively, compared with 12% of the cases which were related to the conventional neuroleptic, haloperidol. In most patients, time to onset of pancreatitis was within 6 months after initiation of treatment (Koller et al, 2003b

b) No significant difference was found in sexual disturbances occurring in clozapine-treated versus haloperidol-treated patients (Hummer et al, 1999). Inpatients receiving either clozapine (n=100) or haloperidol (n=53) were screened. The most common adverse event in both groups was diminished sexu desire occurring in 4 (33.3%) of the haloperidol-treated women, 26 (63.4%) of the haloperidol-treated me 7 (28%) of the clozapine-treated women, and 43 (57.3%) of the clozapine-treated men. Among women treated, amenorrhea occurred in 4 (33.3%) of the haloperidol patients and in 3 (12%) of the clozapine patients. Larger studies may be needed to show differences.

c) In a prospective study, the incidence of alanine aminotransferase (ALT) elevation to more than twice upper normal limit was statistically greater with clozapine (37%, n=167) than with haloperidol (17%, n=71 Among those receiving clozapine, the rates of elevations in aspartate aminotransferase (AST) and gamm glutamyl transpeptidase (GGT) to more than twice the upper normal limit were 12% and 15%, respective No such increases in bilirubin or alkaline phosphatase occurred in clozapine-treated patients. These effe were transient in the majority of patients (disappearing by week 13) with no clinical manifestations report (Hummer et al, 1997).

4.6.R Diazepam

4.6.R.1 Schizophrenia

a) Haloperidol was compared with placebo, chlorpromazine, diazepam, and imipramine as prophylactic agents to prevent relapse of schizophrenic patients. At the end of the three year trial, haloperidol and chlorpromazine significantly prolonged remission as compared to the other three treatments. Daily doses haloperidol were 3 mg; chlorpromazine doses were 75 mg (Nishikawa et al, 1982a).

4.6.S Diphenhydramine

4.6.S.1 Dementia - Restlessness and agitation

a) Oxazepam, haloperidol, and diphenhydramine were equally efficacious in the treatment of agitated behavior in 59 elderly demented inpatients in an 8-week, double-blind study (Coccaro et al, 1990a). The mean daily doses were oxazepam 30 +/- 19.4 mg, haloperidol 1.5 +/- 0.9 mg, and diphenhydramine 81.3 +/- 48.5 mg. Chloral hydrate was given if the study medication did not adequately control agitation. Ratin scale scores indicated that diphenhydramine and haloperidol were more effective than oxazepam, but no of the differences in scores among the groups was significant. Only modest improvement was seen in terms of agitated behavior and activities of daily living. There was only a slight decrease in the use of chloral hydrate in all 3 groups during the study and no difference among the groups.

4.6.T Droperidol

Agitation

Postoperative nausea and vomiting

4.6.T.1 Agitation

a) In equal doses, intramuscular (IM) droperidol controlled agitation more rapidly than haloperidol withou difference in side effect occurrence. A randomized, double-blind, prospective study (Thomas et al, 1992) compared haloperidol versus droperidol for chemical restraint in agitated or violent patients. Sixty-eight patients randomly received 5 mg of haloperidol or droperidol by the intravenous (IV) or IM routes and we monitored for behavior control on a combativeness scale ranging 1 to 5. Patients were also monitored fo side effects and vital sign changes. Patients were compared at 5, 10, 15, 30 and 60 minutes after injectic of drug. Intramuscular droperidol controlled combativeness significantly more than IM haloperidol at ten, and 30 minutes while no significant difference was noted at 60 minutes in equal doses. No significant difference in behavior control was seen when the drugs were given IV.

b) In a double-blind study (Resnick & Burton, 1984), intramuscular droperidol and haloperidol were compared in the treatment of 27 acutely agitated patients. Patients received either droperidol 5 milligram or haloperidol 5 milligrams intramuscularly, and were psychologically evaluated at 15 minutes following initial injection and at 30-minute intervals for 3 hours thereafter. At 30 minutes following the initial treatme 36% of the droperidol-treated and 81% of the haloperidol-treated patients required a second injection. Bo agents were well tolerated. The investigators recognize the greater sedative effect associated with droperidol, and admit that this property may explain the more rapid control of patients in the droperidol-treated group.

4.6.T.2 Postoperative nausea and vomiting

a) Intramuscular (IM) droperidol 5 mg was compared with a single IM dose of haloperidol 2 mg and prochlorperazine 10 mg as a premedicant in a group of 65 patients. The incidence of vomiting with droperidol at 0.5 to 1 hour postoperatively was 50% compared to 7% with haloperidol. However, droperic exerted its antiemetic effect up to 24 hours as compared with haloperidol and prochlorperazine, which ha a duration of only 4 hours. Ideally a combination of droperidol and haloperidol should be used to provide rapid onset with a long duration of effect (Loeser et al, 1979).

4.6.U Flunitrazepam

4.6.U.1 Aggressive behavior - Psychotic disorder

a) Intramuscularly administered flunitrazepam and haloperidol were similarly effective in controlling agitated or aggressive behavior in emergency psychiatric situations (Dorevitch et al, 1999). In the study group of 28 patients, 19 with schizophrenia, 7 with schizoaffective disorder, and 2 with bipolar disorder), intramuscular injection of either flunitrazepam 1 milligram (mg) or haloperidol 5 mg during an acute aggressive outburst significantly reduced Overt Aggression Scale scores (p less than 0.001, time effect). 90 minutes post-administration, the rate of response reduction in total Overt Aggression Scale score was 80% (12/15) in the flunitrazepam group and 92% (12/13) in the haloperidol group (p=0.34). Flunitrazepar reached its maximal antiaggressive effect 30 minutes after administration, while haloperidol increased its activity more gradually, and the difference in antiaggressive effect over time was significant (p less than 0.01, time-by-group interaction). In both groups, the reduction in aggression level lasted for at least 120 minutes after drug administration. Each drug induced marked sedation in 3 patients.

4.6.V Flupenthixol

Psychotic disorder

Schizophrenia

4.6.V.1 Psychotic disorder

a) An open trial of flupenthixol versus haloperidol was conducted in 40 acutely psychotic patients in an open, 28-day controlled study. Patients received oral flupenthixol 32 to 192 milligrams/day (mean dose 1 mg/day) or oral haloperidol 2 to 50 milligrams/day (mean dose 18 mg/day) as required for control of psychotic symptoms. While global assessment revealed a significant reduction in severity of symptoms i both groups, 5 patients receiving flupenthixol had complete or almost complete remission of symptoms a the 28-day assessment, whereas none of those taking haloperidol had achieved this degree of remissior In addition, anxiety/depression scores improved considerably with flupenthixol, whereas haloperidol had little effect. Flupenthixol also had an activating effect, but haloperidol did not. The authors felt that while both drug were effective, flupenthixol had a faster onset of symptom control than haloperidol. However, a these doses it caused more extrapyramidal symptoms than haloperidol (Parent & Toussaint, 1983).

4.6.V.2 Schizophrenia

a) Haloperidol decanoate (mean dose 131 to 151 milligrams/4 weeks) was compared with flupenthixol

decanoate (mean dose 56 to 66 milligrams/4 weeks) in 32 schizophrenic patients in a 48 week, double-blind, crossover study. Side effects of the two drugs were comparable, but therapeutic efficacy near the e of each dosing period was significantly better for haloperidol than flupenthixol. The investigators recommended a shorter dosing interval for flupenthixol (Eberhard & Hellbom, 1986).
b) Haloperidol was reported superior to flupenthixol in producing lower levels of psychopathology in chronic schizophrenic inpatients in a double-blind, crossover study (Ehmann et al, 1987). Average doses haloperidol and flupenthixol at the time of final assessments were 33 milligrams daily (range, 10 to 84 milligrams) and 27 mg daily (range, 8 to 84 mg daily), respectively. Significantly less psychiatric disturba was observed during haloperidol therapy as determined by the Rating Scale of the Mental State (RSMS) and the BPRS Agitation-Excitement Scale: Less psychopathology was also observed with haloperidol or total scores for BPRS but this was not significant. Side effects were similar with both agents, primarily extrapyramidal symptoms. In addition, no evidence was observed to suggest that flupenthixol is useful in "activating" chronic schizophrenic patients, or in alleviating affective symptoms.

4.6.W Fluphenazine

Gilles de la Tourette's syndrome

Schizophrenia

4.6.W.1 Gilles de la Tourette's syndrome

a) In 23 patients with Tourette's syndrome who had previously been treated with haloperidol, fluphenazi treatment was equally efficacious but fluphenazine produced fewer side effects. The previous treatment consisted of haloperidol 1.5 to 9 milligrams/day for 2 months to 9 years and was replaced with fluphenzir 1 to 16 milligrams/day for 1 month to 2.75 years (Singer et al, 1986).

4.6.W.2 Schizophrenia

a) Haloperidol decanoate and fluphenazine decanoate were equally efficacious in an 8-month study in schizophrenic patients (Chouinard et al, 1984). Haloperidol decanoate was given in doses of 15 to 900 milligrams (median, 225 mg) every 2 to 4 weeks with fluphenazine decanoate administered in doses of 2 to 300 milligrams per injection (median, 75 mg) every 2 to 4 weeks. No significant differences between th 2 drugs were observed with regard to therapeutic efficacy; however, tardive dyskinetic movements of the tongue and jaw were more severe in haloperidol-treated patients.
b) Haloperidol decanoate was compared with fluphenazine decanoate in 38 schizophrenic inpatients in parallel, single-blind study which lasted for 60 weeks. Doses were based on standard relative potency assignments calculated from previous neuroleptic medication, and haloperidol and fluphenazine were considered equipotent. The haloperidol patients had better mental states but poorer ward behavior and lower parkinsonism scores compared with the fluphenazine group (McKane et al, 1987).

4.6.X Imipramine

4.6.X.1 Schizophrenia

a) Haloperidol was compared with placebo, chlorpromazine, diazepam, and imipramine as prophylactic agents to prevent relapse of schizophrenic patients. At the end of the three-year trial, haloperidol and chlorpromazine significantly prolonged remission as compared to the other three treatments. Daily doses haloperidol were 3 milligrams; chlorpromazine doses were 75 mg (Nishikawa et al, 1982).

4.6.Y Lithium

4.6.Y.1 Aggressive behavior

a) The same results of the same study were published in two different journals (Platt et al, 1984, 1984a) (Campbell et al, 1984). They compared the effects of lithium (mean dose 1,166 mg/day) to haloperidol (mean dose 2.95 mg/day) on cognition in hospitalized school-age children with conduct disorder. After a two week placebo period to eliminate placebo responders, 61 children were divided into haloperidol, lithium, or placebo groups. Both drugs gave better responses by a variety of tests and were equally effective. Haloperidol produced significantly more side effects.

4.6.Z Lorazepam

Agitation - Psychotic disorder

Delirium

4.6.Z.1 Agitation - Psychotic disorder

a) The combination of haloperidol and lorazepam was suggested to be more effective than lorazepam alone in agitated patients presenting to the psychiatric emergency service (Bieniek et al, 1998). Patients who met clinical criteria for the use of chemical restraints and had a minimum score of 4 on the Overt Aggression Scale received either lorazepam 2 milligrams (mg) (n=11) or haloperidol 5 mg and lorazepan mg (n=9). Combination therapy was significantly better than lorazepam alone after 1 hour according to th Overt Aggression Scale and the visual analog scale (p less than 0.05). However, on the Clinical Global Impressions severity scale, the comparison was not significant. With repeated measures of analyses of variance, both groups improved over time.

b) Repeated doses of either lorazepam 2 milligrams or haloperidol 5 milligrams were equally effective fo the early treatment of acute agitation in psychotic patients (Battaglia et al, 1997). In a double-blind, randomized study, 98 patients received either intramuscular lorazepam, haloperidol, or both. Patients received 1 to 6 injections in a 12-hour period depending upon clinical need. Effective symptom reduction was achieved in each treatment group with significant decreases from baseline at every hourly evaluatio (p less than 0.01). Mean differences on the Agitated Behavior Scale and modified Brief Psychiatric Ratin Scale suggested that tranquilization was most rapid in patients receiving the combination therapy (p less than 0.05).

4.6.Z.2 Delirium

a) Chlorpromazine (n=13) and haloperidol (n=11) were effective and had few side effects in the treatmer of delirium in AIDS patients in a double-blind study; lorazepam (n=6) was not effective and was associat with adverse effects (Breitbart et al, 1996). Average doses for the first 24 hours of treatment were lorazepam 3 mg, chlorpromazine 50 mg, and haloperidol 1.4 mg. There was significant improvement in t 2 neuroleptic-treated groups in the first 24 hours as measured by the Delirium Rating Scale scores (p les than 0.001 for both groups). Very little further improvement was seen after day 2. Delirium symptoms did not improve in the lorazepam-treated group. Cognitive status as measured by the Mini-Mental State scal improved in the chlorpromazine group (p less than 0.001) and haloperidol group (NS), but did not improv in the lorazepam group. Few extrapyramidal side effects were associated with either neuroleptic drug, bu all lorazepam-treated patients developed adverse effects that led to the removal of this drug from the protocol. Breitbart et al recommend further study to confirm their finding that early intervention with low-dose neuroleptics is effective in managing delirium in AIDS patients.

4.6.AA Loxapine

4.6.AA.1 Schizophrenia

a) Intramuscular loxapine and intramuscular haloperidol at the usual therapeutic doses were shown to b comparable in the initial management of hostile and aggressive schizophrenic patients. Both drugs resul in rapid improvement in symptoms of hostility and uncooperativeness, and produced desirable sedation. The maintenance of therapeutic response after conversion to oral medication was also comparable between the 2 drugs (Tuason, 1986).

4.6.AB Melperone

4.6.AB.1 Anxiety

a) The effects of melperone, chlorpromazine, haloperidol, and diazepam on artificially-induced anxiety were compared in normal subjects. Autonomic (skin conductance) response evoked during aversive classical conditioning was measured in eleven healthy subjects. Single oral doses of placebo, melperone 10 mg, melperone 50 mg, chlorpromazine 50 mg, diazepam 10 mg, and haloperidol were administered randomly to each member of the study group. There was a minimum of 10 days between tests. Judging from the data which indicates a subject's anxiety level in this experimental setting, ie, skin conductance level during habituation and reinforcement, its pattern of changes and fluctuations, etc, it may be conclud that diazepam, the higher (50 mg) dose of melperone and chlorpromazine are effective anxiolytics. Whereas melperone 50 mg reduced skin conductance level, and eliminated anticipatory responses, melperone 10 mg (as well as haloperidol) had no effect upon conditioned and unconditioned responses (Molander, 1982).

4.6.AC Mesoridazine

4.6.AC.1 Schizophrenia

a) Mesoridazine was compared with haloperidol in a group of 39 schizophrenic patients in an attempt to correlate the response seen in the first 48 hours, as measured by the Dysphoric Response Index (DRI) v ultimate outcome of therapy (White et al, 1981). The daily dosage of haloperidol was 2 to 100 milligrams (mean 28 mg) and of mesoridazine was 100 to 800 milligrams (mean 421 mg). The outcome as measure by BPRS (Brief Psychiatric Rating Scale and CGI (Clinical Global Impressions Scale), was equivalent fo the two regimens. Side effects for the two regimens were significantly different. Correlation of the DRI to ultimate outcome was poor.

4.6.AD Metoclopramide

4.6.AD.1 Chemotherapy-induced nausea and vomiting

a) Metoclopramide (2 mg/kg) was compared with haloperidol (3 mg total dose) for the control of cisplatir induced emesis (Grunberg et al, 1984). Both drugs were administered intravenously two hours for five doses beginning one-half hour before cisplatin therapy. Twenty-eight patients completed the cross-over study. Metoclopramide resulted in 1.92 vomiting episodes (range 0-5) with 36% exhibiting no vomiting. Haloperidol resulted in 3.04 vomiting episodes (range 0-8) with 20% having no vomiting. Metoclopramide showed a minor but not significant advantage.

4.6.AE Midazolam

4.6.AE.1 Psychotic disorder

a) A single-blind study of fifteen healthy male schizophrenic patients found intramuscular administration 250 milligrams (mg) of sodium amytal or 5 mg of midazolam significantly more effective than 10 mg of haloperidol in controlling motor agitation. Midazolam and sodium amytal were also more effective than haloperidol in controlling hostility, though this did not reach statistical significance. No significant differen in controlling auditory hallucinations or flight of ideas was noted (Wyant et al, 1990a).

4.6.AF Molindone

Psychotic disorder

Tardive dyskinesia

4.6.AF.1 Psychotic disorder

a) Molindone and haloperidol were comparable in a study of 24 acutely psychotic patients (Binder et al, 1981). The dose of molindone was 25 milligrams 2 to 4 times/day (+ as needed) the dose of haloperidol was 5 milligrams 2 to 4 times/day (+ as needed). Both drugs were given intramuscularly. Evaluation of results was based on Brief Psychiatric Rating Scale, Target Symptom Rating Scale, and Clinical Global Impression.

b) Molindone (up to 225 milligrams/day by injection followed by up to 500 mg/day orally) was compared with haloperidol (up to 45 milligrams/day by injection followed by 100 mg/day orally) in 35 acutely schizophrenic patients in a double-blind study. There were no significant differences in efficacy or safety over the 4 weeks of the study (Escobar et al, 1985).

4.6.AF.2 Tardive dyskinesia

a) Haloperidol was more effective than molindone at masking tardive dyskinesia which was exacerbatec by withdrawal of neuroleptic medication. Molindone was compared with haloperidol with regard to their ability to mask neuroleptic withdrawal-exacerbated tardive dyskinesia, using the theoretical proposition th agents less able to mask are less dyskinetogenic (Glazer et al, 1985). In a parallel, double-blind study, 1 patients were given either molindone or haloperidol in doses ranging from 50% to 200% dose equivalenc to the neuroleptics from which they had been removed, at a point after discontinuation where involuntary movements showed a significant increase. At doses that were equivalent to 200% of the prestudy neuroleptic dose, molindone was shown to be less able to mask neuroleptic withdrawal-exacerbated tarc dyskinesia than was haloperidol, thereby suggesting lower dyskinetogenic potential.

4.6.AG Olanzapine

Adverse reaction to cannabis - Drug-induced psychosis

Mania

Schizophrenia

Tardive dyskinesia

4.6.AG.1 Adverse reaction to cannabis - Drug-induced psychosis

a) Olanzapine was as effective as haloperidol in the treatment of cannabis-induced psychotic disorder (Berk et al, 1999). In a double- blind study, patients with a psychotic episode associated with cannabis u were randomized to receive either olanzapine 10 milligrams (n=15) or haloperidol 10 mg (n=15). After 4 weeks there was a significant improvement in both groups as compared to baseline measured on the Bri Psychiatric Rating Scale (p=0.0002 for olanzapine, p=0.0001 for haloperidol). There was no significant

difference between the 2 groups. Olanzapine was associated with fewer extrapyramidal side effects.

4.6.AG.2 Mania

a) Olanzapine and haloperidol therapies were similarly effective in the treatment of acute mania in patie with bipolar disorder. In a randomized, double-blind study, patients with bipolar I disorder, mixed or mani episode and a Young-Mania Rating Scale (Y-MRS) score of at least 20 received either olanzapine (5 to 2 milligram (mg)/day) or haloperidol (3 to 15 mg/day) at flexible doses for 6 weeks. Patients showing symptom improvement entered a 6-week continuation phase in which they received ongoing treatment. Symptomatic remission was defined as a Y-MRS score of 12 or less and a Hamilton Rating Scale for Depression score (HAM-D) of 8 or less at week 6. Symptomatic remission rates for patients in the olanzapine group were similar to those of patients in the haloperidol group at week 6 (52.1% vs 46.1%, respectively; p=NS) and week 12 (51.7% vs 43.8%, respectively; p=NS). However, olanzapine treatment produced greater improvements in health- related quality of life factors as compared with haloperidol treatment (Shi et al, 2002).

4.6.AG.3 Schizophrenia

a) SUMMARY: Olanzapine is more effective than haloperidol for the treatment of negative symptoms of schizophrenia; both agents are similarly effective in managing positive symptoms. Olanzapine is less like to induce extrapyramidal reactions or elevation of serum prolactin levels.

b) Olanzapine and risperidone improved neurocognitive deficits more than did haloperidol or clozapine i patients with schizophrenia or schizoaffective disorder that was refractory to treatment with typical antipsychotics. In a randomized, double-blind study, inpatients were given clozapine (n=24) 200 to 800 milligrams (mg) per day, olanzapine (n=26) 10 to 40 mg/day, risperidone (n=26) 4 to 16 mg day, or haloperidol (n=25) 10 to 30 mg/day. Dose escalation and fixed-dose treatment (target doses: olanzapine mg/day, risperidone 8 mg/day, haloperidol 20 mg/day, clozapine 500 mg/day) occurred during the first 8 weeks of the 14-week study; during the last 6 weeks, dosages were adjusted individually (generally increased if response was insufficient, but sometimes reduced because of adverse effects). Improvemer over time in global neurocognitive score was seen for olanzapine and risperidone. In general executive a perceptual organization and in processing speed and attention, improvement was seen with olanzapine. simple motor function, there was improvement with clozapine. Changes in global neurocognitive performance with olanzapine and risperidone were of medium magnitude (approximately 8 to 9 "IQ equivalents") but large enough to be clinically significant. Beneficial changes with clozapine were modes Despite cognitive gains, patients still had significant impairments of cognitive ability and social/vocationa functioning. Improvements in neurocognitive deficits were associated with improvements in negative symptoms (Bilder et al, 2002).

c) Olanzapine was at least as effective as and safer than haloperidol for the treatment of schizophrenia a large population of Japanese patients with positive and negative symptoms resistant to treatment with typical antipsychotics. In a randomized, double-blind trial, 182 patients were given olanzapine, starting at milligrams (mg) per day and increased to a maximum of 15 mg/day, or haloperidol, starting at 4 mg/day a increasing to 12 mg/day, for 8 weeks. Mean modal daily doses were 10.5 mg for olanzapine and 8 mg fo haloperidol. The proportion of olanzapine-treated patients who showed moderate to remarkable improvement was 44.5%, compared to 40.5% of haloperidol-treated patients. The 95% confidence interv was -8% to 16% favoring olanzapine. Thus, olanzapine was not inferior to haloperidol in efficacy. Total a subscale scores on the Positive and Negative Symptom Scale (PANSS) were numerically better in the olanzapine group than in the haloperidol group, but only on the negative symptoms subscale did the difference reach statistical significance (p=0.024). Eighty-one percent of olanzapine-treated patients and 66% of haloperidol-treated patients finished the study, with fewer dropping out of the olanzapine group because of adverse events or abnormal laboratory values (8 vs 22). Olanzapine-treated patients showe an improvement in extrapyramidal symptoms, whereas haloperidol-treated patients showed a worsening less than 0.001). Treatment-emergent parkinsonism occurred in 3.2% of the olanzapine group and 18.8% of the haloperidol group. By the end of treatment, parkinsonism had resolved in all patients in the olanzapine group but was sustained in 7.8% of the haloperidol group. There was a significantly greater incidence of insomnia, akathisia, tremor, anorexia, increased salivation, bradykinesia, abnormal gait, nausea, and weight decrease in haloperidol-treated patients than in olanzapine-treated patients. Only weight gain was significantly greater with olanzapine (0.96 kilogram vs -0.71 kilogram, p less than 0.001) Thirty-two percent of olanzapine-treated patients showed no adverse drug reaction and no laboratory abnormality, compared to 15.5% of haloperidol-treated patients (p=0.008) (Ishigooka et al, 2001).

d) Olanzapine has been at least as effective as haloperidol, each given for six weeks, in the treatment o schizophrenia (Tollefson et al, 1997); (Beasley et al, 1996)(Anon, 1996; Anon, 1995). Overall improveme based on Brief Psychiatric Rating Scale (BPRS) total scores, has been greater with olanzapine; this reached significance in the largest trial (Anon, 1996). Both agents have produced similar decreases in positive symptoms, and the superior overall improvement with olanzapine is attributed to a greater reduction in negative symptoms in these patients, particularly in higher dosages (12.5 to 17.5 mg daily); decreases in negative symptoms have been significantly greater with olanzapine on the Scale for the Assessment of Negative Symptoms (SANS) and Positive and Negative Syndrome Scale (PANSS), although significance was not achieved on the BPRS-negative scale in one study (Beasley et al, 1996). Significantly more patients have demonstrated greater than 80% improvement in BPRS-total scores with olanzapine, whereas the percentage with lower levels of improvement has not always differed significant

between drugs.
e) Intramuscular (IM) olanzapine successfully treated acutely agitated patients with schizophrenia in 3 clinical trials. Two open-label, single-blind trials evaluated 108 patients receiving fixed or variable doses 2.5, 5.0, 7.5, or 10.0 milligram (mg) given as 1 to 4 injections daily (QD) for 3 days, followed by 10 to 20 orally (PO) QD for 2 days. Response was assessed using the Brief Psychiatric Rating Scale (BPRS); the positive subscale improved during both IM and PO Administration (no statistical analysis was performed) The third study was a multicenter, double-blind, placebo-controlled trial that compared IM olanzapine wit IM haloperidol in the treatment of acute agitation. Patients (n=311) received up to 3 doses of olanzapine (10 mg), haloperidol (7.5 mg) or placebo in 24 hours. Thereafter, patients were treated with oral olanzapi (5 to 20 mg QD) or oral haloperidol (5 to 20 mg QD) for 4 days. Patients treated with IM olanzapine or haloperidol showed significantly greater improvement over placebo at 2 and 24 hours as measured by th BPRS positive subscale, but no differences were observed between olanzapine- and haloperidol-treated patients. Patients treated with intramuscular olanzapine continued to improve to day 5; but, there was nc significant difference between patients treated with IM drug between baseline and day 5 (Jones et al, 20
f) In a study of 300 patients with schizoaffective disorder, olanzapine treated patients showed significant greater improvement than haloperidol treated patients on the Brief Psychiatric Rating Scale (BPRS) total (p=0.002), Positive and Negative Syndrome Scale (PANSS) total (p=0.003), PANSS negative (p=0.006), and Montgomery-Asberg Depression Rating Scale (MADRS) total (p less than 0.001). Patients were take from a larger prospective, double blind study. Patients were assessed weekly for a six week acute phase with responders followed for up to 1-year. Among acute phase patients with bipolar subtype, olanzapine to 20 milligrams) was superior to haloperidol (5 to 20 milligrams) in the BPRS (p=0.012), PANSS negativ (p=0.031) and total (p=0.028), and MADRS (p less than 0.001); however, in depressed subtype patients, no significant differences were seen when compared to haloperidol treated patients. During the double-blind extension phase, the only significant difference between treatment groups was in the MADRS total score in favor of olanzapine (p=0.045). Extrapyramidal symptoms were less severe among olanzapine treated patients (p=0.016), but weight gain was more problematic (p=0.032) (Tran et al, 1997).
g) In a 6-week randomized study of 83 patients with first-episode psychosis (schizophrenia, schizophreniform disorder, or schizoaffective disorder), patients receiving olanzapine showed significantl greater improvement on the Brief Psychiatric Rating Scale (BPRS) and the Positive and Negative Symptoms Scale (PANSS) as compared to patients receiving haloperidol. Patients greater than 45 years age at onset of symptoms with a disease duration of greater than 5 years received olanzapine or haloperidol 5 milligrams (mg) per day and adjusted every 7 days within the range of 5 to 20 mg per day. the BPRS, 67.2% of olanzapine treated patients experienced a 40% or greater improvement from baseli compared to 29.2% of haloperidol treated patients (p=0.003). Olanzapine treated patients also improved more on the PANSS total score (p=0.02) and positive symptom score (p=0.03) compared to haloperidol treated patients. Using the Simpson-Angus scale, olanzapine patients showed improvement in extrapyramidal symptoms, whereas haloperidol treated patients worsened (p less than 0.001). Somnoler was more common in olanzapine treated patients, whereas akathisia and hypertonia were more commor with haloperidol (Sanger et al, 1999).
h) Olanzapine showed a superior and broader spectrum of efficacy over haloperidol in the treatment of schizophrenia and also had a more favorable safety profile (Tollefson et al, 1997). In a large internationa multicenter double-blind trial, olanzapine (N=1336) was compared to haloperidol (N=660) over 6 weeks. Starting doses were 5 milligrams (mg) for both drugs which could be increased by 5 mg increments at th investigator's discretion to a maximum of 20 mg/day. Olanzapine was significantly superior to haloperido on the Brief Psychiatric Rating Scale (p less than 0.02), the Positive and Negative Syndrome Scale (p=0.05), the clinical Global Impression severity score (p less than 0.03), and the Montgomery-Asberg Depression Rating Scale total score (p=0.001). Significant advantages were also seen in the extrapyramidal profiles and effects on prolactin levels. Further analyses revealed that depressive signs a symptoms were also better controlled with olanzapine therapy (Tollefson et al, 1998). On the Montgomer Asberg Depression Rating Scale, olanzapine was significantly more effective than haloperidol (p = 0.001
i) In multiple clinical trials of olanzapine, the incidence of self-directed aggression among patients receiv olanzapine, haloperidol, or placebo, was not significantly different (Keck et al, 2000). These trials indicate a significantly greater improvement in suicidal thoughts in olanzapine-treated patients compared with haloperidol-treated patients. Another analysis demonstrated a 2.3-fold reduction in the annual suicide attempt rate among chronic psychotic patients receiving olanzapine versus haloperidol.

4.6.AG.4 Tardive dyskinesia
a) Olanzapine was associated with a lower incidence of tardive dyskinesia when compared to haloperid (Tollefson, 1997a). Data combined from 3 controlled and blinded studies evaluating patients with schizophrenia, schizophreniform disorder, or schizoaffective disorder treated with olanzapine (n=707) or haloperidol (n=197) were compared. Patients had no evidence of tardive dyskinesia at baseline. At any v after baseline 7.1% of patients in the olanzapine group and 16.2% of patients in the haloperidol group manifested treatment-emergent tardive dyskinesia (p less than 0.001). At the last study visit, 2.3% of olanzapine patients and 7.6% of haloperidol patients manifested tardive dyskinesia (p equal to 0.001). Similar results have been reported (Beasley et al, 1999).
4.6.AG.5 Efficacy
a) Results of a retrospective analysis showed that olanzapine treatment was associated with a lower rat of extrapyramidal symptoms (EPS) than haloperidol, but was similar to rates occurring with risperidone a

clozapine therapy. In a pooled analysis of 23 randomized, controlled clinical trials in 4611 patients with schizophrenia, frequency and severity of EPS associated with olanzapine therapy (2.5 to 20 milligrams (mg)/day) was compared with that of haloperidol (1 to 20 mg/day), risperidone (4 to 12 mg/day), clozapir (25 to 625 mg/day), and placebo. Dystonic events (ie, dystonia, oculogyric crisis, opisthotonos, torticollis occurred in significantly fewer patients during olanzapine treatment as compared with haloperidol (0.5% 5.6%, respectively; p less than 0.001) or risperidone (1% vs 3.2%, respectively; p=0.047) treatment, whil no significant difference was found between olanzapine- and clozapine-treated patients. As compared w olanzapine-treated patients, a significantly higher percentage of haloperidol-treated patients experiencec parkinsonian events (ie, akinesia, cogwheel rigidity, extrapyramidal syndrome, hypertonia, hypokinesia, masked facies, and tremor) (9.3% vs 28.3%, respectively; p less than 0.001) or akathisia events (ie, akathisia, hyperkinesia) (6.7% vs 20.4%, respectively; p less than 0.001) during therapy. However, no significant difference was observed between the olanzapine group as compared with the placebo, risperidone, or clozapine groups in regard to the occurrence of parkinsonian or akathisia events. Overall, EPS occurred in significantly more patients treated with haloperidol as compared with olanzapine (44.4% vs 16.2%, respectively; p less than 0.001) and in fewer patients treated with clozapine as compared with olanzapine (2.6% vs 6.8%, respectively; p=0.047). The overall rate of EPS was similar between the placebo and risperidone groups as compared with olanzapine. Significantly fewer patients received anticholinergic medications in the olanzapine group as compared with the haloperidol (p less than 0.001) risperidone (p=0.018) groups. No difference was found between olanzapine-treated patients as compare with placebo or clozapine in regard to percentage of patients given anticholinergic drugs during therapy (Carlson et al, 2003).

b) Pooled safety results from 3 large double-blind, controlled trials in 2606 patients demonstrated that olanzapine had a significantly lower rate of any extrapyramidal symptoms (EPS) occurring versus haloperidol (p less than 0.001) (Tran et al, 1997). Also statistically fewer patients treated with olanzapine discontinued the study because of EPS (p less than 0.001). This suggests that the use of olanzapine ma be associated with better long-term compliance due to fewer adverse effects.

c) The risk of extrapyramidal adverse effects is lower with olanzapine compared to haloperidol, especial dystonic reactions. Increases in serum prolactin have been significantly less with olanzapine (Tollefson e al, 1997); (Beasley et al, 1996)(Anon, 1996; Anon, 1995).

4.6.AG.6 Adverse Effects

a) The results of one study suggest that patients receiving atypical antipsychotics have a higher incidenc of PANCREATITIS than patients receiving a conventional antipsychotic medication. In a retrospective, pharmacovigilance study, 192 cases of pancreatitis were identified in patients taking clozapine (mean do 306.7 milligrams (mg)/day), olanzapine (mean dose, 15 mg/day), risperidone, (mean dose, 4 mg/day) or haloperidol (mean dose, 8.2 mg/day). Of the identified cases, 40%, 33%, and 16% were related to treatment with the atypical antipsychotic medications clozapine, olanzapine, or risperidone, respectively, compared with 12% of the cases which were related to the conventional neuroleptic, haloperidol. In most patients, time to onset of pancreatitis was within 6 months after initiation of treatment (Koller et al, 2003).

4.6.AH Oxazepam

4.6.AH.1 Dementia - Restlessness and agitation

a) Oxazepam, haloperidol, and diphenhydramine were equally efficacious in the treatment of agitated behavior in 59 elderly demented inpatients in an 8-week, double-blind study (Coccaro et al, 1990). The mean daily doses were oxazepam 30 +/- 19.4 milligrams, haloperidol 1.5 +/- 0.9 milligrams, and diphenhydramine 81.3 +/- 48.5 mg. Chloral hydrate was given if the study medication did not adequately control agitation. Ratings scale scores indicated that diphenhydramine and haloperidol were more effecti than oxazepam, but none of the differences in scores among the groups was significant. Only modest improvement was seen in terms of agitated behavior and activities of daily living. There was only a slight decrease in the use of chloral hydrate in all 3 groups during the study and no difference among the grou

4.6.AI Oxcarbazepine

4.6.AI.1 Bipolar disorder

a) Oxcarbazepine has been compared with with haloperidol in 42 patients with acute mania; mean dose used were 2400 mg/day and 42 mg/day respectively. Although the response to oxcarbazepine was slow by the end of the second week of treatment, results were similar in both treatment groups. Haloperidol-treated patients had a significantly higher incidence of adverse effects (Emrich, 1990).

4.6.AJ Penfluridol

Gilles de la Tourette's syndrome

Schizophrenia

4.6.AJ.1 Gilles de la Tourette's syndrome

a) Haloperidol has been the drug of choice for Tourette's syndrome for many years, producing beneficia effects in up to 90% of patients treated (Shapiro & Shapiro, 1981; Shapiro et al, 1983). However, advers effects with haloperidol, mainly extrapyramidal symptoms, have limited its use in many patients. Penfluri and pimozide have both been evaluated in the treatment of Tourette's syndrome, based upon animal studies suggesting that each drug has catecholamine blocking effects that differ from haloperidol (Nose Takemoto, 1975). Penfluridol is presumed to be a more specific blocker of dopamine than haloperidol. In addition, it is postulated that penfluridol produces less frequent and less severe extrapyramidal toxicity th haloperidol (Ayd, 1972). However, the differences in extrapyramidal symptoms between the 2 agents remain unclear.

b) Penfluridol was evaluated in the treatment of Tourette's syndrome (Shapiro et al, 1983). The study involved 8 patients with Tourette's syndrome and the results with penfluridol were compared to previous therapy with haloperidol or pimozide (6 of 8 patients). There were 7 males and 1 female aged 10 to 33 years. Penfluridol was given initially in oral doses of 10 mg weekly, increasing by 10 mg weekly for 3 to 1 months (mean, 10 months). Dosage during treatment ranged from 20 to 160 mg weekly, with penfluridol being taken every 3 to 7 days. The percent decrease in tic symptoms was significantly higher for penfluri (mean, 74.4%) than previous haloperidol treatment (mean, 61%). Penfluridol was considered to be slight superior to previous pimozide treatment, however, these differences were not considered significant. Sid effects, including extrapyramidal symptoms, were less in penfluridol patients as compared to previous pimozide or haloperidol therapy. The number of patients using antiparkinson drugs was less with penfluridol.

4.6.AJ.2 Schizophrenia

a) Penfluridol administered once weekly is probably as effective as haloperidol administered daily in the treatment of chronic schizophrenia as well as Tourette's syndrome. An investigational preparation of haloperidol decanoate (McNeil Laboratories) can be given IM and has a duration of action of 4 weeks. B haloperidol decanoate and oral penfluridol will have advantages over oral haloperidol for the manageme of chronic schizophrenia, each improving compliance significantly. Other controlled studies have also reported the equivalent efficacy of daily chlorpromazine as compared to weekly penfluridol (Chouinard e 1977; Chouinard & Annable, 1976; Claghorn et al, 1979). Thus, penfluridol appears to be as effective as chlorpromazine with the advantage of once weekly administration. The incidence of extrapyramidal reactions is greater with penfluridol. Penfluridol will be useful in the patients who are non-compliant on chlorpromazine given daily and in some patients who are not responding optimally to chlorpromazine alo

4.6.AJ.3 Efficacy

a) Although penfluridol is considered a diphenylbutylpiperidine derivative, it does have structural similarities to haloperidol, and both drugs have essentially indistinguishable pharmacologic effects (AMA Department of Drugs, 1986). However, the one-week duration of action of penfluridol is significantly long than haloperidol. Although there is some evidence that penfluridol produces a lower incidence of extrapyramidal side effects than haloperidol (Ayd, 1972; Shapiro et al, 1983), there are no direct comparative studies to support these claims.

4.6.AK Perazine

4.6.AK.1 Schizophrenia

a) High-dose haloperidol was not found to be more effective than standard-dose perazine in treating acutely psychotic schizophrenic patients in a double-blind randomized clinical trial of 32 male patients. Patients received between 15 to 45 milligrams (mg) daily of haloperidol or 300 to 900 mg/day of perazine According to the Clinical Global Impression scale 60% of all examined patients achieved satisfactory improvement after 4 weeks of therapy with an average 65% reduction in their symptoms. The number of responders in the haloperidol group (9 of 15) was not statistically different from the responders in the perazine group (9 of 17). Symptoms were measured according to the AMP scale. As expected, the high-dose haloperidol group reported a significantly higher frequency of extrapyramidal symptoms, rigor, and acute dyskinesia; the perazine group had a higher incidence of dry mouth. Overall 4 patients discontinue the study: 2 in the haloperidol group due to extrapyramidal symptoms and 2 in the perazine group who h to be switched to high-dose haloperidol therapy because of uncontrolled symptoms (Schmidt et al, 1982)

4.6.AL Periciazine

4.6.AL.1 Schizophrenia

a) Maintenance therapy with oral periciazine in doses of 10 to 60 milligrams daily has been less effectiv than haloperidol 1 to 6 mg daily in symptom-free schizophrenic patients. This was attributed in part to lac of dose-dependent decreases in relapse rates with periciazine; although the drug increased symptom-fre days over doses of 10 to 30 mg daily, a significant decrease in this parameter (placebo levels) was seen with 60 mg daily, in association with a high incidence of adverse effects (eg, dysarthria, malaise, hypersomnia). These combined results are suggestive of an inverted U-shaped dose-response curve for periciazine. In contrast, haloperidol significantly and dose-dependently increased symptom-free days ov the range of 1 to 6 mg daily, without an increase in adverse effects (Nishikawa et al, 1984).

4.6.AM Perphenazine

Psychotic disorder

Schizophrenia

4.6.AM.1 Psychotic disorder

a) One double-blind study reported the similar efficacy of intramuscular haloperidol 5 milligrams every 8 hours and intramuscular perphenazine 5 milligrams every 8 hours in the treatment of acute psychiatric episodes (Fitzgerald, 1969). Total doses (mean) of haloperidol and perphenazine were 26 mg and 27 mg respectively, over a period of 48 hours.

4.6.AM.2 Schizophrenia

a) Haloperidol decanoate (100 milligrams/4 weeks) was compared with perphenazine enanthate (100 milligrams/2 weeks) in 20 schizophrenic patients in a 48-week, double-blind crossover study. There were no significant differences in either safety or efficacy (Rapp et al, 1986).

b) Perphenazine decanoate and haloperidol decanoate were compared in a 51-week, randomized, double blind, cross-over, multicenter study. There were no significant differences between the two drugs in antipsychotic efficacy or side effects (Dencker et al, 1994).

4.6.AN Phenelzine

4.6.AN.1 Personality disorder

a) Haloperidol was compared to phenelzine in a placebo-controlled, randomized, double-blind study of 1 patients with borderline personality disorder over a 5 week period (Soloff et al, 1993). Thirty-six patients received 4 mg haloperidol, 38 received 60 mg phenelzine and 34 received look-alike placebo tablets. Several measures of effectiveness were evaluated. Haloperidol was found to be ineffective and phenelzi was effective in comparison to both placebo and haloperidol. This study was not able to establish a dissection of borderline personality disorders into affective and schizotypal subtypes.

4.6.AO Physostigmine

4.6.AO.1 Alzheimer's disease

a) Physostigmine was compared with haloperidol in the treatment of behavioral disturbances in 15 patie diagnosed with Alzheimer's disease (Gorman et al, 1993). Physostigmine 15 milligrams/day in two-hourly divided doses was compared to haloperidol to 3 milligrams/day. Both drugs were effective in controlling t behavioral disturbances. Haloperidol produced a high incidence of adverse effects.

b) Physostigmine 6 mg/day was compared with haloperidol 3 mg/day in a double-blind study of two patients with Alzheimer's Disease and prominent delusions. Both patients responded to each treatment with a decrease in delusions and associated hallucinations and agitated behavior. Physostigmine was w tolerated in both patients (Cummings et al, 1993).

4.6.AP Pimozide

Gilles de la Tourette's syndrome

Schizophrenia

4.6.AP.1 Gilles de la Tourette's syndrome

a) The efficacy of pimozide in Tourette's syndrome was evaluated (Colvin & Tankanow, 1985). Although effective, superiority of the drug over haloperidol has not been adequately demonstrated. The drug is indicated as reserve therapy for Tourette's syndrome in patients who have not responded to haloperidol who cannot tolerate toxicity of haloperidol.

b) In a 6-month, controlled crossover trial of children and adolescents (n=22) with Tourette's syndrome, only pimozide demonstrated statistical improvement over placebo on the global rating scale (p less than 0.05). However, pimozide and haloperidol did not differ statistically in efficacy from each other. Overall, 64% of subjects attained the goal of 70% tic reduction with active therapy as compared to only 23% with placebo. The mean effective doses of pimozide and haloperidol were equivalent (3.4 and 3.5 milligrams daily, respectively). Haloperidol was associated with a greater incidence of extrapyramidal symptoms (Sallee et al, 1997).

c) Haloperidol was compared with pimozide in 9 patients with Gilles de la Tourette syndrome (Ross & Moldofsky, 1978). In this double-blind study, patients were assigned to pimozide or haloperidol, each in doses of 2 milligrams (mg) initially every morning, increasing by 2 mg every second day until symptoms

disappeared or until side effects were observed or until maximum doses of 12 mg daily were obtained. A follow-up period of 420 months was undertaken. Both pimozide and haloperidol significantly reduced me 5-minute tic counts, with no significant difference between the 2 drugs. Both haloperidol and pimozide w more effective than placebo. Follow-up at 4 to 20 months indicated that 6 of 7 patients continuing on pimozide and one of 2 patients continuing on haloperidol had a greater than 75% improvement in symptoms. Significantly fewer days of lethargy or tiredness was associated with pimozide than haloperid Anticholinergic and extrapyramidal effects were similar with both agents. Pimozide may be an effective alternative to haloperidol in Gilles de la Tourette syndrome, particularly in haloperidol non-responders or patients receiving haloperidol but developing incapacitating side effects.

d) Haloperidol was compared with pimozide in a double-blind, parallel, crossover study lasting 6 weeks 57 patients with Tourette's syndrome. The maximum dose of haloperidol was 10 milligrams (mg)/day, an for pimozide it was 20 mg/day. Haloperidol was slightly more effective than pimozide in the treatment of Tourette's syndrome. Adverse effects of haloperidol were not significantly different than those of pimozid Clinically significant cardiac effects did not occur. However, due to the potential of pimozide prolonging QTC intervals, haloperidol is the drug of choice for initial treatment of Tourette's syndrome (Shapiro et al 1989).

4.6.AP.2 Schizophrenia

a) SUMMARY: Pimozide is at least as effective as haloperidol in the treatment of chronic schizophrenia.

b) Pimozide was compared with haloperidol (5 to 50 milligrams/day (mg/day) of either) in relation to dopaminergic blockade and clinical response in 22 patients with schizophrenia. The drugs were equally effective. There was no correlation between either dopaminergic blockade or blood level and therapeutic response (Silverstone et al, 1984).

c) Pimozide 306 mg daily was superior to haloperidol 7 to 14 mg daily in chronic schizophrenia in a sma double-blind study. A subsequent report has indicated the equivalent efficacy of pimozide 10 to 60 mg da and haloperidol 10 to 60 mg daily in acute schizophrenia (Haas & Beckmann, 1982). In this study, howev extrapyramidal effects were more pronounced in patients using pimozide (Gowardman et al, 1973).

4.6.AQ Pramipexole

4.6.AQ.1 Schizophrenia

a) Haloperidol 15 mg daily has been superior to pramipexole (0.3, 0.75, or 3 mg daily) in the treatment o schizophrenia (Lecrubier, 1994).

4.6.AR Prochlorperazine

4.6.AR.1 Chemotherapy-induced nausea and vomiting

a) Butyrophenones such as haloperidol and droperidol are more effective than phenothiazines such as prochlorperazine in moderate to highly emetogenic chemotherapy, particularly when used in combinatior with steroids and antihistamines (Wood, 1993; Sridhar & Donnelly, 1988; Kelley et al, 1986); (Mason, 1982).

b) Haloperidol combined with dexamethasone was compared to prochlorperazine combined with dexamethasone in controlling nausea and vomiting in breast cancer patients (Silvey et al, 1988). The prospective study was nonblinded and randomized. The patients received either intravenous cyclophosphamide, doxorubicin, and fluorouracil (a chemotherapy regimen known as CAF) or cyclophosphamide, methotrexate, and fluorouracil) (a chemotherapy regimen known as CMF). Patients received either prochlorperazine 6 mg/m(2) plus dexamethasone 5 mg/m(2) or haloperidol 2 mg/m(2) plu dexamethasone 5 mg/m(2). The patients received the first dose intravenously 30 minutes before the administration of cytotoxic drug, the same dose orally 3.5 hours after therapy and then every 4 hours for hours. Neither the prochlorperazine plus dexamethasone or haloperidol plus dexamethasone was highly effective in preventing nausea and vomiting in the doses and schedules used, although the haloperidol a dexamethasone regimen did reduce the severity of vomiting and nausea to some extent. Based upon thi information, neither regimen can be recommended as standard antiemetic therapy for this patient population.

4.6.AS Quetiapine

4.6.AS.1 Schizophrenia

a) In a study involving 361 patients, quetiapine (across 5 fixed doses) was found to be superior to placel in improving depressive symptoms in schizophrenic patients, while haloperidol (12 milligrams/day) was r Additionally, depressive symptoms were improved in a greater proportion of patients treated with quetiap versus haloperidol or placebo. None of the quetiapine patients withdrew from the study due to extrapyramidal symptoms, while 4 haloperidol and 1 placebo patient withdrew (Keck et al, 2000a; Glazer 2000).

b) A 6-week, multicenter, double-blind trial comparing quetiapine and haloperidol (mean total daily dose of 455 milligrams and 8 milligrams, respectively) in the treatment of acute exacerbation of schizophrenia concluded that quetiapine in as effective and better tolerated than haloperidol. Both agents produced cle reductions in the Positive and Negative Syndrome Scale scores and Clinical Global Impression Severity

Illness and Global Improvement scores. Quetiapine was better tolerated in terms of extrapyramidal symptoms. In addition, mean serum prolactin concentration decreased in quetiapine patients and increas in haloperidol patients (Copolov et al, 2000).

4.6.AT Remoxipride

4.6.AT.1 Schizophrenia

a) SUMMARY: REMOXIPRIDE and HALOPERIDOL have been shown to achieve equal efficacy for the treatment of schizophrenia. In some studies, REMOXIPRIDE produced a lower frequency of extrapyrami or other adverse symptoms.

b) Controlled-release (CR) REMOXIPRIDE and HALOPERIDOL were shown to produce comparable efficacy in the treatment of chronic schizophrenia patients with a preponderance of negative symptoms (ratings based on the Positive and Negative Symptoms Scale (PANSS)) in a multi-center, double-blind tr Following a run-in period, patients were randomized to a 24-week course of remoxipride CR 150 to 600 milligrams (mg)/day (n=97) or haloperidol 5 to 20 mg/day (n=108), given in 2 divided doses. Mean daily doses were 334.1 mg for remoxipride and 10.44 mg for haloperidol during the last study-week. A reducti of 20% in the PANSS negative symptoms scores occurred in 49.4% and 47.6%, respectively, of remoxipride- and haloperidol-treated patients. Clinical Global Impression evaluations rated 33.7% of remoxipride and 30.8% of haloperidol patients much or very much improved. Tolerability was similar for both medications with the overall adverse effects profile of remoxipride not statistically different from haloperidol. The authors noted that the generally low-dosages of haloperidol used in this study may have enhanced its tolerability (Lapierre et al, 1999).

c) Remoxipride showed equal efficacy to haloperidol in a double-blind study using 80 patients with schizophrenia (Ahlfors et al, 1990). Remoxipride is a dopamine D2 receptor blocking agent that shows n effect on serotonin, noradrenaline, histamine, acetylcholine, or GABA receptors. Because remoxipride ha receptor specificity, it suggests low extrapyramidal side-effects. A total of 50 patients were used in the study and were then evaluated at the end of the treatment. The mean daily dose of remoxipride was 316 milligrams as opposed to 8.7 milligrams of haloperidol. The results showed comparable effectiveness in treating schizophrenia. Only 14 patients exhibited extrapyramidal effects, and of these, only three were remoxipride patients. The researchers conclude that remoxipride is a comparable antipsychotic to haloperidol. Similar results have been reported (Andersen et al, 1990; Deo et al, 1990; den Boer et al, 1990; den Boer & Westenberg, 1990); (Lindrom et al, 1990)(Mendlewicz et al, 1990).

d) Haloperidol and remoxipride were equally efficacious in one study (Laux et al, 1990). The study grou was divided into three groups: remoxipride (53 patients) twice daily, remoxipride (52 patients) three times daily, and haloperidol (52 patients) three times daily. The results showed no significant differences in effectiveness. No extrapyramidal effects were noticed in remoxipride patients opposed to 4% affected patients using haloperidol. The researchers' conclusion is that remoxipride is as effective as haloperidol i acute schizophrenia with fewer side-effects. Similar results have been reported by others (Lapierre et al, 1990; Patris et al, 1990).

e) A double-blind multicenter study of 150 schizophrenic or schizophreniform patients compared the efficacy and safety of oral forms of remoxipride immediate-release (IR), remoxipride controlled-release (CR), and haloperidol. Patients randomly received one of the three drugs in mean daily doses of 332 milligrams and 12.5 milligrams, respectively, and were evaluated for a four-week period using two standa neuroleptic efficacy scales as well as the Simpson & Angus scale for extrapyramidal symptoms. There were no statistically significant differences among the treatment groups. The authors concluded that the three drugs were equal in antipsychotic efficacy in treating schizophrenia or schizophreniform behavior while remoxipride, IR and CR had less frequent side effects than haloperidol in therapeutic doses (Hebenstreit et al, 1991).

f) In a four-week study involving 51 previously untreated patients with schizophrenia, remoxipride (mean dose 375 milligrams/day), haloperidol (mean dose 16 milligrams/day), and clozapine (mean dose 350 milligrams/day) were compared (Klieser et al, 1994). There was no significant difference in efficacy amor the three drugs. The incidence of extrapyramidal side effects (EPS) was most frequent with haloperidol a least frequent with clozapine, with remoxipride causing EPS with intermediate frequency.

4.6.AU Risperidone

Cognitive function finding

Dementia

Extrapyramidal disease

Mania

Schizophrenia

4.6.AU.1 Cognitive function finding

a) Results of a multicenter, randomized, double blind trial assessing cognitive function in patients experiencing their first schizophrenic episode or a related psychosis demonstrated that overall improvement in cognitive functioning was superior with risperidone than with haloperidol. Patients (n=53 were randomized to receive either risperidone or haloperidol on a one-to-one randomization basis for a period of 2 years or more. There were no significant differences in sex, race or ethnicity, age, diagnosis, previous neuroleptic treatment in either group. Dosing strategies were equivalent in both groups where patients were started on 1 milligram per day (mg/day) of the study drug and titrated up to 4 mg/day, or in some cases, to a maximum of 8 mg/day. Patients in the risperidone group received the trial medication (mean modal total dose 3.3 mg/day) for an average of 192 days while patients in the haloperidol group received treatment (mean modal total dose 2.9 mg/day) for an average of 218 days. Cognitive assessments, performed at several different follow-up intervals, included examinations of verbal and visuospatial episodic memory, vigilance, executive functioning, processing speed, and verbal fluency. Ar intention-to-treat analysis conducted with a focus on the 3-month assessment revealed that there was significant improvement from baseline in the risperidone group (n=169) for all measures except category verbal fluency and letter verbal fluency (p less than 0.05). In the haloperidol group (n=169), statistically significant improvements from baseline were noted in episodic memory, vigilance, and visuomotor speec but not in executive functioning and verbal fluency. Comparison between the two groups showed that, af 3 months of treatment, the risperidone group was significantly more beneficial than the haloperidol group on the composite measure of cognitive functioning. In addition, cognitive improvement as a result of treatment with risperidone was not affected by changes in symptoms. Risperidone therapy also proved t be superior than haloperidol in relapse prevention and extrapyramidal side effects (Harvey et al, 2005).

b) Risperidone therapy appeared to exert a more favorable effect on verbal working memory in treatmer resistant schizophrenic patients than did haloperidol therapy (Green et al, 1997). In a randomized, doubl blind comparison of treatment with risperidone (n = 30) and haloperidol (n = 29), verbal working memory was measured at baseline and after 4 weeks of both a fixed dose and flexible dose regimen. Risperidone patients showed a significant improvement in memory using a Digit Span Distractibility Test from baselin performance at both the fixed-dose (p less than 0.0001) and the flexible dose (p less than 0.0003) phase The haloperidol-treated patients did not change significantly. Results suggest that treatment of schizophrenia could be broadened to include the impact on neurocognitive abilities.

4.6.AU.2 Dementia

a) Some Chinese patients with dementia, who were non-responders to haloperidol, responded to risperidone with decreased behavioral disturbances and improved mood. Thirty-five Chinese patients wh had shown insufficient response to an 8- week trial with haloperidol (i.e., having a total score of more tha 10 on the Brief Psychiatric Rating Scale (BPRS) at the end of 8 weeks) (typical dose 1 gram/day) were switched abruptly from haloperidol to risperidone 0.5 milligrams (mg) at bedtime for weeks 1 to 4 and the (if tolerated) to 1 mg at bedtime for weeks 5 to 12. At week 13, the regimen was shifted again to haloperi at the dose used in the earlier trial. Twenty-nine patients completed the trial. Sixteen patients responded the end of the risperidone trial (response = a decrease of 25% in the BPRS score). After haloperidol resumption, the mean BPRS score stayed the same, but the number of responders decreased to 15. Patients with vascular dementia were almost 6 times more likely to respond to risperidone than patients with Alzheimer's disease. Mean scores on the Behavioral Pathology in Alzheimer's Disease Rating Scale decreased (6.1 at baseline to 1.9 at 12 weeks of risperidone treatment) and increased after switching ba to haloperidol (to 2.4 after 4 weeks of haloperidol). Thirty- four of the 35 patients tolerated both doses of risperidone and haloperidol 1 mg/day. One patient experienced moderate rigidity with risperidone 1 mg/c which was relieved by reduction of the dose to 0.5 mg/day. Patients experienced fewer extrapyramidal symptoms with risperidone than with haloperidol (Lane et al, 2002).

b) Both risperidone and haloperidol in low doses reduced the severity and frequency of behavioral and psychological symptoms of elderly Chinese patients with dementia. Risperidone was associated with les severe exacerbation of extrapyramidal symptoms (EPS). In a randomized, double-blind trial, 55 elderly Chinese patients (mean age 80 years) with Alzheimer's dementia or vascular dementia and with behavic disturbance, were given either risperidone or haloperidol for 12 weeks after a 2-week washout period for elimination of psychotropic and antiparkinsonian drugs. The starting dose for both treatment drugs was 0 milligrams (mg) at night; doses were adjusted individually in increments of 0.5 mg no faster than every other day, to a maximum of 2 mg/day. At 12 weeks, the mean daily dose of haloperidol was 0.9 mg, and that of risperidone, 0.85 mg. Significant improvements on the Cohen- Mansfield Agitation Inventory (CMA were evident in both groups (haloperidol, p less than 0.001; risperidone, p=0.002). Significant reduction was seen at 2 weeks in the risperidone group and at 4 weeks in the haloperidol group. With risperidone, there were significant improvements in scores for psychosis, activity disturbances, aggressiveness and diurnal rhythm disturbances, whereas with haloperidol, improvement in only the aggressiveness score reached statistical significance. However, none of the measures showed a significant difference betweer the treatment groups. With haloperidol, there was a significant worsening of EPS (p less than 0.001), whereas, with risperidone, EPS scores were only modestly worsened. Final EPS scores were significant higher for haloperidol (p=0.001) (Chan et al, 2001).

4.6.AU.3 Extrapyramidal disease

a) Data from a multicenter comparative study of risperidone, placebo, and haloperidol revealed that risperidone caused few or no extrapyramidal symptoms (Simpson & Lindenmayer, 1997). Mean changes Extrapyramidal Symptom Rating Scale (ESRS) scores from baseline to worst score were significantly lov in each risperidone group than the haloperidol group (P less than 0.001).

4.6.AU.4 Mania

a) A small, controlled study, compared the efficacy and safety of risperidone versus lithium and haloperi in mania and found comparable results with risperidone. Patients (n=45) were assigned to take risperido (as monotherapy), dosed at 6 mg per day, haloperidol at 10mg per day, or 800 to 1000 mg daily of lithiur All 3 groups showed a similar improvement on Brief Psychiatric Rating Scale and Young Mania Rating Scale scores. The EPS of risperidone and haloperidol were not significantly different and mania did not worsen in any of the risperidone treated patients (Segal et al, 1998).

4.6.AU.5 Schizophrenia

a) Olanzapine and risperidone improved neurocognitive deficits more than did haloperidol or clozapine i patients with schizophrenia or schizoaffective disorder that was refractory to treatment with typical antipsychotics. In a randomized, double-blind study, inpatients were given clozapine (n=24) 200 to 800 milligrams (mg) per day, olanzapine (n=26) 10 to 40 mg/day, risperidone (n=26) 4 to 16 mg day, or haloperidol (n=25) 10 to 30 mg/day. Dose escalation and fixed-dose treatment (target doses: olanzapine mg/day, risperidone 8 mg/day, haloperidol 20 mg/day, clozapine 500 mg/day) occurred during the first 8 weeks of the 14-week study; during the last 6 weeks, dosages were adjusted individually (generally increased if response was insufficient, but sometimes reduced because of adverse effects). Improvemer over time in global neurocognitive score was seen for olanzapine and risperidone. In general executive a perceptual organization and in processing speed and attention, improvement was seen with olanzapine. simple motor function, there was improvement with clozapine. Changes in global neurocognitive performance with olanzapine and risperidone were of medium magnitude (approximately 8 to 9 "IQ equivalents") but large enough to be clinically significant. Beneficial changes with clozapine were modes Despite cognitive gains, patients still had significant impairments of cognitive ability and social/vocationa functioning. Improvements in neurocognitive deficits were associated with improvements in negative symptoms (Bilder et al, 2002a).

b) The risk of relapse of schizophrenia was significantly less with long-term treatment with risperidone th with haloperidol. In a randomized, double-blind study, 365 patients meeting DSM-IV criteria for schizophrenia or schizoaffective disorder and in a stable condition were given flexible doses of either risperidone or haloperidol. The trial was continued until the last enrolled patient had completed one year treatment. Means of modal daily doses were 4.9 milligrams (mg) for risperidone and 11.7 mg for haloperidol. At the end of the study, 25% of the risperidone group and 40% of the haloperidol group had relapsed. The risk of relapse was significantly higher among patients assigned to haloperidol (risk ratio 1.93, p less than 0.001). The risk of premature discontinuation was greater for the haloperidol group thar for the risperidone group (risk ratio 1.52), mainly because of relapse. Median duration of treatment for th risperidone group was 364 days and for the haloperidol group, 238 days (p=0.02). The subtypes of relap (psychiatric hospitalization, clinical deterioration, increase in level of care, suicidal or homicidal ideation) were similar in the 2 groups. In the risperidone group, there were improvements from baseline in positive and negative symptoms, disorganized thoughts, and anxiety- depression, whereas symptoms were not improved with haloperidol. The severity of extrapyramidal symptoms was reduced from baseline in the risperidone group and increased in the haloperidol group. Differences between the groups were significa (p less than 0.02 for total score on the Extrapyramidal Symptom Rating Scale). The most frequent adver events were somnolence (14% with risperidone and 25% with haloperidol), agitation (10% and 18% respectively), and hyperkinesia (5% and 20%, respectively). Those taking risperidone had a mean increa in body weight of 2.3 kilograms (kg) and those taking haloperidol had a mean decrease of 0.73 kg (p less than 0.001) (Csernansky et al, 2002).

c) Risperidone was more efficacious and had fewer adverse effects than haloperidol when used to treat refractory schizophrenia in Chinese patients. Chinese patients, meeting DSM-III-R criteria for schizophre and having a history of treatment failure with 3 conventional neuroleptics given at least 3 months at full dose, were randomly assigned to receive risperidone (n=41) or haloperidol (n=37) for a 12-week, double blind trial. The dose of risperidone was increased during the first week to 6 milligrams (mg) per day, and dose of haloperidol to 20 mg/day. By the end of the study, the average score on the Positive and Negativ Syndrome Scale (PANSS) had decreased by 39.8% for the risperidone group and by 28.3% for the haloperidol group (p=0.03). The general psychopathology and negative subscores of the PANSS showe greater improvement with risperidone, but there was no difference between treatments in the positive subscore. The proportion of patients rated as responders was higher in the risperidone group (31 of 41 v 20 of 37, p=0.046). Total scores on the Treatment Emergent Symptoms Scale (TESS) were significantly lower with risperidone than with haloperidol (2.9 vs 6.9, p=0.01). Particular subscores significantly favori risperidone were those showing symptoms of the nervous system (rigidity, tremor, dystonia, and akathisi and of the cardiovascular system (hypotension, dizziness, tachycardia, hypertension and electrocardiogr abnormalities) (p=0.02 and p=0.04, respectively). Patients in the risperidone group required less medicat for extrapyramidal symptoms during the study than did patients in the haloperidol group. The authors mentioned that the dose of haloperidol was higher than the dose recommended in the United States and Europe and may have accounted for some of the difference between treatments in efficacy and adverse

effects (Zhang et al, 2001).
d) Results of a subanalysis of data from the multinational risperidone trial (double-blind, randomized, parallel-group) reported that the reduction in negative symptoms was significantly better in patients receiving risperidone 16 mg/day than haloperidol 10 mg/day (p less than 0.05) (Moller et al, 1997a). Patients with chronic schizophrenia (n=169) were treated with risperidone 1 mg, 4 mg, 8 mg, 12 mg, or 1 mg, or haloperidol 10 mg/day for 8 weeks. Improvement was noted in each group. Risperidone onset wa faster than haloperidol. An analysis of the Positive and Negative Syndrome Scale cluster scores revealed significantly greater improvement in the risperidone-treated patients than in the haloperidol group on 2 clusters: activity and anxiety/depression (p less than 0.05).
e) Risperidone was significantly better than haloperidol in the treatment of chronic schizophrenia using combined data from 2 studies (Chouinard et al, 1993; Marder & Meibach, 1994) to evaluate five factors o the Positive and Negative Syndrome Scale (Marder et al, 1997). Data from 513 patients showed that afte to 8 weeks of therapy, patients receiving risperidone 6 to 16 milligrams had significantly higher adjusted mean changes in total Positive and Negative Syndrome Scale than patients treated with haloperidol (p le than 0.01). The 5 specific symptom areas that risperidone was significantly superior to haloperidol includ negative symptoms (p less than 0.01), positive symptoms (p less than 0.05), disorganized thought (p les than 0.05), uncontrolled hostility/excitement (p less than 0.01), and anxiety/depression (p less than 0.01) One author, however, noted some positive symptoms that reemerged after an initial response to risperidone (Cung & Stimmel, 1997).
f) In a meta-analysis, risperidone (4 to 8 milligrams(mg)/day) was found to be more effective and produc fewer extrapyramidal effects than haloperidol (4 to 20 mg/day). Seven studies done in a double-blind, randomized fashion were included. The primary outcome measure was clinical improvement defined as a 20% reduction in the total scores on the Brief Psychiatric Rating Scale or the Positive and Negative Syndrome Scale. Results showed that patients identified as treatment failures were 50% of those taking risperidone, 66% on haloperidol, and 83% on placebo. There was a highly significant need for anticholinergic medication in the haloperidol-treated patients as compared to risperidone (P less than 0.00001) (de Oliveira et al, 1996).
g) Risperidone was more effective than haloperidol in a double-blind, placebo-controlled, multicenter stu (Marder & Meibach, 1994). 388 schizophrenic patients were randomly assigned to receive 4 fixed doses risperidone (2, 6, 10, and 16 milligrams/day, on a BID schedule), haloperidol 20 milligrams daily or place for 8-weeks (Marder and Meibach, 1994). Patients receiving risperidone 6 to 16 milligrams showed statistically greater improvement than placebo or haloperidol in Clinical Global Impression (CGI) and tota Positive and Negative Syndrome Scale (PANSS) scores. Of the four doses studied, the 6, 10, and 16 milligram doses were all effective with the 6 milligram dose being the most effective. Similar results have been reported (Chouinard et al, 1993; Marder, 1992).
h) In an 8-week, double-blind study, 1362 schizophrenic patients were randomly assigned to receive eit risperidone 1, 4, 8, 12, 16 milligrams/day, on a BID schedule, or haloperidol 10 milligrams daily (Muller-Spahn, 1992). Significantly greater improvement in Positive and Negative Syndrome Scale (PANSS) and Brief Psychiatric Rating Scale (BPRS) total score, the PANSS General Psychopathology subscale, the BPRS Activity and Anxiety/Depression cluster, was observed in the risperidone 4 milligram and 8 milligra groups versus the haloperidol-treated patients. In addition, a greater percentage of patients treated with risperidone 4 and 8 milligrams achieved clinical improvement on the PANSS and BPRS as compared wi the haloperidol group.
i) Risperidone was faster acting, more effective, and had fewer side effects than haloperidol in a study t determine efficacy in treating negative symptoms of schizophrenia (Claus et al, 1992). The multicenter double-blind study that took place over a period of 15 weeks included a two-week run-in period and a on week washout period. The patients (n=42) took one to 5 mg bid of either drug for a period of 12 weeks. T Positive and Negative Syndrome Scale for Schizophrenia was the key efficacy parameter. The Schedule for Affective Disorders and Schizophrenia Change Conversion was used as a diagnostic aid and sympto severity measure. The Clinical Global Impression Scale was complete as a global rating. In addition, the occurrence of extrapyramidal side effects was also monitored. The improvement in PANSS was approximately three times greater in the risperidone group, both at week six and at endpoint. In addition, the onset of therapeutic effects was quicker in the risperidone group. Finally, the risperidone group need 10 times less anticholinergic medication to control the extrapyramidal side effects than did the haloperido group. According to this study, risperidone showed a greater improvement in schizophrenic symptoms th haloperidol.
j) Risperidone was less effective as monotherapy when compared to combination therapy of haloperidol and amitriptyline in patients with coexisting psychotic and depressive disorders. In this double-blind multicenter study, 123 patients were randomized to receive either risperidone (dose titrated to 8 milligram (mg) by the end of week 1) or the combination of haloperidol and amitriptyline (doses titrated to 10 mg a 200 mg by the end of week 1). For all patients, doses were then adjusted under double blind conditions over the next 5 weeks based on response. At endpoint, the mean effective daily dose was 6.9 mg risperidone, and 9 mg haloperidol in combination with 180 mg amitriptyline. In the 98 patients who completed at least 3 weeks of treatment, Brief Psychiatric Rating Scale (BPRS) scores decreased in both treatment groups, but the reduction in the combination treatment group was significantly greater than the risperidone treated group (p=0.004). The proportion of patients achieving at least 50% improvement in BPRS scores was also significantly higher with combination therapy (p = 0.002). Greater benefit by combination therapy was still observed in an intent-to-treat analyses of the 123 patients. Use of

anticholinergic medication for extrapyramidal symptoms was higher in the risperidone group (Muller-Siecheneder et al, 1998)

4.6.AU.6 Adverse Effects

a) The results of one study suggest that patients receiving atypical antipsychotics have a higher incidenc of PANCREATITIS than patients receiving a conventional antipsychotic medication. In a retrospective, pharmacovigilance study, 192 cases of pancreatitis were identified in patients taking clozapine (mean do 306.7 milligrams (mg)/day), olanzapine (mean dose, 15 mg/day), risperidone, (mean dose, 4 mg/day) or haloperidol (mean dose, 8.2 mg/day). Of the identified cases, 40%, 33%, and 16% were related to treatment with the atypical antipsychotic medications clozapine, olanzapine, or risperidone, respectively, compared with 12% of the cases which were related to the conventional neuroleptic, haloperidol. In most patients, time to onset of pancreatitis was within 6 months after initiation of treatment (Koller et al, 2003a

4.6.AV Sertindole

4.6.AV.1 Schizophrenia

a) Sertindole appears to be as effective as haloperidol in the treatment of schizophrenia. In a placebo-controlled, double-blind, multicenter trial involving 497 hospitalized patients, sertindole 12 milligrams (n=76), 20 mg (n=68), or 24 mg (n=72) was compared with haloperidol 4 mg (n=71), 8 mg (n=67), or 16 (n=70) and placebo (n=73). All doses of both sertindole and haloperidol were significantly more effective than placebo in treating the positive symptoms of schizophrenia (hallucinations, delusions and disorganiz thinking) as measured by Positive and Negative Symptom Scale (PANSS) scores. With negative sympto (emotional withdrawal and paucity of thoughts), only sertindole 20 mg was significantly more effective tha placebo in reducing PANSS negative scale scores. Extrapyramidal symptoms (EPS) were not observed with sertindole; in contrast, patients receiving any dose of haloperidol experienced significantly more EPS than patients receiving placebo or any dose of sertindole. The most common adverse effects associated with sertindole included nasal congestion and decreased ejaculatory volume, thought to be related to its alpha-1 activity; other adverse effects were mild prolongation and mild weight gain (Anon, 1996a; Anon, 1996b).

4.6.AW Sulpiride

4.6.AW.1 Schizophrenia

a) Sulpiride in doses of 300 to 1200 milligrams daily has been comparable in efficacy to chlorpromazine 150 to 675 mg daily (Peselow & Stanley, 1982; Bratfos & Haug, 1979), trifluoperazine 15 to 45 mg daily (Edwards et al, 1980), haloperidol 0.5 to 10.5 milligrams daily (Cassano et al, 1975), and perphenazine 4 80 mg daily) (Peselow & Stanley, 1982) in patients with acute or chronic schizophrenia. One study (Taverna et al, 1972) reported the superiority of sulpiride 200 to 800 mg/day over haloperidol 1 to 4 mg/d with regard to overall global improvement, as well as improvement of thought content and mood state; however, the doses of haloperidol in this study may have been too low to enable a fair comparison.

b) In patients with severe chronic schizophrenia, higher doses of sulpiride (800 to 3200 milligrams daily) were as effective as haloperidol 6 to 24 milligrams daily in controlling symptoms (Gerlach et al, 1985; Munk-Andersen et al, 1984). Median doses in these studies were 1600 to 2000 mg sulpiride and 12 mg haloperidol daily.

c) In some studies, greater benefits of sulpiride have been observed on certain target symptoms, includi more improvement in thought content and mood state as compared with haloperidol (Taverna et al, 1972 and greater reductions in aggressiveness and hyperactivity as compared with chlorpromazine (Peselow Stanley, 1982). However, haloperidol tended to be more effective than sulpiride in a subgroup of chronic disturbed patients who had received long-term neuroleptic therapy in one study (Munk-Andersen et al, 1984), and perphenazine had a greater effect on hallucinations in another (Peselow & Stanley, 1982).

4.6.AW.2 Adverse Effects

a) Haloperidol, chlorpromazine, and sulpiride were compared in normal volunteers to test mood state (McClelland et al, 1990). The twelve volunteers were assessed using sixteen visual analog scales such a elapsed time estimation, tapping rate, body sway and tremor, etc. The volunteers were divided into four groups: haloperidol (3 milligrams per day), chlorpromazine (50 mg per day), sulpiride (400 milligrams per day), and a placebo group. The results showed chlorpromazine and haloperidol users experienced reduc alertness and well-being. Haloperidol reduced feelings of "calmness" in the volunteers. Sulpiride did not significantly alter vision in the volunteers. Haloperidol affected the information processing function, but di not affect motor ability and speed in the group taking this drug.

4.6.AX Sultopride

4.6.AX.1 Psychotic disorder, acute

a) A double-blind, randomized, multicenter study was carried out in a total of 64 acutely psychotic inpatients (32 on sultopride 800 milligrams (mg), and 32 on haloperidol 20 mg daily) over a 15-day perio Efficacy of treatment was assessed using Diagnostic Statistical Manual (DSM) III criteria, a visual analog scale evaluating overall symptom severity, a positive symptom scale, the Arbeitsgemeinschaft fuer Methodik und Dokumentation in der Psychatrie (AMDP)-4 and -5 scales, and an alertness scale. At study end, both groups had improved significantly and comparably. Sultopride was more effective than

haloperidol after 3 days of treatment on several AMDP items, such as mental dissociation, anxiety, cognitive disturbances, depression and apathy. According to the CHESS list of somatic symptoms, haloperidol induced more extrapyramidal symptoms than sultopride (Ropert et al, 1989).

4.6.AY Tetrabenazine

4.6.AY.1 Tardive dyskinesia

a) Tetrabenazine and haloperidol were similarly effective in an 18-week randomized study (n=13); haloperidol tended to be more effective during the first two weeks of therapy (Kazamatsuri et al, 1973). T small patient population in this study limits adequate comparison.

4.6.AZ Tetrahydrocannabinol

4.6.AZ.1 Chemotherapy-induced nausea and vomiting

a) Tetrahydrocannabinol was compared with haloperidol in 52 patients experiencing nausea and vomitir resulting from cancer chemotherapy. Subjective evaluation was made by the patient with regard to numb of vomiting episodes, preference, "efficacy", and adverse reactions. Doses were 10 mg tetrahydrocannabinol and 2 mg haloperidol, given 2 hours prior and 30 minutes prior to cancer chemotherapy then at 1 hour and then 3 to 4 hour intervals times 8 doses after cancer chemotherapy. Efficacy was judged equal for the two regimens, and about one-half had relief with the crossover regime when the first regimen failed. Adverse effects were more frequent and more severe in the tetrahydrocannabinol group (Neidhart et al, 1981).

4.6.BA Thioridazine

4.6.BA.1 Psychotic disorder

a) In a single-blind, randomized parallel study lasting six weeks, haloperidol (mean dose of 2.9 milligrams/day) was compared with thioridazine (mean dose of 145 milligrams/day) in 13 patients with psychosis associated with HIV infection. Based on several scales for assessing psychoses, the two drug produced modest improvement, but were not statistically different in the outcomes produced. All haloperidol-treated patients developed extrapyramidal side effects, while 60% of those taking thioridazin developed them (Sewell et al, 1994).

4.6.BB Thiothixene

4.6.BB.1 Psychotic disorder

a) Thiothixene is not as useful as haloperidol in the treatment of psychotic symptomatology including schizophrenia, manic-depression, psychotic reactions secondary to trauma, and psychosis with mental deficiencies (Howard, 1974).

b) A single-blind study compared the efficacy of haloperidol and thiothixene in the treatment of acute organic mental syndromes in 14 patients in a general hospital setting (Peterson & Bongar, 1989). The do of haloperidol was 4.8 to 15 milligrams and for thiothixene, 2 to 7 milligrams. Evaluations were performed using the Brief Psychiatric Rating Scale (BPRS). There was a trend toward greater reductions in magnitu of BPRS scores in patients treated with thiothixene. Symptoms most affected by treatment included: anergia, thought disturbance, level of activity, hostility, and suspicion. The small sample size was a limitation of this study and larger studies are needed to adequately compare the 2 agents.

c) In a double-blind study of borderline and schizotypal patients treated with thiothixene or haloperidol, 84% of patients improved markedly or moderately by 3 months (Serban & Siegel, 1984). A better respon was seen in those patients receiving thiothixene as compared with haloperidol. Mean dosages were 9.4 7.6 milligrams/day for thiothixene and 3 +/- 0.8 milligrams/day for haloperidol.

d) A 24-week, double-blind study compared the safety and efficacy of haloperidol and thiothixene in 46 schizophrenic outpatients (Abuzzahab & Zimmerman, 1982). Mean dosages used were 17.5 milligrams/ for haloperidol and 31.8 milligrams/day for thiothixene. Haloperidol was equal to, and in some parameter superior to, thiothixene in these patients. Haloperidol also appeared to produce fewer central nervous system adverse effects.

4.6.BC Timiperone

4.6.BC.1 Schizophrenia

a) Haloperidol (maximum dose 18 mg/day) was compared with timiperone (maximum dose 12 mg/day) i 206 patients treated for schizophrenia for up to 12 weeks. The authors concluded that timiperone was superior to haloperidol in efficacy and that the drugs were comparable in safety (Kariya et al, 1983).

4.6.BD Trifluoperazine

4.6.BD.1 Psychotic disorder

a) Trifluoperazine 1 mg milligram orally twice a day was reported similarly effective as haloperidol 0.5 milligram orally twice a day in the treatment of behavioral symptoms associated with chronic brain

syndrome and senile psychosis in a controlled study involving 54 elderly patients (Lovett et al, 1987). Based upon CGI scores, improvement was observed in 86% and 90% of patients receiving trifluoperazin and haloperidol, respectively. Several other rating scales demonstrated significant advantages of trifluoperazine. Due to the small number of patients in this trial, it is unclear if these findings are significa and more studies are required in larger patient populations.

4.6.BE Trimethobenzamide

4.6.BE.1 Vomiting

a) SUMMARY: Trimethobenzamide does not appear to be as effective as the phenothiazines for reducti of nausea and vomiting (Purkis, 1965; Bardfeld, 1966; Shields et al, 1971).

b) Trimethobenzamide was compared with haloperidol and prochlorperazine for emesis. In this study of males, aged 17 to 49 years, 6 patients received trimethobenzamide in a dose of 2.5 mg/kg IM as a single dose. Emesis was induced with a threshold emetic dose of apomorphine. Trimethobenzamide was found be effective in only 50% of the cases at the recommended dose. All patients responded to prochlorperaz 0.1 mg/kg and haloperidol 0.007 mg/kg (Shields et al, 1971).

4.6.BF Valproic Acid

4.6.BF.1 Mania

a) Divalproex and haloperidol were found to be equally efficacious in the management of acute psychoti mania in patients with bipolar disorder. In this study, patients (n=36) were randomized to therapy with divalproex (20 mg/kg/day) or haloperidol (0.2 mg/kg/day) for a period of six days. Divalproex was given a dosage considered to be a loading dose to produce valproate concentrations of approximately 80 mg/L after one day of treatment. Improvement was greatest during the first three days of treatment; extrapyramidal side effects were observed much more often in patients treated with haloperidol (McElroy al, 1996).

4.6.BG Ziprasidone

Chronic schizophrenia

Schizophrenic episode, acute

4.6.BG.1 Chronic schizophrenia

a) Ziprasidone was as effective as haloperidol in treating overall symptomatology, was more effective in the treatment of negative symptoms, and was better tolerated, in the long-term treatment of outpatients v stable schizophrenia. In a 28-week, double-blind, flexible-dose, parallel-group clinical trial, ziprasidone a haloperidol both improved overall symptomatology in 227 patients with chronic or subchronic schizophrenia. Patients who received ziprasidone had a significantly higher rate of improvement in the treatment of negative symptoms (48% of patients showed improvement) compared to patients who received haloperidol (33% of patients showed improvement). For patient assessment, the Positive and Negative Syndrome Scale (PANSS), the Clinical Global Impressions-Severity of Illness scale (CGI-S), a the Montgomery-Asberg Depression Rating Scale (MADRS) were used at baseline and weeks 3, 6, 16, a 28. In the ziprasidone group, patients received a starting dose of 40 milligrams per day (mg/d) on the firs days and 80 mg/d on day 3. The ziprasidone dose could be increased to a maximum of 120 mg/d in the second week and up to 160 mg/d in the third week. For the haloperidol group, patients received a startin dose of 5 mg/d, which could be increased to a maximum of 10 mg/d during the second week and 15 mg/ during the third week of treatment. At week 28, the mean doses of ziprasidone and haloperidol were 116 mg/d and 8.6 mg/d, respectively. Adverse events were evaluated using the Simpson-Angus scale, the Barnes Akathisia scale, and the Abnormal Involuntary Movement Scale (AIMS). Adverse events were reported in 85% of patients in the haloperidol group and 77% in the ziprasidone group; twice as many patients receiving haloperidol (16%) compared to ziprasidone (8%) discontinued the study due to treatment-related adverse events. There was also a distinct difference in the percentage of patients who developed movement disorders; 41% in the haloperidol group compared to 15% in the ziprasidone group although this difference was not statistically significant (Hirsch et al, 2002).

4.6.BG.2 Schizophrenic episode, acute

a) Acute exacerbations: ziprasidone 160 mg daily, haloperidol 15 mg daily comparable in efficacy (reduction of BPRS scores). Ziprasidone 4 to 40 mg/day less effective (Anon, 1996a).

b) Ziprasidone 160 milligrams (mg) and haloperidol 15 mg were both effective in improving overall psychopathology in patients with an acute exacerbation of schizophrenia or schizoaffective disorder (Go et al, 1998). In a double-blind, dose-ranging study, patients received either haloperidol 15 mg/day (n=17) or ziprasidone 4 mg (n=19), ziprasidone 10 mg (n=17), ziprasidone 40 mg (n=17), or ziprasidone 160 mg (n=20). Despite 46 patients failing to complete the study, intention-to-treat analysis showed a trend towa

significance for the ziprasidone dose response on the Brief Psychiatric Rating scale (p=0.08) and a statistically significant dose response for the Clinical Global Impression (CGI) scale (p less than 0.001). Changes in the CGI severity score were significantly changed from baseline as compared to the ziprasidone 4 mg group for both the haloperidol group (p less than 0.01) and the ziprasidone 160 mg gro (p=0.001). Study termination was due to 18 patients having a lack of efficacy (4 in the haloperidol group) due to liver transaminase elevations in ziprasidone groups, and 23 for unrelated reasons.
c) In hospitalized patients, the mean reductions in BPRS total, BPRS agitation items, and CGI were statistically greater after INTRAMUSCULAR (IM) ziprasidone than IM haloperidol, and this continued following conversion to oral treatment. The study was a multicenter, 7-day, randomized, open-label, parallel-group study in 7 countries (n=132). Patients received either an initial dose of ziprasidone 10 milligrams (mg) IM, followed by up to 3 days of flexible-dose IM ziprasidone (5 mg to 20 mg every 4 to 6 hours prn) and continued with oral treatment (80 mg to 200 mg/day) to day 7 (n = 90), or haloperidol IM (2.5 mg to 10 mg) on entry, followed by 2.5 mg to 10 mg IM every 4 to 6 hours prn up to 3 days followed oral haloperidol 10 mg/day to 80 mg/day to day 7 (n = 32). Ziprasidone was associated iwth a lower incidence of movement disorders compared to haloperidol (Brook et al, 2000).

4.6.BH Zotepine

Delusional disorder - Depression

Schizophrenia

4.6.BH.1 Delusional disorder - Depression

a) Zotepine 150 to 200 mg/day was as effective as a butyrophenone (haloperidol or bromperidol) approximately 10 mg/day, and had a better adverse effect profile than the butyrophenones, in two open, four-week studies of 31 patients with delusional depression (Wolfersdorf et al, 1994). All patients receive an antidepressant (maprotiline or amitriptyline, 150 mg/day) in addition to zotepine or the butyrophenone According to a 24-item version of the Hamilton depression scale, significant overall improvement was obtained with both zotepine and haloperidol or bromperidol. After one and two weeks of treatment, the improvement was significantly greater with zotepine. For a six-item list of delusional symptoms alone, bo groups improved significantly, and for the remaining non-delusional symptoms, the improvement was significant for both groups again (with significantly greater improvement with zotepine in the first two weeks). Zotepine, with its greater tolerability, is thus in many instances a viable alternative to highly pote butyrophenones in the treatment of delusional depression.

4.6.BH.2 Schizophrenia

a) There was no difference in efficacy between zotepine 50 milligrams (mg) 3 times daily and haloperido mg 3 times daily in the treatment of positive symptoms of schizophrenia in Chinese patients. After a washout period, patients (n=70) were randomly assigned to double-blind treatment with fixed doses of zotepine or haloperidol for 6 weeks. Although all of the efficacy measures tended to have greater score changes for haloperidol than for zotepine, there were no statistically significant differences between grou The greater score changes with haloperidol may have represented a lack of equivalency of doses. Dizziness, weight gain, and pulse rate were significantly higher with zotepine than with haloperidol, while the haloperidol group reported significantly more akathisia (Hwang et al, 2001).
b) Zotepine (mean dosage 309 mg/day) was as effective as haloperidol (mean dosage 14.5 mg/day) ora for six weeks in a randomized, double-blind study of 40 schizophrenics, and had a better side effect profi than haloperidol. Improvement measured according to the Brief Psychiatric Rating Scale (BPRS) total score reached statistical significance for both drugs on day 3, and at no point was there a significant difference between the two groups. For the individual BPRS factors, anxiety/depression was significantly improved in the zotepine group on day 14, as compared to haloperidol. Clinical Global Impression scores decreased similarly for both groups. Anticholinergic and extrapyramidal side effects were more common the haloperidol group. Liver function abnormalities were recorded in 12 and 6 patients from the zotepine and haloperidol groups, respectively, with one zotepine patient withdrawing from the study due to elevate liver enzymes (Fleischhacker et al, 1989).
c) Zotepine was more effective than haloperidol in controlling the negative effects of schizophrenia, and demonstrated better tolerability than haloperidol in a randomized, double-blind study of thirty schizophrer patients with similar characteristics (Barnas et al, 1992). The patients randomly received either zotepine to 150 mg/day (mean 94.4 mg/day) or haloperidol 2 to 6 mg/day (mean 4.2 mg/day) in oral capsule form the study period of seven weeks. Only zotepine significantly decreased schizophrenic behavior scores in the rating scales. Eight haloperidol patients did not complete the course due to side effects, while none o the zotepine patients experienced significant adverse effects. The authors noted that as most improved symptomatology was seen in the zotepine group after many haloperidol patients had already dropped ou of the study, longer therapy with haloperidol may have been more effective. However, zotepine was mor useful as it was better tolerated, and this must be recognized as a benefit of zotepine over haloperidol.
d) Similar advantages for zotepine (150 to 300 mg/day) versus haloperidol (10 to 20 mg/day) were

obtained in an 8-week, randomized, double-blind study of 126 schizophrenic patients. The mean reductic in Brief Psychiatric Rating Scale score was greater for zotepine compared to haloperidol (17.03 vs 13.45 not statistically significant). According to the Scale for Assessment of Negative Symptoms, zotepine was significantly more effective (p less than 0.05), and the adverse effect profile favored zotepine, particularly with respect to extrapyramidal symptoms. There were no occurrences of akathisia in patients treated wit zotepine compared with seven for haloperidol (Petit et al, 1996). Fixed doses of zotepine (225 mg/day) a haloperidol (12 mg/day) for four weeks in 26 schizophrenic patients resulted in comparable therapeutic efficacy with a clear advantage for zotepine with respect to global tolerability and extrapyramidal adverse effects (Klieser et al, 1991).

4.6.BI Zuclopenthixol

Dementia

Psychotic disorder

Tardive dyskinesia

4.6.BI.1 Dementia

a) Zuclopenthixol 4 to 5 milligrams orally daily was at least as effective as the combination of haloperido to 1.5 milligrams daily plus levomepromazine 6 to 8 milligrams daily in the treatment of elderly demented patients (over 80 years of age) with primary symptoms of agitation and aggressiveness in a 4-week, double-blind study (Fuglum et al, 1989). Zuclopenthixol was significantly superior to the combination at 2 weeks of treatment, but not at 4 weeks.

b) In an earlier double-blind study, oral zuclopenthixol 5 milligrams daily and oral haloperidol 0.5 milligra daily were associated with similar but minimal improvement in several rating scales (Clinical Global Impressions, Gottfries-Cronholm geriatric rating scale, Crichton geriatric rating scale) in elderly patients with dementia (Gotestam et al, 1981). Trends toward the superiority of zuclopenthixol were reported in some areas but these differences are of doubtful clinical significance.

4.6.BI.2 Psychotic disorder

a) Oral zuclopenthixol was similarly as effective as oral haloperidol in the treatment of chronic schizophrenia in a double-blind study involving 63 inpatients (Heikkila et al, 1981a). Mean daily doses of zuclopenthixol at week 1 and week 12 of therapy were 36 mg and 40 mg, respectively; corresponding doses of haloperidol were 7 mg and 10 mg, respectively. Adverse effects occurred with similar frequency although there was a trend toward a lower incidence of extrapyramidal effects in zuclopenthixol-treated patients. Similar findings were reported in another controlled study comparing oral haloperidol and zuclopenthixol in acute psychosis (Wistedt et al, 1991).

b) In 1 randomized study, intramuscular zuclopenthixol acetate was reported comparable in efficacy to parenteral haloperidol in treating patients with acute psychosis or an exacerbation of chronic psychosis; extrapyramidal symptoms were more frequent in haloperidol-treated patients (Bobon & De Bleeker, 1989

c) Intramuscular zuclopenthixol decanoate and haloperidol decanoate were similarly effective in the maintenance treatment of chronic schizophrenia in a 9-month double-blind study involving 64 patients (Wistedt et al, 1991). The average doses of zuclopenthixol decanoate and haloperidol decanoate at wee 36 of treatment were 284 milligrams and 92 milligrams, respectively; most patients received injections every 4 weeks. The incidence of extrapyramidal reactions was similar with both agents in this study, whic is in contrast to studies comparing shorter-acting formulations of haloperidol and zuclopenthixol. Other adverse effects also occurred with similar frequency; however, autonomic symptoms (eg, orthostatic dizziness, palpitations) tended to decrease with zuclopenthixol decanoate over the 9 months of treatmen whereas they increased with haloperidol decanoate during this period.

d) A double-blind, randomized study in 49 hospitalized patients with acute psychosis or exacerbation of chronic psychosis compared the clinical profile and frequency and severity of unwanted effects of oral zuclopenthixol and haloperidol (Heikkila et al, 1992). Patients initially received one of the two drugs with average daily dose of 33.5 milligrams or 7.6 milligrams, respectively, with doses titrated depending on patient response. Clinical efficacy scales and a side effect monitor were employed to evaluate efficacy a safety at baseline, one, two, four, six, and eight weeks with four weeks being the minimum study period analyzed. Both drugs were found to be effective in controlling psychotic episodes with no significant difference, and no difference in the incidence of side effects was seen. Zuclopenthixol had a slightly mor rapid onset of action as well as an earlier onset and elimination of extrapyramidal symptoms. Zuclopenthixol also appeared to have a stronger anxiolytic-antidepressant effect than haloperidol. The authors suggested that this study confirmed previous studies that both zuclopenthixol and haloperidol ar very efficacious and equally safe in treating acute psychoses.

e) Haloperidol (53 to 120 milligrams intramuscularly or orally over 6 days), zuclopenthixol (64 to 259 milligrams intramuscularly and orally over 6 days) and zuclopenthixol acetate (162 to 220 milligrams intramuscularly over 6 days) were compared in the treatment of acute psychoses (48 patients), mania (2

patients) and exacerbation of chronic psychoses (73 patients). Several measures of effectiveness, differi according to the initial diagnosis, were evaluated. The number of doses administered was significantly different in the zuclopenthixol acetate group (1 to 4) versus the haloperidol group (1 to 26) and the zuclopenthixol group (1 to 22). There was no significant difference in efficacy among any treatment regimens or initial diagnoses. Haloperidol caused significantly more hypokinesia during the first 24 hours but after that period there were no significant differences in any adverse effects. Based on the decreased number of doses administered, the authors concluded that zuclopenthixol acetate would be a useful addition to the therapeutic armamentarium (Baastrup et al, 1993).

4.6.BI.3 Tardive dyskinesia

a) It has been hypothesized that neuroleptics with both D1 and D2 antagonist activity are better drugs fo suppressing tardive dyskinesia than pure D2 antagonists. A study compared the effects of the mixed D1/ antagonist zuclopenthixol to that of the pure D2 antagonist haloperidol (Lublin et al, 1991). The double-blind crossover study consisted of 15 patients, who took each drug for three weeks. There was a six wee washout period. The subjects took either oral haloperidol 0.5 milligram twice a day, or oral zuclopenthixo milligrams twice a day. During treatment, benzodiazepines were prescribed on a prn basis for anxiety. Tardive dyskinesia and Parkinson-like symptoms were recorded on video tape and were scored by two raters. The changes and differences in the two groups regarding aggravation and suppression of tardive dyskinesia and Parkinson-like symptoms were compared using a paired t-test. There was no significant difference in the induction of tardive dyskinesia suppression and tardive dyskinesia withdrawal. Both drug induced or aggravated Parkinson-like symptoms. There were no differences between the groups. This study did not support the animal findings that a D1 component in a neuroleptic drug would lead to a stronger tardive dyskinesia suppression and to less withdrawal tardive dyskinesia.

DRUGDEX® Evaluations

PALIPERIDONE

0.0 Overview

1) Class
- **a)** This drug is a member of the following class(es):
  Antipsychotic
  Benzisoxazole

2) Dosing Information
- **a)** Adult
  - **1)** Schizophrenia
    - **a)** extended-release tablets, initial 6 mg/day ORALLY; may increase by 3 mg/day increments at intervals of r maximum of 12 mg/day (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

3) Contraindications
- **a)** hypersensitivity to paliperidone, risperidone, or to any product component (Prod Info INVEGA(R) extended-release

4) Serious Adverse Effects
- **a)** Death
- **b)** Ischemia
- **c)** Tachyarrhythmia

5) Clinical Applications
- **a)** FDA Approved Indications
  - **1)** Schizophrenia

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms
Paliperidone

C) Physicochemical Properties
- **1)** Molecular Weight
  - **a)** 426.49 (Prod Info INVEGA(TM) extended-release oral tablets, 2006)
- **2)** Solubility
  - **a)** Paliperidone is practically insoluble in water, 0.1N sodium hydroxide solution, and hexane; slightly soluble dimethylformamide; and sparingly soluble in 0.1N hydrochloric acid and methylene chloride (Prod Info INVEG release oral tablets, 2006).

1.2 Storage and Stability

A) Preparation
- **1)** Oral route
  - **a)** ADMINISTRATION
    - **1)** Paliperidone may be taken without regard to meals (Prod Info INVEGA(TM) extended-release oral tal
    - **2)** Extended-release tablets must be swallowed whole with liquid, do not chew, divide, or crush (Prod In extended-release oral tablets, 2006)

B) Oral route
- **1)** Tablet, Extended Release
  - **a)** Store paliperidone extended-release tablets at 25 degrees Celsius (77 degrees Fahrenheit), with excursio 30 degrees Celsius (59 to 86 degrees Fahrenheit). Protect from moisture (Prod Info INVEGA(TM) extended-r 2006).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

1.3.1 Normal Dosage

1.3.1.A Oral route

1.3.1.A.1 Schizophrenia

a) The recommended dose of extended-release oral tablets is 6 milligrams/day (mg/day) with increases intervals of at least 5 days, to a maximum of 12 mg/day. In some patients, a lower starting dose of 3 mg/ Dose increases above 6 mg/day should only be made after clinical reassessment (Prod Info INVEGA(TM oral tablets, 2006).

1.3.2 Dosage in Renal Failure

A) In mild renal impairment (creatinine clearance 50 to less than 80 milliliters/minute (mL/minute)), the maximum 6 mg once daily. In moderate to severe renal impairment (creatinine clearance 10 to less than 50 mL/minute), the recommended dose is 3 mg once daily (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

2.0 Pharmacokinetics

Drug Concentration Levels

ADME

2.2 Drug Concentration Levels

A) Peak Concentration

1) 8.85 ng/mL (single-dose, oral solution) (Vermeir et al, 2008)

a) The mean Cmax (standard deviation) was 8.85 ng/mL (+/- 1.31 ng/mL) after a single, 1-mg dose of palipe administered to healthy, caucasian, male volunteers in the fasted state, in an open-label pharmacokinetic stu were 40 to 63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean, 73.38 kg) with a mean 25.5 kg/m(2) (range, 24 to 28 kg/m(2)). There was no difference in the Cmax between the 2 poor and 3 exten metabolizers. Nor was there a difference in Cmax and the genotypic expression of UGT1A1 and UGT1A6 me (Vermeir et al, 2008).

B) Time to Peak Concentration

1) 24 hours (extended-release tablets) (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

a) After a single dose of paliperidone, plasma concentration reaches its peak in approximately 24 hours (Pro extended-release oral tablets, 2006).

b) The median Tmax was 1.5 hr (range, 1 to 1.5 hr) after a single, 1-mg dose of paliperidone solution admini caucasian, male volunteers in the fasted state, in an open-label pharmacokinetic study (n=5). The males wer age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean, 73.38 kg) with a mean body mass index of 25 to 28 kg/m(2) (Vermeir et al, 2008).

C) Steady State

1) 4 to 5 days (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

a) Paliperidone reaches steady-state concentration within 4 to 5 days after initiation of therapy. The steady-s ratio for a 9-mg dose was 1.7 (range, 1.2 to 3.1) (Prod Info INVEGA(TM) extended-release oral tablets, 2006

D) Area Under the Curve

1) 187 ng x hr/mL (Vermeir et al, 2008)

a) The mean AUC (0 to infinity) was 187 ng x hr/mL (standard deviation of +/- 29.3 ng x hr/mL) after a single paliperidone solution administered to healthy, caucasian, male volunteers in the fasted state, in an open-labe study (n=5). The males were 40 to 63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean mean body mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m(2)). There was no difference in the AUC (0 to in 24 hr) between the 2 poor and 3 extensive CYP2D6 metabolizers. Nor was there a difference in AUC and the of UGT1A1 and UGT1A6 metabolizing enzymes (Vermeir et al, 2008).

b) The area under the curve concentration (AUC) of paliperidone was not reported in patients with normal re the average AUC was increased among patients with renal impairment due to reduced clearance. Following a milligram dose of paliperidone extended-release, there was a 1.5-fold increase in drug exposure among patie impairment (creatinine clearance (CrCl) 50 to less than 80 milliliters/minute (mL/min)); a 2.6-fold increase am moderate renal impairment (CrCl 30 to less than 50 mL/min); and a 4.8-fold increase among those with severe (CrCl 10 to less than 30 mL./min) (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Bioavailability

1) 28% (extended-release tablet) (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

a) The absolute oral bioavailability of paliperidone extended-release tablet is 28% (Prod Info INVEGA(TM oral tablets, 2006).

B) Effects of Food

1) Increase peak concentration (Cmax) by 60% and mean area under the curve (AUC) by 54% (Prod Info IN release oral tablets, 2006)

a) After administration of paliperidone extended-release 12 milligrams to healthy ambulatory individuals, calorie meal increased mean peak concentration (Cmax) and mean area under the curve concentration (by 60% and 54%, respectively, compared with administration under fasting states (Prod Info INVEGA(TM oral tablets, 2006).

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding

a) 74% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

1) The plasma protein binding of paliperidone is 74% (Prod Info INVEGA(TM) extended-release ora

B) Distribution Kinetics

1) Volume of Distribution

a) 487 L (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

1) Paliperidone has a volume of distribution (Vd) of 487 liters (L) (Prod Info INVEGA(TM) extended- 2006).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) Liver: limited (Vermeir et al, 2008; Prod Info INVEGA(TM) extended-release oral tablets, 2006)

a) While in vitro data indicated that paliperidone was metabolized by cytochrome P450 2D6 (CYP2D6) a isozymes, these isozymes played a limited role in the overall elimination of paliperidone based on in vivo was found between extensive and poor metabolizers of CYP2D6 substrates in the clearance or exposure Info INVEGA(TM) extended-release oral tablets, 2006).

b) There were 4 primary metabolic pathways identified in vivo, each accounting for no more than 10% o dealkylation, hydroxylation, dehydrogenation, and benzisoxazole scission (Vermeir et al, 2008).

c) Metabolism was limited after a single, 1-mg dose of paliperidone solution administered to healthy, cau volunteers in the fasted state, in an open-label pharmacokinetic study (n=5). On average the 4 identified accounted for approximately 3% to 5% of the dose. The males were 40 to 63 years of age (mean, 51.2 y 68.7 kg to 78.6 kg (mean, 73.38 kg) with a mean body mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m 2008).

B) Metabolites

1) M1 (Vermeir et al, 2008)

a) The pathway for paliperidone to M1 formation was oxidative N-dealkylation, after a single, 1-mg dose solution administered to healthy, caucasian, male volunteers in the fasted state, in an open-label pharma The males were 40 to 63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean, 73.38 mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m(2)). A mean of 4.55% (standard deviation, +/-1.42%) o excreted in the urine as M1 metabolite (Vermeir et al, 2008).

2) M9 (Vermeir et al, 2008)

a) The pathway for paliperidone to M9 formation was monohydroxylation, after a single, 1-mg dose of pa administered to healthy, caucasian, male volunteers in the fasted state, in an open-label pharmacokineti males were 40 to 63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean, 73.38 kg) w mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m(2)). A mean of 3.75% (standard deviation, +/-1.42%) o excreted in the urine as M1 metabolite. The detection of M9 was in the urine of extensive metabolizers b metabolizers (Vermeir et al, 2008).

3) M10 (Vermeir et al, 2008)

a) The pathway for paliperidone to M10 formation was benzisoxazole scission and hydroxylation, after a paliperidone solution administered to healthy, caucasian, male volunteers in the fasted state, in an open- study (n=5). The males were 40 to 63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (m mean body mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m(2)). M10 was excreted in the feces (Verme

4) M11 (Vermeir et al, 2008)

a) The pathway for paliperidone to M11 formation was benzisoxazole scission, after a single, 1-mg dose

solution administered to healthy, caucasian, male volunteers in the fasted state, in an open-label pharma
The males were 40 to 63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean, 73.38
mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m(2)). M11 was excreted in the feces (Vermeir et al, 200

5) M12 (Vermeir et al, 2008)

a) The pathways for paliperidone to M12 formation was alcohol dehydrogenation and also nonenzymati
mg dose of paliperidone solution administered to healthy, caucasian, male volunteers in the fasted state,
pharmacokinetic study (n=5). The males were 40 to 63 years of age (mean, 51.2 years) and weighed 68
(mean, 73.38 kg) with a mean body mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m(2)). A mean of 2.7
deviation, +/-1.66%) of the dose was excreted in the urine as M12 metabolite (Vermeir et al, 2008).

6) M16 (Vermeir et al, 2008)

a) The pathway for paliperidone to M16 formation was glucuronidation, after a single, 1-mg dose of palip
administered to healthy, caucasian, male volunteers in the fasted state, in an open-label pharmacokineti
males were 40 to 63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean, 73.38 kg) v
mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m(2)). A mean of 4.06% (standard deviation, +/-1.03%) c
excreted in the urine as M16 metabolite (Vermeir et al, 2008).

2.3.4 Excretion

A) Kidney

1) Renal Clearance (rate)

a) 53.1 +/- 9.47 mL/min (Vermeir et al, 2008)

1) The mean renal clearance was 53.1 +/- 9.47 mL/min after a single, 1-mg dose of paliperidone so
healthy, caucasian, male volunteers in the fasted state, in an open-label pharmacokinetic study (n=5
to 63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean, 73.38 kg) with a mean
25.5 kg/m(2) (range, 24 to 28 kg/m(2)). The mean clearances (standard deviation) were as follow: cr
113 +/- 10.3 mL/min, glomerular filtration rate, 25.9 +/- 2.36 mL/min; and active renal clearance, 27.
(Vermeir et al, 2008).

2) Renal Excretion (%)

a) 59% (range, 51% to 67%) unchanged (Vermeir et al, 2008; Prod Info INVEGA(TM) extended-release

1) One week following administration of a single oral dose of immediate-release radioactive-paliperi
in 5 healthy volunteers, 59% (range, 51% to 67%) of the dose was excreted into the urine unchange
26% to 41%) was recovered as metabolites, 6% to 12% of the dose was not recovered (Prod Info IN
release oral tablets, 2006).

2) The mean total dose excreted in the urine was 59.4% (standard deviation +/- 7.12%) after a sing
paliperidone solution administered to healthy, caucasian, male volunteers in the fasted state, in an o
pharmacokinetic study (n=5). About half of the renal excretion occurred by active secretion. The M1
metabolites were detected in the urine. The males were 40 to 63 years of age (mean, 51.2 years) ar
78.6 kg (mean, 73.38 kg) with a mean body mass index of 25.5 kg/m(2) (range, 24 to 28 kg/m(2)) (V

B) Feces

1) Not detected (Vermeir et al, 2008)

a) No unchanged drug was recovered in the feces. Fecal excretion did not differ between poor and exte
metabolizers. The M10 and M11 metabolites were detected in the feces (Vermeir et al, 2008).

C) Total Body Clearance

1) Not reported (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

a) Clearance of paliperidone was not reported in patients with normal renal function. However, total clea
was reduced with decreasing estimated creatinine clearance (CrCl). Following administration of a 3-milli
paliperidone extended release, there was a 32% reduction in patients with mild renal impairment (CrCl 5
milliliters/minute (mL/min)); a 64% reduction in patients with moderate renal impairment (CrCl 30 to less
a 71% reduction in patients with severe renal impairment (CrCl 10 to less than 30 mL./min) (Prod Info IN
release oral tablets, 2006).

b) The mean total plasma clearance was 91 +/- 15 mL/min after a single, 1-mg dose of paliperidone solu
healthy, caucasian, male volunteers in the fasted state, in an open-label pharmacokinetic study (n=5). Th
63 years of age (mean, 51.2 years) and weighed 68.7 kg to 78.6 kg (mean, 73.38 kg) with a mean body
kg/m(2) (range, 24 to 28 kg/m(2)) (Vermeir et al, 2008).

2.3.5 Elimination Half-life

A) Parent Compound

1) approximately 23 hours (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

a) The terminal elimination half-life of paliperidone is approximately 23 hours (Prod Info INVEGA(TM) ex
tablets, 2006).

2) renal impairment, 24 hours to 51 hours

a) The mean terminal elimination half-lives of paliperidone following administration of a 3-milligram dose
extended-release were increased to 24 hours, 40 hours, and 51 hours among individuals with mild (creat
50 to less than 80 milliliters/minute (mL/min)), moderate renal impairment (CrCl 30 to less than 50 mL/mi
10 to less than 30 mL./min) renal impairment, respectively. The elimination half-life was 23 hours among
renal function (CrCl at or above 80 mL/min) (Prod Info INVEGA(TM) extended-release oral tablets, 2006

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING

1) Oral (Tablet, Extended Release)

a) Increased Mortality in Elderly Patients with Dementia-Related Psychosis: Elderly patients with dementia-relate with antipsychotic drugs are at an increased risk of death. Analyses of 17 placebo-controlled trials (modal duratio in patients taking atypical antipsychotic drugs, revealed a risk of death in drug-treated patients of between 1.6 to 1 death in placebo-treated patients. Over the course of a typical 10-week controlled trial, the rate of death in drug-tr about 4.5%, compared to a rate of about 2.6% in the placebo group. Although the causes of death were varied, m appeared to be either cardiovascular (eg, heart failure, sudden death) or infectious (eg, pneumonia) in nature. Ob suggest that, similar to atypical antipsychotic drugs, treatment with conventional antipsychotic drugs may increase to which the findings of increased mortality in observational studies may be attributed to the antipsychotic drug as characteristic(s) of the patients is not clear. Paliperidone is not approved for the treatment of patients with dement (Prod Info INVEGA(R) extended-release oral tablets, 2008).

3.1 Contraindications

A) hypersensitivity to paliperidone, risperidone, or to any product component (Prod Info INVEGA(R) extended-release

3.2 Precautions

A) elderly patients with dementia-related psychosis (unapproved use); increased risk of death; most deaths were attri cardiovascular events (eg, heart failure or sudden death) or infections (eg, pneumonia) (Prod Info INVEGA(R) extende 2008)

B) bradycardia; increased risk of torsade de pointes and/or sudden death (Prod Info INVEGA(R) extended-release or

C) cardiac arrhythmias; use should be avoided due to risk of prolonged QT interval (Prod Info INVEGA(R) extended-r 2008)

D) cardiovascular or cerebrovascular disease or conditions that predispose patients to hypotension (eg, dehydration, antihypertensive medications); increased risk of orthostatic hypotension and syncope (Prod Info INVEGA(R) extended 2008)

E) concomitant use of other drugs known to prolong the QTc interval, such as Class IA (eg, quinidine, procainamide) amiodarone, sotalol) antiarrhythmics, antibiotics (eg, gatifloxacin, moxifloxacin), and antipsychotics (eg, chlorpromazin should be avoided (Prod Info INVEGA(R) extended-release oral tablets, 2008)

F) conditions that may contribute to elevated body temperature (eg, strenuous exercise, extreme heat exposure, dehy anticholinergic use); may disrupt body temperature regulation (Prod Info INVEGA(R) extended-release oral tablets, 20

G) congenital long QT syndrome; increased risk of torsade de pointes and/or sudden death (Prod Info INVEGA(R) ex tablets, 2008)

H) diabetes mellitus or risk factors for diabetes mellitus; increased risk of severe hyperglycemia; monitor blood glucos (R) extended-release oral tablets, 2008)

I) elderly patients, especially elderly women are at increased risk of tardive dyskinesia (Prod Info INVEGA(R) extende 2008)

J) esophageal dysmotility and aspiration may occur; use cautiously in patients at risk for aspiration pneumonia (Prod extended-release oral tablets, 2008)

K) gastrointestinal narrowing, severe (eg, esophageal motility disorders, small bowel inflammatory disease, short gut adhesions or decreased transit time, peritonitis, cystic fibrosis, chronic intestinal pseudoobstruction, or Meckel's diverti swallow a tablet whole; ingestion of drugs in nondeformable controlled-release formulations may cause obstructive sy INVEGA(R) extended-release oral tablets, 2008)

L) hyperglycemia (some cases extreme and associated with ketoacidosis, hyperosmolar coma, or death) is a risk (Pr extended-release oral tablets, 2008)

M) hypokalemia or hypomagnesemia; increased risk of torsade de pointes and/or sudden death (Prod Info INVEGA(R oral tablets, 2008)

N) increased duration of therapy and/or higher cumulative doses; increased risk of tardive dyskinesia (Prod Info INVE release oral tablets, 2008)

O) neuroleptic malignant syndrome, potentially fatal, has been reported in association with antipsychotic drugs; imme drug (Prod Info INVEGA(R) extended-release oral tablets, 2008)

P) Parkinson's disease or dementia with Lewy bodies; increased sensitivity to antipsychotic medications (Prod Info IN release oral tablets, 2008)

Q) seizure disorder, history, or conditions that lower the seizure threshold (Prod Info INVEGA(R) extended-release or

R) suicide risk (Prod Info INVEGA(R) extended-release oral tablets, 2008)

S) tardive dyskinesia, potentially irreversible, may occur (Prod Info INVEGA(R) extended-release oral tablets, 2008)

3.3 Adverse Reactions

Cardiovascular Effects

Endocrine/Metabolic Effects

Gastrointestinal Effects

Hematologic Effects

Immunologic Effects

Neurologic Effects

Other

3.3.1 Cardiovascular Effects

Bradyarrhythmia

Hypotension

Ischemia

Orthostatic hypotension

Prolonged QT interval

Tachyarrhythmia

Tachycardia

3.3.1.A Bradyarrhythmia

1) During the pre-marketing phase, bradycardia was reported infrequently (1 in 100 to 1 in 1000) in patients t paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=2,720); however, causal relationship to p been determined (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3.3.1.B Hypotension

1) Incidence: 5% geriatric (Tzimos et al, 2008)

2) Geriatric

a) During the double-blind phase of a safety trial in 114 geriatric patients, the incidence of hypotension v patients receiving paliperidone extended-release (ER), compared with 0% (0/38) in patients receiving pla prospective, 6-week, double-blind, randomized, placebo-controlled, optional 24-week open-label extensi the open-label phase, the incidence of hypotension was 0% (0/30) of patients switched to paliperidone E was 2% (1/58) in patients continuing with paliperidone ER treatment from the double-blind phase. In gen was well tolerated in the geriatric population compared with placebo. The study included 114 patients (m with 99% having moderate to severe schizophrenia, receiving either placebo or median mean dose of pa milligrams/day (mg/day) during the double-blind phase and median mean doses of 7.4 mg and 8.5 mg in placebo/paliperidone ER and paliperidone ER/paliperidone ER groups, respectively, during the open-lab 2008).

3.3.1.C Ischemia

1) Incidence: rare (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) During the pre-marketing phase, ischemia was reported rarely (less than 1 in 1000) in patients treated wit ranging from 3 mg to 12 mg orally once daily (n=2,720); however, causal relationship to paliperidone has not (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3.3.1.D Orthostatic hypotension

1) Incidence: 1% to 4% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, orthostatic hypotension occurred in 1% to 4 with paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 1% in placebo-tre The incidence of orthostatic hypotension increased with the dose, occurring particularly at the 9-mg and 12-m INVEGA(TM) extended-release oral tablets, 2006).

3) Geriatric

a) During the double-blind phase of a safety trial in 114 geriatric patients, the incidence of orthostatic hy (3/76) in patients receiving paliperidone extended-release (ER), compared with 0% (0/38) in patients rec according to a prospective, 6-week, double-blind, randomized, placebo-controlled, optional 24-week ope safety trial. In general, paliperidone ER was well tolerated in the geriatric population compared with place included 114 patients (mean age of 70 years), with 99% having moderate to severe schizophrenia, recei median mean dose of paliperidone ER 8.4 milligrams/day (mg/day) during the double-blind phase and m 7.4 mg and 8.5 mg in the placebo/paliperidone ER and paliperidone ER/paliperidone ER groups, respect label phase (Tzimos et al, 2008).

3.3.1.E Prolonged QT interval

1) Incidence: 3% to 7% (Tzimos et al, 2008; Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, prolongation of QTc interval occurred in 3% treated with paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 3% in plac (n=355). Among ECG measurements taken during these trials, a change in QTc interval exceeding 60 millise occurred only in 1 subject in the 12-mg group. Overall, none of the subjects had a QTc interval exceeding 50 time point (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3) Geriatric

a) During the double-blind phase of a safety trial in 114 geriatric patients, the incidence of electrocardiog prolongation was 7% (5/76) in patients receiving paliperidone extended-release (ER), compared with 3% receiving placebo according to a prospective, 6-week, double-blind, randomized, placebo-controlled, opt label extension safety trial. During the open-label phase, the incidence of QTc interval prolongation was switched to paliperidone ER from placebo, and 3% (2/58) in patients continuing with paliperidone ER trea double-blind phase. Prolonged QTcB prolongation of 500 milliseconds or greater led to discontinuation o patients assigned to paliperidone ER. In general, paliperidone ER was well tolerated in the geriatric popu placebo. The study included 114 patients (mean age of 70 years), with 99% having moderate to severe s receiving either placebo or median mean dose of paliperidone ER 8.4 milligrams/day (mg/day) during the and median mean doses of 7.4 mg and 8.5 mg in the placebo/paliperidone ER and paliperidone ER/palip respectively, during the open-label phase (Tzimos et al, 2008).

3.3.1.F Tachyarrhythmia

1) Incidence: 12% to 14% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, tachyarrhythmia occurred in 12% to 14% of paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 7% in placebo-treated Additional cardiac disorders occurring at a higher incidence than placebo included first-degree atrioventricula block, and sinus arrhythmia (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3.3.1.G Tachycardia

1) Incidence: 16% geriatric (Tzimos et al, 2008)

2) Geriatric

a) During the double-blind phase of a safety trial in 114 geriatric patients, the incidence of tachycardia w patients receiving paliperidone extended-release (ER), compared with 0% (0/38) in patients receiving pla prospective, 6-week, double-blind, randomized, placebo-controlled, optional 24-week open-label extensi the open-label phase, the incidence of tachycardia was 13% (4/30) of patients switched to paliperidone E was 10% (6/58) in patients continuing with paliperidone ER treatment from the double-blind phase. Hear beats/minute or greater occurred in 25% in the paliperidone ER group compared with 5% in placebo duri phase. During the open-label phase, the incidence of heart rates of 100 beats/minute or greater was 20% to paliperidone ER from placebo, and was 16% in patients continuing with paliperidone ER treatment fro phase. Pulse rate increases were more prominent in patients aged 70 to 75 years compared with age 64 general, paliperidone ER was well tolerated in the geriatric population compared with placebo. The study (mean age of 70 years), with 99% having moderate to severe schizophrenia, receiving either placebo or paliperidone ER 8.4 milligrams/day (mg/day) during the double-blind phase and median mean doses of 7 the placebo/paliperidone ER and paliperidone ER/paliperidone ER groups, respectively, during the open et al, 2008).

3.3.3 Endocrine/Metabolic Effects

Hyperprolactinemia

Metabolic syndrome

Weight gain

3.3.3.A Hyperprolactinemia

1) Incidence: geriatric, 45% to 49% (Tzimos et al, 2008)

2) Antipsychotic-induced hyperprolactinemia was reported in 65.6%, 45.1%, and 42.4% of women of childbe postmenopausal women, and men, respectively, in an open-label, clinical trial of patients treated with first-ge or risperidone at average doses of 4.2 to 5.2 mg/day. Compared to baseline, prolactin levels were significantl 0.05) following use of first-generation antipsychotics (ie, chlorpromazine, droperidol, flupenthixol, fluphenazin paliperidone, perazine, perphenazine, pimozide, trifluoperazine, and zuclopenthixol) or risperidone in several patients with schizophrenia. Younger patients and women of childbearing potential have a greater risk for hyp following treatment with higher doses of these antipsychotics. Hyperprolactinemia may potentially result in m sexual dysfunction, bone mineral density (ie, osteopenia and osteoporosis), and breast and pituitary tumors (

3) Geriatric

a) During the double-blind phase of a safety trial in 114 geriatric patients, the incidence of increased pro male patients and 49% in female patients receiving paliperidone extended-release (ER), according to a p double-blind, randomized, placebo-controlled, optional 24-week open-label extension safety trial. The ma was 75.3 +/- 10.8 nanograms/mL in females and 27.2 +/- 8.7 nanograms/mL in males. During the open-l levels increased in patients switched to paliperidone ER from placebo, and was stable for patients contin ER treatment from the double-blind phase. In general, paliperidone ER was well tolerated in the geriatric with placebo. The study included 114 patients (mean age of 70 years), with 99% having moderate to sev receiving either placebo or median mean dose of paliperidone ER 8.4 mg/day during the double-blind ph doses of 7.4 mg and 8.5 mg in the placebo/paliperidone ER and paliperidone ER/paliperidone ER group the open-label phase (Tzimos et al, 2008).

4) Management

a) Appropriate drug selection, monitoring and management are all important when prescribing antipsych potential for inducing hyperprolactinemia. Prior to treatment with an antipsychotic, question patients rega or galactorrhea. Female patients should be assessed for menstrual abnormalities and male patients, for dysfunction. In the event that any of these symptoms are present, consider obtaining baseline prolactin l be informed of the potential for sexual dysfunction with antipsychotic use. Several weeks after an antipsy obtain a prolactin level measurement. In cases where the patient experiences troublesome adverse effe prolactin levels and discontinuing the antipsychotic is not an option, treatment with a dopamine agonist (cabergoline) should be considered (Bostwick et al, 2009).

3.3.3.B Metabolic syndrome

See Drug Consult reference: ANTIPSYCHOTIC AGENTS - METABOLIC SYNDROME

3.3.3.C Weight gain

1) Incidence: 6% to 9% (Prod Info INVEGA(R) extended-release oral tablets, 2008a)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, weight gain of at least 7% of body weight w 9% of patients treated with paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compare treated patients (n=355). The incidence of weight gain increased with the dose, particularly at the 9-mg and 1 INVEGA(R) extended-release oral tablets, 2008a).

3.3.4 Gastrointestinal Effects

Abdominal pain

Xerostomia

3.3.4.A Abdominal pain

1) Incidence: 1% to 3% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, upper abdominal pain occurred in 1% to 3% with paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 1% in placebo-tre (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3.3.4.B Xerostomia

1) Incidence: 1% to 3% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, dry mouth occurred in 1% to 3% of patients paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 1% in placebo-treated (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3.3.5 Hematologic Effects

3.3.5.A Thrombocytopenia

1) Incidence: rare (Prod Info INVEGA(TM) extended-release oral tablets, 2006)
2) During the pre-marketing phase, thrombocytopenia was reported rarely (less than 1 in 1000) in patients tr paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=2,720); however, causal relationship to p been determined (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3.3.7 Immunologic Effects

3.3.7.A Anaphylaxis

1) Incidence: rare (Prod Info INVEGA(TM) extended-release oral tablets, 2006)
2) During the pre-marketing phase, anaphylactic shock occurred rarely (less than 1 in 1000) in patients treat doses ranging from 3 mg to 12 mg orally once daily (n=2,720); however, causal relationship to paliperidone h determined (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3.3.9 Neurologic Effects

Akathisia

Dizziness

Dystonia

Extrapyramidal disease

Headache

Somnolence

Tremor

3.3.9.A Akathisia

1) Incidence: 3% to 10% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)
2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, akathisia occurred in 3% to 10% of patients paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 4% in placebo-treated incidence of akathisia increased with the dose, occurring particularly at the 9-mg and 12-mg doses (Prod Info extended-release oral tablets, 2006).

3.3.9.B Dizziness

1) Incidence: 7% geriatric (Tzimos et al, 2008)
2) Geriatric
a) During the double-blind phase of a safety trial in 114 geriatric patients, the incidence of dizziness was receiving paliperidone extended-release (ER), compared with 0% (0/38) in patients receiving placebo ac prospective, 6-week, double-blind, randomized, placebo-controlled, optional 24-week open-label extensi the open-label phase, the incidence of dizziness was 3% (1/30) of patients switched to paliperidone ER f 10% (6/58) in patients continuing with paliperidone ER treatment from the double-blind phase. In genera well tolerated in the geriatric population compared with placebo. The study included 114 patients (mean 99% having moderate to severe schizophrenia, receiving either placebo or median mean dose of paliper milligrams/day (mg/day) during the double-blind phase and median mean doses of 7.4 mg and 8.5 mg in placebo/paliperidone ER and paliperidone ER/paliperidone ER groups, respectively, during the open-lab 2008).

3.3.9.C Dystonia

1) Incidence: 1% to 5% (Prod Info INVEGA(R) extended-release oral tablets, 2008b)
2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, dystonia occurred in 1% to 5% of patients t paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared with 1% in placebo-treate Dystonic reactions included muscle spasms, oculogyration, and trismus. The incidence of dystonia increased occurring particularly at the 9-mg and 12-mg doses (Prod Info INVEGA(R) extended-release oral tablets, 200
3) During the first few days after initiating treatment with an antipsychotic medication, symptoms of dystonia susceptible individuals. Symptoms may include spasm of neck muscles, which may progress to tightening of difficulty, breathing difficulty, and/or protrusion of the tongue. These symptoms can occur at low doses but m occur with a greater severity) with high potency and at higher doses of first generation antipsychotic medicati younger age groups appear to be at greater risk for developing acute dystonia (Prod Info INVEGA(R) extend 2008b).

3.3.9.D Extrapyramidal disease

1) Incidence: 2% to 7% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, extrapyramidal disorders occurred in 2% to with paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 2% in placebo-tre Extrapyramidal symptoms (EPS) included akathisia, dyskinesia, dystonia, hyperkinesia, and tremor, and Parl involved bradykinesia, cogwheel rigidity, drooling, hypertonia, hypokinesia, muscle rigidity, and musculoskele incidence of EPS increased with the dose, occurring particularly at the 9-mg and 12-mg doses (Prod Info INV release oral tablets, 2006).

See Drug Consult reference: NEUROLEPTIC-INDUCED EXTRAPYRAMIDAL REACTIONS

3.3.9.E Headache

1) Incidence: 11% to 14% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, headache occurred in 11% to 14% of patier paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 12% in placebo-treate (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3.3.9.F Somnolence

1) Incidence: 6% to 11% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, somnolence occurred in 6% to 11% of patie paliperidone doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 7% in placebo-treated incidence of somnolence increased with the dose, particularly at the 9-mg and 12-mg doses (Prod Info INVE release oral tablets, 2006).

3) Geriatric

a) During the double-blind phase of a safety trial in 114 geriatric patients, the incidence of somnolence v patients receiving paliperidone extended-release (ER), compared with 5% (2/38) in patients receiving pla prospective, 6-week, double-blind, randomized, placebo-controlled, optional 24-week open-label extensi the open-label phase, the incidence of somnolence was 7% (2/30) of patients switched to paliperidone E was 0% (0/58) in patients continuing with paliperidone ER treatment from the double-blind phase. During phase, an age-related increase in the incidence of somnolence was seen in patients receiving paliperido to 69 years, 11% in age 70 to 75 years, and 14% in age greater than 75 years. In general, paliperidone E in the geriatric population compared with placebo. The study included 114 patients (mean age of 70 yea moderate to severe schizophrenia, receiving either placebo or median mean dose of paliperidone ER 8.4 (mg/day) during the double-blind phase and median mean doses of 7.4 mg and 8.5 mg in the placebo/pa paliperidone ER/paliperidone ER groups, respectively, during the open-label phase (Tzimos et al, 2008).

3.3.9.G Tremor

1) Incidence: 3% to 4% (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) In 3 short-term (6-week), fixed-dose, placebo-controlled trials, tremor occurred in 3% to 4% of patients tre doses ranging from 3 mg to 12 mg orally once daily (n=850) compared to 3% in placebo-treated patients (n=3 INVEGA(TM) extended-release oral tablets, 2006).

3.3.16 Other

Death

Extrapyramidal disease

3.3.16.A Death

1) Results of a population-based, retrospective cohort study demonstrated that the use of conventional antip associated with an even greater risk for death than atypical antipsychotics when administered to elderly patie and older) with dementia. Atypical versus no antipsychotic use and conventional versus atypical antipsychoti comparisons were made. A total of 27,259 matched pairs were identified and the dementia cohort was stratifi residence (community versus long-term care facilities). In order to adjust for difference in baseline health stat matching was used. The primary outcome of the study was all-cause mortality. The risk for death was evalua 180 days after the antipsychotic medications were initially dispensed. There was a statistically significant incr death at 30 days associated with new use of atypical antipsychotic medications compared with nonuse in bot dwelling cohort (adjusted hazard ratio (HR), 1.31 (95% confidence interval (CI), 1.02 to 1.70); absolute risk di percentage point) and long-term care cohort (adjusted HR, 1.55 (95% CI, 1.15 to 2.07); absolute risk differen points). For both cohorts, the risk associated with atypical antipsychotics appeared to persist to 180 days. Th associated with conventional antipsychotics was even greater than the risk identified with atypical antipsycho adjusted HR for the community-dwelling cohort was 1.55 (95% CI, 1.19 to 2.02) and 1.26 (95% CI, 1.04 to 1.5 care cohort (adjusted risk difference for both was 1.1 percentage points). The risk appeared to persist to 180 Some important limitations to the study include unknown or unmeasured confounders may influence the resu could not be examined (Gill et al, 2007).

2) Results of a population-based, retrospective cohort study demonstrated comparable to possibly greater ris

with the use of conventional antipsychotic medications in the elderly (aged 65 years and older) compared wit
antipsychotic medications. The analysis excluded patients with cancer and included only new users of antips
The primary study outcome was 180-day all-cause mortality. A set of potential confounders was measured ba
utilization data within 6 months before the initiation of antipsychotic medications. Of the 37,241 elderly patien
and 24,359 received conventional and atypical antipsychotic medications, respectively. The risk of death in th
group within the first 180 days was 14.1% compared with 9.6% in the atypical drug group (unadjusted mortali
confidence interval (CI), 1.39 to 1.56). In the multi-variable analysis which controlled for potential confounders
mortality ratio for the risk of death within 180 days for conventional versus atypical drug therapy was 1.32 (95
When the most frequently prescribed conventional antipsychotic drugs were compared with risperidone, the r
associated with haloperidol was 2.14 (95% CI, 1.86 to 2.45) and loxapine was 1.29 (95% CI, 1.19 to 1.40), wh
difference associated with olanzapine. The increased mortality risk for conventional versus atypical drug thera
when doses higher (above median) doses were used (mortality ratio 1.67; 95% CI, 1.5 to 1.86) and also durin
therapy (mortality ratio 1.6; 95% CI, 1.42 to 1.8). Confirmatory analyses consisting of multi-variable Cox regre
score, and instrumental variable estimation confirmed the results of the study (Schneeweiss et al, 2007).

3.3.16.B Extrapyramidal disease

See Drug Consult reference: NEUROLEPTIC-INDUCED EXTRAPYRAMIDAL REACTIONS

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info INVEGA(TM) extended-relea
(All Trimesters)

a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other)
controlled studies in women or studies in women and animals are not available. Drugs should be given only if
justifies the potential risk to the fetus.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

2) Crosses Placenta: Unknown

3) Clinical Management

a) Adequate and well controlled studies with paliperidone have not been conducted in pregnant women. Whi
generation antipsychotic drugs during the last trimester of pregnancy has been linked to extrapyramidal symp
unknown whether paliperidone could lead to similar neonatal effects. Until further data are available, it is recc
paliperidone be used during pregnancy only if the potential benefit to the mother justifies the potential risk to
INVEGA(TM) extended-release oral tablets, 2006).

4) Literature Reports

a) No human studies of pregnancy outcomes after exposure to paliperidone have been published, and there
of outcomes after inadvertent exposure during pregnancy. In studies in rats and rabbits, no increases in fetal
noted at the highest oral paliperidone dose, which was approximately 8 times the maximum recommended hu
Paliperidone is the major active metabolite of risperidone. In rat reproduction studies with risperidone, increas
noted at oral doses that were less than the MRHD of risperidone. Use of first-generation antipsychotic drugs
trimester of pregnancy has been linked to extrapyramidal symptoms in neonates. However, it is unknown whe
could lead to similar neonatal effects (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk wh
breastfeeding. Weigh the potential benefits of drug treatment against potential risks before prescribing this dr
breastfeeding.

2) Literature Reports

a) Lactation studies with paliperidone have not been conducted in humans. In animal studies, paliperidone w
milk. Paliperidone is the major active metabolite of risperidone, which is excreted into human milk. Therefore,
paliperidone recommended that women receiving paliperidone should not breast-feed infants (Prod Info INVE
release oral tablets, 2006).

3.5 Drug Interactions

3.5.1 Drug-Drug Combinations

Acecainide

Ajmaline

Amiodarone

Arsenic Trioxide

Azimilide

Bretylium

Carbamazepine

Chlorpromazine

Disopyramide

Dofetilide

Gatifloxacin

Hydroquinidine

Ibutilide

Iloperidone

Lapatinib

Levodopa

Mesoridazine

Methadone

Moxifloxacin

Nilotinib

Paroxetine

Pirmenol

Prajmaline

Procainamide

Prochlorperazine

Ranolazine

Sematilide

Sotalol

Tedisamil

Tetrabenazine

Thioridazine

Trifluoperazine

3.5.1.A Acecainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventr ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM) e tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2(
7) Probable Mechanism: additive QT prolongation

3.5.1.B Ajmaline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, halop paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM Prod Info Solian(R), 1999b; O'Brien et al, 1999b; Prod Info INVEGA(TM) extended-release oral tablets, 2006 Duenas-Laita et al, 1999b; Agelink et al, 2001b; Lande et al, 1992b; Prod Info GEODON(R) intramuscular inj 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and incre arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended ((TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is r
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperic day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide ther Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antip studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. Th significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1 haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) we changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible fo changes than an elimination alteration (Young et al, 1993).

3.5.1.C Amiodarone

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventr ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM) e tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2(
7) Probable Mechanism: additive QT prolongation

3.5.1.D Arsenic Trioxide

1) Interaction Effect: prolongation of the QTc interval and/or torsades de pointes
2) Summary: Arsenic trioxide can prolong the QT interval in some patients, which may result in ventricular ta fibrillation, and torsades de pointes and should not be administered with other drugs that may prolong the QT Trisenox(R), 2001a). Several antipsychotic agents have demonstrated QT prolongation including amisulpride 1999), haloperidol (O'Brien et al, 1999), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2 (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001), quetiapine (Owens, 2001), sultopride (Lande et al (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of arsenic trioxide and antipsychotics is not recomme
7) Probable Mechanism: additive effects on QTc prolongation

8) Literature Reports

a) QT/QTc prolongation should be expected during treatment with arsenic trioxide and torsade de pointe heart block has been reported. Over 460 ECG tracings from 40 patients with refractory or relapsed APL t trioxide were evaluated for QTc prolongation. Sixteen of 40 patients (40%) had at least one ECG tracing greater than 500 msec. Prolongation of the QTc was observed between 1 and 5 weeks after arsenic triox returned towards baseline by the end of 8 weeks after arsenic trioxide infusion. In these ECG evaluations experience more pronounced QT prolongation than men, and there was no correlation with age (Prod Inf

3.5.1.E Azimilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventri ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM) e tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 20

7) Probable Mechanism: additive QT prolongation

3.5.1.F Bretylium

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventri ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM) e tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 20

7) Probable Mechanism: additive QT prolongation

3.5.1.G Carbamazepine

1) Interaction Effect: decreased paliperidone concentration

2) Summary: Concomitant use of paliperidone and carbamazepine decreased the maximum concentration (C under the concentration-time curve (AUC) values of paliperidone by 37%. Coadministration with carbamazep inducer, could increase paliperidone renal clearance by 35%. The dose of paliperidone should be evaluated v concurrently with carbamazepine. If therapy with carbamazepine is discontinued, the dose of paliperidone sh necessary (Prod Info INVEGA(TM) extended-release oral tablets, 2007).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Coadministration of paliperidone and carbamazepine resulted in decreased paliperi Dosing of paliperidone should be evaluated when it is administered concurrently with carbamazepine. If thera carbamazepine is discontinued, the dose of paliperidone should be decreased if necessary(Prod Info INVEGA release oral tablets, 2007).

7) Probable Mechanism: induction of paliperidone metabolism

8) Literature Reports

a) Coadministration of paliperidone 6 mg daily and carbamazepine 200 mg twice daily decreased the pa steady-state maximum concentration (Cmax) and area under the concentration-time curve (AUC) by app decrease is caused by a 35% increase in renal clearance of paliperidone. There is little effect on the met bioavailability of paliperidone when coadministered with carbamazepine. Carefully evaluate paliperidone discontinuation of carbamazepine (Prod Info INVEGA(TM) extended-release oral tablets, 2007).

3.5.1.H Chlorpromazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects on the recommended. Q and T wave distortions have been observed in patients taking phenothiazines (Prod Info Co Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info haloperidol (O'Brien et al, 1999a), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), 2001a), risperidone (Duenas-Laita et al, 1999a), sertindole (Agelink et al, 2001a), sultopride (Lande et al, 199 (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).

3) Severity: major

4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phen antipsychotics, is not recommended.
7) Probable Mechanism: additive QT prolongation

3.5.1.I Disopyramide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, halop paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM Prod Info Solian(R), 1999b; O'Brien et al, 1999b; Prod Info INVEGA(TM) extended-release oral tablets, 2006 Duenas-Laita et al, 1999b; Agelink et al, 2001b; Lande et al, 1992b; Prod Info GEODON(R) intramuscular inj 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and incre arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended ((TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is r
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperi day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide ther Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antip studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. Th significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1 haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) we changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible fo changes than an elimination alteration (Young et al, 1993).

3.5.1.J Dofetilide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest
2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventr ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM) e tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2
7) Probable Mechanism: additive QT prolongation

3.5.1.K Gatifloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest
2) Summary: Gatifloxacin may prolong the QTc interval in some patients, which may result in ventricular tach ventricular fibrillation. Additionally, rare cases of torsades de pointes have been reported with quinolones, inc post-marketing surveillance (Prod Info TEQUIN(R) tablets, injection, 2006). Modest increases in the QTc inte with paliperidone use (Prod Info INVEGA(TM) extended-release oral tablets, 2006). Although pharmacokineti gatifloxacin and other drugs which prolong the QT interval have not been performed, an additive effect canno Therefore, the concurrent administration of gatifloxacin and paliperidone should be avoided (Prod Info INVEG release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of gatifloxacin and paliperidone should be avoided as additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.L Hydroquinidine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, halop paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM

Prod Info Solian(R), 1999b; O'Brien et al, 1999b; Prod Info INVEGA(TM) extended-release oral tablets, 2006 Duenas-Laita et al, 1999b; Agelink et al, 2001b; Lande et al, 1992b; Prod Info GEODON(R) intramuscular inj 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and incre arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended ((TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).

3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is r
7) Probable Mechanism: additive cardiac effects
8) Literature Reports

a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperic day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).

b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide ther Norpace(R), 1997).

c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antip studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. Th significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1 haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) we changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible fo changes than an elimination alteration (Young et al, 1993).

3.5.1.M Ibutilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in ventr ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM) e tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 20
7) Probable Mechanism: additive QT prolongation

3.5.1.N Iloperidone

1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Due to the potential for additive effects on the QT interval and increased risk of torsade de poin used when iloperidone and drugs that prolong the QT interval are given concomitantly. Consideration should cardiac function periodically with on-treatment ECGs and evaluating electrolyte (ie, magnesium, potassium) le iloperidone in patients with persistent QTc measurements greater than 500 msec (Prod Info FANAPT(TM) ora
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of iloperidone and drugs that prolong the QT interval may result in the QT interval and an increased risk of torsade de pointes. Iloperidone should be avoided in patients with sig cardiovascular illness, eg, cardiac arrhythmia, QT prolongation, recent acute myocardial infarction, and uncon failure. If concomitant use is necessary, consider monitoring cardiac function periodically with on-treatment E electrolyte (ie, magnesium, potassium) levels. Discontinue iloperidone in patients with persistent QTc measur 500 msec(Prod Info FANAPT(TM) oral tablets, 2009).
7) Probable Mechanism: additive effects on the QT interval
8) Literature Reports

a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperic day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).

3.5.1.O Lapatinib

1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Due to the potential for additive effects on the QT interval and increased risk of torsade de poin used when lapatinib and drugs that prolong the QT interval are given concomitantly. Consideration should be cardiac function periodically with on-treatment ECGs and evaluating electrolyte (ie, magnesium, potassium) le TYKERB oral tablets, 2008). Thirteen patients had either QTcF (corrected QT by the Friedericia method) grea an increase in QTcF of greater than 60 msec in an uncontrolled, open-label, dose escalation study in advanc (n=81) who received lapatinib doses ranging from 175 mg/day to 1800 mg/day, with serial ECGs collected on Info TYKERB oral tablets, 2008).
3) Severity: major

4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of lapatinib and drugs that prolong the QT interval may result in ac QT interval and an increased risk of torsade de pointes. Therefore, caution should be used when these agent concomitantly. Consider monitoring cardiac function periodically with on-treatment ECGs and evaluating elec magnesium, potassium) levels (Prod Info TYKERB oral tablets, 2008).
7) Probable Mechanism: additive effects on the QT interval

3.5.1.P Levodopa
1) Interaction Effect: loss of levodopa efficacy
2) Summary: Because paliperidone is an antagonist with a high affinity for dopamine type 2 receptors, it is ex the effects of levodopa and other dopamine agonists (Prod Info INVEGA(TM) extended-release oral tablets, 2 paliperidone is used concurrently in patients receiving levodopa. Monitor patients for loss of levodopa efficacy
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concurrent use with paliperidone is expected to antagonize the effects of levodopa agonists due to pharmacologic antagonism (Prod Info INVEGA(TM) extended-release oral tablets, 2006). Us paliperidone is used concurrently in patients receiving levodopa. Monitor patients for loss of levodopa efficacy
7) Probable Mechanism: pharmacologic antagonism

3.5.1.Q Mesoridazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although citing no data, the manufacturer of mesoridazine states that concomitant use with oth prolong the QT interval is contraindicated (Prod Info Serentil(R), 2001). Several antipsychotic agents have de prolongation including amisulpride (Prod Info Solian(R), 1999d), haloperidol (O'Brien et al, 1999d), paliperido (TM) extended-release oral tablets, 2006), quetiapine (Owens, 2001d), risperidone (Duenas-Laita et al, 1999 et al, 2001c), sultopride (Lande et al, 1992d), ziprasidone (Prod Info GEODON(R) intramuscular injection, ora zotepine (Sweetman, 2004).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as antips mesoridazine, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.R Methadone
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Cases of QT interval prolongation and serious arrhythmias, including torsade de pointes, have methadone use (Prod Info DOLOPHINE(R) HYDROCHLORIDE oral tablets, 2006). Treatment with paliperido associated with QTc prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2006a). The coadm paliperidone and other drugs known to prolong the QTc interval, including methadone, should be avoided due additive QT interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2006a).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive effects on the QT interval, avoid concomitant use of methadone (Prod Info INVEGA(TM) extended-release oral tablets, 2006a).
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.S Moxifloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Moxifloxacin has been shown to prolong the QTc interval in some patients (Prod Info AVELOX injection, 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVE release oral tablets, 2006). Although pharmacokinetic studies between moxifloxacin and paliperidone have no additive effect cannot be excluded. Therefore, the concurrent administration of moxifloxacin and paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of moxifloxacin and paliperidone should be avoided a additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.T Nilotinib
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Due to the potential for additive effects on the QT interval and increased risk of torsade de poin of nilotinib with drugs that prolong the QT interval should be avoided. However, if concomitant use is required

closely monitored for prolongation of the QT interval (Prod Info TASIGNA(R) oral capsules, 2007).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of nilotinib with drugs that prolong the QT interval should be avoid for additive effects on the QT interval and increased risk of torsade de pointes. However, if concurrent therap patient closely for prolongation of the QT interval (Prod Info TASIGNA(R) oral capsules, 2007).
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.U Paroxetine
1) Interaction Effect: increased plasma concentrations of paliperidone
2) Summary: Concurrent use of paliperidone and paroxetine may result in increased paliperidone plasma co Paliperidone (9-hydroxyrisperidone) is the major active metabolite of risperidone (Prod Info INVEGA(TM) exte tablets, 2007). Concomitant use of paroxetine and risperidone has resulted in increased plasma concentratio and 9-hydroxyrisperidone, particularly at higher (40 mg) paroxetine doses (Saito et al, 2005; Spina et al, 200 paliperidone and paroxetine are used concomitantly. Consider monitoring for increased paliperidone side effe neuroleptic malignant syndrome, QTc prolongation, or tardive dyskinesia.
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Use caution when paliperidone and paroxetine are used concomitantly as this may paliperidone plasma concentrations (Prod Info INVEGA(TM) extended-release oral tablets, 2007). Consider r increased paliperidone side effects, including neuroleptic malignant syndrome, QTc prolongation, or tardive d
7) Probable Mechanism: inhibition of the CYP2D6-mediated metabolism of paliperidone
8) Literature Reports
a) In a drug interaction study, paliperidone exposures were a significant 16% (90% confidence interval, average in CYP2D6 extensive metabolizers who were treated concomitantly with a single dose of palipe paroxetine 20 mg/day. Studies with higher paroxetine doses have not been conducted. The clinical relev (Prod Info INVEGA(TM) extended-release oral tablets, 2007).
b) Paroxetine, a potent inhibitor of cytochrome CYP2D6, may impair the elimination of risperidone, prim CYP2D6-mediated alpha-hydroxylation and, to a lesser extent, by simultaneously affecting the further m hydroxyrisperidone (9-OH-risperidone) or other pathways of risperidone biotransformation. In a study inc diagnosed with schizophrenia (n=7) or schizoaffective disorder depressive type (n=3), risperidone plasm increased when paroxetine was coadministered with risperidone. Patients were stabilized on risperidone and received adjunctive paroxetine 20 mg/day to treat negative symptoms, concomitant depression, or b dosage remained constant throughout the duration of the study. A significant elevation in risperidone pla less than 0.01) and a slight, nonsignificant decrease in 9-OH-risperidone occurred. After 4 weeks of parc total concentration of risperidone and 9-OH-risperidone was increased by 45% (p less than 0.05). The m risperidone to 9-OH-risperidone ratio also changed significantly (p less than 0.001) with concomitant par Extrapyramidal side effects occurred in one patient during the second week of paroxetine coadministratio of risperidone in this patient increased 62% over baseline values during paroxetine coadministration. The extrapyramidal symptoms in patients after addition of SSRIs to antipsychotics might also be caused by a pharmacodynamic effect of paroxetine (Spina et al, 2001).
c) Risperidone plasma concentrations increased when risperidone-treated inpatients (n=12) with schizo symptoms were coadministered incremental doses of paroxetine. Prior to initiating paroxetine, patients w risperidone 2 mg twice daily for at least 6 weeks and steady-state plasma concentrations of risperidone a hydroxyrisperidone (9-OH-risperidone) had been achieved. Paroxetine doses were administered in 3 cor increments of 10 mg/day, 20 mg/day, and 40 mg/day. Mean risperidone plasma concentrations during 1(paroxetine treatment were 3.8- (95% confidence interval (CI), 3.2 to 5.8; p less than 0.01) , 7.1- (95% CI than 0.01), and 9.7-fold (95% CI, 7.8 to 22.5; p less than 0.01) higher compared with baseline. Increases concentrations were not significant with paroxetine use. Mean active moiety (risperidone plus 9-OH-rispe concentrations increased by 1.8-fold (95% CI, 1.4 to 2.7; p less than 0.05) during the 40-mg paroxetine c not significant with 10- or 20-mg doses. Metabolic ratio was significantly increased (p less than 0.01) by to 6.2) with 10 mg of paroxetine, by 8.2-fold (95% CI, 6 to 16) with 20 mg, and by 12.6-fold (95% CI, 9.6 Negative symptom scores were significantly improved during all paroxetine doses; however, extrapyrami were significantly higher during 20- and 40-mg doses. The authors suggest that low-dose coadministratio risperidone may be safe and effective for treating schizophrenia with negative symptoms (Saito et al, 20(

3.5.1.V Pirmenol
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, halop paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM Prod Info Solian(R), 1999b; O'Brien et al, 1999b; Prod Info INVEGA(TM) extended-release oral tablets, 2006 Duenas-Laita et al, 1999b; Agelink et al, 2001b; Lande et al, 1992b; Prod Info GEODON(R) intramuscular inj 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and incre arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended ((TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major

4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is r
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperic day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide ther Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antip studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. Th significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1 haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) we changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible fo changes than an elimination alteration (Young et al, 1993).

3.5.1.W Prajmaline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, halop paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM Prod Info Solian(R), 1999b; O'Brien et al, 1999b; Prod Info INVEGA(TM) extended-release oral tablets, 2006 Duenas-Laita et al, 1999b; Agelink et al, 2001b; Lande et al, 1992b; Prod Info GEODON(R) intramuscular inj 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and incre arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended ((TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is r
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperic day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide ther Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antip studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. Th significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1 haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) we changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible fo changes than an elimination alteration (Young et al, 1993).

3.5.1.X Procainamide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride, halop paliperidone, quetiapine, risperidone, sertindole, sultopride, ziprasidone, and zotepine (Prod Info FANAPT(TM Prod Info Solian(R), 1999b; O'Brien et al, 1999b; Prod Info INVEGA(TM) extended-release oral tablets, 2006 Duenas-Laita et al, 1999b; Agelink et al, 2001b; Lande et al, 1992b; Prod Info GEODON(R) intramuscular inj 2005; Sweetman, 2003). Because Class IA antiarrhythmic agents may also prolong the QT interval and incre arrhythmias, the concurrent administration of antipsychotics with a drug from this class is not recommended ((TM) oral tablets, 2009; Prod Info Quinaglute(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic and an antipsychotic is r
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) In an open-label QTc study of patients with schizophrenia or schizoaffective disorder (n=160), iloperic day was associated with QTc prolongation of 9 msec (Prod Info FANAPT(TM) oral tablets, 2009).
b) QRS widening, QTc interval prolongation, and torsades de pointes may occur with disopyramide ther Norpace(R), 1997).
c) The effects of combined therapy with quinidine (Class IA antiarrhythmic agent) and haloperidol (antip studied by giving 12 healthy volunteers haloperidol 5 mg alone and with 250 mg of quinidine bisulfate. Th significant increases in the plasma concentrations of haloperidol when given concurrently with quinidine

treatment alone. The mean area under the concentration curve (AUC) was increased from 54.3 ng/h/mL to 103.2 ng/h/mL on combined therapy. The peak concentration (Cmax) also showed an increase from 1 haloperidol to 3.8 ng/mL on combined therapy. Half-life (T1/2) and time to peak concentration (Tmax) we changed, thereby suggesting to the authors that a tissue binding mechanism is more likely responsible fo changes than an elimination alteration (Young et al, 1993).

3.5.1.Y Prochlorperazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects on the recommended. Q and T wave distortions have been observed in patients taking phenothiazines (Prod Info Co Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info haloperidol (O'Brien et al, 1999a), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), 2001a), risperidone (Duenas-Laita et al, 1999a), sertindole (Agelink et al, 2001a), sultopride (Lande et al, 199 (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phen antipsychotics, is not recommended.
7) Probable Mechanism: additive QT prolongation

3.5.1.Z Ranolazine

1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Paliperidone causes an increase of QTc interval and ranolazine prolongs the QTc interval in a If concomitant administration is unavoidable, use caution when paliperidone is coadministered with ranolazin for additive effects on QT interval prolongation (Prod Info INVEGA(R) extended-release oral tablets, 2008a).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Paliperidone causes an increase of QTc interval and ranolazine prolongs the QTc i related manner. If concomitant administration is unavoidable, use caution when paliperidone is coadministere to the potential for additive effects on QT interval prolongation (Prod Info INVEGA(R) extended-release oral t
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.AA Sematilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in venti ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM) tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2
7) Probable Mechanism: additive QT prolongation

3.5.1.AB Sotalol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in venti ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM) tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2
7) Probable Mechanism: additive QT prolongation

3.5.1.AC Tedisamil

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class III antiarrhythmics have been shown to prolong the QT interval, which may result in venti ventricular fibrillation, and torsades de pointes (Prod Info CORDARONE(R) oral tablets, 2006; Prod Info sotal 2005). Modest increases in the QTc interval have been noted with paliperidone use (Prod Info INVEGA(TM)

tablets, 2006). Due to the risk of additive QTc prolongation, the concurrent administration of paliperidone and antiarrhythmic agents should be avoided (Prod Info INVEGA(TM) extended-release oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of paliperidone and class III antiarrhythmic agents sh this may result in additive QTc interval prolongation (Prod Info INVEGA(TM) extended-release oral tablets, 2(
7) Probable Mechanism: additive QT prolongation

3.5.1.AD Tetrabenazine
1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Due to the potential for additive effects on the QT interval and increased risk of torsade de poir of tetrabenazine with drugs that prolong the QT interval should be avoided. However, if concomitant use is re should be closely monitored for prolongation of the QT interval (Prod Info XENAZINE(R) oral tablets, 2008). I double-blind, placebo controlled crossover study of healthy subjects, the effect of a single 25 mg or 50 mg do the QT interval was studied with moxifloxacin as a positive control. The 50 mg dose of tetrabenazine caused millisecond mean increase in QT (Prod Info XENAZINE(R) oral tablets, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of tetrabenazine with drugs that prolong the QT interval should be potential for additive effects on the QT interval and increased risk of torsade de pointes. However, if concurre monitor patient closely for prolongation of the QT interval (Prod Info XENAZINE(R) oral tablets, 2008).
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.AE Thioridazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although citing no data, the manufacturer of thioridazine states that concomitant use with other the QT interval is contraindicated (Prod Info Mellaril(R), 2001). Several antipsychotic agents have demonstra including amisulpride (Prod Info Solian(R), 1999c), haloperidol (O'Brien et al, 1999c), pimozide (Prod Info Ora quetiapine (Owens, 2001c), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), risper et al, 1999c), sertindole (Agelink et al, 2001c), sultopride (Lande et al, 1992c), ziprasidone (Prod Info GEODO injection, oral capsule, 2005), and zotepine (Sweetman, 2004).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as antips thioridazine, is contraindicated.
7) Probable Mechanism: additive QT prolongation

3.5.1.AF Trifluoperazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Concomitant use of phenothiazines and antipsychotic agents may cause additive effects on the recommended. Q and T wave distortions have been observed in patients taking phenothiazines (Prod Info Co Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, available. Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod Info haloperidol (O'Brien et al, 1999a), paliperidone (Prod Info INVEGA(TM) extended-release oral tablets, 2006), 2001a), risperidone (Duenas-Laita et al, 1999a), sertindole (Agelink et al, 2001a), sultopride (Lande et al, 199 (Prod Info GEODON(R) intramuscular injection, oral capsule, 2005), and zotepine (Sweetman, 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of agents that prolong the QT interval, such as phen antipsychotics, is not recommended.
7) Probable Mechanism: additive QT prolongation

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters

A) Therapeutic

1) Physical Findings

a) Schizophrenia

1) Patients should be monitored for signs of improvement in the target positive and negative symptoms as improved communication, decreased hallucinations and delusions, improved socialization, and decrea of improvement in socialization, grooming, and attention to activities of daily living should also be monito

B) Toxic

1) Laboratory Parameters

a) Fasting glucose test in patients with a diagnosis or with risk factors for diabetes mellitus at the initiation of periodically during treatment (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

2) Physical Findings

a) Hyperglycemia symptom monitoring in all patients for polydipsia, polyuria, polyphagia, and weakness (Prc extended-release oral tablets, 2006)

b) Neuroleptic malignant syndrome has been reported and patients should be monitored for the signs and sy syndrome (hyperpyrexia, muscle rigidity, altered mental status, and autonomic instability) (Prod Info INVEGA release oral tablets, 2006).

c) Orthostatic vital sign monitoring in patients susceptible to hypotension (Prod Info INVEGA(TM) extended-r 2006)

d) QT prolongation has been reported with paliperidone, a baseline EKG may be considered (Prod Info INVE release oral tablets, 2006)

e) Suicide monitoring in high-risk patients (Prod Info INVEGA(TM) extended-release oral tablets, 2006)

4.2 Patient Instructions

A) Paliperidone (By mouth)

Paliperidone

Treats schizophrenia (a mental disorder).

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to paliperidone or risperidone.

How to Use This Medicine:
Long Acting Tablet

Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed order to find out what works best for you. Do not use more medicine or use it more often than your doctor tell
You may take this medicine with or without food.
Swallow the extended-release tablet whole. Do not crush, break, or chew it. Swallow the tablet with a liquid, s
While taking the extended-release form of this medicine, part of the tablet may pass into your stools. This is r to worry about.

If a Dose is Missed:

If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next d use the medicine and skip the missed dose. Do not use extra medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:

Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after your treatment. You will also need to throw away old medicine after the expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a

Make sure your doctor knows if you are using medicines for heart rhythm problems (such as amiodarone, qui sotalol, Betapace®, Cordarone®, Procanbid®) or a diuretic, also called a "water pill" (such as furosemide, hy Aldactazide®, Aldactone®, Lasix®, Maxzide®).
Tell your doctor if you are using levodopa (Dopar®, Larodopa®), any medicine for mental illness (such as chl thioridazine, Thorazine®, Mellaril®), or certain antibiotic medicines (such as gatifloxacin, moxifloxacin, Tequi
Tell your doctor if you are using any medicines that make you sleepy. These include sleeping pills, cold and a narcotic pain relievers, and sedatives.
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:

Make sure your doctor knows if you are pregnant, planning to become pregnant, or if you are breastfeeding. T
have a history of seizures, heart disease, kidney disease, stroke, or breast cancer. Make sure your doctor kn
Parkinson's disease, any trouble with swallowing, or a history of blocked bowels or stomach and intestine pro
doctor if you have ever had thoughts of hurting yourself.

Make sure your doctor knows if you or a family member has a heart condition called congenital long QT synd
if you have ever had a condition called neuroleptic malignant syndrome (NMS) that was caused by a medicin
disorders.

This medicine may cause an increase in your blood sugar. If you have diabetes, you may need to check your
often. If you are using medicine for diabetes, your doctor may need to change your dose.

This medicine is not approved to treat behavior disorders in older people who have dementia. Using this med
problem could increase the risk of death. This risk has not been shown for the approved uses of this medicin
Some side effects are more likely to happen in elderly people who have memory problems or other reduced r
sure the doctor knows if the person who will be using this medicine has Alzheimer's disease or similar proble
"dementia").

This medicine may cause tardive dyskinesia, which is a movement disorder. If you have muscle spasms, twit
body, or uncontrolled tongue or jaw movements, stop taking this medicine and call your doctor right away. Ta
the risk of this side effect.

This medicine may make you dizzy or drowsy. Avoid driving, using machines, or doing anything else that cou
are not alert. You may also feel lightheaded or dizzy when you get up quickly from a sitting or lying position. I
should get up slowly.

This medicine might reduce how much you sweat. Your body could get too hot if you do not sweat enough. If
hot, you might feel dizzy, weak, tired, or confused. You might vomit or have an upset stomach. Do not get too
exercising. Avoid places that are very hot. Call your doctor if you are too hot and cannot cool down.

Your doctor will need to check your progress at regular visits while you are using this medicine. Be sure to ke

If your symptoms do not improve or if they get worse, call your doctor.

Possible Side Effects While Using This Medicine:

Call your doctor right away if you notice any of these side effects:

Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, c
breathing.

Dry mouth, increased thirst, muscle cramps, nausea, or vomiting.

Fast, slow, pounding, or irregular heartbeat.

Fever, confusion, sweating, or muscle stiffness.

Lightheadedness, dizziness, or fainting.

Neck muscle spasm, throat tightness, difficulty swallowing or breathing, or sticking out of the tongue.

Painful or prolonged erection of the penis.

Pinpoint red spots on skin.

Problems with speech, balance, or walking.

Seizures or tremors.

Swelling of breasts or unusual milk production.

Twitching or muscle movements you cannot control (often in your face, tongue, or jaw).

If you notice these less serious side effects, talk with your doctor:

Anxiety or restlessness.

Drooling.

Headache.

Sleepiness or unusual drowsiness.

Stomach pain or upset stomach.

Unusual tiredness or weakness.

Weight gain.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Current users of atypical antipsychotic drugs (including paliperidone) and typical antipsychotic drugs had a similar
of sudden cardiac death, according to a retrospective cohort of 93,300 adult users of antipsychotic drugs and 186,600
The study included patients age 30 to 74 years (mean 45.7 +/- 11.8 years) with similar cardiovascular risk at baseline
filled prescription and had 1 outpatient visit in each of the 2 preceding years. Sudden cardiac death was defined as oc
community and excluded deaths of patients admitted to the hospital, non-sudden deaths, deaths due to extrinsic caus
related to ventricular tachyarrhythmia. Current use was defined as the interval between the time the prescription was f
the day's supply. Low and high doses was defined as comparable to less than 100 milligrams (mg) of chlorpromazine,
comparable to chlorpromazine 300 mg or greater, respectively. The adjusted rate of sudden cardiac death (incidence-
users of atypical antipsychotic drugs in 79,589 person-years was 2.26 (95% CI, 1.88 to 2.72, p less than 0.001) which
in current users of typical antipsychotic drugs in 86,735 person-years which was 1.99 (95% CI, 1.68 to 2.34, p less tha
sudden cardiac death significantly increased with increasing dose in both the typical and atypical antipsychotic drug gr
antipsychotic use, the incidence rate ratio increased from 1.59 (95% CI, 1.03 to 2.46) in low-dose use to 2.86 (95% CI
dose use. To limit the effects of confounding of the study results, there was a secondary analysis performed in a coho

by propensity score, which resulted in a similar risk of sudden death as the primary cohort analysis (Ray et al, 2009). I New England Journal of Medicine, it has been suggested that antipsychotic drugs continue to be used in patients with benefit, but in vulnerable populations with cardiac risk profiles (eg, elderly patients), there should be an age-dependen prior to administration. It has also been suggested (although not formally tested) that ECGs be performed before and s of antipsychotic therapy to screen for existing or emergent QT interval prolongation (Schneeweiss & Avorn, 2009).
B) Paliperidone is a benzisoxazole derivative, and an active metabolite of risperidone. It is indicated for the treatment efficacy in improving positive symptoms, negative symptoms, disorganized thoughts, uncontrolled hostility/excitement, anxiety/depression among patients with schizophrenia has been established in three 6-week, multinational, fixed-dose and active-controlled (olanzapine) trials. While the mechanism of action of paliperidone is unclear, it is thought to bloc dopamine Type 2 (D(2)) and serotonin Type 2 (5HT(2A)) receptors, and has antagonistic effects on the alpha-1 adren adrenergic, and H1 histaminergic receptors (Prod Info INVEGA(TM) extended-release oral tablets, 2006). Due to the l efficacy data with haloperidol, fluphenazine, risperidone, and other conventional neuroleptics, the role of paliperidone i schizophrenia is unclear. Concomitant use of paliperidone with risperidone has not been studied.
C) Paliperidone extended-release is also being investigated as a monotherapy and as an adjunctive therapy to lithium treatment of acute manic and mixed episodes associated with bipolar I disorder, as well as in schizoaffective disorder.
See Drug Consult reference: FIRST- VS SECOND-GENERATION ANTIPSYCHOTIC AGENTS FOR SCHIZOPHREN

4.4 Mechanism of Action / Pharmacology

A) Paliperidone is the major active metabolite of risperidone. While the mechanism of action is unknown, its proposed antagonism of both the central dopamine Type 2 (D(2)) and serotonin Type 2 (5HT(2A)) receptors. It also has antagon alpha-1 adrenergic, alpha-2 adrenergic, and H1 histaminergic receptors; however, the degree of affinity is unclear. Pal known affinity for cholinergic muscarinic or beta-1 and beta-2 adrenergic receptors (Prod Info INVEGA(TM) extended- 2006).

4.5 Therapeutic Uses

4.5.A Schizophrenia

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Paliperidone is indicated for the treatment of schizophrenia (Prod Info INVEGA(TM) extended-release or
A 6-week, randomized, double-blind, placebo- and active-controlled, dose-response study (n=630) demo daily paliperidone (6 milligrams (mg), 9 mg, and 12 mg) extended-release (ER) was effective in significar schizophrenia symptoms, personal functioning, and social functioning (Kane et al, 2007).
In a randomized, double-blind, placebo-controlled study (n=113), paliperidone extended-release (ER) tab delayed time-to-recurrence of schizophrenia symptoms and maintained symptom stability relative to plac 2007).
Geriatric patients (n=114) were safely treated with paliperidone extended-release tablets and although n for efficacy or safety and tolerability, clinical improvements were seen, according to a prospective, 6-wee randomized, placebo-controlled, optional 24-week open-label extension safety trial (Tzimos et al, 2008).

3) Adult:

a) Acute Therapy

1) A 6-week, randomized, double-blind, placebo- and active-controlled, dose-response study demonstra paliperidone (6 milligrams (mg), 9 mg, and 12 mg) extended-release (ER) was effective in significantly in symptoms, personal functioning, and social functioning. The enrolled patients (n=630) were greater than of age (mean age, 37.1 years), experiencing an acute episode of schizophrenia (Positive and Negative S (PANSS) score between 70 and 120), and had a diagnosis of schizophrenia according to the Diagnostic of Mental Disorders Fourth Edition (DSM-IV) for at least 1 year. After discontinuation of previous medicat antiparkinsonian drugs, beta-blockers or other psychotropic agents) for three days prior to randomization group (n=628) received either paliperidone ER 6 mg (n=123), paliperidone ER 9 mg (n=122), paliperidon olanzapine 10 mg (n=128), or placebo (n=126) once daily for 6 weeks. The primary efficacy variable was PANSS score from baseline to 6 weeks for each dose of paliperidone ER compared to placebo. The mea deviation (SD)) decrease in PANSS score was 17.9 (+/-22.2), 17.2 (+/-20.2), 23.3 (+/-20.1) for the 6 mg, paliperidone ER groups (p less than 0.001 vs placebo), respectively, compared with 4.1 (+/-23.2), and 19 placebo and olanzapine groups, respectively. All doses of paliperidone ER resulted in statistically signific placebo (p less than 0.001) in all PANSS Marder factor scores. Clinical response (defined as a greater th decrease in PANSS total score) was achieved in 56%, 51%, 61%, and 30% for the paliperidone ER 6 mg placebo groups, respectively (p less than 0.001 for all groups vs placebo). Improvement in personal and (+/- SD) scores was 9.1 (+/-15.5), 8.1 (+/-14.5), 11.5 (+/-16), and 0.5 (+/-15.5) for the paliperidone 6 mg, placebo groups, respectively (p less than 0.001). At 6 weeks, fewer patients were classified as marked o the Clinical and Global Impressions-Severity scale scores (paliperidone ER 6 mg: 62.6% at baseline vs 2 paliperidone ER 9 mg: 57.3% at baseline vs 23% at 6 weeks, paliperidone ER 12 mg: 64.4% at baseline placebo: 59.5% at baseline vs 50.8% at 6 weeks, p less than 0.001 for all doses vs placebo). The numbe

adverse effects in the safety analysis group (n=629) was similar among all groups. The most common ac
to discontinuation of the study was tachycardia (2% for paliperidone ER 12 mg, 1% in all other groups). F
showed no observable dose-response relationship for the severity of adverse events. The most common
effect was psychosis which occurred in 2% of the paliperidone ER 12 mg group, 1% of the placebo, palip
olanzapine groups, and in 0% of the paliperidone ER 9 mg group. Most movement disorder-related adve
to moderate in severity; 3 patients discontinued the study because of movement disorder-related adverse
paliperidone ER 6 mg group, 2 in the 12 mg group) (Kane et al, 2007).

b) Maintenance Therapy

1) In a randomized, double-blind, placebo-controlled study, paliperidone extended-release (ER) tablets s
time-to-recurrence of schizophrenia symptoms and maintained symptom stability relative to placebo. The
65 years old and had a diagnosis of schizophrenia according to the Diagnostic and Statistical Manual of
Fourth Edition (DSM-IV) for at least 1 year. The patients were also experiencing an acute episode of sch
and Negative Syndrome Scale (PANSS) total score of 70-120). The study consisted of an 8-week run-in
patients received open-label paliperidone ER, starting at 9 milligrams (mg) once daily and adjusted until
for at least 2 weeks (dose range: 3 to 15 mg once daily). This was followed by a 6-week open-label stabi
they remained on their stabilized dose. Patients then entered a double-blinded treatment phase in which
randomized to receive paliperidone ER or placebo for maintenance therapy. The patients remained in th
until they experienced a recurrence event (defined as: psychiatric hospitalization, a pre-defined increase
Clinical and Global Impression-Severity (CGI-S) score, deliberate self-injury, aggressive behavior, suicid
homicidal ideation), until they withdrew from the study or until the end of the study. The time to first recur
double-blind phase was the primary efficacy variable. At the interim analysis (n=113), the study was term
significant efficacy was established; 14 patients (25%) in the paliperidone ER group experienced a recur
to 29 patients (53%) in the placebo group. In the final analysis (n=205), paliperidone ER significantly dela
recurrence (25% quantile of time-to-recurrence was 83 days for paliperidone ER vs 23 days for placebo,
open-label phases of the trial, 73% of patients reported treatment-related adverse events while 37% of p
treatment-related adverse events in the double-blind phase. A 2 fold increase in treatment-related advers
reported for the placebo group than for the paliperidone ER group; most related to the underlying psycho
psychosis and aggressive reaction occurred more frequently in the placebo group (n=102, 23% and 6%,
the paliperidone ER group (n=104, 7% and 1%, respectively) (Kramer et al, 2007).

c) Geriatric

1) According to a prospective, 6-week, double-blind, randomized, placebo-controlled, optional 24-week
safety trial, paliperidone treatment was well tolerated in the geriatric population compared with placebo.
adverse events in geriatric patients receiving paliperidone extended-release tablets in general were simil
increased age-related incidences of somnolence and elevated pulse rate. Although the study was not su
efficacy or safety and tolerability, clinical improvements were seen in the Positive and Negative Syndrom
paliperidone-treated (n=76) versus placebo-treated patients (n=38) during the 6-week double-blind perio
difference in the change from baseline of -14.6 vs -9.9, respectively yielding a difference between groups
confidence interval, -9.9 to -1.1, p=0.014). There were nonsignificant differences seen between treatmen
Clinical Global Impressions Severity (CGI-S) scale, Personal and Social Performance Scale, and the Scl
Life Scale. The study included 114 patients (mean age of 70 years) with 99% having moderate to severe
receiving either placebo or median mean dose of paliperidone ER 8.4 milligrams/day (mg/day) during the
and median mean doses of 7.4 mg and 8.5 mg in the placebo/paliperidone ER and paliperidone ER/palip
respectively during the open-label phase (Tzimos et al, 2008).

4.6 Comparative Efficacy / Evaluation With Other Therapies

4.6.A Quetiapine Fumarate

4.6.A.1 Schizophrenia, Recent exacerbation, in hospitalized patients

a) In a randomized, double-blind, placebo- and active-controlled clinical trial (n=394), treatment with paliperid
(ER) produced significantly improved Positive and Negative Syndrome Scale (PANSS) total scores compared
hospitalized patients with a recent exacerbation of schizophrenia. Hospitalized patients 18 to 65 years of age
(defined as lasting less than 4 weeks but more than 4 days) of schizophrenia (paranoid, disorganized, or und
diagnosed using Diagnostic and Statistical Manual of Mental Disorders Fourth edition (DSM-IV)), a Clinical G
Severity (CGI-S) scale score of 5 or greater, and symptom scores of 4 or greater on 2 or more of the following
hostility, excitement, tension, uncooperativeness, and poor impulse control (with a combined score of these it
were eligible for enrollment. Following the discontinuation of all psychotropic agents, patients were randomize
paliperidone ER (n=157; baseline mean PANSS total score, 102.8 +/- 13.1 points), quetiapine (n=157; baseli
score, 101.3 +/- 13.3 points), or placebo (n=80; baseline mean PANSS total score, 103.8 +/- 15.7 points). In a
phase, paliperidone ER was initiated at 6 milligrams (mg)/day on days 1 to 3 and then increased to 9 mg/day
an optional dose increase to 12 mg/day starting on day 8 if necessary (mean dose, 10.4 +/- 1.7 mg/day) and
at 50 mg/day on day 1, 100 mg/day on day 2, 200 mg/day on day 3, 400 mg/day on day 4, 600 mg/day on da
dose increase to 800 mg/day on day 8 (mean dose, 690.9 +/- 134.3 mg/day). Psychotropic medications (excl
additional paliperidone ER or quetiapine) could be added following the 14-day monotherapy phase (one or m
agents: paliperidone ER, 52.9%; quetiapine, 55.4%; placebo, 66.7%). The least-squares mean PANSS total s
baseline to day 14 was significantly decreased in the paliperidone ER arm (-23.4 +/- 1.8 (standard error (SE)
with the quetiapine arm (-17.1 +/- 1.8 (SE) points; p less than 0.001) (primary endpoint) and the placebo arm
between group analyses (using a least-squares mean differences in change scores with the last observation

patients in the paliperidone ER arm had significantly improved PANSS total score, PANSS scale negative sy
PANSS scale disorganized thoughts scores, PANSS scale uncontrolled hostility/excitement scores, and CGI-
with patients in the quetiapine and placebo arms at day 14 and at the end of 6 weeks of treatment (day 42) (T

DRUGDEX® Evaluations

LAMOTRIGINE

0.0 Overview

1) Class

a) This drug is a member of the following class(es):
Anticonvulsant
Phenyltriazine

2) Dosing Information

a) Adult

1) caution for potential for dispensing errors involving similarly named medications (Prod Info LAMICTAL chewab disintegrating tablets, 2009)

2) safety and efficacy as initial monotherapy, for conversion to monotherapy from a non-enzyme-inducing antiepi conversion to monotherapy from 2 or more concomitant antiepileptic drugs has not been established (Prod Info L orally disintegrating tablets, 2009)

a) Bipolar I disorder

1) (patients not taking enzyme-inducing drugs or valproic acid) 25 mg/day orally for 2 weeks, then 50 m 200 mg/day; usual maintenance dose of lamotrigine in patients not taking enzyme-inducing drugs or valp dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

2) (added to valproic acid regimen) 25 mg/day orally every other day for 2 weeks, then 25 mg/day for 2 usual maintenance dose of lamotrigine in patients taking valproic acid is 100 mg/day (Prod Info LAMICT disintegrating tablets, 2009)

3) (added to enzyme-inducing antiepileptic drug regimen without valproic acid) 50 mg/day orally for 2 we then 200 mg/day for 1 week (in divided doses), then 300 mg/day for 1 week (in divided doses), then may mg/day (in divided doses) (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disi

b) Lennox-Gastaut syndrome; Adjunct

1) (added to antiepileptic drug regimen with valproic acid) 25 mg/day ORALLY every OTHER day for 2 dosage by 25 to 50 mg/day ORALLY every 1 to 2 weeks to the usual maintenance dose of 100 to 400 m of patients adding lamotrigine to valproic acid ALONE ranges from 100 to 200 mg/day (Prod Info LAMIC disintegrating tablets, 2009)

2) (added to antiepileptic drug regimen not containing enzyme-inducing antiepileptic drugs or valproic ac 2 weeks; may increase dosage by 50 mg/day every 1 to 2 weeks to the usual maintenance dose of 225 chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

3) (added to enzyme-inducing antiepileptic drug regimen without valproic acid) 50 mg/day ORALLY for 2 weeks; may increase dosage by 100 mg/day ORALLY every 1 to 2 weeks to the usual maintenance dos LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

c) Partial seizure, Adjunct or monotherapy

1) (chewable dispersible or orally disintegrating tablets; added to antiepileptic drug regimen with valproic then 25 mg/day for 2 weeks; may increase dosage by 25 to 50 mg/day ORALLY every 1 to 2 weeks to th 2 divided doses; usual maintenance dose of patients adding lamotrigine to valproic acid ALONE ranges dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

2) (chewable dispersible or orally disintegrating tablets; added to antiepileptic drug regimen not containi ORALLY for 2 weeks, then 50 mg/day for 2 weeks; may increase dosage by 50 mg/day every 1 to 2 wee in 2 divided doses (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrati

3) (chewable dispersible or orally disintegrating tablets; added to antiepileptic drug regimen containing e mg/day orally for 2 weeks, then 100 mg/day (in 2 divided doses) for 2 weeks; may increase dosage by 1 maintenance dose of 300 to 500 mg/day (in 2 divided doses) (Prod Info LAMICTAL chewable dispersible 2009)

4) (chewable dispersible or orally disintegrating tablets; conversion to monotherapy in patients, 16 yr an inducing antiepileptic drug) 500 mg/day orally (in 2 divided doses); titrate lamotrigine to the targeted dos withdraw the other drug by 20% decrements each week over a 4-week period (Prod Info LAMICTAL che disintegrating tablets, 2009)

5) (chewable dispersible or orally disintegrating tablets; conversion to monotherapy in patients, 16 yr an lamotrigine to 200 mg/day while maintaining valproic acid dose, the maintain lamotrigine dose at 200 mg by decrements no greater than 500 mg/day per week and then maintain the dose at 500 mg/day for 1 we while simultaneously decreasing the valproic acid to 250 mg/day and maintain this for 1 week, finally dis 100 mg/day each week until the maintenance dose of 500 mg/day is reached(Prod Info LAMICTAL chew disintegrating tablets, 2009)

6) (extended-release tablets; added to antiepileptic drug regimen with valproic acid) weeks 1 and 2, 25 mg/day; week 5, 50 mg/day; week 6, 100 mg/day; week 7, 150 mg/day; weeks 8 onwards to maintenanc 200 to 250 mg/day (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

7) (extended-release tablets; added to antiepileptic drug regimen not containing enzyme-inducing drugs weeks 3 and 4, 50 mg/day; week 5, 100 mg/day; week 6, 150 mg/day; week 7, 200 mg/day; weeks 8 on at weekly intervals), 300 to 400 mg/day (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

8) (extended-release tablets; added to antiepileptic drug regimen containing enzyme-inducing drugs and ORALLY; weeks 3 and 4, 100 mg/day; week 5, 200 mg/day; week 6, 300 mg/day; week 7, 400 mg/day; v 100 mg/day at weekly intervals), 400 to 600 mg/day (Prod Info LAMICTAL XR oral extended-release tab
9) (extended-release tablets; conversion from immediate-release lamotrigine tablets) initial, should matc need adjustments depending on therapeutic response after conversion (Prod Info LAMICTAL XR oral ex

d) Tonic-clonic seizure, Primary generalized; Adjunct

1) (added to antiepileptic drug regimen with valproic acid) 25 mg/day orally every other day for 2 weeks, 25 to 50 mg/day orally every 1 to 2 weeks to the usual maintenance dose of 100 to 400 mg/day in 1 to 2 adding lamotrigine to valproic acid alone ranges from 100 to 200 mg/day (Prod Info LAMICTAL chewable disintegrating tablets, 2009)
2) (added to antiepileptic drug regimen not containing enzyme-inducing antiepileptic drugs or valproic ac weeks; may increase dosage by 50 mg/day every 1 to 2 weeks to the usual maintenance dose of 225 to chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)
3) (added to enzyme-inducing antiepileptic drug regimen without valproic acid) 50 mg/day orally for 2 we may increase dosage by 100 mg/day orally every 1 to 2 weeks to the usual maintenance dose of 300 to chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

b) Pediatric

1) safety and efficacy of extended-release lamotrigine in patients below 13 years of age has not been established tablets, 2009)
2) safety and efficacy in pediatric patients with acute mood disorders has not been established (Prod Info LAMIC 2007)
3) efficacy in pediatric patients (age range, 1 to 24 months) for the treatment of partial seizures was not demonst tablets, oral tablets, orally disintegrating tablets, 2009)

a) Lennox-Gastaut syndrome; Adjunct

1) (2 to 12 yr; added to antiepileptic drug regimen with valproic acid) 0.15 mg/kg/day (rounded down to t doses for 2 weeks, then 0.3 mg/kg/day (rounded down to the nearest whole tablet) in 1 to 2 divided dose every 1 to 2 weeks (rounded down to the nearest whole tablet) to the usual maintenance dose of 1 to 5 r usual maintenance dose for children adding lamotrigine to valproic acid ALONE ranges from 1 to 3 mg/k tablets, oral tablets, orally disintegrating tablets, 2009)
2) (2 to 12 yr; added to antiepileptic drug regimen not containing enzyme-inducing antiepileptic drugs or nearest whole tablet) ORALLY in 1 to 2 divided doses for 2 weeks, then 0.6 mg/kg/day (rounded down to weeks; may increase dosage by 0.6 mg/kg/day every 1 to 2 weeks (rounded down to the nearest whole t mg/kg/day in 2 divided doses (max 300 mg/day) (Prod Info LAMICTAL chewable dispersible oral tablets,
3) (2 to 12 yr; added to enzyme-inducing antiepileptic drug regimen without valproic acid) 0.6 mg/kg/day 2 divided doses for 2 weeks, then 1.2 mg/kg/day (rounded down to the nearest whole tablet) in 2 divided mg/kg/day every 1 to 2 weeks (rounded down to the nearest whole tablet) to the usual maintenance dose mg/day) (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets
4) (over age 12; added to antiepileptic drug regimen with valproic acid) 25 mg/day ORALLY every OTHE increase dosage by 25 to 50 mg/day ORALLY every 1 to 2 weeks to the usual maintenance dose of 100 maintenance dose of patients adding lamotrigine to valproic acid ALONE ranges from 100 to 200 mg/day tablets, oral tablets, orally disintegrating tablets, 2009)
5) (over age 12; added to antiepileptic drug regimen not containing enzyme-inducing antiepileptic drugs 50 mg/day for 2 weeks; may increase dosage by 50 mg/day every 1 to 2 weeks to the usual maintenanc Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)
6) (over age 12; added to enzyme-inducing antiepileptic drug regimen without valproic acid) 50 mg/day doses) for 2 weeks; may increase dosage by 100 mg/day ORALLY every 1 to 2 weeks to the usual main (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

b) Partial seizure, Adjunct or monotherapy

1) (chewable dispersible or orally disintegrating tablets; 2 to 12 yr; added to antiepileptic drug regimen w nearest whole tablet) ORALLY in 1 to 2 divided doses for 2 weeks, then 0.3 mg/kg/day (rounded down to weeks; may increase dosage by 0.3 mg/kg/day every 1 to 2 weeks (rounded down to the nearest whole t mg/kg/day in 1 to 2 divided doses (max 200 mg/day); usual maintenance dose for children adding lamotr mg/kg/day (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating table
2) (chewable dispersible or orally disintegrating tablets; 2 to 12 yr; added to antiepileptic drug regimen n valproic acid) 0.3 mg/kg/day (rounded down to the nearest whole tablet) ORALLY in 1 to 2 divided doses nearest whole tablet) in 2 divided doses for 2 weeks; may increase dosage by 0.6 mg/kg/day every 1 to 2 the usual maintenance dose of 4.5 to 7.5 mg/kg/day in 2 divided doses (max 300 mg/day) (Prod Info LAM orally disintegrating tablets, 2009)
3) (chewable dispersible or orally disintegrating tablets; 2 to 12 yr; added to enzyme-inducing antiepilept (rounded down to the nearest whole tablet) ORALLY in 2 divided doses for 2 weeks, then 1.2 mg/kg/day doses for 2 weeks; may increase dosage by 1.2 mg/kg/day every 1 to 2 weeks (rounded down to the nea 15 mg/kg/day in 2 divided doses (max 400 mg/day) (Prod Info LAMICTAL chewable dispersible oral table
4) (chewable dispersible or orally disintegrating tablets, over age 12; added to antiepileptic drug regimen day for 2 weeks, then 25 mg/day for 2 weeks; may increase dosage by 25 to 50 mg/day ORALLY every 400 mg/day in 1 to 2 divided doses; usual maintenance dose of patients adding lamotrigine to valproic ac LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)
5) (chewable dispersible or orally disintegrating tablets; over age 12; added to antiepileptic drug regimen valproic acid) 25 mg/day ORALLY for 2 weeks, then 50 mg/day for 2 weeks; may increase dosage by 50

dose of 225 to 375 mg/day in 2 divided doses (Prod Info LAMICTAL chewable dispersible oral tablets, or
6) (chewable dispersible or orally disintegrating tablets; over age 12; added to enzyme-inducing antiepil
ORALLY for 2 weeks, then 100 mg/day (in 2 divided doses) for 2 weeks; may increase dosage by 100 m
maintenance dose of 300 to 500 mg/day (in 2 divided doses) (Prod Info LAMICTAL chewable dispersible
2009)
7) (extended-release tablets; age 13 and older; added to antiepileptic drug regimen with valproic acid) w
weeks 3 and 4, 25 mg/day; week 5, 50 mg/day; week 6, 100 mg/day; week 7, 150 mg/day; week 8 onwa
100 mg/day at weekly intervals), 200 to 250 mg/day (Prod Info LAMICTAL XR oral extended-release tab
8) (extended-release tablets; age 13 and older; added to antiepileptic drug regimen not containing enzy
mg/day ORALLY; weeks 3 and 4, 50 mg/day; week 5, 100 mg/day; week 6, 150 mg/day; week 7, 200 mg
should not exceed 100 mg/day at weekly intervals), 300 to 400 mg/day (Prod Info LAMICTAL XR oral ex
9) (extended-release tablets; age 13 and older; added to antiepileptic drug regimen containing enzyme-i
2, 50 mg/day ORALLY; weeks 3 and 4, 100 mg/day; week 5, 200 mg/day; week 6, 300 mg/day; week 7,
increase should not exceed 100 mg/day at weekly intervals), 400 to 600 mg/day (Prod Info LAMICTAL X
10) (extended-release tablets; age 13 and older; conversion from immediate-release lamotrigine tablets)
release lamotrigine; may need adjustments depending on therapeutic response after conversion (Prod In

c) Tonic-clonic seizure, Primary generalized; Adjunct
1) (2 to 12 yr; added to antiepileptic drug regimen with valproic acid) 0.15 mg/kg/day (rounded down to t
for 2 weeks, then 0.3 mg/kg/day (rounded down to the nearest whole tablet) in 1 to 2 divided doses for 2
to 2 weeks (rounded down to the nearest whole tablet) to the usual maintenance dose of 1 to 5 mg/kg/da
maintenance dose for children adding lamotrigine to valproic acid ALONE ranges from 1 to 3 mg/kg/day
oral tablets, orally disintegrating tablets, 2009)
2) (2 to 12 yr; added to antiepileptic drug regimen not containing enzyme-inducing antiepileptic drugs or
nearest whole tablet) ORALLY in 1 to 2 divided doses for 2 weeks, then 0.6 mg/kg/day (rounded down to
weeks; may increase dosage by 0.6 mg/kg/day every 1 to 2 weeks (rounded down to the nearest whole t
mg/kg/day in 2 divided doses (max 300 mg/day) (Prod Info LAMICTAL chewable dispersible oral tablets,
3) (2 to 12 yr; added to enzyme-inducing antiepileptic drug regimen without valproic acid) 0.6 mg/kg/day
divided doses for 2 weeks, then 1.2 mg/kg/day (rounded down to the nearest whole tablet) in 2 divided d
mg/kg/day every 1 to 2 weeks (rounded down to the nearest whole tablet) to the usual maintenance dose
mg/day) (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets
4) (over age 12; added to antiepileptic drug regimen with valproic acid) 25 mg/day orally every other day
increase dosage by 25 to 50 mg/day ORALLY every 1 to 2 weeks to the usual maintenance dose of 100
maintenance dose of patients adding lamotrigine to valproic acid alone ranges from 100 to 200 mg/day (
oral tablets, orally disintegrating tablets, 2009)
5) (over age 12; added to antiepileptic drug regimen not containing enzyme-inducing antiepileptic drugs
mg/day for 2 weeks; may increase dosage by 50 mg/day every 1 to 2 weeks to the usual maintenance d
LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)
6) (over age 12; added to enzyme-inducing antiepileptic drug regimen without valproic acid) 50 mg/day
for 2 weeks; may increase dosage by 100 mg/day ORALLY every 1 to 2 weeks to the usual maintenance
Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

3) Contraindications
a) hypersensitivity to lamotrigine or any component of the product (Prod Info LAMICTAL chewable dispersible oral tab
Prod Info LAMICTAL XR oral extended-release tablets, 2009)

4) Serious Adverse Effects
a) Anemia
b) Angioedema
c) Disseminated intravascular coagulation
d) Eosinophil count raised
e) Erythema multiforme
f) Leukopenia
g) Liver failure
h) Stevens-Johnson syndrome
i) Thrombocytopenia
j) Toxic epidermal necrolysis

5) Clinical Applications
a) FDA Approved Indications
1) Bipolar I disorder
2) Lennox-Gastaut syndrome; Adjunct
3) Partial seizure, Adjunct or monotherapy
4) Tonic-clonic seizure, Primary generalized; Adjunct

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms

Lamotrigine

C) Orphan Drug Status

1) Lamotrigine has been designated an orphan product for use in the treatment of Lennox-Gastaut syndrome.

D) Physicochemical Properties

1) Molecular Weight

a) 256.09 (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) pKa

a) 5.7 (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

3) Solubility

a) Lamotrigine is very slightly soluble in water (0.17 mg/mL at 25 degrees C) and slightly soluble in 0.1 mola LAMICTAL XR oral extended-release tablets, 2009).

1.2 Storage and Stability

A) Preparation

1) Oral route

a) Chewable Dispersible Tablets

1) Chewable dispersible tablets may be swallowed whole, chewed, or dispersed in water or diluted fruit nearest whole tablet. Disperse by adding tablets to a small amount of liquid (1 teaspoon, or enough to co dispersed (approximately 1 min), swirl solution and consume entire volume immediately (Prod Info LAMI orally disintegrating tablets, 2009).

b) Orally Disintegrating Tablets

1) Orally disintegrating tablets should be placed onto the tongue and moved around in the mouth. The ta without water and may be taken with or without food (Prod Info LAMICTAL chewable dispersible oral tab

c) Extended-Release Tablets

1) Extended-release tablets must be swallowed whole with or without food. The tablet must not be chew extended-release tablets, 2009).

B) Lamotrigine 25 milligrams (mg) tablets and lamotrigine chewable dispersible 2 mg, 5 mg and 25 mg tablets should Fahrenheit (F)) with excursions permitted between 15 and 30 degrees C (59 to 86 degrees F) in a dry place. Lamotrigi stored at 25 degrees C (77 degrees F) with excursions permitted between 15 to 30 degrees C (59 to 86 degrees F) in (R), 2003f).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Other Disease States

1.3.1 Normal Dosage

1.3.1.A Oral route

Bipolar I disorder

Lennox-Gastaut syndrome; Adjunct

Partial seizure, Adjunct or monotherapy

Tonic-clonic seizure, Primary generalized; Adjunct

1.3.1.A.1 Bipolar I disorder

a) Not Taking Enzyme-Inducing Antiepileptic Drugs or Valproic Acid

1) The target dose of lamotrigine is 200 milligrams (mg)/day. Doses up to 400 mg/day as monothera benefit was observed at 400 mg/day as compared to 200 mg/day (Prod Info LAMICTAL chewable di tablets, 2009)

2) For patients not taking carbamazepine (or other enzyme-inducing drugs) or valproic acid:

Weeks 1 and 2:	25 mg/day
Weeks 3 and 4:	50 mg/day
Week 5:	100 mg/day
Week 6:	200 mg/day
Week 7:	200 mg/day (target dose)

b) Added to Valproic Acid Regimen

1) The target dose of lamotrigine in combination with valproic acid is 100 mg/day (Prod Info LAMIC disintegrating tablets, 2009):

2) For patients taking valproic acid:

Weeks 1 and 2:	25 mg every other day
Weeks 3 and 4:	25 mg/day
Week 5:	50 mg/day
Week 6:	100 mg/day
Week 7:	100 mg/day (target dose)

c) Added to Enzyme-Inducing Antiepileptic Drug Regimen (Without Valproic Acid)

1) The target dose of lamotrigine in combination with carbamazepine or other enzyme-inducing dru dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009).

2) For patients taking carbamazepine (or other enzyme-inducing drugs), but not taking valproic acid

Weeks 1 and 2:	50 mg/day
Weeks 3 and 4:	100 mg/day (divided doses)
Week 5:	200 mg/day (divided doses)
Week 6:	300 mg/day (divided doses)
Week 7:	400 mg/day (divided doses) (target dose)

d) Adjustment - Discontinuation of Psychotropics

1) For discontinuation of psychotropic drugs excluding valproic acid, carbamazepine, or other enzyr dose (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablet

e) Adjustment - Discontinuation of Valproic Acid

1) For patients discontinuing valproic acid, the dose of lamotrigine should be doubled over a 2-weel LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009):

AFTER DISCONTINUATION OF VALPROIC ACID	
Current lamotrigine dose:	100 mg/day
Week 1:	150 mg/day
Week 2:	200 mg/day
Week 3 and onward:	200 mg/day

f) Adjustment - Discontinuation of Carbamazepine

1) For patients discontinuing carbamazepine or other enzyme-inducing agents, the dose of lamotrig should be decreased by half over a 2-week period in equal weekly decrements. The dose may then mg/day (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tab

AFTER DISCONTINUATION OF CARBAMAZEPINE OR OTHER ENZYME-INDUCING DRUGS	
Current lamotrigine dose:	400 mg/day
Week 1:	400 mg/day
Week 2:	300 mg/day
Week 3 and onward:	200 mg/day

1.3.1.A.2 Lennox-Gastaut syndrome; Adjunct

a) With Valproic Acid

1) For adult patients adding lamotrigine to an antiepileptic drug (AED) regimen containing valproic a tablets, oral tablets, orally disintegrating tablets, 2009):

Lamotrigine added to antiepileptic drug (AED) regimen containing valproic acid:

Weeks 1 and 2: 25 milligrams (mg) every other day

Weeks 3 and 4: 25 mg every day

Week 5 and onward: Doses may be increased by 25 to 50 mg/day every 1 to 2 weeks to ac
Usual maintenance dose: 100 to 400 mg/day (1 or 2 divided doses)
The usual maintenance dose in patients adding lamotrigine to valproic acid alone rang

b) Without Valproic Acid

1) For adult patients receiving enzyme-inducing antiepileptic drugs (EIAED) (carbamazepine, phen
(Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 20(
Lamotrigine added to EIAED regimen without valproic acid:
Weeks 1 and 2: 50 mg/day
Weeks 3 and 4: 100 mg/day (in 2 divided doses)
Week 5 and onward: Doses may be increased by 100 mg/day every 1 to 2 weeks to achiev
Usual maintenance dose: 300 to 500 mg/day (in two divided doses)

c) With Antiepileptic Drugs Not Containing Enzyme-Inducing Properties or Valproic Acid

1) For adult patients adding lamotrigine to an antiepileptic drug (AED) regimen not containing enzyr
LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009) :
Lamotrigine added to AED regimen not containing drug-inducing AED or valproic acid:
Weeks 1 and 2: 25 mg/day
Weeks 3 and 4: 50 mg/day
Wee 5 and onward: Doses may be increased by 50 mg/day every 1 to 2 weeks to achieve
Usual maintenance dose: 225 to 375 mg/day (in 2 divided doses)

1.3.1.A.3 Partial seizure, Adjunct or monotherapy

a) With Valproic Acid

1) For patients age 13 years or older adding extended-release lamotrigine to an antiepileptic drug (A
LAMICTAL XR oral extended-release tablets, 2009):
Extended-release lamotrigine added to AED regimen containing valproic acid:
Weeks 1 and 2: 25 milligrams (mg) once every other day
Weeks 3 and 4: 25 mg once daily
Week 5: 50 mg once daily
Week 6: 100 mg once daily
Week 7: 150 mg once daily
Week 8 onwards to maintenance: 200 to 250 mg once daily
Dose increase at week 8 or later should not exceed 100 mg daily at weekly intervals

2) For adult patients adding chewable dispersible or orally disintegrating lamotrigine to an antiepilep
Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009):
Chewable dispersible or orally disintegrating lamotrigine added to AED regimen containing valp
Weeks 1 and 2: 25 milligrams (mg) every other day
Weeks 3 and 4: 25 mg every day
Week 5 and onward: Doses may be increased by 25 to 50 mg/day every 1 to 2 weeks to ac
Usual maintenance dose: 100 to 400 mg/day (1 or 2 divided doses)
The usual maintenance dose in patients adding lamotrigine to valproic acid alone rang

b) Without Valproic Acid

1) (extended-release tablets) For patients 13 years or older receiving enzyme-inducing antiepileptic
phenobarbital, or primidone) without valproic acid (Prod Info LAMICTAL XR oral extended-release ta
Extended-release lamotrigine added to EIAED regimen without valproic acid:
Weeks 1 and 2: 50 mg once daily
Weeks 3 and 4: 100 mg once daily
Week 5: 200 mg once daily
Week 6: 300 mg once daily
Week 7: 400 mg once daily
Week 8 onwards to maintenance: 400 to 600 mg once daily
Dose increase at week 8 or later should not exceed 100 mg daily at weekly intervals

2) (chewable dispersible or orally disintegrating tablets) For adult patients receiving enzyme-inducir
phenytoin, phenobarbital, or primidone) without valproic acid (Prod Info LAMICTAL chewable disper
tablets, 2009):
Chewable dispersible or orally disintegrating lamotrigine added to EIAED regimen without valpr
Weeks 1 and 2: 50 mg/day
Weeks 3 and 4: 100 mg/day (in 2 divided doses)
Week 5 and onward: Doses may be increased by 100 mg/day every 1 to 2 weeks to achiev
Usual maintenance dose: 300 to 500 mg/day (in two divided doses)

c) With Antiepileptic Drugs Not Containing Enzyme-Inducing Properties or Valproic Acid

1) For patients 13 years or older adding extended-release lamotrigine to an antiepileptic drug (AED)
valproic acid (Prod Info LAMICTAL XR oral extended-release tablets, 2009):
Extended-release lamotrigine added to EIAED regimen without valproic acid:
Weeks 1 and 2: 25 mg once daily
Weeks 3 and 4: 50 mg once daily
Week 5: 100 mg once daily
Week 6: 150 mg once daily
Week 7: 200 mg once daily

Week 8 onwards to maintenance: 300 to 400 mg once daily
Dose increase at week 8 or later should not exceed 100 mg daily at weekly intervals

2) For adult patients adding chewable dispersible or orally disintegrating lamotrigine to an antiepilep properties or valproic acid (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orall

Chewable dispersible or orally disintegrating lamotrigine added to AED regimen not containing

Weeks 1 and 2: 25 mg/day
Weeks 3 and 4: 50 mg/day
Week 5 and onward: Doses may be increased by 50 mg/day every 1 to 2 weeks to achieve
Usual maintenance dose: 225 to 375 mg/day (in 2 divided doses)

d) Conversion from Immediate-Release to Extended-Release Formulation

1) The initial dose of extended-release lamotrigine in patients age 13 years and older should match Depending on the therapeutic response after conversion, the total daily dose may need to be adjust Info LAMICTAL XR oral extended-release tablets, 2009).

e) Conversion to Monotherapy, With Enzyme-Inducing Antiepileptic Drug

1) The recommended dose for conversion from adjunctive therapy with a single-enzyme-inducing a patients 16 years-old and older, is 500 milligrams/day (mg/day) given in 2 divided doses. Lamotrigin maintaining the first drug at a fixed level. Lamotrigine should be titrated as follows (Prod Info LAMIC orally disintegrating tablets, 2009):

Weeks 1 and 2: 50 mg/day
Weeks 3 and 4: 100 mg/day (in two divided doses)
Doses may be increased by 100 mg/day every 1 to 2 weeks to achieve maintenance.
After achieving a dose of 500 mg/day of lamotrigine, withdrawal of the concomitant drug should each week.

f) Conversion to Monotherapy, With Valproic Acid

The recommended dose for conversion from adjunctive therapy with valproic acid to monotherapy w 500 milligrams/day (mg/day) given in 2 divided doses. The conversion regimen involves 4 steps. Firs dose while maintaining the valproic acid dose at a fixed level. Lamotrigine should be titrated as follo tablets, oral tablets, orally disintegrating tablets, 2009):

Weeks 1 and 2: 25 mg every other day
Weeks 3 and 4: 25 mg every day
Doses may be increased by 25 to 50 mg/day every 1 to 2 weeks to achieve the target dose.

Secondly, while maintaining the lamotrigine dose at 200 mg/day, valproic acid should be gradually d 500 mg/day per week. This regimen should be maintained for 1 week. Thirdly, the lamotrigine dose acid is simultaneously decreased to 250 mg/day. This regimen should also be maintained for 1 weel completely and lamotrigine should be increased by 100 mg/day every week until the recommended LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009).

g) Conversion to Monotherapy, With Non-Enzyme-Inducing Antiepileptic Drug

1) The effects of non-enzyme-inducing antiepileptic drugs other than valproic acid on the metabolis no dosing guidelines can be provided for the safe and effective conversion to monotherapy with lam tablets, oral tablets, orally disintegrating tablets, 2009).

h) Partial Seizures - Refractory

1) In the treatment of simple and complex partial seizures refractory to multiple combinations of ant milligrams/day has been effective. Dose adjustments are made based on clinical response rather th had trough plasma levels in the range of 1 to 4 micrograms/milliliter (Graves & Leppik, 1991; Jawad

1.3.1.A.4 Tonic-clonic seizure, Primary generalized; Adjunct

a) With Valproic Acid

1) For adult patients adding lamotrigine to an antiepileptic drug (AED) regimen containing valproic a tablets, oral tablets, orally disintegrating tablets, 2009):

Lamotrigine added to antiepileptic drug (AED) regimen containing valproic acid:

Weeks 1 and 2: 25 milligrams (mg) every other day
Weeks 3 and 4: 25 mg every day
Week 5 and onward: Doses may be increased by 25 to 50 mg/day every 1 to 2 weeks to ac
Usual maintenance dose: 100 to 400 mg/day (1 or 2 divided doses)
The usual maintenance dose in patients adding lamotrigine to valproic acid alone rang

b) Without Valproic Acid

1) For adult patients receiving enzyme-inducing antiepileptic drugs (EIAED) (carbamazepine, pheny (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 20

Lamotrigine added to EIAED regimen without valproic acid:

Weeks 1 and 2: 50 mg/day
Weeks 3 and 4: 100 mg/day (in 2 divided doses)
Week 5 and onward: Doses may be increased by 100 mg/day every 1 to 2 weeks to achiev
Usual maintenance dose: 300 to 500 mg/day (in two divided doses)

c) With Antiepileptic Drugs Not Containing Enzyme-Inducing Properties or Valproic Acid

1) For adult patients adding lamotrigine to an antiepileptic drug (AED) regimen not containing enzyr LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009):

Lamotrigine added to AED regimen not containing drug-inducing AED or valproic acid:

Weeks 1 and 2: 25 mg/day

Weeks 3 and 4: 50 mg/day
Wee 5 and onward: Doses may be increased by 50 mg/day every 1 to 2 weeks to achieve
Usual maintenance dose: 225 to 375 mg/day (in 2 divided doses)

1.3.1.B Important Note

1) Use caution when dispensing lamotrigine (Lamictal(R), Lamisil(R), lamivudine, Ludiomil(R), labetalol, and errors involving these similarly named medications (Prod Info LAMICTAL chewable dispersible oral tablets, o

2) Safety and efficacy of lamotrigine has not been established (Prod Info LAMICTAL chewable dispersible or 2009):

- as initial monotherapy
- for conversion to monotherapy from a non-enzyme-inducing antiepileptic agent other than valproic acid
- for simultaneous conversion to monotherapy from 2 or more concomitant antiepileptic drugs

1.3.1.C Withdrawal

1) In patients requiring discontinuation of lamotrigine, the dosage should be decreased by about 50% per we patient's safety require a more rapid withdrawal. Discontinuing an enzyme-inducing antiepileptic agent should valproic acid should shorten the half-life of lamotrigine (Prod Info LAMICTAL(R) oral tablets, chewable disper extended-release tablets, 2009).

1.3.2 Dosage in Renal Failure

A) Use reduced maintenance doses in patients with significant renal impairment. Use with caution in patients with Prod Info LAMICTAL XR oral extended-release tablets, 2009).

B) Twenty volunteers with chronic renal failure (mean creatinine clearance 13 milliliters/minute) were given a sing prolonged compared to that observed in volunteers with normal renal function (50 hours vs 25 hours). Another 6 p milligram dose of lamotrigine. On average, approximately 17% (range 5.6% to 35.1%) of lamotrigine was removed life in these patients during hemodialysis was 12.2 hours, while that between sessions was 59.6 hours (Fillastre e

C) Dosage of lamotrigine need not be altered in the presence of impaired renal function since lamotrigine disposi the pharmacokinetics of lamotrigine in 10 subjects with renal failure (estimated creatinine clearance of 10.6 to 25. maximum concentration and area-under-the curve were similar since lamotrigine was largely cleared by metabolis to accumulate. Therefore, impaired renal function would have little effect on the plasma concentrations of lamotrig

1.3.3 Dosage in Hepatic Insufficiency

A) The manufacturer recommends that in patients with moderate and severe liver impairment without ascites, the reduced by approximately 25%. In patients with severe hepatic impairment with ascites, the initial, escalation, and approximately 50%. Clinical response should also be considered during escalation and maintenance dosing (Prod oral tablets, 2006) (Prod Info LAMICTAL XR oral extended-release tablets, 2009).

1.3.6 Dosage in Other Disease States

A) Hyperbilirubinemia

1) Elimination of lamotrigine is not significantly impaired in patients with Gilbert's syndrome (unconjugated hy

B) Pregnancy

1) Dose-normalized lamotrigine concentrations progressively decreased during pregnancy with a 40% and 6 women on lamotrigine monotherapy in 2 retrospective studies (n=12 and n=11. respectively). Lamotrigine cle trimester in a retrospective (n=12) and prospective (n=14) study, respectively. The clearance and concentrati delivery. Other evidence suggest that there was a less pronounced reduction in lamotrigine plasma concentra enzyme-inducing antiepileptic drugs or valproic acid (Tomson & Battino, 2007).

2) Lamotrigine clearance increased by more than 50% in some women at the onset of pregnancy with a drar reversed soon after delivery. Increased doses of lamotrigine may be required to maintain therapeutic levels d following pregnancy (Tran et al, 2002a).

1.4 Pediatric Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Other Disease States

1.4.1 Normal Dosage

1.4.1.A Oral route

Convulsions in the newborn, Intractable

Epilepsy, Refractory

Lennox-Gastaut syndrome; Adjunct

Partial seizure, Adjunct or monotherapy

Status epilepticus

Tonic-clonic seizure, Primary generalized; Adjunct

1.4.1.A.1 Convulsions in the newborn, Intractable

a) Adjunctive lamotrigine was successful in reducing the number of seizures in patients with intractable | label study. In neonates who were taking enzyme-inducing agents, doses up to 10 milligrams per kilogra between 1 and 12 months of age, who were taking enzyme- inducing agents, final doses ranged betwee of age, taking valproate and enzyme inducers, were dosed between 5 to 10 mg/kg/day. In infants betwee mg/kg/day was the final dose (Mikati et al, 2002).

1.4.1.A.2 Epilepsy, Refractory

a) Lamotrigine is effective in intractable childhood epilepsy. Doses of lamotrigine 2 to 15 milligrams/kilog (maximum of 15 milligrams/kilogram/day used in patients on enzyme-inducing antiepileptic drugs (AEDs) valproate only) (Gibbs et al, 1992); (Yven et al, 1992)(Mims, 1992; Hosking, 1993; Pons, 1993).

1.4.1.A.3 Lennox-Gastaut syndrome; Adjunct

a) Age 2 to 12 Years

1) With Valproic Acid

a) For patients 2 to 12 years of age adding lamotrigine to an antiepileptic drug (AED) regimen dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009):

Lamotrigine added to AED regimen containing valproic acid in patients 2 to 12 years of age

Weeks 1 and 2: 0.15 milligram/kilogram/day (mg/kg/day) in one or two divided doses, tablets should be used for dosing

Weeks 3 and 4: 0.3 mg/kg/day in one or two divided doses, rounded down to the neare

Week 5 and onward: Doses may be increased every 1 to 2 weeks by 0.3 mg/kg/day, r the previously administered daily dose to achieve maintenance.

Usual maintenance dose: 1 to 5 mg/kg/day (maximum 200 mg/day in 1 or 2 divided do

The usual maintenance dose in patients adding lamotrigine to valproic acid alone

Maintenance doses in patients weighing less than 30 kg may need to be increase

INITIAL WEIGHT BASED DOSING GUIDE:

Patient weight 6.7 to 14 kg, dose for weeks 1 and 2 is 2 mg every other day; dose

Patient weight 14.1 to 27 kg, dose for weeks 1 and 2 is 2 mg every day; dose for

Patient weight 27.1 to 34 kg, dose for weeks 1 and 2 is 4 mg every day; dose for

Patient weight 34.1 to 40 kg, dose for weeks 1 and 2 is 5 mg every day; dose for

2) Without Valproic Acid

a) For patients age 2 to 12 years old receiving enzyme-inducing antiepileptic drugs (EIAED) (c without valproic acid (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally

Lamotrigine added to EIAED regimen without valproic acid in patients 2 to 12 years of age:

Weeks 1 and 2: 0.6 milligram/kilogram/day (mg/kg/day) in two divided doses, rounded

Weeks 3 and 4: 1.2 mg/kg/day in two divided doses, rounded down to the nearest whc

Week 5 and onward: Doses may be increased every 1 to 2 weeks by 1.2 mg/kg/day, r the previously administered daily dose to achieve maintenance.

Usual maintenance dose: 5 to 15 mg/kg/day (maximum 400 mg/day in 2 divided doses

Maintenance doses in patients weighing less than 30 kg may need to be increase

3) With Antiepileptic Drugs Not Containing Enzyme-Inducing Properties or Valproic Acid

a) For patients 2 to 12 years of age adding lamotrigine to an antiepileptic drug (AED) regimen acid (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating ta

Lamotrigine added to an antiepileptic drug (AED) regimen not containing drug-inducing AE

Weeks 1 and 2: 0.3 milligram/kilogram/day (mg/kg/day) in one or two divided doses, r tablets should be used for dosing.

Weeks 3 and 4: 0.6 mg/kg/day in two divided doses, rounded down to the nearest whc

Week 5 and onward: Doses may be increased every 1 to 2 weeks by 0.6 mg/kg/day, r the previously administered daily dose to achieve maintenance.

Usual maintenance dose: 4.5 to 7.5 mg/kg/day (maximum 300 mg/day in 2 divided dos

Maintenance doses in patients weighing less than 30 kg may need to be increase

b) Age 12 Years and Older

1) With Valproic Acid

a) For patients 12 years and older adding lamotrigine to an antiepileptic drug (AED) regimen cc
dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009):
Lamotrigine added to antiepileptic drug (AED) regimen containing valproic acid:
Weeks 1 and 2: 25 milligrams (mg) every other day
Weeks 3 and 4: 25 mg every day
Week 5 and onward: Doses may be increased by 25 to 50 mg/day every 1 to 2 weeks
Usual maintenance dose: 100 to 400 mg/day (1 or 2 divided doses)
The usual maintenance dose in patients adding lamotrigine to valproic acid alone

2) Without Valproic Acid
a) For patients 12 years and older receiving enzyme-inducing antiepileptic drugs (EIAED) (carb
without valproic acid (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally
Lamotrigine added to EIAED regimen without valproic acid:
Weeks 1 and 2: 50 mg/day
Weeks 3 and 4: 100 mg/day (in 2 divided doses)
Week 5 and onward: Doses may be increased by 100 mg/day every 1 to 2 weeks to ac
Usual maintenance dose: 300 to 500 mg/day (in two divided doses)

3) With Antiepileptic Drugs Not Containing Enzyme-Inducing Properties or Valproic Acid
a) For patients 12 years and older adding lamotrigine to an antiepileptic drug (AED) regimen nc
acid (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating ta
Lamotrigine added to AED regimen not containing drug-inducing AED or valproic acid:
Weeks 1 and 2: 25 mg/day
Weeks 3 and 4: 50 mg/day
Wee 5 and onward: Doses may be increased by 50 mg/day every 1 to 2 weeks to achi
Usual maintenance dose: 225 to 375 mg/day (in 2 divided doses)

1.4.1.A.4 Partial seizure, Adjunct or monotherapy

a) Extended-release Tablets, Age 13 Years and Older

1) With Valproic Acid
a) For patients 13 years of age and older adding extended-release lamotrigine to an antiepilept
Info LAMICTAL XR oral extended-release tablets, 2009):
Extended-release lamotrigine added to AED regimen containing valproic acid:
Weeks 1 and 2: 25 milligrams (mg) once every other day
Weeks 3 and 4: 25 mg once daily
Week 5: 50 mg once daily
Week 6: 100 mg once daily
Week 7: 150 mg once daily
Week 8 onwards to maintenance: 200 to 250 mg once daily
Dose increase at week 8 or later should not exceed 100 mg daily at weekly intervals

1) Without Valproic Acid
a) (extended-release tablets) For patients 13 years or older receiving enzyme-inducing ant
phenobarbital, or primidone) without valproic acid (Prod Info LAMICTAL XR oral extended-
Extended-release lamotrigine added to EIAED regimen without valproic acid:
Weeks 1 and 2: 50 mg once daily
Weeks 3 and 4: 100 mg once daily
Week 5: 200 mg once daily
Week 6: 300 mg once daily
Week 7: 400 mg once daily
Week 8 onwards to maintenance: 400 to 600 mg once daily
Dose increase at week 8 or later should not exceed 100 mg daily at weekly interva

2) With Antiepileptic Drugs Not Containing Enzyme-Inducing Properties or Valproic Acid
a) For patients 13 years or older adding extended-release lamotrigine to an antiepileptic dr
properties or valproic acid (Prod Info LAMICTAL XR oral extended-release tablets, 2009):
Extended-release lamotrigine added to EIAED regimen without valproic acid:
Weeks 1 and 2: 25 mg once daily
Weeks 3 and 4: 50 mg once daily
Week 5: 100 mg once daily
Week 6: 150 mg once daily
Week 7: 200 mg once daily
Week 8 onwards to maintenance: 300 to 400 mg once daily
Dose increase at week 8 or later should not exceed 100 mg daily at weekly interva

2) Conversion from Immediate-Release to Extended-Release Formulation
a) The initial dose of extended-release lamotrigine in patients age 13 years and older should m
lamotrigine. Depending on the therapeutic response after conversion, the total daily dose may r
instructions (Prod Info LAMICTAL XR oral extended-release tablets, 2009).

b) Chewable Dispersible or Orally Disintegrating Tablets, Age 2 to 12 Years

1) With Valproic Acid
a) For patients 2 to 12 years of age adding chewable dispersible or orally disintegrating lamotri
valproic acid (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disinteg

Chewable dispersible or orally disintegrating lamotrigine added to AED regimen containing
Weeks 1 and 2: 0.15 milligram/kilogram/day (mg/kg/day) in one or two divided doses,
tablets should be used for dosing
Weeks 3 and 4: 0.3 mg/kg/day in one or two divided doses, rounded down to the neare
Week 5 and onward: Doses may be increased every 1 to 2 weeks by 0.3 mg/kg/day, r
the previously administered daily dose to achieve maintenance.
Usual maintenance dose: 1 to 5 mg/kg/day (maximum 200 mg/day in 1 or 2 divided do
The usual maintenance dose in patients adding lamotrigine to valproic acid alone
Maintenance doses in patients weighing less than 30 kg may need to be increase
INITIAL WEIGHT BASED DOSING GUIDE:

Usual maintenance dose: 225 to 375 mg/day (in 2 divided doses)

1.4.1.B Important Note

1) Safety and efficacy of extended-release lamotrigine has not been established in patients below 13 years c tablets, 2009)

2) The risk of developing a potentially life-threatening rash is appreciably higher in children than in adults. Do escalation regimens (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2007) (Prod Info may also be higher with concomitant valproic acid and divalproex sodium use (Prod Info LAMICTAL(R) oral t Info LAMICTAL XR oral extended-release tablets, 2009).

3) Only whole tablets of the chewable dispersible tablets should be used. Doses should be rounded down to tablets, chewable dispersible oral tablets, 2007).

1.4.2 Dosage in Renal Failure

A) Use reduced maintenance doses in patients with significant renal impairment. Use with caution in patients with (Prod Info LAMICTAL XR oral extended-release tablets, 2009).

B) Dosage of lamotrigine need not be altered in the presence of impaired renal function since lamotrigine disposi the pharmacokinetics of lamotrigine in 10 subjects with renal failure (estimated creatinine clearance of 10.6 to 25. maximum concentration and area-under-the curve were similar since lamotrigine was largely cleared by metabolis to accumulate. Therefore, impaired renal function would have little effect on the plasma concentrations of lamotrig

C) Twenty volunteers with chronic renal failure (mean creatinine clearance 13 milliliters/min) were given a single prolonged compared to that observed in volunteers with normal renal function (50 hours vs 25 hours). Another 6 p milligrams dose of lamotrigine. On average, approximately 17% (range 5.6 to 35.1%) of lamotrigine was removed life in these patients during hemodialysis was 12.2 hours, while that between sessions was 59.6 hr (Fillastre et al,

1.4.3 Dosage in Hepatic Insufficiency

A) The manufacturer recommends that in patients with moderate and severe liver impairment without ascites, the reduced by approximately 25%. In patients with severe hepatic impairment with ascites, the initial, escalation, and approximately 50%. Clinical response should also be considered during escalation and maintenance dosing (Prod oral tablets, 2006; Prod Info LAMICTAL XR oral extended-release tablets, 2009).

1.4.5 Dosage in Other Disease States

A) Hyperbilirubinemia

1) Elimination of lamotrigine is not significantly impaired in patients with Gilbert's syndrome (unconjugated hy

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Initial Response

a) Seizure, oral: 3 months (Gibbs et al, 1992a; Jawad et al, 1989c).

B) Duration

1) Multiple Dose

a) Seizure, oral: at least 6 months (Gibbs et al, 1992a).

2.2 Drug Concentration Levels

A) Therapeutic Drug Concentration

1) Seizure, 1 to 4 mcg/mL (not well-established) (Garnett, 1997; Cohen et al, 1987a).

a) The therapeutic concentration range for lamotrigine has not been determined (Brodie, 1992) (Goa et al, 19 dosage titration should be based on clinical response rather than plasma concentrations (Goa et al, 1993b; M

b) Many patients have required higher levels (Garnett, 1997).

c) In children optimal levels have been between 0.5 to 5.4 mcg/ml (Battino et al, 1996)(Battino et al, 1995a).

d) Pharmacokinetics remained approximately linear within individuals (Battino et al, 1997; Bartoli et al, 1997;

e) Adults have a higher concentration to dose ratio than children (Battino et al, 1997; Bartoli et al, 1997).

f) Extended Release Tablets

1) In an open-label, crossover study of 44 epileptic patients on concomitant ant-epileptic drugs (AEDs) a extended-release lamotrigine once daily with immediate-release lamotrigine twice daily showed that stea lamotrigine were not significantly different from those of the immediate-release product. The degree of flu decreased by 17%, 34% and 37% for extended-release lamotrigine administered concomitantly with enz phenytoin, phenobarbital, and primidone), valproic acid, or all other AEDS, respectively, compared with t release lamotrigine was associated with lower peaks, longer time to peaks and lower peak-to-trough fluc lamotrigine (Prod Info LAMICTAL XR oral extended-release tablets, 2009).

B) Peak Concentration
1) Oral, single dose: 0.58 to 4.63 mg/L (50 to 400 mg)(Goa et al, 1993b; Prod Info Lamictal, 94; Prod Info Lamicta
a) Peak plasma concentrations increased linearly from 0.58 to 4.63 mg/L in healthy subjects administered si
mg(Goa et al, 1993b; Prod Info Lamictal, 94; Prod Info Lamictal, 97; Goa et al, 1993b).
b) In two small studies of patients with epilepsy, plasma concentrations increased linearly with doses of 50 to
11/22/95.).
c) Extended Release Tablet
1) In an open-label, crossover study of 44 epileptic patients on concomitant anti-epileptic drugs (AEDs) a
extended-release lamotrigine once daily with immediate-release lamotrigine twice daily showed a mean r
release lamotrigine. Analysis of the data based on concomitant AED use showed, the decrease in Cmax
inducing AEDs (ie, carbamazepine, phenytoin, phenobarbital, and primidone), 12% for patients receiving
receiving all other AEDs. Some of the patients receiving the extended-release lamotrigine with concomita
reduction in Cmax (Prod Info LAMICTAL XR oral extended-release tablets, 2009).
d) Rectal Administration
1) A peak concentration of 0.54 mcg/mL was achieved in 6.5 hours in 12 healthy adults after rectal adm
with a peak concentration of 1.43 mcg/mL in 0.79 hour after oral administration of lamotrigine 100 mg ch
2001).
C) Time to Peak Concentration
1) Oral: (adult) 1.4 hours to 4.8 hours (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally
hours (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009).
2) Oral: (pediatric) 1.6 hours to 5.2 hours (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, ora
(Mikati et al, 2003)
a) Adults
1) Immediate-Release
a) In healthy volunteers and adult patients with epilepsy, peak plasma concentration was achieved
administration (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrat
b) A second peak has been reported at 4 to 6 hours, possibly due to enterohepatic recycling (Garne
2) Extended Release Tablet
a) In an open-label, crossover study of 44 epileptic patients on concomitant anti-epileptic drugs (AE
comparison of extended-release lamotrigine once daily with immediate-release lamotrigine twice dai
(Tmax) following administration of extended-release lamotrigine was 4 to 11 hours compared with 1
Specifically, in patients receiving concomitant enzyme inducing AEDs (ie carbamazepine, phenytoin
approximately 4 to 6 hours; in patients receiving concomitant valproic acid, the Tmax was 9 to 11 ho
was 6 to 10 hours (Prod Info LAMICTAL XR oral extended-release tablets, 2009).
3) Rectal Administration
a) A peak concentration of 0.54 mcg/mL was achieved in 6.5 hours in 12 healthy adults after rectal
compared with a peak concentration of 1.43 mcg/mL in 0.79 hour after oral administration of lamotri
(Birnbaum et al, 2001).
b) Pediatrics
1) In pediatric patients with epilepsy, ages 10 months to 5.3 years old, the peak concentration was achie
concomitant carbamazepine, phenytoin, phenobarbital or valproate. The mean time to peak was 5.2 hou
drugs with no known effect on the apparent clearance of lamotrigine (Prod Info LAMICTAL chewable disp
tablets, 2009).
2) In pediatric patients with epilepsy, ages 5 to 11 years old, the mean peak concentration of lamotrigine
concomitant carbamazepine, phenytoin, phenobarbital, or primidone; to 4.5 hours among patients taking
dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009).
3) Peak concentrations in 3 neonates between the ages of 3 and 4 weeks, were obtained at 4 hours, wit
lamotrigine (Mikati et al, 2003).
D) Area Under the Curve
1) Oral, (adult) 56.6 mg x hr/L (Garnett, 1997).
2) Oral (elderly) 91.8 mg x hr/L (Garnett, 1997)
3) Oral (pediatric) 61 mcg x hr/mL (Chen et al, 1999)
a) The AUC in adults was 56.6 mg x hr/L (Garnett, 1997)
b) Area under the curve was 55% higher in the elderly (91.8 mg x hr/L) (Garnett, 1997).
c) The AUC in children was 61 mcg x hr/mL (Chen et al, 1999).
d) Extended Release Tablet
1) In an open-label, crossover study of 44 epileptic patients on concomitant anti-epileptic drugs (AEDs) a
extended-release lamotrigine once daily with immediate-release lamotrigine twice daily, showed the mea
lamotrigine was approximately 21% lower than immediate-release lamotrigine in patients receiving conc
phenytoin, phenobarbital, and primidone), 6% lower in patients receiving concomitant valproic acid, and
patients in this study, experienced up to 70% decrease in AUC when switched to the extended-release la
release tablets, 2009).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

Extracorporeal Elimination

2.3.1 Absorption

A) Bioavailability

1) Oral tablets: 98% (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating

a) Lamotrigine is rapidly and completely absorbed after oral administration with an absolute bioavailabili oral tablets, oral tablets, orally disintegrating tablets, 2009).

b) Lamotrigine chewable/dispersible tablets are equivalent to the compressed tablets in terms of rate an dispersed in water, chewed, swallowed as whole or disintegrated in the mouth (Prod Info LAMICTAL che disintegrating tablets, 2009).

c) The relative bioavailability was 0.52 when a lamotrigine 100-mg chewable dispersible tablet was adm orally and swallowed whole in 12 healthy adults (Birnbaum et al, 2001). The rectal suspension was prepa and placing it into 6 mL of tap water (room temperature), followed by two 2-mL syringe-tubing rinses, wit under the curve (AUC) for rectally administered lamotrigine was 29.68 mcg/mL x hr compared with 54.94 than 0.001).

B) Effects of Food

1) No effect on systemic availability (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, oral

a) The bioavailability of lamotrigine is not affected by food (Prod Info LAMICTAL chewable dispersible o 2009; Prod Info LAMICTAL XR oral extended-release tablets, 2009).

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding

a) Plasma protein: 55% (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disin

1) Lamotrigine is approximately 55% bound to human plasma proteins at concentration from 1 to 10 oral tablets, oral tablets, orally disintegrating tablets, 2009).

B) Distribution Kinetics

1) Volume of Distribution

a) adult, 0.9 to 1.3 L/kg(Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disinte 1999)

1) The mean apparent volume of distribution of lamotrigine after oral administration ranges from 0.9 volunteers (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating

2) The volume of distribution in patients receiving concurrent antiepileptic therapy is 1.2 to 1.5 L/kg

3) The volume of distribution in children was 1.5 L/kg (Chen et al, 1999).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) Liver, extensive (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating t

2) Lamotrigine is metabolized primarily by glucuronic acid conjugation into inactive metabolites. When given metabolism; however, in patients receiving other anticonvulsants this may not occur (Prod Info LAMICTAL ch disintegrating tablets, 2009).

2.3.4 Excretion

A) Kidney

1) Renal Clearance (rate)

a) Adult, (healthy volunteers) 0.18 to 0.58 mL/min/kg; (epilepsy), 0.28 to 1.21 mL/min/kg(Prod Info LAMI orally disintegrating tablets, 2009)

1) The mean apparent plasma clearance of lamotrigine was between 0.44 and 0.58 mL/min/kg in he medications, between 0.18 and 0.3 mL/min/kg in patients taking concomitant valproic acid (n=24) (P oral tablets, orally disintegrating tablets, 2009).

2) The mean apparent plasma clearance of lamotrigine in adult patients with epilepsy taking concor When lamotrigine was taken concomitantly with valproic acid and an enzyme-inducing antiepileptic r 0.53 mL/min/kg (n=25). When taken concomitantly with an enzyme-inducing antiepileptic medicatior mL/min/kg (n=41) (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disinte

b) Elderly, 0.26 to 0.48 mL/min/kg (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, o

1) In 12 elderly volunteers between the ages of 65 and 76 years (mean creatinine clearance, 61 mL

was 0.40 mL/min/kg (range, 0.26 to 0.48 mL/min/kg) following a single 150-mg dose of lamotrigine (oral tablets, orally disintegrating tablets, 2009).

c) Gender, no effect(Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegra

1) In general, the clearance of lamotrigine is not affected by gender. However, during dose escalati dose of valproic acid (n=77), the mean trough lamotrigine concentrations, unadjusted for weight, we than in males (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrati

d) Hepatic Impairment, 0.15 to 0.3 mL/min/kg (Prod Info LAMICTAL chewable dispersible oral tablets, o

1) Following a single 100-mg dose of lamotrigine the mean apparent clearances of lamotrigine in pa ascites (n=2), and severe with ascites (n=5) hepatic impairment were 0.30 +/- 0.09, 0.24 +/- 0.1, 0.2 compared with 0.37 +/- 0.1 mL/min/kg in the healthy control patients (Prod Info LAMICTAL chewable disintegrating tablets, 2009).

e) Pediatric, 0.24 to 3.62 mL/min/kg (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets

1) The mean apparent plasma clearance of lamotrigine in pediatric patients with epilepsy (age rang enzyme-inducing antiepileptic medication regimen was 3.62 mL/min/kg (n=10). When lamotrigine wa antiepileptic medication regimen, the mean plasma clearance was 1.2 mL/min/kg (n=7), and was 0.4 acid (n=8) (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating

2) The mean apparent plasma clearance of lamotrigine in pediatric patients with epilepsy (age rang inducing antiepileptic medication regimen was 2.54 mL/min/kg (n=7). When lamotrigine was taken c antiepileptic medication regime, the mean plasma clearance was 0.89 mL/min/kg (n=8), and was 0.2 acid (n=3) (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating

3) The mean apparent plasma clearance of lamotrigine in pediatric patients with epilepsy (age rang inducing antiepileptic medication regimen was 1.3 mL/min/kg (n=11). When lamotrigine was taken c antiepileptic medication regimen, the mean plasma clearance was 0.5 mL/min/kg (n=8), and was 0.3 (n=4) (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating table

4) The mean apparent clearance in infants less than 2 months old was 0.119 liter per hour per kilog 2 to 12 months old and who were administered oral lamotrigine (Mikati et al, 2003).

f) Race, 25% lower in non-Caucasians (Prod Info LAMICTAL chewable dispersible oral tablets, oral tabl

1) The apparent clearance of lamotrigine was 25% lower in non-Caucasians than in Caucasians (Pr oral tablets, orally disintegrating tablets, 2009).

g) Renal Impairment, 2 mL/min (Garnett, 1997)

1) The clearance was reduced to 2 mL/min in patients with renal failure (Garnett, 1997).

2) Renal Excretion (%)

a) 94% (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets,

1) Following oral administration in healthy volunteers, 94% of the drug was recovered in the urine (P oral tablets, orally disintegrating tablets, 2009; Peck, 1991e).

B) Feces

1) Feces, 2% (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablet

a) After oral administration of lamotrigine, 2% was recovered in the feces (Prod Info LAMICTAL chewab disintegrating tablets, 2009).

2.3.5 Elimination Half-life

A) Parent Compound

1) ELIMINATION HALF-LIFE

a) Adult, (healthy volunteers) 25.4 to 70.3 hours; (epilepsy), 12.6 to 58.8 hours (Prod Info LAMICTAL ch disintegrating tablets, 2009)

1) The elimination half-life of lamotrigine in healthy adult volunteers (n=215) taking no other medica between 48.3 and 70.3 hours taken concomitantly with valproic acid (n=24) (Prod Info LAMICTAL ch disintegrating tablets, 2009).

2) The elimination half-life of lamotrigine in adult patients with epilepsy taking lamotrigine concomita when taken concomitantly with valproic acid and an enzyme-inducing antiepileptic medication regim concomitantly with an enzyme-inducing antiepileptic medication regimen (n=41) (Prod Info LAMICTA disintegrating tablets, 2009).

b) Elderly, 31.2 hours(Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disinteg

1) In 12 elderly volunteers between the ages of 65 and 76 years (mean creatinine clearance, 61 mL half-life was 31.2 hours (range, 24.5 to 43.4 hours) following a single 150-mg dose of lamotrigine (P oral tablets, orally disintegrating tablets, 2009).

c) Hepatic Impairment, 46 +/- 20 hours to 100 +/- 48 hours(Prod Info LAMICTAL chewable dispersible o 2009)

1) Following a single 100-mg dose of lamotrigine the mean half-life elimination of lamotrigine in pati ascites (n=2), and severe with ascites (n=5) hepatic impairment were 46 +/- 20 hours, 72 +/- 44 hou as compared with 33 +/- 7 hours in healthy control patients (Prod Info LAMICTAL chewable dispersi 2009).

d) Pediatric, 7 hours to 65.8 hours (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets,

3.3.1 Cardiovascular Effects

Chest pain

EKG finding

Hypotension

3.3.1.A Chest pain

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)
2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, chest pain was treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (Prod

2009).

3.3.1.B EKG finding

1) Premarketing studies have shown a minor incidence of increased PR interval, which were not clinically sig (Matsuo et al, 1993a). One case of a patient who had first-degree heart block was also reported (Betts et al,

2) Literature Reports

a) First-degree heart block was reported in one patient receiving lamotrigine therapy; however, this was an athlete, continued to run marathons while continuing lamotrigine treatment. Another patient had invert electrocardiogram (EKG) performed 2 weeks after discontinuing lamotrigine was still abnormal, so this e 1991).

3.3.1.C Hypotension

1) Two children had hypotensive episodes, with blood pressure 77/45 millimeters of mercury in one child, aft Both children subsequently suffered multiorgan dysfunction, which reversed several days following discontinu represents lamotrigine-associated anticonvulsant hypersensitivity syndrome (Chattergoon et al, 1997b).

3.3.2 Dermatologic Effects

Alopecia

Erythema multiforme

Fixed drug eruption

Flushing

Rash

Stevens-Johnson syndrome

Summary

Toxic epidermal necrolysis

3.3.2.A Alopecia

1) Incidence: 2% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, alopecia was e treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (Prod 2009).

3.3.2.B Erythema multiforme

1) Summary

a) Multiforme erythema has been rarely reported during clinical trials of pediatric and adult patients rece tablets, chewable dispersible oral tablets, 2006).

2) Incidence: rare (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)

3.3.2.C Fixed drug eruption

1) Case Report

a) Lamotrigine was associated with an extensive fixed drug eruption developed in a 54-year-old man. La Rapid improvement occurred (Hsiao et al, 2001).

2) Literature Reports

a) A 54-year-old man developed an extensive fixed drug eruption caused by lamotrigine. His medical his spinocerebellar degeneration; his medications were haloperidol 1 to 5 milligrams (mg) as required, baclo daily, and bisacodyl 10 mg at bedtime. For the previous month and one-half, the patient had been taking seizures. Due to poor control of his seizures, lamotrigine 50 mg twice daily was added to the valproate. T developed a rash, described as red to violaceous, round patches and plaques with central erosions or ve periorbital area and subsequently spread to the trunk and extremities. Skin biopsy revealed extensive va infiltration of lymphocytes, histiocytes, eosinophils, and melanophages. Fixed drug eruption due to lamot withdrawn, and Solu-Medrol 40 mg/day initiated. Rapid improvement occurred. Nine weeks later, patch t lamotrigine was the causal agent. When patch-test lamotrigine was applied to previously uninvolved area appeared only on the previously involved areas (Hsiao et al, 2001).

3.3.2.D Flushing

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)
2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, hot flush was e
treatment with lamotrigine extended-release (n=118) compared with 0% who received placebo (n=121) (Prod
2009).

3.3.2.E Rash

1) Incidence: 10% adult; 14% pediatric (immediate-release) (Prod Info LAMICTAL(R) oral tablets, chewable
(Prod Info LAMICTAL XR oral extended-release tablets, 2009)
2) Immediate Release
a) Maculopapular and erythematous rashes have been reported with therapeutic doses of lamotrigine (F
dispersible oral tablets, 2006; Messenheimer et al, 1998; Matsuo et al, 1993a). Retrospective evaluation
United Kingdom epilepsy clinics identified 12 cases of serious skin rash (1.1%). Nonserious rashes occu

Patients/study design	Total patients rechallenged or continued	Successful rechallenge/ continuation	
Children epilepsy case series (age 5 to 19 years)	7	7	Re-initiated after a m mg/day; week 2: 0.1 and 5: 1 mg/day; wee 10: 6.25 mg/day; wee doubled in increment dose of 50 mg/day. T mg/day.
Adult epilepsy case series	6	6	Rechallenged with 12 specified
Adult epilepsy case series	8	7	Titration doses varied varying from 24 days
Adult epilepsy case reports	2	2	Re-initiated at a dose dose of 50 mg/day
Adult epilepsy retrospective review	19	16	5 mg/day or every se weeks to 25 mg/day.
Adult bipolar disorder case report	1	0	Rechallenged with 5 dose of 300 mg/day
Adult bipolar disorder case	1	1	Restarted at 12.5 mg

report			wks, 50 mg/day for 2
Total	44	39	

(Lorberg et al, 2009)

5) Extended Release

a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, rash was e treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121). extended-release is not expected to be different from the immediate-release formulation (Prod Info LAMI

3.3.2.F Stevens-Johnson syndrome

1) Incidence: 0.08% to 0.8% (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)

2) Severe and potentially life-threatening rashes, including Stevens-Johnson syndrome, have been reported and 0.8% of pediatric epilepsy patients. Serious rashes were also reported in clinical trials of adult patients w lamotrigine as initial monotherapy and 0.13% for adjunctive therapy. Most cases have presented within 2 to 8 occurred after long-term treatment (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 20

3) A Stevens-Johnson-like syndrome appeared in one of 16 patients during the first year of lamotrigine treatr discontinuation (Cocito et al, 1994).

4) Literature Reports

a) A case of Stevens-Johnson-Syndrome associated with lamotrigine therapy in a 30-year-old male was initiation of lamotrigine, which was added to valproic acid therapy (2500 milligrams/day) and was diagnos to the drug. The patient developed a skin eruption and had complaints of influenza-like symptoms (Sachs

3.3.2.G Summary

1) Lamotrigine should be discontinued at the first sign of a rash, unless the rash is clearly not drug related. P also been noted. The risk of severe rash may be increased by the coadministration of lamotrigine with valproi lamotrigine or by exceeding the recommended dose escalation recommendations. However, cases have bee manufacturer recommends that lamotrigine not be restarted in patients who have previously discontinued lam drug clearly outweigh the risks. If a patient has discontinued lamotrigine for greater than 5 half-lives, the initia LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

3.3.2.H Toxic epidermal necrolysis

1) Incidence: 0.08% to 0.8% (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)

2) Severe and potentially life-threatening rashes, including toxic epidermal necrolysis (TEN), have been repo adult and 0.8% of pediatric epilepsy patients. Serious rashes were also reported in clinical trials of adult patie receiving lamotrigine as initial monotherapy and 0.13% for adjunctive therapy. Most cases have presented wi but some occurred after long-term treatment (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral

3) Literature Reports

a) A 54-year-old man developed fatal toxic epidermal necrolysis (TEN) 4 weeks after beginning lamotrig glioblastoma multiforme brain tumor. The patient was also receiving allopurinol, captopril, and valproic a started and was then increased to 50 mg twice daily within 1 week. He died 17 days after the onset of TE

b) A 74-year-old man developed toxic epidermal necrolysis (TEN) 14 days after beginning lamotrigine th rash, which progressed in 4 days to TEN. After 5 days the lamotrigine was discontinued and the patient & Davis, 1997).

c) A 22-month-old child developed toxic epidermal necrolysis 14 days after the addition of lamotrigine to maculopapular rash developed and worsened involving the conjunctivae, oral cavity and trachea. Lamot weeks (Vukelic et al, 1997).

d) Three cases of toxic epidermal necrolysis (TEN), verified by skin biopsies, were reported, which deve were treated in burn units of hospitals. The authors speculated immune sensitization occurred; however, incidence of rash with lamotrigine is especially high when combined with valproic acid, but it is unknown 1996).

3.3.3 Endocrine/Metabolic Effects

Hyponatremia

Weight gain

3.3.3.A Hyponatremia

1) Hyponatremia occurred in 2 young girls (12 and 15 years of age) with cranial diabetes insipidus who were had primary panhypopituitarism, and the second patient developed panhypopituitarism secondary to removal desmopressin therapy at the time lamotrigine was introduced. The first patient was given lamotrigine 50 millig had lamotrigine dose increases of 7 milligrams/kilogram (mg/kg) (initial dose not specified). In both cases, the requirements as lamotrigine doses increased. The authors suggested that the effect of lamotrigine on fluid ba 2000).

3.3.3.B Weight gain

1) Incidence: 2% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, weight gain was treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (Prod 2009).

3) Lamotrigine is not associated with clinically significant weight gain. Based on a retrospective review of ma the average weight change was only 0.5 kilogram at a mean lamotrigine daily dose and duration of 259 millig age- or gender-related differences in body weight changes (Devinsky et al, 2000).

3.3.4 Gastrointestinal Effects

Abdominal pain

Constipation

Diarrhea

Indigestion

Loss of appetite

Nausea

Vomiting

Xerostomia

3.3.4.A Abdominal pain

1) Incidence: 10% (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)

2) Abdominal pain has been reported in 10% of pediatric epilepsy patients receiving lamotrigine compared w tablets, chewable dispersible oral tablets, 2006).

3) Incidence: 6% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

4) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, abdominal pain treatment with lamotrigine extended-release (n=118) compared with 4% who received placebo (n=121) (Prod 2009).

3.3.4.B Constipation

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, constipation wa treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (Prod 2009).

3.3.4.C Diarrhea

1) Incidence: 8% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, diarrhea was ev treatment with lamotrigine extended-release (n=118) compared with 5% who received placebo (n=121) (Prod 2009).

3.3.4.D Indigestion

1) Incidence: 7% (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)

2) In a monotherapy trial for adults with partial seizures, 7% of patients receiving lamotrigine reported dyspep valproate (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

3.3.4.E Loss of appetite

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, decreased appe adjunctive treatment with lamotrigine extended-release (n=118) compared with 2% who received placebo (n= tablets, 2009).

3.3.4.F Nausea

1) Incidence: 7% to 25%(immediate-release) (Prod Info LAMICTAL(R) oral tablets, chewable dispersible ora LAMICTAL XR oral extended-release tablets, 2009)

2) Immediate Release

a) Nausea has been reported in 7% of adult partial seizure patients treated with lamotrigine compared w
epilepsy patients receiving lamotrigine compared with 10% of placebo patients, and in 10% of pediatric e
2% of placebo patients. A randomized trial of adult epilepsy patients found that incidence of nausea was
with 500 mg, compared with 11% with placebo (Prod Info LAMICTAL(R) oral tablets, chewable dispersib

3) Extended Release

a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, nausea wa
treatment with lamotrigine extended-release (n=118) compared with 2% who received placebo (n=121) (
2009)

3.3.4.G Vomiting

1) Incidence: 9%(immediate-release) (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets

2) Immediate Release

a) Vomiting has been reported in 9% of adult epilepsy patients receiving lamotrigine compared with 4%
seizure patients treated with lamotrigine compared with none of the patients treated with low-dose valproc
that incidence of vomiting was dose-related, increasing from 11% with 300 mg to 18% with 500 mg, com
oral tablets, chewable dispersible oral tablets, 2006).

3) Extended Release

a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, vomiting w
treatment with lamotrigine extended-release (n=118) compared with 2% who received placebo (n=121) (
2009).

3.3.4.H Xerostomia

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, dry mouth was
treatment with lamotrigine extended-release (n=118) compared with 2% who received placebo (n=121) (Prod
2009).

3.3.5 Hematologic Effects

Anemia

Disseminated intravascular coagulation

Eosinophil count raised

Leukopenia

Neutropenia

Pure red cell aplasia

Thrombocytopenia

Thrombocytosis

3.3.5.A Anemia

1) Anemia has been reported as an uncommon adverse effect of lamotrigine. Anemias (aplastic anemia, her
reversible after discontinuation of lamotrigine. Patients with anemias were also taking other anticonvulsants,
LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006; Pulik et al, 2000; Esfahani & Dasheiff, 19

2) Literature Reports

a) Complete erythroblastopenia occurred several weeks after initiation of lamotrigine (50 milligrams (mg
for uncontrolled epilepsia in a 29- year-old woman who had been diagnosed at age 4 months with Diamo
aplasia). Treatment with folinic acid 25 mg/day returned hemoglobin levels to normal within 2 months, ar
et al, 2000).

b) In one patient, lamotrigine treatment was stopped after 23 months due to macrocytic anemia (Cocito

3.3.5.B Disseminated intravascular coagulation

1) Two children (3.5- and 11-years-old) suffered multiorgan dysfunction and disseminated intravascular coag
current valproic acid therapy. Symptoms began 9 days after starting lamotrigine therapy and included a syndr
urticarial/maculopapular rash, hepatic, and renal dysfunction, hypoalbuminemia, and changes in alertness. D
were also reported, along with evidence of rhabdomyolysis in one patient. No seizures were noted during this
lamotrigine. This probably represents lamotrigine- associated anticonvulsant hypersensitivity syndrome (Chat

2) Disseminated intravascular coagulation has been reported in a 45-year-old female after 2 weeks of upwar

previously been maintained on carbamazepine and clonazepam for seizures with poor control prior to lamotri
partial thromboplastin times were significantly prolonged, fibrinogen was decreased, and fibrin degradation pr

3.3.5.C Eosinophil count raised

1) Eosinophilia has been infrequently reported with lamotrigine use (Prod Info LAMICTAL(R) oral tablets, che

3.3.5.D Leukopenia

1) Although uncommon, leukopenia has resulted from therapeutic dosages of lamotrigine. Neutropenia, panc
in postmarketing experiences, causality has not been established (Prod Info LAMICTAL(R) oral tablets, chew
2) Leukopenia progressing to agranulocytosis occurred within days of discontinuing lamotrigine due to rash i
lamotrigine 50 milligrams/day two weeks prior to this event. No concomitant medications were taken. The agr
count of 3.1 x 10(9)/liter (92% lymphocytes and 8% monocytes) and accompanied by slight transaminase ele
improved to 6.5 x 10(9)/liter with 50% neutrophils (Kraus de Camargo & Bode, 1999).
3) A 35-year-old woman presented with leukopenia, which progressed to sepsis following 10 days of therapy
valproate sodium and propranolol. On admission to the hospital she was hypoxic, hypotensive and feverish, v
therapy, her condition stabilized and she fully recovered (Nicholson et al, 1995).

3.3.5.E Neutropenia

1) Neutropenia induced by lamotrigine was experienced by a 50-year-old woman with schizoaffective disorde
the patient presented with mood swings, alopecia, and weight gain. Lamotrigine was administered at 12.5 mg
and then by 50 mg/day every 2 weeks until a total of 150 mg twice daily was reached. Sodium valproate was
in mood symptoms. Her WBC count and absolute neutrophil count was 4.9 x 10(9) and 2.8 x 10(9)/L, respect
months later, her WBC count was 3.8 x 10(9)/L and absolute neutrophil count was 2.2 x 10(9)/L. Due to decli
decreased by 50 mg/day. Briefly her counts returned to baseline only to continue downward. Consequently, l
on therapy for approximately 10 months. Her WBC count and neutrophil count at discontinuation was 2.8 x 10
returned to baseline without any recurrence of neutropenia. A year and a half later, the patient was rechallen
decreased once again after 2 months of lamotrigine therapy. Following discontinuation, her counts returned t
al, 2007).

3.3.5.F Pure red cell aplasia

1) Incidence: rare (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)
2) Pure red cell aplasia, possibly related to hypersensitivity syndrome, has been noted as an adverse reactio
experiences (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

3.3.5.G Thrombocytopenia

1) A 15-year-old female with therapy-resistant Lennox-Gastaut syndrome experienced severe thrombocytop
mucosal edema two weeks after initiation of add-on lamotrigine therapy (25 milligrams every other day). The
valproate sodium 2400 milligrams/day. After discontinuation of lamotrigine and introduction of prednisone 10
edema cleared and the thrombocyte level returned to the normal range. The authors assume that the thromb
close time relationship involved, although other possible causes (hypersensitivity reaction, bone marrow aller
(Laengler & Meusers, 1995).

3.3.5.H Thrombocytosis

1) Two cases of decreased hematocrit with thrombocytosis were reported approximately 2 months after begi
reversed after discontinuation of lamotrigine.

3.3.6 Hepatic Effects

Hepatitis

Hyperbilirubinemia

Increased liver enzymes

Liver failure

3.3.6.A Hepatitis

1) Acute hepatitis occurred in a 28-year-old woman after lamotrigine (25 milligrams every other day) was adc
had used for 12 years to treat a generalized seizure disorder (Sauve et al, 2000).
2) Twelve days after initiation of lamotrigine, a 28-year-old patient developed headache, fever, and diplopia a
day. The lamotrigine had been added to her current dose of valproate 14 milligrams/kilogram/day. Clinical sy
amoxicillin therapy, and the patient was admitted. An atypical headache, hyperthermia, drowsiness, and majc
results showed a 10-fold increase in aspartate aminotransferase and alanine aminotransferase, plus a low pr
indicating coagulopathy). All medications were immediately withdrawn. To prevent seizures, gabapentin (400

by clonazepam (1 milligram/day continuous intravenous infusion). Two days after admission, the patient bega peaked on day 3, then declined and became normal within 2 weeks, when she was discharged. A liver biopsy lymphocytes and eosinophils; focal acidophil hepatocellular necrosis was also noted (Sauve et al, 2000).

3.3.6.B Hyperbilirubinemia

1) Slight elevations in plasma bilirubin have been reported with lamotrigine (Cohen et al, 1987b); however, th

3.3.6.C Increased liver enzymes

1) A case report described acute liver failure with significant elevations in liver enzymes in a 21-year-old mal time of admission to the inpatient psychiatry unit for paranoid delusions, home medications included aripiprazo nonadherence to aripiprazole was reported by the patient's family. Although the overall duration and titration 200 mg/day for 2 months prior to admission. While acute findings were not present on physical examination, based on aspartate aminotransferase (AST) and alanine aminotransferase (ALT) serum levels of 960 units/L were normal, and the patient was afebrile with no signs of infection. Liver function tests 2 months prior to adm serology and autoimmune tests ruled out other etiologies of hepatic failure, lamotrigine was determined to be Instead, the patient was restarted on aripiprazole, titrating up to 25 mg/day. Five days after stopping lamotrigi (102 units/L). The Naranjo Probability Scale indicated a probable causative relationship of lamotrigine and ac

2) Elevated aspartate transaminase (AST) (1,066 units/liter (L)), alanine aminotransferase (ALT) (279 units/L units/L), and alkaline phosphatase (ALP) (145 units/L) serum levels were reported in an 11-year-old female a therapy. Multiorgan dysfunction developed, with rhabdomyolysis and no seizures. After discontinuation of her returned to normal over 10 days (Chattergoon et al, 1997b). This probably represents lamotrigine-associated

3.3.6.D Liver failure

1) A case report described acute liver failure with significant elevations in liver enzymes in a 21-year-old mal time of admission to the inpatient psychiatry unit for paranoid delusions, home medications included aripiprazo nonadherence to aripiprazole was reported by the patient's family. Although the overall duration and titration 200 mg/day for 2 months prior to admission. While acute findings were not present on physical examination, based on aspartate aminotransferase (AST) and alanine aminotransferase (ALT) serum levels of 960 units/L were normal, and the patient was afebrile with no signs of infection. Liver function tests 2 months prior to adm serology and autoimmune tests ruled out other etiologies of hepatic failure, lamotrigine was determined to be Instead, the patient was restarted on aripiprazole, titrating up to 25 mg/day. Five days after stopping lamotrigi (102 units/L). The Naranjo Probability Scale indicated a probable causative relationship of lamotrigine and ac

2) A 35-year-old woman, with a history of bipolar disorder and poly substance abuse, developed a fatal prog treatment. Thirty-nine days after starting lamotrigine 400 milligrams/day, she had a four-day history of fevers, addition to lamotrigine she was also receiving Tylenol 3, chloral hydrate, olanzapine, topiramate, and trazodo papular rash, fever (104 degrees Farenheit) and elevated liver function tests were noted. On day 48 lamotrigi chloral hydrate, olanzapine, and trazodone were discontinued. On day 55, a liver biopsy showed centrilobular hepatocytes. Despite treatment, the liver necrosis progressed over the next 3 weeks and the patient died. An extensive, well developed, bile duct proliferation which was suggestive of a protracted and subacute course. damage, the authors suspected that lamotrigine was the cause of the hepatic necrosis due to the rash preced 2002).

3) An 8-year-old boy developed acute hepatic failure 2 weeks after beginning lamotrigine therapy. The patien 50 milligrams, 3 times daily (6 milligrams/kilogram/day) with 3 days of overlapping drugs. Two weeks later, he coagulopathy. His lamotrigine level was 30.2 micrograms/milliliter (mcg/mL) (normal 1 to 3 mcg/mL). He reco and supportive care (Arnon, 1998).

3.3.7 Immunologic Effects

3.3.7.A Immune hypersensitivity reaction

1) Some fatal or life-threatening hypersensitivity reactions have occurred which included clinical features of r vasculitis, lupus-like syndrome, flu-like symptoms and/or disseminated intravascular coagulation. Even thoug hypersensitivity are present, such as fever, or lymphadenopathy, the patient should be evaluated immediately dispersible oral tablets, 2006; Schlienger et al, 1998).

2) Literature Reports

a) Anticonvulsant hypersensitivity syndrome (AHS) - consisting of fever, skin eruption or lymphadenopat associated with lamotrigine therapy in 26 reported cases. Effects appear similar to AHS induced by other have fever (100%), exanthematous rashes (77%), eosinophilia (19%) and lymphadenopathy (12%). Four intravascular coagulopathy. The most commonly reported internal organ toxicities were hematologic and followed by renal (23%) and musculoskeletal (8%). Concomitant anticonvulsant drugs were used in all 26

b) Acute granulomatous interstitial nephritis, along with colitis and ileitis, occurred in a 17-year-old woma weeks after the start of lamotrigine, she developed an pruritic rash; lamotrigine was withdrawn. A week la she developed a fever and progressing flu-like symptoms (sore throat, nausea/vomiting, diarrhea, and ur Lymphadenopathy was found to be present, and liver enzymes were abnormal. Occult blood was found i necrotizing epithelioid granuloma. Renal function deteriorated, with development of oliguria requiring her steroid treatment. The authors concluded that this was a case of anticonvulsant hypersensitivity syndrom

c) A 6-year-old boy being treated with lamotrigine and valproic acid for generalized tonic-clonic seizures lamotrigine, he developed a pruritic eruption (predominantly trunk and extremities), facial swelling, nause white blood cell count had increased to 9500 cells/cubic millimeter, liver enzymes were elevated, and che

Lamotrigine was discontinued but the symptoms persisted until valproic acid was discontinued 2 days lat
laboratory abnormalities (Brown et al, 1999).
d) A 27-year-old female developed multisystem hypersensitivity reaction, with disseminated intravascula
dysfunction, 11 days after starting lamotrigine therapy. Adjunctive therapy included phenobarbital. After s
spontaneously with no interventions other than steroid therapy (Sarris & Wong, 1999).
e) A 47-year-old man developed a hypersensitivity syndrome to lamotrigine that included neuralgic amy
valproate and had lamotrigine titrated to 50 milligrams/day over 1 month. He developed a rash, fever, an
was discontinued but 3 days later he developed left shoulder pain and numbness. Neuralgic amyotrophy
followed by focal neurologic symptoms restricted to that limb. It resolved over 8 months (Hennessy et al,
f) A 35-year-old man developed pseudolymphoma (which may develop as a hypersensitivity reaction to
patient was receiving lamotrigine 225 milligrams along with valproic acid, carbamazepine, and clobazam
The frozen section diagnosis was consistent with lymphoma. With further testing a pathologic diagnosis
of lymphoid hyperplasia was established. Lymphadenopathy resolved 1 month after lamotrigine was disc

3.3.8 Musculoskeletal Effects

Asthenia

Myalgia

Rhabdomyolysis

3.3.8.A Asthenia

1) Summary

a) In premarketing clinical trials of monotherapy for epilepsy, asthenia has been reported in at least 5%
(Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

b) Asthenia led to discontinuation of therapy in 2.4% of adult patients (n=420)(Prod Info LAMICTAL(R) o

2) Incidence: 5% or greater (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)

3.3.8.B Myalgia

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, muscle pain wa
treatment with lamotrigine extended-release (n=118) compared with 0% who received placebo (n=121) (Prod
2009).

3.3.8.C Rhabdomyolysis

1) Rhabdomyolysis has been reported in hypersensitive patients during postmarketing surveillance (Prod Inf
tablets, 2006).

2) Rhabdomyolysis in the absence of seizures is reported in an 11-year-old female 9 days after the addition
dose was halved). Serum creatine kinase level was reported to be 40,952 units/liter (normal less than 255 un
creatine kinase levels returned to normal. This probably represents lamotrigine-associated anticonvulsant hy

3) A case of myopathy with elevated creatine kinase levels (7770 International Units/liter) and myoglobin lev
absence of generalized seizures following a 2 week period of lamotrigine initialization and increasing therape

3.3.9 Neurologic Effects

Amnesia

Aphasia

Aseptic meningitis

Ataxia

Aura, Loss

Blepharospasm

Coordination problem

Dizziness

Drug withdrawal seizure

Encephalopathy

Gilles de la Tourette's syndrome

Headache

Insomnia

Myoclonus

Nystagmus

Somnolence

Status epilepticus

Tremor

Unsteady gait

Vertigo

3.3.9.A Amnesia

1) Incidence: greater than 1% to less than 5% (Prod Info LAMICTAL(R) chewable dispersible oral tablets, or

2) Amnesia has been reported in greater than 2% and less than 5% of adult patients with epilepsy who recei received placebo (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral tablets, 2009).

3) Amnesia has also been reported in greater than 1% and less than 5% of adult patients with bipolar disord more frequently than in those who received placebo (Prod Info LAMICTAL(R) oral tablets, chewable dispersib

3.3.9.B Aphasia

1) An 11-year-old girl with atypical, benign partial epilepsy showed a loss of previously acquired communicat milligrams/kilogram/day for a recurrence of absence seizures. An increase in the dose of lamotrigine to 2.5 m age 5, she had been treated successfully for absence seizures with valproate and phenobarbital. At the onse the normal range. The girl at age 6 had shown mild learning difficulties, and tests showed low normal intellige was accompanied by marked electroencephalographic (EEG) activation, especially during sleep, when a patt weaning from lamotrigine, EEG patterns and language function returned to pre-lamotrigine levels (Battaglia e

3.3.9.C Aseptic meningitis

1) A 25-year-old woman developed aseptic meningitis 8 days after starting lamotrigine 25 mg/day for epileps resolved; however the symptoms returned upon rechallenge with lamotrigine. The patient presented with mer glutamyl transpeptidase (GGT), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and cerebros erythrocytes, and leukocytes were elevated; however, CSF cultures for bacteria, fungi, and viruses were nega empiric ceftriaxone 2 g twice daily was initiated The patient had mild leukopenia and thrombocytopenia were viral meningitis. One hour after lamotrigine was re-initiated on day 19, the patient experienced a severe head dysesthesia, tachycardia, and a fever of 39.9 degrees C. Lab findings showed leukopenia, an elevated GGT Again, the CSF cultures for bacteria, fungi, and viruses were negative. Subsequently, lamotrigine was discon initiated until CSF results were negative. Symptoms improved; however, a mild right abducens nerve palsy w good recovery with the exception of incomplete resolution of the abducens palsy. Upon questioning, the patie eyes and mouth, was diagnosed with Sjogren's syndrome that was confirmed by a positive antinuclear antibo with a stabilized erythrocyte sedimentation rate. (Boot, 2009).

2) Lamotrigine-induced aseptic meningitis was reported in a 50-year-old female after the first dose of lamotri mixed episode of bipolar disorder with suicidal thoughts. Within a few hours of the first dose of lamotrigine 25 40.1 degrees C, difficult breathing, tachycardia, headache, photophobia, neck stiffness and increasing myalg inflammation; however, cerebrospinal fluid (CSF) Gram-stains and bacterial cultures found no evidence of an subsequently discontinued and the symptoms improved over the next few days. It was then discovered that t was started on lamotrigine 25 mg daily 7 months prior to the current incident. Lamotrigine was also discontinu subsequently discharged with a presumptive diagnosis of aseptic meningitis. The time between the administr of meningitis, which completely resolved upon discontinuation, as well as recurrence of symptoms upon rech aseptic meningitis in this patient. Aseptic meningitis is a rare side effect of lamotrigine with only 4 cases previ

3.3.9.D Ataxia

1) Incidence: adults, greater than 2% to 28%; children, 11% (Prod Info LAMICTAL(R) chewable dispersible o

2) In premarketing clinical trials of adjunctive epilepsy therapy, ataxia was reported in 22% of adult patients r those receiving placebo (n=419) (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral tablets, 200

3) In a randomized, placebo-controlled, parallel study, ataxia was one of the more common dose-related adv adult patients with epilepsy treated with lamotrigine 300 mg/day (n=71), lamotrigine 500 mg/day (n=72), and chewable dispersible oral tablets, oral tablets, 2009).

4) In a controlled, monotherapy trial, ataxia was reported in greater than 2% and less than 5% of adult patier (n=43) following discontinuation of carbamazepine or phenytoin and was reported at a greater frequency thar (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral tablets, 2009).

5) In placebo-controlled, adjunctive trials, ataxia was reported in 11% of pediatric patients with epilepsy rece 750 mg/day (n=168) compared to 3% of patients receiving placebo (n=171) (Prod Info LAMICTAL(R) chewab

3.3.9.E Aura, Loss

1) Three patients experienced loss of aura after switching from conventional antiepileptic therapy to lamotrig had been refractory to conventional therapy. Two of the patients sustained injuries due to loss of aura (Deleu

3.3.9.F Blepharospasm

1) Blepharospasm was attributed to lamotrigine monotherapy in a 51-year-old male with secondarily general blepharospasm appeared 4 months after lamotrigine initiation, his current dose and serum level were 500 mg remitted after a 4-week gradual taper and withdrawal of lamotrigine. The authors discuss possible mechanisn inhibitory effect on glutamate release, which may indirectly affect basal ganglia function (Verma et al, 1999).

3.3.9.G Coordination problem

1) Incidence: 5% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, cerebellar coor who received adjunctive treatment with lamotrigine extended-release (n=118) compared with 0% who receive extended-release tablets, 2009).

3.3.9.H Dizziness

1) Incidence: adults, 7% to 54%; children, 14% (immediate-release) (Prod Info LAMICTAL(R) chewable disp release)

2) Immediate Release

a) In premarketing clinical trials of adjunctive epilepsy therapy, dizziness was reported in 38% of adult p 13% of those receiving placebo (n=419) (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral

b) In a randomized, placebo-controlled, parallel study, dizziness was one of the more common dose-rel and 27% of adult patients with epilepsy treated with lamotrigine 300 mg/day (n=71), lamotrigine 500 mg/ LAMICTAL(R) chewable dispersible oral tablets, oral tablets, 2009).

c) In a controlled, monotherapy trial, dizziness was reported in 7% of adult patients with epilepsy who re discontinuation of carbamazepine or phenytoin compared to 0% of those who received valproate monoth dispersible oral tablets, oral tablets, 2009).

d) In placebo-controlled, adjunctive trials, dizziness was reported in 14% of pediatric patients with epilep maximum of 750 mg/day (n=168) compared to 4% of patients receiving placebo (n=171) (Prod Info LAM 2009).

3) Extended Release

a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, dizziness v treatment with lamotrigine extended-release (n=118) compared with 5% who received placebo (n=121) (2009).

3.3.9.I Drug withdrawal seizure

1) Drug withdrawal seizure has been reported in patients with bipolar disorder in clinical trials (Prod Info LAM tablets, 2009; Guerrini et al, 1999).

3.3.9.J Encephalopathy

1) Reversible encephalopathy associated with high lamotrigine blood levels (19 mg/L), with a concurrent urir Concomitant medication included valproic acid, which remained at therapeutic blood levels. Symptoms includ incontinence and primitive reflexes. Symptoms improved concurrent with a fall in lamotrigine levels after her l mg/day (Hennessy & Wiles, 1996).

3.3.9.K Gilles de la Tourette's syndrome

1) Lamotrigine caused dose-related symptoms of Tourette syndrome in 3 children (Lombroso, 1999).

2) A 7-year-old girl with partial motor seizures with secondary generalization was treated with valproic acid a developed tic-like movements and vocalizations. Lamotrigine was discontinued and all symptoms abated. Se up to 250 mg daily. Vocalizations were worse but abated after lamotrigine was reduced to 175 mg daily. A 12 lamotrigine 450 mg added to carbamazepine. He began tic-like movements, vocalizations, and rituals consist Lamotrigine was discontinued and the ticks resolved within 2 weeks and the OCD symptoms resolved over s and the symptoms have not returned. An 8-year-old boy with complex partial seizures received lamotrigine 2 repetitive head shaking, hand rubbing, throat clearing, and facial grimaces. His tics abated within a few days

remained under control with lamotrigine 200 mg daily (Lombroso, 1999).

3.3.9.L Headache

1) Incidence: 29% (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral tablets, 2009)

2) In a premarketing clinical trial, headache was reported in 29% of adult epilepsy patients receiving lamotrig patients, and resulted in drug discontinuation in 3.1% of lamotrigine patients (Prod Info LAMICTAL(R) chewal

3.3.9.M Insomnia

1) Incidence: 5% to 10% (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral tablets, 2009)

2) In premarketing clinical trials of adjunctive epilepsy therapy, insomnia was reported in 6% of adult patients those receiving placebo (n=419) (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral tablets, 200

3) In a controlled, monotherapy trial, insomnia was reported in 5% of adult patients with epilepsy who receive discontinuation of carbamazepine or phenytoin compared to 2% of those who received valproate monotherap oral tablets, oral tablets, 2009).

4) In two placebo-controlled trials, insomnia was reported in 10% of adults with bipolar I disorder receiving la after being converted from add-on therapy with other psychotropic medications compared to 6% of those rec chewable dispersible oral tablets, oral tablets, 2009).

3.3.9.N Myoclonus

1) Three case reports describe lamotrigine-associated myoclonus. Two cases involved young adult males (a epilepsies since early childhood. After 2 to 3 years of lamotrigine-valproic acid therapy resulting in a seizure-f myoclonic jerking. In both cases, the lamotrigine serum level was higher than usual (16.5 and 17.7 mg/L). My yet greatly diminished after lamotrigine was stopped or its dose reduced (Janszky et al, 2000).

3.3.9.O Nystagmus

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure nystagmus was lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (Prod Info LAMICTA

3.3.9.P Somnolence

1) Incidence: adults, 9% to 14%; children, 17% (immediate-release) (Prod Info LAMICTAL(R) chewable disp release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) Immediate Release

a) In premarketing clinical trials of adjunctive epilepsy therapy, somnolence was reported in 14% of adul patients receiving placebo (n=419) (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral table

b) In placebo-controlled, adjunctive trials, somnolence was reported in 17% of pediatric patients with ep maximum of 750 mg/day (n=168) compared to 15% of patients receiving placebo (n=171) (Prod Info LA tablets, 2009)

c) In two placebo-controlled trials, somnolence was reported in 9% of adults with bipolar I disorder recei monotherapy after being converted from add-on therapy with other psychotropic medications compared LAMICTAL(R) chewable dispersible oral tablets, oral tablets, 2009).

d) Somnolence and ataxia were also reported in a 45-year-old female following a 2-week upward titratio signs were present. Her neurological status improved over the next 2 weeks following discontinuation of

3) Extended Release

a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, somnolenc treatment with lamotrigine extended-release (n=118) compared with 5% who received placebo (n=121) (2009)

3.3.9.Q Status epilepticus

1) Status epilepticus has been reported in a minimum of 7 of 2,343 adult patients receiving lamotrigine (Prod oral tablets, 2009; Guerrini et al, 1999).

2) An 8-year-old female diagnosed 4 years previously with Lennox-Gastaut syndrome developed myoclonic clobazam/vigabatrin regimen. Lamotrigine had been initiated at 2 mg/kg, then gradually increased to 20 mg/k the parents reported increasingly frequent episodes of irregular multifocal jerks. Long-term electroencephalo myoclonus, which resolved shortly upon lamotrigine discontinuation (Guerrini et al, 1999).

3.3.9.R Tremor

1) Incidence: adults, 4%; children, 10% (immediate-release) (Prod Info LAMICTAL(R) chewable dispersible (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) Immediate Release

a) In premarketing clinical trials of adjunctive epilepsy therapy, tremor was reported in 4% of adult patie those receiving placebo (n=419) (Prod Info LAMICTAL(R) chewable dispersible oral tablets, oral tablets,

b) In placebo-controlled, adjunctive trials, tremor was reported in 10% of pediatric patients with epilepsy of 750 mg/day (n=168) compared to 1% of patients receiving placebo (n=171) (Prod Info LAMICTAL(R)

c) Disabling tremors with dysarthria and mild truncal ataxia have also been reported in 3 patients followi valproate sodium. Tremor resolved with reduction in dose of lamotrigine or valproate sodium (Reutens e

3) Extended Release

a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, tremor was

treatment with lamotrigine extended-release (n=118) compared with 2% who received placebo (n=121) (2009).

3.3.9.S Unsteady gait

1) Incidence: 2% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, gait disturbance treatment with lamotrigine extended-release (n=118) compared with 0% who received placebo (n=121) (Prod 2009).

3.3.9.T Vertigo

1) Incidence: 4% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, vertigo was evi treatment with lamotrigine extended-release (n=118) compared with 0% who received placebo (n=121) (Prod 2009).

3.3.10 Ophthalmic Effects

Blurred vision

Diplopia

3.3.10.A Blurred vision

1) Incidence: 11% to 25% (immediate-release) (Prod Info LAMICTAL(R) oral tablets, chewable dispersible o LAMICTAL XR oral extended-release tablets, 2009)

2) Immediate Release

a) In an adjunctive trial, blurred vision was reported in 16% of adult epilepsy patients receiving lamotrigi trial of adult epilepsy patients found that incidence of blurred vision was dose-related, increasing from 11 10% with placebo (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

3) Extended Release

a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, blurred visi adjunctive treatment with lamotrigine extended-release (n=118) compared with 2% who received placeb release tablets, 2009).

3.3.10.B Diplopia

1) Incidence: 24% to 49% (immediate-release) (Prod Info LAMICTAL(R) oral tablets, chewable dispersible o LAMICTAL XR oral extended-release tablets, 2009)

2) Immediate Release

a) In an adjunctive trial, diplopia was reported in 28% of adult epilepsy patients receiving lamotrigine co of adult epilepsy patients found that incidence of diplopia was dose-related, increasing from 24% with 30 placebo (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

3) A comprehensive review of manufacturer data encompassing 13 clinical trials (n=1096) characterize lamo population. As add-on therapy, the mean lamotrigine dose and duration were 5.5 milligrams/kilogram/day (m the mean dose and duration were 2.9 mg/kg/day and 22 weeks, respectively. In placebo-controlled studies, a frequency among lamotrigine recipients included diplopia at 5.4% (Messenheimer et al, 2000).

a) Extended Release

1) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, diplop adjunctive treatment with lamotrigine extended-release (n=118) compared with 0% who received pla release tablets, 2009).

3.3.12 Psychiatric Effects

Anxiety

Depression

Dyssomnia

Suicidal thoughts

Visual hallucinations

3.3.12.A Anxiety

1) Incidence: 5% (immediate release)(Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets XR oral extended-release tablets, 2009)
2) Immediate Release
a) In a monotherapy trial of adult partial seizure patients, anxiety was reported in 5% of patients treated treated with low-dose valproate (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2
3) Extended Release
a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, anxiety wa treatment with lamotrigine extended-release (n=118) compared with 0% who received placebo (n=121) (2009).

3.3.12.B Depression
1) Incidence: 4% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)
2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, depression was treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (Prod 2009).

3.3.12.C Dyssomnia
1) A 42-year-old healthy woman experienced dose-related visual hallucinations as well as sleep disturbance citalopram 40 mg/day for 6 months for depression. She was then diagnosed with bipolar affective disorder typ subsequent dose increase to 50 mg/day, then 100 mg/day in 2 week intervals. Initial symptoms after dose inc wakening and vivid dream-like experiences without being completely asleep. Five days later she experienced headaches and hypersensitivity to noise. The hallucinations resolved over 2 to 3 days after reducing the lamo disturbances and nightmares returned within 1 week of a dose increase to 75 mg/day. Three months later, th disturbed sleep and nightmares. She continued on 100 mg/day, which resulted in visual hallucinations descri that she perceived as real. The events occurred at times of clear consciousness during both daytime and nigl in hallucinations resolving over 3 days. Hallucinations and nightmares have not recurred despite continued tr mg/day. She had no past history of hallucinations (Uher & Jones, 2006).

3.3.12.D Suicidal thoughts
1) Data reviewed by the US Food and Drug Administration suggest an increased risk of suicidal behavior or antiepileptic drugs (AEDs). The analysis included 199 placebo-controlled clinical studies covering 11 different epilepsy, selected psychiatric illnesses, and other conditions, including migraine and neuropathic pain syndro AEDs and 16,029 patients who received placebo, and patients were aged 5 years and older. There were 4 co groups versus (vs) none in the placebo groups. Suicidal behavior or ideation occurred in 0.43% of patients in patients in the placebo groups. This corresponded to an estimated 2.1 per 1000 (95% confidence interval, 0.7 having suicidal behavior or ideation than the placebo groups. The increased risk of suicidality was noted at 1 weeks. When compared to placebo, results were generally consistent among the drugs and were seen in all psychiatric disorders, or other conditions were all at an increased risk for suicidality compared to placebo. Clo or worsening of depression, suicidality and other unusual changes in behavior, which may include symptoms hypomania (US Food and Drug Administration, 2008).

3.3.12.E Visual hallucinations
1) A 42-year-old healthy woman experienced dose-related visual hallucinations as well as sleep disturbance citalopram 40 mg/day for 6 months for depression. She was then diagnosed with bipolar affective disorder typ subsequent dose increase to 50 mg/day, then 100 mg/day in 2 week intervals. Initial symptoms after dose inc wakening and vivid dream-like experiences without being completely asleep. Five days later she experienced headaches and hypersensitivity to noise. The hallucinations resolved over 2 to 3 days after reducing the lamo disturbances and nightmares returned within 1 week of a dose increase to 75 mg/day. Three months later, th disturbed sleep and nightmares. She continued on 100 mg/day, which resulted in visual hallucinations descri that she perceived as real. The events occurred at times of clear consciousness during both daytime and nigl in hallucinations resolving over 3 days. Hallucinations and nightmares have not recurred despite continued tr mg/day. She had no past history of hallucinations (Uher & Jones, 2006).

3.3.13 Renal Effects

Hematuria

Renal failure

3.3.13.A Hematuria
1) Hematuria was reported in 5% of patients receiving lamotrigine in one clinical trial (Jawad et al, 1989d); h In overall clinical experience with the drug, hematuria infrequently occurred (1% or less) (Prod Info LAMICTA 2006).

3.3.13.B Renal failure

1) Acute renal failure, in the absence of predisposing factors, occurred in a 45-year-old female after 14 days for complex partial seizures. Carbamazepine and clonazepam had been used previously by this patient. Seru Rhabdomyolysis developed and may have contributed to the renal failure. Generalized seizures were not rep

3.3.14 Reproductive Effects

3.3.14.A Dysmenorrhea

1) Incidence: 5% (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)

2) In a monotherapy trial for adults with partial seizures, 5% of female patients receiving lamotrigine reportec low-dose valproate (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

3.3.15 Respiratory Effects

Apnea

Congestion of nasal sinus

Epistaxis

Influenza

Pain in throat

Rhinitis

Sinusitis

3.3.15.A Apnea

1) Summary

a) Apnea has been reported in postmarketing surveys, but causality has not been established (Prod Infc tablets, 2006).

3.3.15.B Congestion of nasal sinus

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, sinus congestic adjunctive treatment with lamotrigine extended-release (n=118) compared with 0% respectively who receivec extended-release tablets, 2009).

3.3.15.C Epistaxis

1) Incidence: 2% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, epistaxis was e treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (Prod 2009).

3.3.15.D Influenza

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, influenza or infl received adjunctive lamotrigine extended-release (n=118) compared with 2% who received placebo (n=121) 2009).

3.3.15.E Pain in throat

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, pharyngolaryng adjunctive treatment with lamotrigine extended-release (n=118) compared with 2% who received placebo (n= tablets, 2009).

3.3.15.F Rhinitis

1) Incidence: 7% (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)

2) In a monotherapy trial of adult partial seizure patients, rhinitis was reported in 7% of patients treated with l low-dose valproate (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

3.3.15.G Sinusitis

1) Incidence: 3% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, sinusitis was ev
treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (Prod
2009).

3.3.16 Other

Angioedema

Asthenia

Drug withdrawal

Fever

Multiorgan failure, acute

Pain

3.3.16.A Angioedema

1) Incidence: rare (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006)
2) Angioedema has been rarely reported with lamotrigine therapy (Prod Info LAMICTAL(R) oral tablets, chev

3.3.16.B Asthenia

1) Incidence: 9% (extended-release) (Prod Info LAMICTAL XR oral extended-release tablets, 2009)
2) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, asthenia condit
adjunctive treatment with lamotrigine extended-release (n=118) compared with 5% who received placebo (n=
tablets, 2009).

3.3.16.C Drug withdrawal

1) A 26-year-old man developed anhedonia, visual hallucinations, tremor, slight tachycardia, and hyperhidros
discontinuation of his antiepileptic medications (valproic acid 1220 milligrams (mg) per day, lamotrigine 200 n
mg/day for the first 7 days and 2000 mg/day thereafter) in combination with valproic acid was prescribed to re
psychomotor symptoms had begun before he took the first dose of levetiracetam. Therefore, the authors attri
symptoms resolved within a few days (Gelisse et al, 2002).

3.3.16.D Fever

1) Increased temperature related to leukopenia and sepsis has been reported in a patient following 10 days
included valproate sodium and propranolol (Nicholson et al, 1995). Another case was reported of a 45-year-o
disseminated intravascular coagulation, and acute renal failure 14 days after beginning lamotrigine therapy. C
carbamazepine (Schaub et al, 1994).

3.3.16.E Multiorgan failure, acute

1) Acute multiorgan failure, which has sometimes been fatal or irreversible, has been reported in patients tak
associated with multiorgan failure and hepatic failure in 2 of 3,796 adult patients and 4 of 2,435 pediatric pati
other serious medical complications (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2
2) Two children (3.5- and 11-years-old) suffered multiorgan dysfunction and disseminated intravascular coag
current valproic acid therapy. Symptoms began 9 days after starting lamotrigine therapy and included a syndi
urticarial/maculopapular rash, hepatic, and renal dysfunction, hypoalbuminemia, and changes in alertness. D
were also reported, along with evidence of rhabdomyolysis in one patient. No seizures were noted during this
lamotrigine. This probably represents lamotrigine- associated anticonvulsant hypersensitivity syndrome (Chat

3.3.16.F Pain

1) Incidence: 5% (immediate-release)(Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets
XR oral extended-release tablets, 2009)
2) Immediate Release
a) In a monotherapy trial of adult partial seizure patients, nonspecific body pain was reported in 5% of pa
the patients treated with low-dose valproate (Prod Info LAMICTAL(R) oral tablets, chewable dispersible c
3) Extended Release
a) In a 19-week, double-blind, placebo-controlled study of patients with partial onset seizure, pain was e
treatment with lamotrigine extended-release (n=118) compared with 1% who received placebo (n=121) (
2009).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info LAMICTAL(R) oral tablets, c
a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other) in women and animals are not available. Drugs should be given only if the potential benefit justifies the poten
2) Australian Drug Evaluation Committee's (ADEC) Category: B3(Australian Drug Evaluation Committee, 1999)
a) Drugs which have been taken by only a limited number of pregnant women and women of childbearing ag or other direct or indirect harmful effects on the human fetus having been observed. Studies in animals have damage, the significance of which is considered uncertain in humans.
See Drug Consult reference: PREGNANCY RISK CATEGORIES
3) Crosses Placenta: Yes
4) Clinical Management
a) A major risk for congenital malformations or fetal loss after first trimester exposure to lamotrigine is not ev Inherently epileptic women have a greater risk of delivering a malformed infant than those without epilepsy, b with maternal seizures or with the treatment drug (Hvas et al, 2000; Morrell, 1996). Based on preliminary data Pregnancy, a possible link may exist between exposure to lamotrigine monotherapy during the first trimester and Drug Administration, 2006). A, large, case-controlled study showed a nonsignificant difference in risk of c compared with non-exposed infants(Dolk et al, 2008). In animal studies, lamotrigine decreases folate concen further data are available, lamotrigine should be used during pregnancy only if the potential benefit to the mot manufacturer maintains a Lamotrigine Pregnancy Registry to monitor outcomes of exposure to lamotrigine du encouraged to report such prenatal exposure, before fetal outcome (eg, ultrasound, amniocentesis results, bi 1-800-336-2176. Patients or prescribers may also enroll in the NAAED by calling (888) 233-2334 (Prod Info L tablets, 2007).
5) Literature Reports
a) There was not an increased risk of isolated orofacial cleft (OC) relative to other malformations in neonates with those who were not exposed to any antiepileptic drugs in a population-based, case-control study (n=85,5 5511 orofacial cleft (OC) cases and 80,052 non-OC controls. For isolated OC in lamotrigine-exposed neonate malformations (odds ratio adjusted for maternal age (adjOR) equal to 0.8, 95% confidence interval (CI), 0.11 other malformations for any of the other 3 OC categories: isolated and multiply malformed OC (adjOR equal t (adjOR equal to 1.01, 95% CI, 0.03 to 5.57), and isolated and multiply malformed CP (adjOR equal to 0.79, 9 exposure. There were 72 lamotrigine mono- or polytherapy-exposed registrations, 40 of which were lamotrigi total cases corresponded to a prevalence of 0.47 cases of OC per 1000 registrations (Dolk et al, 2008).
b) As of September 2006, preliminary data collected by the North American Antiepileptic Drug (NAAED) preg prevalence of isolated, non-syndromic, cleft palate and/or cleft lip in infants of women exposed to lamotrigine Five cases of oral cleft (2 isolated cleft lip, 3 isolated cleft palate) occurred among 564 women who received l resulting in a total prevalence of 8.9 per 1000. However, other pregnancy registries have not reported a simila until further data are available (US Food and Drug Administration, 2006).
c) A July 2005 report from the Lamotrigine Pregnancy Registry, established by the manufacturer to collect da 648 instances of mothers treated with lamotrigine monotherapy during the first trimester of pregnancy. Sixtee abnormalities were noted in this group. In mothers treated with lamotrigine plus one or more other anticonvuls presented with anomalies. However, there was no consistent pattern of anomalies among the birth defects re
d) A series of observational cohort studies suggested that lamotrigine does not cause an increased rate of c 68 pregnant women who took the drug, three discontinued the drug before the last menstrual period; 59 were second or third trimester. Of the 59 exposed during the first trimester, there were 39 births (31 without congen abortion, and nine pregnancies intentionally terminated. Three infants were delivered full term with congenita (mother also exposed to phenytoin), palatal cleft, hypospadias, and undescended testes (mother also expose ventricular septal defect (mother also exposed to phenobarbitone and valproic acid). One infant was delivered abdominal intestinal obstruction. The mother had been exposed to labetalol and had experienced pre-eclamp
e) Lamotrigine clearance increased by more than 50% in some women at the onset of pregnancy with a sign reversed soon after delivery. Increased doses of lamotrigine may be required to maintain therapeutic levels d following pregnancy (Tran et al, 2002).

B) Breastfeeding
1) Thomson Lactation Rating: Infant risk cannot be ruled out.
a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk wh benefits of drug treatment against potential risks before prescribing this drug during breastfeeding.
2) Clinical Management
a) Lamotrigine milk to plasma (M/P) ratio was 41.3% (range, 5.7% to 147.1%) and infant/maternal ratio of tot prospective, observational study of 30 nursing mothers treated with lamotrigine and their infants (Newport et exposed to lamotrigine from the mother's breast milk are not known, breast-feeding is not recommended in w oral tablets, chewable dispersible oral tablets, 2007).
3) Literature Reports
a) Lamotrigine milk to plasma (M/P) ratio was 41.3% (95% confidence interval (CI), 33% to 49.6%) and infan 18.3% (95% CI, 9.5% to 27%) in a prospective, observational study of 30 nursing mothers treated with lamotr M/P ratio, calculated using each participant's mean breast milk concentration, ranged from 5.7% to 147.1%. U concentrations for each participant, M/P ratios were 26.5% (95% CI, 20.2% to 32.9%) and 63.1% (95% CI, 47 free lamotrigine concentration was 30.9% (95% CI, 13.4% to 48.3%), 1.7 times higher than the total. Infants h lamotrigine compared with their mothers (53.5% vs 29.5%, paired t=2.91, p less than 0.02). Theoretical infant mg/kg/d (95% CI, 0.37 to 0.65 mg/kg/d) and 9.2% (95% CI, 7.4% to 10.9%), respectively. Univariate Pearson p values less than 0.0001) positive correlations of lamotrigine concentration in breast milk with maternal daily plasma (r=0.37), and free lamotrigine in maternal plasma (r=0.51). Maternal dose (F(1147)=25.62) and free la

=17.31) were significant predictors of lamotrigine breast milk concentration (p values less than 0.0001) in a m
predictors was also significant (F(1147)=6.44, p less than 0.02). The final regression model accounted for 45
concentrations (F(3147)=41.11; p less than 0.0001) (Newport et al, 2008).
b) Evaluation of six infants who were breast fed by mothers treated with lamotrigine (mean doses of 400 mg/
infant dose of lamotrigine received through breast milk was 0.45 mg/kg/day. The mean infant plasma concen
concentration was 18% (Page-Sharp et al, 2006).
c) Lamotrigine levels were measured on day 10 of life in 4 full-term nursing infants born to epileptic mothers
ranged from less than 1 to 2 mcg/mL, and were an average of 30% (range 20 to 43%) of maternal lamotrigine
with repeated levels at 2 months. Both infants were nursing with supplemental formula 2 to 3 times a day. Th
levels in the neonate were a result of immature enzyme systems in the infants, specifically hepatic glucuronic
the infants (Liporace et al, 2004).
d) Serum lamotrigine levels in three women and their nursed infants were measured and the infants' intake c
None of the infants experienced adverse effects (Ohman & Vitols, 2000).

4) Drug Levels in Breastmilk
- **a)** Parent Drug
  - **1)** Percent Adult Dose in Breastmilk
    - **a)** 9% (2-20%) (Ohman & Vitols, 2000)
  - **2)** Milk to Maternal Plasma Ratio
    - **a)** 0.61 (0.5-0.77) (Ohman & Vitols, 2000)

3.5 Drug Interactions

3.5.1 Drug-Drug Combinations

Acetaminophen

Carbamazepine

Desogestrel

Escitalopram

Estradiol Cypionate

Ethinyl Estradiol

Ethynodiol Diacetate

Etonogestrel

Evening Primrose

Fosphenytoin

Ginkgo

Levonorgestrel

Lopinavir

Mestranol

Methsuximide

Norethindrone

Norgestimate

Norgestrel

Oxcarbazepine

Phenobarbital

Phenytoin

Primidone

Rifampin

Risperidone

Ritonavir

Rufinamide

Sertraline

Valproic Acid

3.5.1.A Acetaminophen

1) Interaction Effect: decreased lamotrigine effectiveness

2) Summary: In a randomized study, the effect of acetaminophen on the pharmacokinetics of lamotrigine wa area under the plasma concentration-time curve of lamotrigine decreased by 15% and 20% respectively. Rer al, 1990a).

3) Severity: minor

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Monitor the clinical effectiveness of lamotrigine therapy. Routine increases in lamot failure occurs. An occasional dose of acetaminophen is unlikely to significantly decrease lamotrigine concent

7) Probable Mechanism: increased renal clearance

8) Literature Reports

a) Acetaminophen enhances the urinary elimination of lamotrigine after single doses of the anticonvulsa mg dose of lamotrigine followed by acetaminophen 900 mg 3 times a day resulted in a decrease in AUC compared to administration of lamotrigine with placebo. No differences in peak plasma concentration or t lamotrigine recovered in the urine was also higher when administered with acetaminophen. It was sugge lamotrigine from the circulation (Depot et al, 1990).

3.5.1.B Carbamazepine

1) Interaction Effect: reduced lamotrigine efficacy, loss of seizure control, and a potential risk of neurotoxicity

2) Summary: The clearance of lamotrigine may double during concomitant therapy with carbamazepine (Goa 1991a; Mikati et al, 1989a; Jawad et al, 1987a). In addition, increased serum concentrations of carbamazepir carbamazepine) and neurotoxicity have been reported during concomitant administration of carbamazepine a investigators have found that lamotrigine had no effect on either carbamazepine or its metabolite (Schapel et While lamotrigine has no appreciable effect on the steady-state carbamazepine concentration, carbamazepin (Prod Info Lamictal(R), 2003e).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor seizure control and follow patients for signs of neurotoxicity (nausea, vertig increase lamotrigine doses and/or reduce carbamazepine doses. It may be advantageous to monitor the seru metabolite, carbamazepine-10,11-epoxide. Increased side effects have been associated with carbamazepine When given in combination with an enzyme-inducing antiepileptic agent, the manufacturer recommends an ir two weeks for adult patients, followed by 50 mg twice daily for the third and fourth weeks, advancing by 100 r to 500 mg administered in two divided doses.

7) Probable Mechanism: hepatic induction by carbamazepine of lamotrigine metabolism; possible alteration

8) Literature Reports

a) While lamotrigine alone has a steady-state elimination half-life of between 25 to 37 hours, coadminist approximately 14 or 15 hours (Binnie et al, 1986c; Jawad et al, 1987; Peck, 1991d). Lamotrigine clearan mL/min/kg) in healthy volunteers given lamotrigine alone (Cohen et al, 1987; Posner et al, 1989; Posner therapy ranged from 0.044 to 0.084 L/h/kg (0.73 to 1.4 mL/min/kg) (Jawad et al, 1987; Mikati et al, 1989; decrease incrementally the half-life of lamotrigine by 1.7 hours for every 100 mg of carbamazepine withir

1987).

b) If phenytoin or carbamazepine (or any prodrugs) is used in pregnant women, there is a substantially i of other anticonvulsants. The teratogenicity of these drugs is largely or wholly related to the levels of the Dyke et al, 1991b; Finnell et al, 1992b). The epoxide/parent drug ratio is generally increased when phen any other drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide lamotrigine (Bianchetti et al, 1987b; Ramsay et al, 1990b; Spina et al, 1996b). Such combinations increa monotherapy and about 10-fold over background rates.

c) No pharmacokinetic interaction between carbamazepine and lamotrigine was found in children. Three generalized epilepsy who had been treated with carbamazepine for longer than one year started lamotrig lamotrigine dose was increased by 1 mg/kg/day every other week until clinical response or side effects o change significantly from baseline when lamotrigine was coadministered (29.9 mmol/L vs. 28.8 mmol/L). metabolite of carbamazepine, carbamazepine-10,11-epoxide, significantly decreased from 6.4 mmol/L to Boreus, 1997).

d) Carbamazepine reduces the plasma levels of lamotrigine. A 65-year-old male suffering from complex carbamazepine (400 mg three times daily) and lamotrigine (200 mg three times daily). Seizures occurred and a beta-agonist were used for an obstructive lung disease. A current pneumonia was being treated w was 1.7 mcmol/mL and a trough carbamazepine was 11 mcmol/mL. The patient continued to suffer from levitiracetam (1500 mg twice daily) within 4 weeks. After 4 weeks of levitiracetam therapy the patient's ca lamotrigine plasma levels were 12.1 mcmol/mL. Lamotrigine levels increased rapidly after reductions in t combination was well tolerated and seizures stopped completely after 4 weeks. A drug interaction should result in ineffective antiepileptic therapy (Koch et al, 2003).

3.5.1.C Desogestrel

1) Interaction Effect: decreased plasma lamotrigine concentrations

2) Summary: The concomitant use of combined hormonal contraceptives and lamotrigine has resulted in sig Info ORTHO EVRA(R) transdermal system patch, 2008). A sudden change in a patient's clinical condition an the use or changes in the use of oral contraceptives (Christensen et al, 2007; Sabers et al, 2003; Sabers et a lamotrigine concentrations following introduction of oral contraceptives and reports of increased lamotrigine c contraceptives in women taking lamotrigine. Dosage adjustments may be necessary when starting or discont maintain clinical response (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: Estrogen-containing oral contraceptives have been shown to significantly decrease use. Carefully monitor and adjust lamotrigine doses in women who choose estrogen-containing hormonal cor system patch, 2008; Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).

7) Probable Mechanism: induction of lamotrigine glucuronidation by combination contraceptive

8) Literature Reports

a) Evidence from a double-blind, placebo-controlled trial involving 7 women with epilepsy suggests that lamotrigine. All patients were treated with lamotrigine monotherapy and taking combination oral contrace a crossover fashion to receive either placebo or contraceptive (35 mcg ethinyl estradiol/250 mcg norgest a 7-day pause). Steady-state blood samples were collected as trough levels (just prior to the next dose) and morning doses. Mean lamotrigine plasma concentrations increased by 84% (95% CI, 45% to 134%) contraceptive treatment for 21 days. Urine excretion of lamotrigine metabolites, measured as the N-2-glu (95% CI, -20% to 61%) when placebo was taken instead of oral contraceptive. Seizures occurred in 3 pa seizures occurred during placebo therapy. The mechanism of the interaction is likely the induction of gluc lamotrigine and ethinyl estradiol (Christensen et al, 2007).

b) Several cases in which oral contraceptives changed the plasma levels of lamotrigine as well as the pa patients who were seizure-free (one with epilepsy, two with complex partial seizures, and two with absen concentrations after oral contraceptives were initiated. Two other patients, one with simple partial seizure discontinued their oral contraceptives. Plasma levels of lamotrigine in these two patients had increased s plasma levels of lamotrigine 41% to 64% (mean 49%). As a result, seizure control deteriorated when ora when oral contraceptives were discontinued. These effects were independent of whether the oral contrac norethindrone. The author concludes that there is a need for careful monitoring and adjustment of the lar combination contraceptives (Sabers et al, 2001).

c) Lamotrigine plasma levels are reduced by greater than 50% during oral contraceptive co-medication. used oral contraceptives, and 30 who did not. The mean lamotrigine dose was 349 mg/day among wome those who did not. Mean plasma level of lamotrigine was 13 mcmol/L in patients on oral contraceptives a (p less than 0.0001). Oral contraceptives markedly decrease plasma concentrations of lamotrigine (Sabe

d) In a study of 16 female volunteers, estrogen-containing oral contraceptive (30 mcg ethinyl estradiol/1 clearance of 300 mg/day lamotrigine by approximately 2-fold with a mean decrease in AUC of 52% and i concentrations gradually increased and were approximately 2-fold higher at the end of the week of inacti serum lamotrigine concentrations at the end of the active hormone cycle. This increase occurred in wom lamotrigine (carbamazepine, phenytoin, phenobarbital, primidone, or rifampin). Dosage adjustment of lar containing oral contraceptives (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 20

3.5.1.D Escitalopram

1) Interaction Effect: an increased risk of myoclonus

2) Summary: Myoclonus occurred in 2 patients receiving escitalopram and lamotrigine concomitantly, where escitalopram in 1 patient. There was no evidence of a metabolic enzyme interaction with lamotrigine, and the additive/synergistic effect of lamotrigine and escitalopram on the 5-HT1A receptors, or by an additive inhibitio (Rosenhagen et al, 2006). Exercise caution when using both drugs concurrently and monitor for signs and sy and jerking.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Use caution if escitalopram and lamotrigine are used concurrently as this resulted i resolved after escitalopram was withdrawn (Rosenhagen et al, 2006). Monitor for signs and symptoms of myo
7) Probable Mechanism: additive inhibition of voltage-gated calcium channels; additive or synergistic effects
8) Literature Reports
a) Myoclonus occurred in 2 patients following concomitant treatment with escitalopram and lamotrigine. escitalopram 30 mg/day for depression, developed daytime and nighttime myoclonus after 8 weeks of re treatment of bipolar type II disorder. Serum levels of both drugs, measured after the onset of myoclonus, escitalopram levels remained stable compared to a baseline level drawn prior to starting lamotrigine ther continued to have myoclonus while on escitalopram and lamotrigine therapy. Further analysis revealed t CYP2C19, and CYP2D6 enzymes. The second patient, a 28-year-old woman taking lamotrigine 300 mg/ nighttime myoclonus after 2 weeks of receiving escitalopram (titrated to 20 mg/day) for generalized anxie same frequency of myoclonus while on both therapies; however, the myoclonus resolved 2 weeks after e measured at the onset and after the myoclonus resolved, did not change. Although escitalopram is meta CYP2D6, there was no evidence of a metabolic enzyme interaction with lamotrigine. It was postulated th or synergistic effect of lamotrigine and escitalopram on the 5-HT1A receptors, or by an additive inhibition (Rosenhagen et al, 2006).

3.5.1.E Estradiol Cypionate

1) Interaction Effect: decreased plasma lamotrigine concentrations
2) Summary: The concomitant use of combined hormonal contraceptives and lamotrigine has resulted in sig Info ORTHO EVRA(R) transdermal system patch, 2008). A sudden change in a patient's clinical condition an the use or changes in the use of oral contraceptives (Christensen et al, 2007; Sabers et al, 2003; Sabers et a lamotrigine concentrations following introduction of oral contraceptives and reports of increased lamotrigine c contraceptives in women taking lamotrigine. Dosage adjustments may be necessary when starting or discont maintain clinical response (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: Estrogen-containing oral contraceptives have been shown to significantly decrease use. Carefully monitor and adjust lamotrigine doses in women who choose estrogen-containing hormonal cor system patch, 2008; Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).
7) Probable Mechanism: induction of lamotrigine glucuronidation by combination contraceptive
8) Literature Reports
a) Evidence from a double-blind, placebo-controlled trial involving 7 women with epilepsy suggests that lamotrigine. All patients were treated with lamotrigine monotherapy and taking combination oral contrace a crossover fashion to receive either placebo or contraceptive (35 mcg ethinyl estradiol/250 mcg norgest a 7-day pause). Steady-state blood samples were collected as trough levels (just prior to the next dose) and morning doses. Mean lamotrigine plasma concentrations increased by 84% (95% CI, 45% to 134%) contraceptive treatment for 21 days. Urine excretion of lamotrigine metabolites, measured as the N-2-glu (95% CI, -20% to 61%) when placebo was taken instead of oral contraceptive. Seizures occurred in 3 pa seizures occurred during placebo therapy. The mechanism of the interaction is likely the induction of gluc lamotrigine and ethinyl estradiol (Christensen et al, 2007).
b) Several cases in which oral contraceptives changed the plasma levels of lamotrigine as well as the p patients who were seizure-free (one with epilepsy, two with complex partial seizures, and two with absen concentrations after oral contraceptives were initiated. Two other patients, one with simple partial seizure discontinued their oral contraceptives. Plasma levels of lamotrigine in these two patients had increased s plasma levels of lamotrigine 41% to 64% (mean 49%). As a result, seizure control deteriorated when ora when oral contraceptives were discontinued. These effects were independent of whether the oral contrac norethindrone. The author concludes that there is a need for careful monitoring and adjustment of the lar combination contraceptives (Sabers et al, 2001).
c) Lamotrigine plasma levels are reduced by greater than 50% during oral contraceptive co-medication. used oral contraceptives, and 30 who did not. The mean lamotrigine dose was 349 mg/day among wome those who did not. Mean plasma level of lamotrigine was 13 mcmol/L in patients on oral contraceptives a (p less than 0.0001). Oral contraceptives markedly decrease plasma concentrations of lamotrigine (Sabe
d) In a study of 16 female volunteers, estrogen-containing oral contraceptive (30 mcg ethinyl estradiol/1 clearance of 300 mg/day lamotrigine by approximately 2-fold with a mean decrease in AUC of 52% and i concentrations gradually increased and were approximately 2-fold higher at the end of the week of inacti serum lamotrigine concentrations at the end of the active hormone cycle. This increase occurred in wom lamotrigine (carbamazepine, phenytoin, phenobarbital, primidone, or rifampin). 3.5.1.I Evening Primrose

1) Interaction Effect: reduced anticonvulsant effectiveness
2) Summary: Theoretically, evening primrose oil may reduce the effectiveness of anticonvulsants by lowering

contraindicated in patients with epilepsy (Barber, 1998; Newall et al, 1996).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Avoid concomitant use of evening primrose oil with anticonvulsants.
7) Probable Mechanism: evening primrose oil may reduce the seizure threshold

3.5.1.J Fosphenytoin
1) Interaction Effect: reduced lamotrigine efficacy
2) Summary: Fosphenytoin is a prodrug of phenytoin and the same interactions that occur with phenytoin are Cerebyx(R), 1999). Potent hepatic enzyme-inducing drugs including phenytoin enhance the metabolic cleara steady-state elimination half-life of approximately 24 to 30 hours, coadministration of phenytoin reduces the h et al, 1986; Jawad et al, 1989; Peck, 1991).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Higher doses of lamotrigine are needed when given concurrently with enzyme-indu When given in combination with an enzyme-inducing antiepileptic agent, the manufacturer recommends an ir two weeks for adult patients, followed by 50 mg twice daily for the third and fourth weeks, advancing by 100 r to 500 mg administered in two divided doses.
7) Probable Mechanism: increased lamotrigine metabolism
8) Literature Reports
a) If phenytoin or carbamazepine (or any prodrugs) is used in pregnant women, there is a substantially i of other anticonvulsants. The teratogenicity of these drugs is largely or wholly related to the levels of the Dyke et al, 1991; Finnell et al, 1992). The epoxide/parent drug ratio is generally increased when phenyto other drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide hyc lamotrigine (Bianchetti et al, 1987; Ramsay et al, 1990; Spina et al, 1996). Such combinations increase t monotherapy and about 10-fold over background rates.

3.5.1.K Ginkgo
1) Interaction Effect: decreased anticonvulsant effectiveness
2) Summary: In a case report, 2 patients with epilepsy previously well controlled by valproate sodium develo extract. Seizure control was regained after ginkgo was withdrawn (Granger, 2001a). An infant developed seiz from ingestion of ginkgo seeds (Yagi et al, 1993a). The compound 4'-O-methylpyridoxine, a neurotoxin, is fou in leaves, the ginkgo component from which commercially available extracts are derived (Arenz et al, 1996a). sufficient amounts of 4'-O-methylpyridoxine to cause seizures. However, ginkgo products are not commonly a contained in the commercial product. Of concern are those instances where, depending on the harvest seasc methylpyridoxine may be present in sufficient amounts to be problematic in vulnerable populations (eg, infant
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Avoid concomitant use of ginkgo and anticonvulsants in patients with epilepsy. If se previously controlled by anticonvulsant medication, inquire about the use of ginkgo seed or leaf extract. If pos product to ascertain if 4'-O-methylpyridoxine is present.
7) Probable Mechanism: neurotoxin 4'-O-methylpyridoxine (found in leaves and seeds of ginkgo biloba) may
8) Literature Reports
a) The serum of a 21-month-old patient with gin-nan food poisoning was assayed for 4'-O-methylpyridox micrograms/milliliter (mcg/mL) at 8.5 hours after ingesting ginkgo seeds, decreasing to 0.05 mcg/mL at 1 methylpyridoxine content was responsible for the tonic/clonic convulsions and loss of consciousness obs particularly vulnerable (Yagi et al, 1993).
b) Four to six milligrams of the neurotoxin 4'-O-methylpyridoxine have been isolated from 2 kilograms of commercially-available products. Highest amounts were found in seeds (85 micrograms (mcg)/seed) and July and beginning of August. The albumen of the seed can contain 105.15 mcg/gram dry weight, but thi boiled. The unprocessed seed coats contain from 5.44-7.15 mcg/gram dry weight. The neurotoxin in gink detectable in homeopathic preparations. Specifically, 8.13 mcg/mL of 4'-O-methylpyridoxine was found in mcg/mL in Kaveri Forte(R), and 7.18 mcg/mL in Gingium(R). Based on recommended daily intake, this tr methylpyridoxine of 48.78 mcg, 58.62 mcg, 11.40 mcg, and 43.08 mcg for Tebonin Forte(R), Rokan(R), the homeopathic products, Ginkgo biloba Urtinktur Hanosan(R) and Ginkgo biloba Urtinktur DHU(R) con methylpyridoxine, respectively. However, the authors note that the amount contained in medicinal extrac significance. Concern remains with the variance in 4'-O-methylpyridoxine content depending on the seas 1996).
c) Seizures recurred in 2 patients, both with epilepsy that was well controlled prior to ingesting ginkgo bi 78-year-old man) had been free of seizures for at least 18 months prior to beginning therapy with Gb 120 developed seizures within 2 weeks of beginning Gb therapy, and both remained seizure-free (without cha (Granger, 2001).

3.5.1.L Levonorgestrel
1) Interaction Effect: decreased plasma lamotrigine concentrations

2) Summary: The concomitant use of combined hormonal contraceptives and lamotrigine has resulted in sig
Info ORTHO EVRA(R) transdermal system patch, 2008). A sudden change in a patient's clinical condition an
the use or changes in the use of oral contraceptives (Christensen et al, 2007; Sabers et al, 2003; Sabers et a
lamotrigine concentrations following introduction of oral contraceptives and reports of increased lamotrigine c
contraceptives in women taking lamotrigine. Dosage adjustments may be necessary when starting or discont
maintain clinical response (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).
3) Severity: moderate

3.5.1.M Lopinavir

1) Interaction Effect: decreased lamotrigine serum concentrations
2) Summary: Coadministration of lamotrigine and lopinavir/ritonavir in healthy subjects significantly decrease
lamotrigine clearance in an open-label, sequential, 3-period trial. The postulated mechanism of action is enha
and/or lopinavir on lamotrigine, which is metabolized by direct glucuronidation. A doubling of the lamotrigine d
lopinavir/ritonavir in this study (vanderLee et al, 2006). Monitor patients for loss of lamotrigine efficacy and ac
3) Severity: moderate
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: Coadministration of lamotrigine and lopinavir/ritonavir in healthy subjects significant
increased lamotrigine clearance. A doubling of the lamotrigine dose was required to overcome the interaction
al, 2006). If these agents are coadministered, monitor patients for loss of lamotrigine efficacy and adjust lamo
7) Probable Mechanism: increased lamotrigine metabolism
8) Literature Reports

a) In an open-label, sequential, 3-period trial, coadministration of lamotrigine and lopinavir/ritonavir in he
exposure and half-life, and increased lamotrigine clearance; a doubling of the lamotrigine dose is require
to 65 years (n=24) received oral lamotrigine 50 mg once daily for days 1 and 2, followed by 100 mg twice
100 mg twice daily was added on day 11. Lamotrigine trough levels (Cmin) were measured between day
300 mg twice daily depending on the percentage of decrease. Among 18 patients who completed the stu
day 20 (lamotrigine plus lopinavir/ritonavir) compared to day 10 (lamotrigine alone). The median AUC, C
were not bioequivalent to those on day 10, with a geometric mean ratio (GMR) for lamotrigine AUC (day
0.54). Consequently, the lamotrigine dose was increased to 200 mg twice daily from day 23 to day 31 in
bioequivalent to that on day 10, with a GMR (day 31/day 10) of 0.91 (90% CI, 0.82 to 1.02). The median
metabolite to lamotrigine on day 20 was almost double to that on day 10 (0.57 on day 10 versus 1.12 on
induction of glucuronidation of lamotrigine by ritonavir, and possibly also due to lopinavir. The pharmacol
altered (vanderLee et al, 2006).

3.5.1.N Mestranol

1) Interaction Effect: decreased plasma lamotrigine concentrations

2) Summary: The concomitant use of combined hormonal contraceptives and lamotrigine has resulted in sig
Info ORTHO EVRA(R) transdermal system patch, 2008). A sudden change in a patient's clinical condition an
the use or changes in the use of oral contraceptives (Christensen et al, 2007; Sabers et al, 2003; Sabers et a
lamotrigine concentrations following introduction of oral contraceptives and reports of increased lamotrigine c

those who did not. Mean plasma level of lamotrigine was 13 mcmol/L in patients on oral contraceptives a
(p less than 0.0001). Oral contraceptives markedly decrease plasma concentrations of lamotrigine (Sabe

d) In a study of 16 female volunteers, estrogen-containing oral contraceptive (30 mcg ethinyl estradiol/1
clearance of 300 mg/day lamotrigine by approximately 2-fold with a mean decrease in AUC of 52% and i
concentrations gradually increased and were approximately 2-fold higher at the end of the week of inacti
serum lamotrigine concentrations at the end of the active hormone cycle. This increase occurred in wom
lamotrigine (carbamazepine, phenytoin, phenobarbital, primidone, or rifampin). Dosage adjustment of lar
containing oral contraceptives (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 20

3.5.1.O Methsuximide

1) Interaction Effect: reduced lamotrigine concentrations and possible loss of seizure control

2) Summary: During a retrospective study, it was determined that methsuximide significantly decreases lamo
receiving combination therapy, lamotrigine concentrations were 69.7% lower than compared to lamotrigine m
induces lamotrigine metabolism (May et al, 1999a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor seizure control and anticipate a possible need to increase lamotrigine dose
methsuximide is withdrawn from therapy, doses of lamotrigine may need to be reduced.

7) Probable Mechanism: hepatic induction by methsuximide of lamotrigine metabolism

8) Literature Reports

a) Lamotrigine serum concentrations from 222 patients receiving lamotrigine monotherapy (n = 64) or co
evaluated. Thirteen patients were being treated with lamotrigine and methsuximide. In the lamotrigine mo
7.14 mcg/mL while the mean dose was 7.27 mg/dose/kg. The lamotrigine level-to-dose ratio (LDR) in thi
subjects receiving methsuximide in addition to lamotrigine, the plasma concentration was 3.06 mcg/mL v
lamotrigine LDR in this group was 0.31 mcg/mL/mg/kg, demonstrating the inducing properties of methsu

3.5.1.P Norethindrone

1) Interaction Effect: decreased plasma lamotrigine concentrations

2) Summary: The concomitant use of combined hormonal contraceptives and lamotrigine has resulted in sig
Info ORTHO EVRA(R) transdermal system patch, 2008). A sudden change in a patient's clinical condition an
the use or changes in the use of oral contraceptives (Christensen et al, 2007; Sabers et al, 2003; Sabers et a

lamotrigine concentrations following introduction of oral contraceptives and reports of increased lamotrigine c
contraceptives in women taking lamotrigine. Dosage adjustments may be necessary when starting or discont
maintain clinical response (Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: Estrogen-containing oral contraceptives have been shown to significantly decrease
use. Carefully monitor and adjust lamotrigine doses in women who choose estrogen-containing hormonal cor
system patch, 2008; Prod Info LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006).
7) Probable Mechanism: induction of lamotrigine glucuronidation by combination contraceptive
8) Literature Reports
a) Evidence from a double-blind, placebo-controlled trial involving 7 women with epilepsy suggests that
lamotrigine. All patients were treated with lamotrigine monotherapy and taking combination oral contrace
a crossover fashion to receive either placebo or contraceptive (35 mcg ethinyl estradiol/250 mcg norgest
a 7-day pause). Steady-state blood samples were collected as trough levels (just prior to the next dose)
and morning doses. Mean lamotrigine plasma concentrations increased by 84% (95% CI, 45% to 134%)
contraceptive treatment for 21 days. Urine excretion of lamotrigine metabolites, measured as the N-2-glu
(95% CI, -20% to 61%) when placebo was taken instead of oral contraceptive. Seizures occurred in 3 pa
seizures occurred during placebo therapy. The mechanism of the interaction is likely the induction of gluc
lamotrigine and ethinyl estradiol (Christensen et al, 2007).
b) Several cases in which oral contraceptives changed the plasma levels of lamotrigine as well as the pa
patients who were seizure-free (one with epilepsy, two with complex partial seizures, and two with absen
concentrations after oral contraceptives were initiated. Two other patients, one with simple partial seizure
discontinued their oral contraceptives. Plasma levels of lamotrigine in these two patients had increased s
plasma levels of lamotrigine 41% to 64% (mean 49%). As a result, seizure control deteriorated when ora
when oral contraceptives were discontinued. These effects were independent of whether the oral contrac

3.5.1.S Oxcarbazepine

1) Interaction Effect: reduced lamotrigine concentrations and possible loss of seizure control

2) Summary: Oxcarbazepine is structurally similar to carbamazepine but does not form an epoxide metabolit
effects of carbamazepine. When lamotrigine and oxcarbazepine were administered concurrently to 14 epilept
decreased 28.7% compared to lamotrigine monotherapy (May et al, 1999c). In two patients who had received
ulcers occurred several weeks after oxcarbazepine discontinuation or dose reduction. Induction of lamotrigine
the mechanism, such oxcarbazepine discontinuation or a dose reduction may have resulted in a slow increas
(O'Neill & deLeon, 2007). Concomitant use of lamotrigine and oxcarbazepine may require monitoring the pati
lamotrigine dose as necessary. Conversely, in patients receiving these agents concurrently, if oxcarbazepine

doses may need to be reduced. Additionally, the patient may need to be monitored over several weeks for sig
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor seizure control and anticipate a possible need to increase lamotrigine dose oxcarbazepine is withdrawn from therapy or if dosage is reduced, lamotrigine doses may need to be reduced weeks for symptoms of lamotrigine toxicity.
7) Probable Mechanism: hepatic induction by oxcarbazepine of lamotrigine metabolism
8) Literature Reports
a) Two patients, receiving lamotrigine and oxcarbazepine concurrently, experienced oral ulcers several reduction. In the first case, a 35-year-old woman being treated for bipolar II disorder (BD II), hypothyroidi experiencing one week of worsening depression and two days of suicidal thoughts and treated with oxca aripiprazole, quetiapine, lithium, naproxen, pantoprazole, amoxicillin, and levothyroxine. On day 2, lamot mg/day by day 6. Oxcarbazepine dose was decreased and stopped by day 5, and she was discharged o aripiprazole, escitalopram, naproxen, pantoprazole, levothyroxine, and hydroxyzine. On day 42 (41 days oxcarbazepine), she developed painful tongue ulcers. Subsequently, lamotrigine was stopped and the ul old man with BD II, hypertension, and GERD was admitted following a suicide attempt and prescribed ox venlafaxine, mirtazapine, metoprolol, and famotidine. Lamotrigine 50 mg/day was initiated on day 11 and discharged on day 14 with lamotrigine 100 mg and oxcarbazepine 1200 mg (along with other medication mg/day after discharge. On day 44 (22 days after oxcarbazepine dose decrease), he developed several lamotrigine and oxcarbazepine were discontinued and the ulcers resolved completely (O'Neill & deLeon,
b) Lamotrigine serum concentrations from 222 patients receiving lamotrigine monotherapy (n = 64) or co evaluated. Fourteen patients were being treated with lamotrigine and oxcarbazepine. In the lamotrigine r 7.14 mcg/mL while the mean dose was 7.27 mg/dose/kg. The lamotrigine level-to-dose ratio (LDR) in thi subjects receiving oxcarbazepine in addition to lamotrigine, the plasma concentration was 4.73 mcg/mL lamotrigine LDR in this group was 0.71 mcg/mL/mg/kg, demonstrating the inducing properties of oxcarba

3.5.1.T Phenobarbital
1) Interaction Effect: reduced lamotrigine efficacy, loss of seizure control
2) Summary: Potent hepatic enzyme-inducing drugs including phenobarbital enhance the metabolic clearanc state elimination half-life of approximately 24 to 30 hours, coadministration of phenobarbital reduces the half- al, 1989a; Peck, 1991a) and decreases the lamotrigine steady-state concentration by approximately 40% (Pr therapy with lamotrigine, valproic acid, and an enzyme inducer on lamotrigine metabolism does not appear to
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Higher doses of lamotrigine are needed when given concurrently with enzyme-indu given in combination with an enzyme-inducing antiepileptic agent, the manufacturer recommends an initial la weeks for adult patients, followed by 50 mg twice daily for the third and fourth weeks, advancing by 100 mg d 500 mg administered in two divided doses.
7) Probable Mechanism: hepatic induction by phenobarbital of lamotrigine metabolism
8) Literature Reports
a) In 13 patients treated with either carbamazepine or phenobarbital with lamotrigine, the half-life of lam children over the age of 2 years and young adults with epilepsy that was not controlled with a single age subjects taking lamotrigine alone has been 25.4 hours with repeated dosing (Prod Info Lamictal(R), 2003

3.5.1.U Phenytoin
1) Interaction Effect: reduced lamotrigine efficacy
2) Summary: Potent hepatic enzyme-inducing drugs including phenytoin enhance the metabolic clearance o elimination half-life of approximately 24 to 30 hours, coadministration of phenytoin reduces the half-life of lam Jawad et al, 1989b; Peck, 1991b). The addition of phenytoin decreases the lamotrigine steady-state concentr phenytoin. Lamotrigine has no significant effect on steady-state phenytoin concentrations (Prod Info Lamictal
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Higher doses of lamotrigine are needed when given concurrently with enzyme-indu When given in combination with an enzyme-inducing antiepileptic agent, the manufacturer recommends an ir two weeks for adult patients, followed by 50 mg twice daily for the third and fourth weeks, advancing by 100 r to 500 mg administered in two divided doses.
7) Probable Mechanism: increased lamotrigine metabolism
8) Literature Reports
a) If phenytoin or carbamazepine (or any prodrugs) is used in pregnant women, there is a substantially i of other anticonvulsants. The teratogenicity of these drugs is largely or wholly related to the levels of the Dyke et al, 1991a; Finnell et al, 1992a). The epoxide/parent drug ratio is generally increased when pheny any other drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide lamotrigine (Bianchetti et al, 1987a; Ramsay et al, 1990a; Spina et al, 1996a). Such combinations increa monotherapy and about 10-fold over background rates.

3.5.1.V Primidone

1) Interaction Effect: decreased lamotrigine efficacy

2) Summary: When primidone is added to lamotrigine therapy, the steady-state lamotrigine concentration de 2003).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Higher doses of lamotrigine are needed when given concurrently with enzyme-indu given in combination with an enzyme-inducing antiepileptic agent, the manufacturer recommends an initial la weeks for adult patients, followed by 50 mg twice daily for the third and fourth weeks, advancing by 100 mg d 500 mg administered in two divided doses.

7) Probable Mechanism: hepatic enzyme induction

3.5.1.W Rifampin

1) Interaction Effect: decreased lamotrigine exposure

2) Summary: Coadministration of a single 25-mg dose of lamotrigine in healthy volunteers receiving rifampin increased apparent clearance of lamotrigine (approximately 2-fold). Lamotrigine's AUC decreased by approxi chewable dispersible oral tablets, 2006). Use caution if these agents are coadministered. Monitor patients for doses accordingly.

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Coadministration of lamotrigine and rifampin has led to significantly increased lamo LAMICTAL(R) oral tablets, chewable dispersible oral tablets, 2006). Monitor patients for loss of lamotrigine ef

7) Probable Mechanism: increased lamotrigine clearance

3.5.1.X Risperidone

1) Interaction Effect: increased risperidone plasma concentrations and risk of adverse effects

2) Summary: Increased risperidone plasma concentrations, with signs of toxicity, developed in a patient adm regimen of risperidone and clozapine (Bienentreu & Kronmuller, 2005).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Clinicians should be aware of the increased risk of risperidone adverse effects in pa When concomitant lamotrigine is initiated, discontinued, or the dose of lamotrigine is changed, re-evaluate th

7) Probable Mechanism: unknown

8) Literature Reports

a) Increased risperidone plasma concentrations and subsequent toxicity were reported in a patient recei risperidone and clozapine. The patient, a 26-year-old woman diagnosed with schizophrenia, had sustain clozapine 550 milligrams (mg) daily and risperidone 8 mg daily. Baseline plasma concentrations of risper (ng/mL) and 800-1100 ng/mL, respectively. Lamotrigine was initiated, with the dose incrementally titrated concentrations increased to 1300 ng/mL and 263 ng/mL, respectively; no symptoms of intoxication were of 225 mg daily, after which risperidone plasma concentration increased to 412 ng/mL, accompanied by dose was reduced to 2 mg daily and completely withdrawn shortly thereafter (Bienentreu & Kronmuller, 2

3.5.1.Y Ritonavir

1) Interaction Effect: decreased lamotrigine serum concentrations

2) Summary: Coadministration of ritonavir and lamotrigine may result in decreased serum concentrations of solution, 2006). Coadministration of lamotrigine and lopinavir/ritonavir in healthy subjects significantly decrea lamotrigine clearance in an open-label, sequential, 3-period trial. The postulated mechanism of action is enha drugs that are metabolized by direct glucuronidation (vanderLee et al, 2006). If lamotrigine and ritonavir are a need to be increased (Prod Info NORVIR(R) oral capsules, solution, 2006). In one study, a doubling of the la effect (vanderLee et al, 2006). Monitor patients for loss of lamotrigine efficacy.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: Coadministration of lamotrigine and ritonavir may result in decreased lamotrigine se be increased (Prod Info NORVIR(R) oral capsules, solution, 2006). In one study, a doubling of the lamotrigine (vanderLee et al, 2006). Monitor patients for loss of lamotrigine efficacy.

7) Probable Mechanism: increased lamotrigine metabolism

8) Literature Reports

a) In an open-label, sequential, 3-period trial, coadministration of lamotrigine and lopinavir/ritonavir in he exposure and half-life, and increased lamotrigine clearance; a doubling of the lamotrigine dose is require to 65 years (n=24) received oral lamotrigine 50 mg once daily for days 1 and 2, followed by 100 mg twice 100 mg twice daily was added on day 11. Lamotrigine trough levels (Cmin) were measured between day 300 mg twice daily depending on the percentage of decrease. Among 18 patients who completed the stu day 20 (lamotrigine plus lopinavir/ritonavir) compared to day 10 (lamotrigine alone). The median AUC, C were not bioequivalent to those on day 10, with a geometric mean ratio (GMR) for lamotrigine AUC (day

0.54). Consequently, the lamotrigine dose was increased to 200 mg twice daily from day 23 to day 31 in bioequivalent to that on day 10, with a GMR (day 31/day 10) of 0.91 (90% CI, 0.82 to 1.02). The median metabolite to lamotrigine on day 20 was almost double to that on day 10 (0.57 on day 10 versus 1.12 on induction of glucuronidation of lamotrigine by ritonavir, and possibly also due to lopinavir. The pharmacol altered (vanderLee et al, 2006).

3.5.1.Z Rufinamide

1) Interaction Effect: decreased lamotrigine plasma concentrations

2) Summary: Concomitant administration of lamotrigine and rufinamide may result in lamotrigine concentrati dependent on the concentration of rufinamide, so maximum changes will most likely occur in children and oth rufinamide (Prod Info BANZEL(TM) oral tablets, 2008).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Caution is advised if lamotrigine and rufinamide are coadministered as this may res Risk is increased in children and in other patients who achieve significantly higher levels of rufinamide (Prod

7) Probable Mechanism: unknown

3.5.1.AA Sertraline

1) Interaction Effect: an increased risk of lamotrigine toxicity (fatigue, sedation, confusion, decreased cogniti

2) Summary: Two case reports describe epileptic patients who experienced lamotrigine toxicity when sertrali primarily via glucuronidation, while sertraline relies on N-demethylation, hydroxylation, oxidative deamination decreases lamotrigine metabolism through competitive inhibition of glucuronidation (Kaufman & Gerner, 199

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Caution should be exercised when combining sertraline and lamotrigine therapy. La dosages adjusted accordingly.

7) Probable Mechanism: inhibition of lamotrigine glucuronidation

8) Literature Reports

a) A 39-year-old female with epilepsy was maintained on lamotrigine 200 mg daily with a baseline lamot intermittent explosive disorder, sertraline 25 mg daily was initiated. Six weeks later, the lamotrigine level confusion and cognitive impairment. Sertraline was increased to 50 mg daily while lamotrigine was decre eliminated the patient's confusion and impaired cognition, and the blood level of lamotrigine stabilized at

b) Lamotrigine 450 mg daily was not controlling seizures in a 17-year-old female with mixed epileptic dis and titrated to 75 mg daily without any side effects. Lamotrigine was also increased to 600 mg daily, and fatigue, and decreased cognition. The lamotrigine blood level was 19.3 mcg/mL at this time. The sertralir lamotrigine level was increased to 800 mg daily, resulting in a new steady-state lamotrigine level of 9.8 n decreased to approximately 50% with a 33% decrease in the sertraline daily dose, even though the lamo Gerner, 1998).

3.5.1.AB Valproic Acid

1) Interaction Effect: increased elimination half-life of lamotrigine leading to lamotrigine toxicity (fatigue, drow rashes

2) Summary: Valproic acid interferes with the metabolic clearance of lamotrigine. The normal elimination half receiving concomitant valproic acid therapy, the half-life increases to approximately 40 to 60 hours. The mecl the two drugs for hepatic metabolism (Binnie et al, 1986b; Peck, 1991c; Eriksson et al, 1996a; Sallustio & Mo disseminated intravascular coagulation, and fatal toxic necrolysis have been reported with this combination ir Page II et al, 1998a). Given the increased risk of rash in pediatric patients, careful monitoring of lamotrigine s younger than 16 years of age, for whom the indication for lamotrigine is restricted to those who have been dia syndrome. The dose of lamotrigine should be reduced when coadministered with valproate (Prod Info Depak 2006).

3) Severity: major

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: Dosage reductions of lamotrigine are necessary with concurrent valproic acid thera inducing medications. The manufacturer recommends a lamotrigine dose of 25 mg every other day for the firs next two weeks, advancing to a maintenance dose of 100 mg to 400 mg daily in increments of 25 mg to 50 m only other antiepileptic medication, the usual maintenance dose of lamotrigine is 100 to 200 mg daily. Discon the rash is clearly not drug related (Prod Info lamotrigine oral tablets, 2006).

7) Probable Mechanism: decreased lamotrigine metabolism

8) Literature Reports

a) A 23-year-old woman presented to the emergency room with generalized rash, redness and swelling sore throat 3 weeks after lamotrigine was added to her anti-epilepsy regimen. Her initial regimen consist 500 mg twice daily was added 2 months and lamotrigine 50 mg twice daily was added 3 weeks prior to c erythrocyte sedimentation rate and C-reactive protein. However, serum carbamazepine and valproic acic lamotrigine concentrations were not measured. She was diagnosed with lamotrigine-induced Stevens-Jo Reactions Probability Scale score of 6 (probably drug induced). Lamotrigine was discontinued and treatn

day 18 on oral carbamazepine 400 mg twice daily and oral valproic acid 1500 mg/day. At the one month
oromucosal and skin lesions, with areas of hyperpigmentation. The patient's increased risk of developing
combination of lamotrigine and valproic acid leading to decreased metabolism of lamotrigine, or due to ir
manufacturer's recommended starting dose of 25 mg per day (Kocak et al, 2007).
b) Fever, rash, multiorgan dysfunction, and disseminated intravascular coagulation were reported in two
Both children were receiving valproic acid for treatment of seizures. Lamotrigine was added because of p
starting lamotrigine, but did not abate after lamotrigine was discontinued (Chattergoon et al, 1997).
c) A 54-year-old male presented to the hospital with a five-day history of facial swelling, intermittent feve
extremities, neck, and back. He had been taking allopurinol 100 mg daily and captopril 50 mg daily for fo
multiforme brain tumor, valproic acid and lamotrigine therapy was begun and the doses were titrated to v
50 mg twice daily approximately four weeks prior to his hospital admission. By hospital day 7, the patient

antiepileptic drugs (AEDs). The increased risk of suicidality was noted at 1 week after starting an AED and co
epilepsy, psychiatric disorders, or other conditions were all at an increased risk for suicidality compared to pla
emergence or worsening of depression, suicidality, and other unusual changes in behavior, which may includ
and hypomania (US Food and Drug Administration, 2008).

4.2 Patient Instructions

A) Lamotrigine (By mouth)
Lamotrigine

Treats certain types of seizures and mood disorders. Often used along with other medicines.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to lamotrigine.

How to Use This Medicine:
Tablet, Chewable Tablet, Dissolving Tablet, Long Acting Tablet
Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed
you. Do not use more medicine or use it more often than your doctor tells you to.
You may take this medicine with or without food.
It is best to swallow the regular tablet whole. You may break or crush the tablet if your doctor tells you to, but
The chewable tablet may be swallowed whole, or chewed and taken with a small amount of water or diluted f
a teaspoon of water or fruit juice and swallow the mixture after 1 minute.
If you are using the disintegrating tablet, make sure your hands are dry before you handle the tablet. Do not o
are ready to take it. Remove the tablet from the blister pack by peeling back the foil, then taking the tablet out
in your mouth. It should melt quickly. After the tablet has melted, swallow or take a drink of water.
Swallow the extended-release tablet whole. Do not crush, break, or chew it.
Use only the brand of this medicine that your doctor prescribed. Different brands may not work the same way
This medicine can be used with other seizure medicines. Keep using all of your seizure medicines unless you
This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your d
pharmacist for the Medication Guide if you do not have one. Your doctor might ask you to sign some forms to
This medicine comes with patient instructions. Read and follow these instructions carefully. Ask your doctor o

If a Dose is Missed:
If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next o
missed dose. Do not use extra medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:
Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after
throw away old medicine after the expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a
Make sure your doctor knows if you are using any other medicine to control seizures (such as carbamazepine
primidone, valproic acid, valproate, Depakene®, Depakote®, Dilantin®, Mysoline®, or Tegretol®). Make sure

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat,
Blistering, peeling, or red skin rash.
Bloody stools.
Blurred or double vision.
Changes in your menstrual cycle (period).
Chest pain.
Extreme weakness, dizziness, or fainting.
Feeling unusually sleepy, sad, grouchy, moody, or nervous.
Fever, chills, cough, sore throat, and body aches.
Nosebleed.
Pain, soreness, or itching in your vagina.
Painful sores in your mouth or around your eyes.
Painful urination or a change in how much or how often you urinate.
Problems with balance or walking.
Swelling in your face, hands, ankles, or feet.
Swollen, painful, or tender lymph glands in your neck, armpit, or groin.
Thoughts of killing yourself.
Tremors.
Unusual bleeding, bruising, or weakness.
Wheezing or troubled breathing.
Yellowing of your skin or the whites of your eyes.

If you notice these less serious side effects, talk with your doctor:
Dry mouth.
Eye twitching or eye movements you cannot control.
Headache, neck pain, back pain, or joint pain.
Increased sexual desire.
Loss of appetite, or weight loss.
Mild rash.
Nausea, vomiting, diarrhea, stomach upset or pain, or passing gas.
Runny or stuffy nose, or nose irritation.
Unable to concentrate or remember things.
Unable to sleep, or sleeping too much.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Bipolar I Disorder

1) Lamotrigine is indicated as maintenance treatment of Bipolar I Disorder to delay the time to occurrence of moc
acute mood episodes (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tab

B) Seizure

1) Extended-release lamotrigine is indicated as adjunctive therapy for partial onset seizures with or without secor
(Prod Info LAMICTAL XR oral extended-release tablets, 2009). Chewable dispersible or orally disintegrating lamo
seizures, the generalized seizures of Lennox-Gastaut syndrome, and primary tonic-clonic seizures in adults and
indicated as monotherapy in the treatment of epilepsy in patients 16 years or older who are being converted from
valproic acid as the single antiepileptic agent (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets,
efficacy in controlling partial and tonic-clonic seizures, primarily generalized seizures (absence and myoclonic), ju
syndrome (Trevathan et al, 2006)

2) Lamotrigine is an anticonvulsant with excellent potential in the management of various types of seizures. Its ar

carbamazepine; however, it is associated with less sedative effects and other neurotoxicity than many existing an
lamotrigine, including its rapid and complete oral absorption, long elimination half-life, relatively low protein bindin
lack of active or toxic metabolites, makes it desirable as an anticonvulsant.
3) The major drawback to the use of lamotrigine is that Stevens-Johnson syndrome occurs in approximately 1/10
4) Initiating lamotrigine at conservative doses and titrating lamotrigine slowly when added to concomitant valproic
(Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009).

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) The exact mechanism of action of lamotrigine has not been fully elucidated. It is thought to act by inhibiting rel
inhibition of voltage-sensitive sodium channels (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablet
1987a; Meldrum, 1991; O'Donohoe, 1991; Porter, 1989; Reynolds, 1993; Perucca, 1993). In animals, plasma con
(mcg/mL) are of similar protective efficacy as therapeutic concentrations of phenytoin and carbamazepine in the m
tests. It also reduces or abolishes the afterdischarge induced by focal stimulation of the cortex or hippocampus in
not block or reduce the rate of development of kindling, it does decrease the number of kindled responses and the
Lamotrigine is not effective in threshold tests (Jawad et al, 1989c; Leach et al, 1991; Peck, 1991e).
2) Further evidence that lamotrigine inhibits glutamate release is exhibited in the rat model, in which kainic acid n
inhibited, whereas quinolinic acid and ibotenic acid neurotoxicity, mediated by N-methyl-D-aspartate (NMDA) rece
3) The pharmacological profile of lamotrigine is similar to that of phenytoin. In vitro animal studies have shown it t
release in brain tissue, with no effect on potassium-induced amino acid release. This suggests that the drug acts a
neuronal membranes and inhibit neurotransmitter release, namely glutamate (Leach et al, 1986).
4) Single doses of lamotrigine cause an acute reduction in or abolition of photosensitivity in patients with epilepsy
hallmarks of epileptic activity (Binnie et al, 1986d; Jawad et al, 1986).

4.5 Therapeutic Uses

Absence seizure; Adjunct

Bipolar disorder, depressed phase

Bipolar I disorder

Brain injury

Cancer pain

Convulsions in the newborn, Intractable

Dementia of frontal lobe type

Depersonalization disorder

Depression, Treatment-resistant; Adjunct

Epilepsy, Refractory

Epileptic psychosis

Infantile neuronal ceroid lipofuscinosis

Juvenile myoclonic epilepsy

Lennox-Gastaut syndrome; Adjunct

Migraine

Mood swings

Neuropathic pain

Obesity

Pain

Palatal myoclonus

Parkinson's disease, Idiopathic

Paroxysmal choreoathetosis, Paroxysmal

Partial seizure, Adjunct or monotherapy

Reflex epilepsy

Rett's disorder

Schizophrenia, Refractory

Sexual dysfunction

Shortlasting, unilateral, neuralgiform pain with conjunctival injection and tearing syndrome

Status epilepticus

Tinnitus

Tonic-clonic seizure, Primary generalized; Adjunct

Trigeminal neuralgia

West syndrome

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

In an 8-week open-label study (n=20) of lamotrigine in adolescents ages 12 to 17 years (mean age 15.8; depressive episode, lamotrigine was effective, whether as adjunctive or monotherapy, in decreasing dep

3) Pediatric:

a) In an 8-week open-label study (n=20) of lamotrigine in adolescents ages 12 to 17 years (mean age 15.8; 7 depressive episode, lamotrigine was effective, whether as adjunctive or monotherapy, in decreasing depress lamotrigine with a mean final dose of 132 +/- 31 milligrams (mg)/day. Seven patients had the diagnosis of bip patients had bipolar disorder not otherwise specified. The primary measure for response was a "1" or "2" on t secondary measure for response was at least a 50% decrease in the Children's Depression Rating Scale-Re were 19 evaluable patients with 16 (84%) considered responders by primary criteria and 12 (63%) considered of 28 or less on the CDRS-R and a CGI Severity scale (CGI-S) score of 1 or 2) was attained by 11 of 19 (58% R scores from baseline to study end (mean change -30.1 +/- 11.9; p less than 0.001). Patients with a baseline than 20 were less likely to be responders by secondary criteria (p=0.04), but YMRS scores did decrease sign on adjunctive medication (n=7) showed no significant differences in CADRES scores compared with those or week 8 (p=0.35). Patients on adjunctive medication did not have a better response than those on monotherap Modified also improved from baseline to week 8 with decreases in total aggression (48.9 +/- 50.2 to 16.7 +/- 2 +/- 2.5; p less than 0.001), and suicide (1.56 +/- 2.1 to 0.26 +/- 0.65; p=0.02). There was no significant weight (kg); p=0.34). Adverse events reported were headache (84%), fatigue (58%), nausea (53%), sweating (47%) reported rash, but on further investigation, it was concluded that they experienced skin irritations, not true ras events, and no patients had any significant laboratory abnormalities during the study (Chang et al, 2006).

4.5.C Bipolar I disorder

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Indicated for the maintenance therapy of bipolar 1 disorder to delay the time to occurrence of mood episo standard therapy (Prod Info LAMICTAL chewable dispersible oral tablets, oral tablets, orally disintegratin Effective in refractory bipolar disorder in case reports and open studies (Robillard & Conn, 2002; Calabre Some patients with rapid-cycling bipolar disorder succeeded on lamotrigine maintenance monotherapy (

3) Adult:

a) The results of a small, open label study indicate that adjunctive lamotrigine therapy may be effective in the this uncontrolled study, five hospitalized, geriatric patients (ages 65 to 85 years) with bipolar disorder in the d milligrams (mg) at bedtime, titrated weekly in 12.5 mg/day increments to a total dose of 75 or 100 mg) in addi receiving both lithium and valproate therapy for at least 4 months prior to beginning the study and were nonre selective serotonin reuptake inhibitor or a tricyclic antidepressant. Following six weeks of treatment, at least a Rating Scale scores of 3 patients. All three patients had rapid- cycling bipolar disorder. Nonresponsive patien bipolar disorder. Lamotrigine was well tolerated, however one patient developed coarse hand tremor that imp randomized studies are needed to confirm these findings (Robillard & Conn, 2002).

b) Oral lamotrigine as maintenance monotherapy was effective prophylactic treatment for some patients with placebo-controlled trial (n=180). Prior to the double-blind phase of the study, patients entered an open-label p 8 weeks to a target of 200 milligrams (mg)/day (weeks 1 and 2: 25 mg/day; weeks 3 and 4: 50 mg/day; week up to 300 mg/day); after 4 to 8 weeks of lamotrigine, all other psychotropic medications were tapered off. The to vary; after the preliminary phase, mean daily dose was 287.9 mg/day. Randomization placed patients on p proportion of patients who were able to maintain on placebo or lamotrigine without requiring added pharmacc the difference was not significant (p=0.177). Median survival time without added treatment was 18 weeks and patients, respectively. The percentage of patients able to complete 6 months of the randomized phase withou group (41% versus 26%, p=0.03), and especially among those with bipolar II subtype. Most adverse events w most common side effects (Calabrese et al, 2000).

c) Data from a 48-week open-label trial lend support to lamotrigine's effectiveness as add-on (n=60) or monc other therapies for bipolar I or II disorder. Of 40 evaluable subjects with depressive symptoms, 48% and 20% respectively, with a mean 42% decrease in Hamilton Depression Scale scores. Of 31 evaluable subjects with marked and moderate improvement, respectively, with a mean 74% decrease in Mania Rating Scale scores. Adverse effects included dizziness (29%), tremor (23%), somnolence (21%), headache (19%), nausea (15%) rate was 51%. Controlled trials are in progress (Calabrese et al, 1999).

d) Lamotrigine appeared to have some mood-stabilizing and antidepressant effects in 5 rapid-cycling bipolar lamotrigine at an average dose of 185 milligrams/day. Three scales were used to measure improvement with improvement after therapy as compared to before therapy (p less than 0.006). The other scales did not show less than 0.289) and Young Mania Rating Scale (p less than 0.552). Further randomized studies are needed

e) In an open trial of lamotrigine therapy in 7 patients with treatment-refractory mood disorder, mixed results used with 2 patients showing marked improvement, 2 had a moderate response, 2 had no response and 1 di Sternbach, 1997).

f) In a 41-year-old female with longstanding bipolar disorder, add-on lamotrigine effectively substituted for lit high-dose steroid therapy. Prednisone was necessary to treat lithium-induced interstitial nephritis. Lamotrigin increased to 200 mg every 12 hours within 9 days. Despite escalating prednisone doses to 120 mg/day, her r concurrent medications included perphenazine, temazepam, clonazepam, and nifedipine (Preda et al, 1999).

g) A 48-year-old man with treatment-refractory bipolar disorder had a good response to lamotrigine titrated t psychotic mania and depression and responded to a combination of lamotrigine, paroxetine and levothyroxin

4.5.D Brain injury

Treatment with add-on oral lamotrigine led to similar efficacy results as lithium augmentation in patients v
label, randomized, prospective study (n=34) (Schindler & Anghelescu, 2007)
Results of a retrospective chart review (n=37) showed that adjunctive lamotrigine was efficacious and we
refractory, unipolar depression in adults (Barbee & Jamhour, 2002)

3) Adult:

a) General Information

1) Treatment with oral lamotrigine used as an add-on to antidepressant therapy was safe and demonstra
treatment-refractory, unipolar depression (Schindler & Anghelescu, 2007; Barbee & Jamhour, 2002; Roc
prospective study (n=34), lamotrigine, initiated at 25 milligrams (mg) per day and titrated up to 250 mg/da
augmentation (Schindler & Anghelescu, 2007). Two other retrospective chart reviews found similar impro
mg/day (Barbee & Jamhour, 2002; Rocha & Hara, 2003). Notably, responses in both reviews were base
scores, which were culled retrospectively from chart notes. Patients included in the open-label study as v
anxiety comorbidity and had received a variety of prior antidepressant and/or combination augmentation
studies and there were no instances of skin rash or other dermatological toxicity.

b) Clinical Trials

1) In an open-label, randomized, prospective study (n=34), treatment with add-on oral lamotrigine was v
augmentation in patients with treatment-resistant, unipolar depression. Patients who had experienced a
according to the DSM-IV (Text Revised), with a minimum score of 17 points on the Hamilton Rating Scal
study purposes, treatment-resistant depression was defined as non-response (less than 50% reduction o
classes of antidepressants for at least 6 weeks. Patients were randomized to receive augmentation with
lithium (n=17; mean age, 50.3 years) orally for 8 weeks. Lamotrigine was initiated at 25 milligrams (mg) o
week 3) and 50 mg (at weeks 5 and 6) to a target daily dosage of 150 mg. In cases of non-response or p
Lithium was titrated over several days to a blood level of 0.6 to 0.8 millimoles/liter. Prior antidepressant th
augmentation strategies were discontinued. Based on clinical need, concomitant use of benzodiazepines
(n=27) were treated as inpatients during this study. Weekly assessments were conducted using the HRS
Prior to study initiation, most patients had received treatment with a variety of augmentation or combinati
therapy (n=20), atypical antipsychotics (n=27), and right unilateral electroconvulsive therapy (n=5), and 4
axis I or II disorder. At baseline, the mean duration of current depressive episode (lamotrigine, 6.9 month
prior episodes (lamotrigine, 2.94; lithium, 2.76; p=0.84) was similar between the groups. An intention-to-t
in HRSD scores in both groups. The mean +/- standard deviation (SD) HRSD score decreased from 22.7
group and from 21.5 +/- 3.8 at baseline to 13.3 +/- 5.7 in the lithium group (p=0.11 between groups at we
regards to the time point of onset of symptom resolution. The mean +/- SD CGI scores decreased from 6
(mildly ill) in the lamotrigine group and from 6.24 +/- 0.66 (severely ill) at baseline to 4.12 +/- 1.22 (moder
score of 7 points or less) occurred in 23% (n=4) and 18% (n=3) of lamotrigine- and lithium-treated patien
treated patients versus 41% (n=7) of lithium-treated patients responded (ie, 50% or greater reduction in i
(ie, 25%-49% reduction in HRSD score) occurred in 47% (n=8) and 35% (n=6) of lamotrigine- and lithium
side effects were dry mouth, blurred vision, headache, tremor, weight gain, vertigo, constipation, and dia
tremor (lamotrigine, n=2; lithium, n=5), frequencies for all effects were similar in both groups. Dermatolog
study (Schindler & Anghelescu, 2007).

2) A retrospective chart review (n=37) revealed that add-on treatment with lamotrigine was efficacious a
depression. Charts of patients (mean age 50.22 years; range, 18-75 years) with a diagnosis of major dep
who had received lamotrigine augmentation following failure of at least two adequate trials (minimum of
antidepressants were reviewed. Patients with current psychotic symptoms, or hypomania/mania were ex
at bedtime for 2 weeks and then increased to 50 mg/day for 2 weeks; further dosage increases were ma
improved or the patient was no longer able to tolerate further dosage increases. Patients included in the
continued on treatment with their primary antidepressant or concomitant augmentation medications with
those agents; one patient discontinued all antidepressant therapy prior to initiation of lamotrigine treatme
generalized anxiety disorder (n=16), panic disorder (n=5), social or specific phobia (n=5, n=2), posttraum
disorder (n=3), and anxiety not otherwise specified (n=1). With the exception of two patients, none of the
initiation of lamotrigine, study patients had received a mean of 13.27 (range, 2-29) antidepressant trials a

medications during lamotrigine therapy. The mean duration of lamotrigine treatment was 35.41 weeks (ra
Functioning (GAF) scores were recorded at the time of each visit. Prior to initiation of lamotrigine, the me

nausea (n=5), and tremor (n=4). There were no instances of skin rash during this study (Barbee & Jamh

4.5.J Epilepsy, Refractory

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective as add-on therapy in treatment-resistant focal and generalized epilepsy (Huber et al, 1998)
May be useful in the treatment of intractable childhood epilepsy (Lerman-Sagie & Lerman, 1998)

3) Adult:

a) In an observational study, lamotrigine was useful as add-on therapy in a group of 125 multi-handicapped, epilepsy . Although most effects were only partial, 28.8% of patients had a reduction of 50% or more in seizu epilepsies, 26.7% with generalized epilepsies, and 22.4% with both. A mean lamotrigine dose of 391 milligra combination of valproic acid and lamotrigine was particularly effective(Huber et al, 1998).

b) Lamotrigine was reported to be useful in treating 10 adult patients (23 to 44 years old) with intractable abs started in childhood and persisted into adulthood . Lamotrigine was initially started at 0.2 milligrams/kilogram maximum of 5 mg/kg. All patients were receiving valproic acid. Except for valproic acid, all other antiepileptic optimal lamotrigine dose. Valproic acid doses ranged from 600 to 2000 mg/day and lamotrigine doses were 1 tonic-clonic seizures was achieved in all patients; 7 patients achieved cessation of absence seizures with 3 p Sagie & Lerman, 1998).

4) Pediatric:

a) In an open-label, long-term study (n=41), add-on lamotrigine therapy proved successful in 44% of study su years of age; mean 12 years) with refractory severe partial epilepsy (mean seizure frequency 3.6/day). All en major antiepileptic drugs. Eighteen patients (44%) remained on lamotrigine after 12 to 48 months of follow-up occurred in 15 patients (34%) (p less than 0.00006), with 6 of these subjects remaining seizure-free. Three of marked improvement in behavior, although seizure frequency was unchanged. Higher response rates were o symptomatic of cerebral malformation. Seizure worsening occurred in 9 patients; transient rash developed in starting daily dose was 0.2 to 2.5 milligrams/kilogram (mg/kg) titrated over 2 to 4 weeks to an initial maintena subsequently adjusted based on clinical response up to a maximum of 1.8 to 15 mg/kg/day; mean dose was valproate, median dose was 4.8 mg/kg/day; for those on enzyme-inducing drugs except valproate, median do

b) In an open trial, 16 out of 63 children had a complete response to lamotrigine add-on treatment for their re types with a mean of 1.72 seizure types per child. Seizure types included infantile spasms, simple partial seiz seizures, myoclonic seizures, typical absence seizures, and atypical absence seizures. A complete response achieved a 50% to 90% decrease in seizures (Buoni et al, 1998).

c) In an open, prospective trial, 30 of 56 children with generalized epilepsies were improved with lamotrigine than 18 years old and suffered from Lennox-Gastaut syndrome (15), childhood absence (4), severe myocloni symptomatic generalized (24) and other epilepsies (5). An improvement of greater than 50% was observed ir in 11 of 24 children with other symptomatic generalized epilepsy (p less than 0.09). Rash occurred in 4 patier was discontinued and lamotrigine was restarted without recurrence of rash (Farrell et al, 1997).

d) In an open trial, lamotrigine was useful as add-on therapy in about one-third of patients (2 to 22 years old) lamotrigine 5 to 15 milligrams/kilogram/day (lower doses for patients receiving concomitant valproic acid). Aft seizure frequency of more than 50% and 8 of these patients became seizure-free. Lamotrigine was most effe absences, and atonic seizures (Coppola & Pascotto, 1997).

e) Fourteen children suffering from refractory epilepsy received lamotrigine as add-on therapy. A decrease ir lamotrigine was observed in 6 of the 7 patients who completed the study. The median total seizure frequency study, seizure frequency had decreased by more than 50% in 2 patients, by more than 75% in 2 patients, and seizure frequency was unchanged (Battino et al, 1996)(Battino et al, 1995b).

f) In one series, 8 of 10 children with various seizure disorders had decreased total seizure count when lamo used in increasing doses up to 2 milligrams/kilogram/day (mg/kg/day) in patients taking valproic acid, and in c phenytoin, phenobarbital, or carbamazepine. After 3 months, the dose was increased by 50%. The median to 21 to 916) to 46/month (range 6 to 644) after 6 months. Patients with atypical absence and complex partial se patients, respectively, experiencing greater than 50% reduction in seizure frequency. Myoclonic seizures dec remission; however, 4 patients had an increased frequency of myoclonic seizures. Tonic-clonic seizures decr significant adverse effect noted was drowsiness in 3 patients; however, this did not require dosage reduction

g) In 161 patients remaining on lamotrigine during a 2-year follow-up, 21 of the first 55 patients evaluated ha free. Best response was in generalized epilepsy, particularly absence seizures. Rash was the most commonl valproate (Yuen, 1992).

h) Twelve children with severe or life-threatening epilepsy received lamotrigine (250 to 900 milligrams/day). S
for 12 to 61 months with 4 on monotherapy. No patient was hospitalized for status epilepticus. No adverse ef

4.5.K Epileptic psychosis

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in 2 case reports (DeLeon & Furmaga, 1999)

3) Adult:

a) Two cases were presented describing patients with epilepsy-related psychosis that was resistant to antips
lamotrigine. The first was a 39-year-old woman with seizures and psychosis that included thought broadcasti
clonazepam, phenytoin and gabapentin without improvement in seizure control or decrease in psychotic sym
closed head injury, seizures, delusions of persecution, and aggressive behavior. His treatment consisted of c
improvement in seizure control and relief from psychotic symptoms occurred with the addition of lamotrigine t
twice daily and the man was titrated to 450 mg daily. Also in both cases risperidone was tapered and disconti
the need for antipsychotic therapy (DeLeon & Furmaga, 1999).

4.5.L Infantile neuronal ceroid lipofuscinosis

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

In 1 study, lamotrigine was useful as adjunctive therapy for seizures associated with infantile neuronal ce

3) Pediatric:

a) Lamotrigine was useful in treating seizures associated with infantile neuronal ceroid lipofuscinosis . Lamot
16 children (2.5 to 12 years old) at a dose of 0.5 milligrams/kilogram and increased every 2 weeks as needed
10 patients seizure frequency decreased by more than 50%. In 4 children seizures decreased by 100%. Mon
successful (Aberg et al, 1997).

4.5.M Juvenile myoclonic epilepsy

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Ineffective; Pediatric, Ineffective
Recommendation: Adult, Class III; Pediatric, Class III
Strength of Evidence: Adult, Category C; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Exacerbation of myoclonus reported in juvenile myoclonic epileptic patients treated with lamotrigine (Bira

3) Adult:

a) A group of 7 patients 16 to 32 years of age with juvenile myoclonic epilepsy (JME) experienced immediate
of the cohort had previously used valproic acid. Three patients began lamotrigine as add-on therapy to valpro
therapy. In either instance, JME deteriorated, with worsening of myoclonus in all 7 patients and appearance o
the patients were switched back to valproic acid or to topiramate without further adverse sequelae. Dosing of
given as monotherapy and 150 to 200 mg/day when combined with valproate (Biraben et al, 2000).

4) Pediatric:

a) A group of 7 patients 16 to 32 years of age with juvenile myoclonic epilepsy (JME) experienced immediate
of the cohort had previously used valproic acid. Three patients began lamotrigine as add-on therapy to valpro
therapy. In either instance, JME deteriorated, with worsening of myoclonus in all 7 patients and appearance o
the patients were switched back to valproic acid or to topiramate without further adverse sequelae. Dosing of
given as monotherapy and 150 to 200 mg/day when combined with valproate (Biraben et al, 2000).

4.5.N Lennox-Gastaut syndrome; Adjunct

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes; Pediatric, yes (2 years and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Indicated as adjunctive therapy for the generalized seizures of Lennox-Gastaut syndrome (Prod Info LAM

orally disintegrating tablets, 2009)

3) Adult:

a) In a double-blind, placebo-controlled study, lamotrigine as add-on therapy was effective for seizures asso
years old) received placebo (n=90) or lamotrigine (n=79) with a maximum dose of 100 to 200 milligrams for p
milligrams for other patients. For all seizure types, the median frequency changed from 16.4 and 13.5 per we
to 9.9 and 14.2 per week after 16 weeks of treatment, respectively (p less than 0.002). Reduction of seizure f
lamotrigine group and in 16% of the placebo group (p less than 0.01). The results were similar for drop attack
absence seizures did not significantly change. Two patients on lamotrigine and valproic acid developed rash

b) Thirteen patients with Lennox-Gastaut syndrome (age 5.5 to 27 years) received lamotrigine 100 to 400 mi
seizure-free after 2 months to 2 years of treatment. Eight of 13 achieved control of at least 1 seizure type. Six
1991).

4) Pediatric:

a) In a double-blind, placebo-controlled study, lamotrigine as add-on therapy was effective for seizures asso
years old) received placebo (n=90) or lamotrigine (n=79) with a maximum dose of 100 to 200 milligrams for p
milligrams for other patients. For all seizure types, the median frequency changed from 16.4 and 13.5 per we
to 9.9 and 14.2 per week after 16 weeks of treatment, respectively (p less than 0.002). Reduction of seizure f
lamotrigine group and in 16% of the placebo group (p less than 0.01). The results were similar for drop attack
absence seizures did not significantly change. Two patients on lamotrigine and valproic acid developed rash

b) As part of a larger open, prospective trial, 11 of 15 children with Lennox-Gastaut syndrome were improved
milligrams/kilogram/day (Farrell et al, 1997).

c) Thirteen patients with Lennox-Gastaut syndrome (age 5.5 to 27 years) received lamotrigine 100 to 400 mi
seizure-free after 2 months to 2 years of treatment. Eight of 13 achieved control of at least 1 seizure type. Six
1991).

4.5.O Migraine

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Appears to be effective only in patients with an aura before their migraine (Lampl et al, 1999)

3) Adult:

a) Lamotrigine appears to act specifically on the aura mechanism in relieving migraine headaches and appe
headache (D'Andrea et al, 1999)(Lampl et al, 1999). In one study, 21 patients receiving lamotrigine 100 millig
their attacks from 6.1/month at baseline to 0.7/month after 3 months (p less than 0.0001). In 13 patients the a
reduced. In 5 patients with migraine without aura, there was no change (D'Andrea et al, 1999). Similarly, in 1
migraine, lamotrigine 25 to 100 mg daily produced a significant decrease in aura episodes after 4 months (p l
months from 23 minutes at baseline to 3 minutes (p less than 0.001) (Lampl et al, 1999). In the treatment of g
than placebo in 77 patients (Steiner et al, 1997).

4.5.P Mood swings

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Lamotrigine was beneficial in post-stroke pathological laughing and crying in 1 case study (Ramasubbu,

3) Adult:

a) In a single case report, lamotrigine improved symptoms of pathological laughing and crying in a 60-year-o
affecting the left frontal and temporal lobes. The patient had developed symptoms 3 to 4 weeks after the strok
and inappropriate to the stimuli or felt emotion. Twelve months after the onset of symptoms, lamotrigine was
increased to 75 mg during weeks 3 and 4, and to 100 mg during weeks 5 and 6. Laughing spells gradually de
no spells after week 4 of therapy. Crying spells gradually decreased from 7 to 8 spells per day, lasting for 3 to
therapy. After 8 weeks of follow-up, clinical improvements were still maintained. The patient did not report any
(Ramasubbu, 2003).

4.5.Q Neuropathic pain

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Ineffective for the treatment of chemotherapy-induced peripheral neuropathy in a randomized, placebo-c
Mixed results observed in neuropathic pain due to diabetes (Eisenberg et al, 2001) and HIV (Simpson et
controlled trials
No appreciable effect seen with lamotrigine for intractable neuropathic pain (McCleane, 1999) or neurop
2002) in randomized, double-blind, placebo-controlled trials, although lamotrigine was promising for a sm
(Finnerup et al, 2002)

3) Adult:

a) Lamotrigine was not effective for relieving neuropathic pain symptoms in 125 patients with chemotherapy-
phase 3 randomized, placebo-controlled study. Patients with symptomatic CIPN with pain scores of either gre
Group (ECOG) neuropathy scale (ENS), or greater than 3 on a 0 to 10 Numerical Rating Scale (NRS) were e
numbers correspond to greater severity of symptoms. Participants were randomized to treatment with lamotri
mg/day over 10 weeks; n=63) or placebo (n=62). The primary efficacy measure, patient-reported "average" d
ENS, was assessed weekly. Secondary efficacy measures, such as the World Health Organization (WHO) cl
decreased tendon reflexes, 2 = severe paresthesias and/or mild weakness, 3 = intolerable paresthesias and/
evaluate changes in CIPN symptoms related to, but distinct from, pain. At the time of enrollment, the proporti
chemotherapy was 38% and 45% (p=0.47) for the lamotrigine and placebo arms, respectively, with the remai
arm was similar with regard to demographic factors and chemotherapy drugs responsible for CIPN at baselin
and 3.6 (p=0.22), and symptoms using ENS were 2 and 1.9 (p=0.31) for lamotrigine and placebo, respectivel
severity decreased in both groups without significant differences between them. According to the NRS, the m
units (p=0.56) and symptom severity (by ENS) decreased by 0.4 and 0.3 units (p=0.36) in treatment and plac
least pain scores by NRS (-0.2 and 0.1), and by WHO pain scales (-0.2 and -0.1) were similar between treatm
differences were noted between the 2 groups with regard to some of the secondary endpoints, these were nc
according to those patients still receiving chemotherapy and those who had completed chemotherapy, neithe
compared with placebo. Adverse events were similar for both groups, although patients receiving lamotrigine
adverse events compared to placebo (33% vs 18% respectively, p=0.06). The most common toxicities (grade
placebo groups, respectively, included ataxia (24% vs 16%), rash (6% vs 5%), constipation (0% vs 2%), arthr
vomiting (0% vs 2%), pruritis (2% vs 0%), fatigue (2% each), and headache (0% vs 4%) (Rao et al, 2008).

b) Lamotrigine effectively improved numerical pain scores in patients with diabetic neuropathy but failed to p
indices in a randomized, double-blind, placebo-controlled clinical trial conducted in Israel. Patients (n=53) wit
neuropathy of at least 6 months duration, and pain scores of at least 4 on a scale of 0 (no pain) to 10 (worst i
analgesics for 3 days prior to starting a diary during the baseline period. Patients were randomized to an 8-w
daily for 2 weeks, then 50 mg daily for 2 weeks, and then 100 mg, 200 mg, 300 mg, and 400 mg daily for one
placebo (n=26; mean age, 57.8 +/- 1.7 years). Doses were administered as once daily for the first 2 weeks ar
primary endpoint was a patient-recorded pain intensity score, using the same 0 to 10 numerical pain scale ac
the morning and evening, and patients were instructed not to take any rescue medication for at least 2 hours
characteristics were similar between groups except patients in the lamotrigine group had a significantly longe
patients in the placebo group (9.6 +/- 1.1 years; p=0.04). Distal symmetric pain in the legs (stocking-like distri
abnormal neurologic examinations that indicated peripheral neuropathy. Patients in the lamotrigine group exp
6.4 +/- 0.1 to 4.2 +/- 0.1, while patients in the placebo group had an overall decline of 6.5 +/- 0.1 to 5.3 +/- 0.1
pain intensity scores were observed at lamotrigine doses of 200, 300, and 400 mg compared to placebo. Dur
pain was seen in 12 patients receiving lamotrigine and 5 patients receiving placebo (p=0.05), while the overa
arm compared to 20% in the placebo arm. Of 7 patients in the lamotrigine group who required rescue analge
their use during the last 4 weeks of treatment compared to no changes in analgesic requirements in the 3 pat
No significant differences were found between groups in the McGill Pain Questionnaire, the Beck Depression
assessment of efficacy and tolerability, which were completed at baseline and at week 8. Rash occurred in 2
7th weeks of treatment, although both cases resolved upon discontinuation of lamotrigine (Eisenberg et al, 20

c) Results from a randomized, double-blind, placebo-controlled study demonstrated lamotrigine was well-tole
in patients receiving neurotoxic antiretroviral therapy (ART). Two groups of patients were randomized to plac
those not receiving ART (n=135). The study included a 7-week dose escalation phase followed by a 4-week m
to induce the metabolism of lamotrigine started the dose escalation phase at 25 milligrams (mg) every other d
known to induce metabolism of lamotrigine started at a dose of 25 mg daily. During the 4-week maintenance
for patients not receiving enzyme-inducing drugs and 600 mg/day for patients receiving enzyme-inducing dru
Scale did not differ between lamotrigine and placebo for either group at the end of the maintenance phase. H
Scale reflected greater improvement with lamotrigine than with placebo in the group receiving ART (p=0.004)
also showed greater improvement on the Visual Analogue Scale for Pain Intensity and the McGill Pain Asses
of global impression of change in pain (p less than or equal to 0.02). The incidence of adverse events was sir
2003).

d) In a randomized, double-blind, placebo-controlled crossover trial, lamotrigine treatment had no effect on th
(n=22) of patients with spinal cord injury (SCI) but did reduce pain in a subset of the sample, which was chara
with or without motor function, preserved below the lesion level and including sacral segments S4-S5). Patien
were given lamotrigine, beginning with 25 milligrams (mg) and increasing to a target dose of 400 mg/day, or p
period, crossed over to the other treatment for 9 weeks. The dose of lamotrigine was limited by individual tole
dose of 300 mg/day, and 5 had a final dose of 200 mg/day. Among the 12 patients with incomplete SCI lesion
an 11-point pain scale) to lamotrigine. Three patients also responded to placebo. The median difference in pa
in the group with incomplete lesions. All patients who had evoked pain (brush allodynia or wind-up-like pain) v
evoked pain was a responder (p less than 0.001), suggesting that the presence of evoked pain may be a pre
et al, 2002).

e) In a randomized, placebo-controlled, double-blind trial of 100 adults with intractable neuropathic pain, lam

mg/day exhibited no appreciable analgesic efficacy. Subjects completed daily diaries with visual analog score into weekly scores. With mean scores from week 8 compared to week 1, there were no statistically significant analgesic consumption, overall pain, burning pain, numbness, "pins and needles," shooting pain, skin sensitivity points out that this study does not rule out lamotrigine's efficacy using a different dosing scheme or in other n

4.5.R Obesity

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

In a single center, double-blind, placebo-controlled, randomized study (n=40) of healthy adult volunteers greater or equal to 30 but less than 40), while there was no statistically significant mean change in body subjects who took placebo, lamotrigine showed a statistically significant difference in mean change in BM (Merideth, 2006).

3) Adult:

a) In a single center, double-blind, placebo-controlled, randomized study (n=40) of healthy adult volunteers v greater or equal to 30 but less than 40), while there was no statistically significant mean change in body weig subjects who took placebo, lamotrigine showed a statistically significant difference in mean change in BMI an were randomized to receive lamotrigine 200 milligrams (mg)/day (n=20) or placebo (n=20) for 26 weeks. Initia weeks until the maintenance dose of 150 to 200 mg/day was reached. All patients were titrated to lamotrigine mg/day and was discontinued early from the study. Of those subjects randomly assigned, 28 completed the 2 placebo). Subjects completed the Impact of Weight on Quality of Life (IWQOL) scale at baseline and endpoin difference in baseline body weight between the 2 groups (lamotrigine mean +/- standard deviation (SD) equa equal 225 +/- 32.7 lb; p=0.0588). The primary study outcome of change in body weight from baseline to endp lamotrigine and placebo, respectively (p=0.0623). There was a statistically significant difference in mean chan and -0.1 +/- 1.05 for lamotrigine and placebo, respectively (p=0.0421). A greater change in quality of life satis lamotrigine group (p=0.0065). Other secondary outcomes showed no significant differences. No serious adve in the placebo group discontinued treatment due to edema. No lamotrigine subjects discontinued treatment d the most frequently reported adverse event with a 15% incidence across the study group (Merideth, 2006).

4.5.S Pain

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Possibly effective for different pain syndromes (Eisenberg et al, 2003; Vestergaard et al, 2001; Cianchett
Lamotrigine provided moderate analgesia for central post-stroke pain (Vestergaard et al, 2001)
Open-label data suggest possible benefit in treating resistant paroxysmal limb pain and painful tonic spa 1999)
Possibly effective in treating sciatica (Eisenberg et al, 2003)

3) Adult:

a) Multiple Sclerosis-Related Pain

1) Open-label add-on lamotrigine 25 milligrams/day (mg/day) titrated slowly to a maximum dose of 400 Multiple sclerosis-related pain syndromes refractory to multiple other medications. Improvement in parox eight of 21 (38%) patients, with five of 21 (24%) experiencing improvement in painful tonic spasms. The year in some cases. These results require confirmation in a placebo-controlled trial (Cianchetti et al, 199

b) Postoperative Pain

1) Lamotrigine may be effective in reducing postoperative pain In a double-blind, placebo-controlled stu either lamotrigine 200 milligrams or placebo 1 hour before receiving spinal anesthesia for transurethral p were lower in the lamotrigine group than in the placebo group at 2 hours (p equal to 0.04), 4 hours (p les (Bonicalzi et al, 1997).

c) Post-stroke Pain

1) In a double-blind, randomized, crossover trial (n=30), patients with central post-stroke pain experienc milligrams/day. Subjects were randomized to 8-week courses of lamotrigine and placebo, separated by a lamotrigine was titrated at 2-week intervals from 25 milligrams (mg)/day to 50 mg/day, 100 mg/day, and pain score over the last week of treatment from 7 to 5 (p=0.01 compared with placebo). Twelve of 27 sub defined as a pain score 2 or more points lower than their score using placebo. No significant analgesia o secondary end points, including global physical pain score over last 4 weeks and pain stimulated by a co lamotrigine (p=0.02 and p=0.01, respectively); the trend favored lamotrigine on other secondary end poir events occurred at similar rates in the 2 periods. Mild rash was associated with lamotrigine use in 2 patie during the lamotrigine period due to mild rash, severe headache, and severe pain (Vestergaard et al, 20

d) Sciatica

1) An open-label, non-comparative study involving 14 patients suggests that lamotrigine may be effectiv radiculopathy for 12 to 36 months. They underwent a 1 week washout period from previous analgesics a was initiated at 25 milligrams (mg) once daily and was doubled weekly up to the maintenance dose of 40 dose for 4 weeks. Of the 14 patients, only 7 completed the full 11 weeks. Diarrhea, dizziness and person discontinuation. In patients who received at least 1 week of lamotrigine and in whom drug plasma concer numerical pain scale scores for spontaneous pain decreased from 7.6 to 4.5 at the end of 11 weeks (p le spontaneous pain also decreased from 7.9 to 4.1 (p less than 0.05). Scores from the Short Form of the M less than 0.05). A linear correlation was found between lamotrigine concentrations and the mean weekly analog measurements (both p=0.001). Due to high dropout rates and the open-label design of the study, (Eisenberg et al, 2003).

4.5.T Palatal myoclonus

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Eliminated ear clicks associated with palatal myoclonus in one case (Nasr & Brown, 2002)

3) Adult:

a) Ear-clicking associated with palatal myoclonus (PM) was stopped by lamotrigine treatment in a 37-year-ol admitted to psychiatric services because of an acute psychotic episode associated with excessive alcohol co After alcohol detoxification and antipsychotic treatment (thioridazine 100 milligrams (mg) 3 times daily), he wa patient reported gradual improvement, with disappearance of ear-clicking and slowing of the frequency of pal clinical examination. After discharge, the man began again to drink alcohol and stopped taking lamotrigine, re Brown, 2002).

4.5.U Parkinson's disease, Idiopathic

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Ineffective
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

No beneficial effect (Shinotoh et al, 1997)

3) Adult:

a) Lamotrigine had no beneficial effects on patients with Parkinson's disease treated either during a single d (n=12) (Shinotoh et al, 1997).

4.5.V Paroxysmal choreoathetosis, Paroxysmal

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in 3 children with paroxysmal kinesigenic choreoathetosis (Uberall & Wenzel, 2000)

3) Pediatric:

a) Low-dose lamotrigine was safe and effective in 3 children with idiopathic paroxysmal kinesigenic choreoat year-old girl, and a 10-year-old boy. The first boy was started on lamotrigine 5 milligrams (mg)/day, with titrati mg/kilogram (kg); titration from 5 to 10 to 25 to 50 mg). On that dosage, his attacks were significantly decreas was attack-free. The girl received increasing doses, starting from 5 mg/day ranging up to 100 mg/day (4.7 mg dose, she was attack-free also. The second boy began taking lamotrigine 10 mg/day, with titration biweekly t point his dystonic attacks ceased. In all cases, lamotrigine was well tolerated. Previous medications which ha carbamazepine, phenobarbital, and flunarizine. The patients had used lamotrigine for 16, 19, and 27 months,

4.5.W Partial seizure, Adjunct or monotherapy

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes; Pediatric, yes (13 years and older, extended-release only; 2 years and older, only)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category A; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Extended-release formulation is indicated as adjunctive therapy for partial onset seizures with or without older (Prod Info LAMICTAL XR oral extended-release tablets, 2009)

Indicated as adjunctive therapy in the treatment of partial seizures in adults and pediatric patients with ep tablets, oral tablets, orally disintegrating tablets, 2009)

Indicated for conversion to monotherapy in patients receiving treatment with a single enzyme-inducing a chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

Beneficial in patients with seizures resistant to various combinations of carbamazepine, phenobarbital, p

3) Adult:

a) Extended-release formulation is indicated as adjunctive therapy for partial onset seizures with or without s older (Prod Info LAMICTAL XR oral extended-release tablets, 2009).

b) Of the 527 patients enrolled in a 6-year, open-label, continuation study examining the use of lamotrigine n partial seizures, the clinical status of 58% of patients were judged to have improved from baseline and the lor incidence of adverse effects. Patients were recruited from 5 primary clinical studies of adjunctive lamotrigine. milligrams per day (range 100 to 730 mg per day). Forty-three percent (n=229) of patients completed the stuc 37% of patients, miscellaneous reasons (7%), adverse events (5%) and administrative reasons (5%; eg, prot Overall clinical status was judged on a 7 point scale by the investigators. Mild, moderate, and marked improv the time of discontinuation when compared to pre-lamotrigine clinical status. No change was seen in 30% of and marked deterioration) was seen in 12% of patients. Adverse events were noted in 98% of patients. The n diplopia, ataxia, headache, somnolence, nausea, amblyopia and accidental injury. Serious adverse events w a serious adverse event by 0.4% of patients. No patients developed Stevens-Johnson syndrome (Faught et a

c) As an add-on treatment, lamotrigine (LTG) was effective in the treatment of epileptic drop attacks (EDA) ir patients being treated with antiepileptic drugs but still experiencing at least one EDA per month and at least 4 were observed for 3 months (baseline), given LTG over a 4-month period during which the dose was increase months while taking the maintenance dose. Prior medications were continued throughout the study. In patien milligrams/day (mg/day), which was increased incrementally every 2 weeks to a final dose of 150 mg/day. In was 25 mg/day, which was increased to 300 mg/day. In the last month of the titration period, if necessary, do tolerated dose. Of the 12 patients who completed the study, all had more than a 50% reduction in their total s 75% decrease in seizure frequency. EDA disappeared in 6 patients, improved by 80% in 3 patients and by 50 improvement in EDA frequency. The average maximum LTG dosages were 200 mg/day with valproic acid an al, 2001).

d) Monotherapy with lamotrigine was successful in most patients with partial seizures converted from adjunc double-blind trial, 156 patients who had experienced at least 4 seizures during each of 2 consecutive 4-week monotherapy were randomized to receive adjunct therapy with either valproate 1000 milligrams (mg)/day or l week period with patients then converted to monotherapy with lamotrigine or valproate over the next 4 weeks had: doubling of average monthly seizure count, doubling of highest consecutive 2-day seizure frequency, en prolongation of generalized tonic-clonic seizures. Percentage of patients failing monotherapy in the lamotrigir was 69%. A low dose of valproate was used to demonstrate the efficacy of lamotrigine and provide some pro demonstrate lamotrigine superiority or equivalence.(Gilliam et al, 1998)

e) Double-blind, placebo-controlled add-on trials demonstrated that lamotrigine is efficacious in treating refra produced a 26% or greater reduction in seizure frequency in 48% of patients and 50% or greater reduction in (n=216), observed median reductions in seizures relative to baseline were 8%, 20%, and 36% in patients rec and lamotrigine 500 mg/d, respectively (Matsuo et al, 1993b). In addition, preliminary data indicate that lamot generalized seizures (Binnie et al, 1989); (Sander et al, 1990; Pers Comm, 1993). In one trial, 15 of 19 adult reduction in seizure frequency; some patients were able to withdraw one or more anticonvulsants while maint 1992).

f) In a long-term study, 38% of 16 adult patients with refractory epilepsy had a reduction of seizure frequency year. Further follow-up indicates some decline in efficacy, since the percentage of improved patients droppec al, 1994a).

g) Ten of the 27 patients with refractory complex partial, secondarily generalized tonic clonic, atypical absen 12 months due to lack of efficacy . Patients were studied over a 2-year period with 11 of the remaining patien frequency. Only 3 patients with atypical absence and atonic seizures showed a significant response.

h) In 104 patients remaining in an 11-month, open-label study evaluating add-on lamotrigine for severe refra reduction in seizure frequency (Sander et al, 1990). Nineteen patients withdrew from the study due to advers drowsiness, and rash or due to an increase in seizure frequency (Pisani et al, 1991).

i) In a double-blind, placebo-controlled trial of add-on lamotrigine therapy, 15 of 23 adult patients with refract experienced a 50% or greater reduction in seizure frequency. The blood levels of concomitantly administered adverse effects were noted (Loiseau et al, 1990).

j) Lamotrigine is useful in controlling simple and complex partial seizures and secondarily generalized tonic c crossover trial, 21 patients refractory to multiple anticonvulsants including phenobarbital, phenytoin, primidon 100 milligrams/day (dosage adjusted to produce trough plasma concentrations of 1.5 to 2 micrograms/millilite showed improvement with lamotrigine treatment; the mean reduction in seizure frequency was 59% (confider improvement in simple and complex partial seizures; 8 of 15 showed improvement in secondarily generalizec common adverse reactions included fatigue, diplopia, drowsiness, ataxia, and headache. These were not cor

4) Pediatric:

a) Extended-release formulation is indicated as adjunctive therapy for partial onset seizures with or without s older (Prod Info LAMICTAL XR oral extended-release tablets, 2009).

b) In part of an open-label, prospective study, adjunctive lamotrigine therapy decreased the daily number of

per day (p=0.027) in patients diagnosed with intractable seizures. Enrolled infants had to have been previous
patients were diagnosed with partial seizures, 1 was diagnosed with both infantile spasms and partial seizure
spasms. In this study, one infant had no response and no infants became seizure free. Doses were based up
neonates who were taking enzyme-inducing agents, doses up to 10 milligrams per kilogram per day (mg/kg/d
months of age, who were taking enzyme-inducing agents, final doses ranged between 10 to 20 mg/kg/day. In
and enzyme inducers, were dosed between 5 to 10 mg/kg/day. In infants between 1 and 12 months of age, ta
One case of skin rash, which subsided after a day, and one case of elevated liver enzymes, which subsided
Eleven of the 15 infants had no observed adverse effects (Mikati et al, 2003).

c) In an open-label, long-term study (n=41), add-on lamotrigine therapy proved successful in 44% of study s
years of age; mean 12 years) with refractory severe partial epilepsy (mean seizure frequency 3.6/day). All en
major antiepileptic drugs. Eighteen patients (44%) remained on lamotrigine after 12 to 48 months of follow-up
occurred in 15 patients (34%) (p less than 0.00006), with 6 of these subjects remaining seizure-free. Three of
marked improvement in behavior, although seizure frequency was unchanged. Higher response rates were o
symptomatic of cerebral malformation. Seizure worsening occurred in 9 patients; transient rash developed in
starting daily dose was 0.2 to 2.5 milligrams/kilogram (mg/kg) titrated over 2 to 4 weeks to an initial maintena
subsequently adjusted based on clinical response up to a maximum of 1.8 to 15 mg/kg/day; mean dose was
valproate, median dose was 4.8 mg/kg/day; for those on enzyme-inducing drugs except valproate, median do

d) The efficacy and safety of add-on lamotrigine for treatment of partial seizures in children were demonstrat
entered an 8-week baseline phase to confirm the presence of intractable seizures with their current antiepilep
dose escalation phase and a 12-week maintenance phase. The median reductions in seizure frequency durin
were 36% and 6.7% in lamotrigine and placebo recipients, respectively (p=0.008). Secondarily generalized s
respectively (p=0.003). A decline in seizure frequency of at least 50% occurred in 42% and 16% of the lamot
0.001). Dizziness, tremor, nausea and ataxia were significantly more common with lamotrigine than with plac

4.5.X Reflex epilepsy

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Pilot data from a small case series suggest possible efficacy in startle/noise-induced reflex epilepsy (Fau

3) Adult:

a) Four adults with debilitating, refractory startle-induced seizure disorders gained relief from add-on lamotrig
eliminated "drop attacks" brought on by sudden noise, yet one patient had to discontinue lamotrigine after 10
drop attacks resumed. The other patients maintained excellent seizure control with no adverse effects noted

4.5.Y Rett's disorder

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Lamotrigine controlled seizures and modulated symptoms of Rett syndrome in 2 case reports (Kumanda

3) Pediatric:

a) Two young girls (4.5 and 2.5 years of age) diagnosed with Rett syndrome showed marked improvement o
therapy. In the 4.5-year-old girl, myoclonic seizures were present, along with microcephaly, mental retardatio
unsteadiness, hypertonia, hyperactive deep tendon reflexes, and stereotypical wringing hand movements. La
lamotrigine 3 milligrams/kilogram (mg/kg) daily. At 6 months, she was seizure-free. Hand movements and au
respiratory function was improved. The younger girl exhibited tonic-clonic seizures, hypotonia, hyperactive de
movements. Phenobarbital and valproic acid were given, but did not control the seizures. With lamotrigine 3 m
the girl became seizure-free. Her abnormal hand movements, though continuing, were appreciably decrease
pyruvate in cerebrospinal fluid (CSF) were all normal. The authors suggested that the remedial effects of lam
release (glutamate concentrations in CSF were reported to be elevated in Rett syndrome) (Kumandas et al, 2

4.5.Z Schizophrenia, Refractory

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Adjunctive lamotrigine improved positive symptoms scores but did not improve total symptom scores in a
schizophrenia (Tiihonen et al, 2003)

When added to clozapine treatment, improved psychiatric symptoms in 3 patients (Saba et al, 2002)

3) Adult:

a) In a randomized, double-blinded, placebo-controlled, crossover trial, adjunctive lamotrigine improved the p total symptom scores in patients resistant to clozapine therapy. Patients (n=34) were diagnosed with schizop with no epilepsy or current anticonvulsant or lithium therapy and who had an unsatisfactory response with clo period lasted 14 weeks and started with a 1-week placebo lead-in. Lamotrigine was initiated at 25 milligrams/ followed by 100 mg/d for 2 weeks, 150 mg/d for 2 weeks and then 200 mg/d for 4 weeks. Doses were then ta Negative Syndrome Scale (PANSS) scores changed from 68.55 to 64.31 in the lamotrigine arm and from 69. analysis). PANSS negative symptoms scores changed from 19.97 to 18.69 in the lamotrigine arm and 19.8 tc However, PANSS positive symptom scores improved from 17.24 to 16.24 the lamotrigine arm compared to a intent to treat) and general psychopathological symptoms scores changed from 31.34 to 29.38 in the lamotrig (p=0.03, intent to treat) (Tiihonen et al, 2003).

b) In 3 patients who had responded poorly to 6 months of treatment with clozapine, addition of lamotrigine fo and 28% decrease in BPRS (Brief Psychiatric Rating Scale) scores). Patient 1: clozapine dosage 700 mg/day 50 mg/day), 43 on day 56 (lamotrigine 100 mg/day), 30 on day 84 (lamotrigine 150 mg/day). His degree of im hospitalization. Steady-state concentrations of clozapine, norclozapine, and lamotrigine in plasma were 235 r micrograms/mL (mcg/mL), respectively, on day 83. Patient 2: clozapine 500 mg/day. BPRS score 66 on day (with lamotrigine dose increasing to 75 mg/day. Steady state plasma concentrations for clozapine, norclozapir 0.57 mcg/mL, respectively, at day 56. Patient 3: clozapine dosage 700 mg/day. BPRS score 43 on day 0, 35 (lamotrigine 75 mg/day), and 31 on day 84 (lamotrigine 200 mg/day). Steady-state concentrations of clozapin ng/mL, 420 ng/mL, and 1.28 mcg/mL, respectively, on day 85. No marked side effects, rash, or hematologica 2002).

4.5.AA Sexual dysfunction

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

In three case reports, substitution of lamotrigine for gabapentin resolved impotence in men with epilepsy

3) Adult:

a) Three men who developed impotence while being treated with multiple anticonvulsants for long-standing e on lamotrigine. In each case, lamotrigine was initiated and escalated while gabapentin was tapered and witho frequency in these individuals (Husain et al, 2000).

4.5.AB Shortlasting, unilateral, neuralgiform pain with conjunctival injection and tearing syndrome

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Lamotrigine appeared to be curative in case reports of SUNCT syndrome (short-lasting unilateral neuralg tearing syndrome) (Malik et al, 2002)

3) Adult:

a) Symptoms of SUNCT syndrome resolved following lamotrigine treatment in one female patient. An 80-yea pain with episodes occurring every 15 to 20 minutes failed to respond to treatment with carbamazepine, gaba hydrocodone/acetaminophen. Lamotrigine therapy was initiated at 25 milligrams (mg)/day for 1 week and titra The intensity of her attacks shrunk by half within 1 week of beginning lamotrigine. Her episodes were comple year of follow-up (Malik et al, 2002).

b) A 66-year-old female with SUNCT SYNDROME of 6 months duration with recent worsening (up to 15 atta therapy. SUNCT syndrome was resistant to aspirin and other nonsteroidal agents and carbamazepine. After sudden exacerbation of attacks occurred, which then abated completely following lamotrigine dose escalation 3-month course of therapy, with no further episodes through 15 months of follow-up (D'Andrea et al, 1999).

4.5.AC Status epilepticus

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Successful control of status epilepticus has been reported in one case refractory to intravenous diazepar More data are needed to ascertain the role of lamotrigine in the therapy of status epilepticus (Pisani et al

3) Pediatric:

a) Lamotrigine may be an important adjunct to other drugs in the treatment of status epilepticus. In one case carbamazepine 1200 milligrams/day (mg) and phenobarbital 200 mg/day experienced an unexplained increas generalized convulsive status epilepticus refractory to multiple boluses and continuous infusion of diazepam. followed by 200 mg twice a day, with prompt resolution of status epilepticus and a resulting decrease in seizu discharged on lamotrigine, phenobarbital 100 mg twice a day, and carbamazepine 400 mg 3 times a day (Pis

4.5.AD Tinnitus

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Lamotrigine's effects on chronic tinnitus were equivocal in a placebo-controlled, crossover trial (Simpson

3) Adult:

a) Lamotrigine did not clearly demonstrate efficacy in ameliorating chronic tinnitus in a randomized, double-b patient received lamotrigine in an escalating regimen (25 to 100 milligrams/day) and placebo in two different Patients assessed the loudness, annoyance and awareness of tinnitus on visual analog scales (VAS) at base observed between lamotrigine and placebo in terms of VAS scores or audiometry. According to patient quest (35%) and 6 (19%) patients while on lamotrigine and placebo, respectively. The majority reported "no change correlate with response to lamotrigine (Simpson et al, 1999).

4.5.AE Tonic-clonic seizure, Primary generalized; Adjunct

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes; Pediatric, yes (2 years and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Indicated as adjunctive therapy for primary generalized tonic-clonic seizures in adults and pediatric patie chewable dispersible oral tablets, oral tablets, orally disintegrating tablets, 2009)

The efficacy of lamotrigine as adjunctive therapy for primary generalized tonic-clonic seizures was demo involving 117 adult and pediatric patients (Prod Info LAMICTAL chewable dispersible oral tablets, oral ta

3) Adult:

a) The efficacy of lamotrigine as adjunctive therapy for primary generalized tonic-clonic seizures was demon involving 117 adult and pediatric (at least 2 years of age) patients. The study included an 8-week baseline ph generalized tonic-clonic seizures during the baseline phase were randomized to oral lamotrigine therapy (n=5 their existing antiepileptic drug (AED) regimen of up to 2 drugs. The adult target dose of lamotrigine ranged fr concomitant antiepileptic therapy. Efficacy was based on the percent change from baseline in primary genera primary generalized tonic-clonic seizures in the intent-to-treat population, which included both adult and pedia lamotrigine and placebo, respectively (p=0.006) (Prod Info LAMICTAL chewable dispersible oral tablets, oral

4) Pediatric:

a) The efficacy of lamotrigine as adjunctive therapy for primary generalized tonic-clonic (PGTC) seizures was trial involving a total of 117 adult and pediatric (aged 2 to 19 years; mean age, 11 years) patients with PGTC drugs (AED). The study included an 8-week baseline phase after which patients who had at least 3 primary g phase were randomized. The pediatric subgroup was randomized to oral lamotrigine therapy (n=21) or placel study consisted of an escalation phase (12 weeks for patients 2 to 12 years and 7 weeks for patients greater with a pediatric target dose of lamotrigine ranging from 3 milligrams/kilogram/day (mg/kg/day) to 12 mg/kg/da The most common concomitant antiepileptic drug was valproate which was used in 67% of the lamotrigine gr reduction in PGTC seizures from baseline (primary efficacy measure) was 77% and 40% in patients receiving median percent decrease in PGTC seizures during the escalation phase was 72% and 30% in the lamotrigine decrease during the maintenance phase was 83% and 42%, respectively (p=0.058). The overall median PGT group and 2.5 in the placebo group (p=0.007) (Trevathan et al, 2006; Prod Info LAMICTAL chewable dispers 2009).

4.5.AF Trigeminal neuralgia

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective for essential and symptomatic trigeminal neuralgia (Zakrzewska et al, 1997; Lunardi et al, 1997

3) Adult:

a) Lamotrigine demonstrated antineuralgic properties in 13 patients with trigeminal neuralgia . In a double-bli compared to placebo in patients receiving steady doses of carbamazepine or phenytoin. Each drug was give therapies. Lamotrigine was superior to placebo (p less than 0.011) on a composite efficacy index score which scores, and global evaluations. Interestingly, during the second phase of the trial, those receiving placebo aft improvement observed during lamotrigine therapy. The authors speculated that lamotrigine may have produc drug, or this could have occurred randomly since there were relatively small patient numbers. More studies a (Zakrzewska et al, 1997).

b) In an open, prospective trial, lamotrigine showed impressive results in the treatment of 20 patients with tri to 75 years old) with an "essential" form of trigeminal neuralgia while the second group consisted of 5 patient associated with multiple sclerosis. In the first group, 11 patients had a complete remission with 1 patient attai with 150 to 250 mg/day and 2 patients requiring 400 mg/day. Four patients continued to have pain at the 400 group had full relief of pain with lamotrigine 150 to 200 mg/day. Patients with relief continued to be pain-free a

4.5.AG West syndrome

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Spasms resolved in three infants following treatment with low-dose lamotrigine (Cianchetti et al, 2002).

3) Pediatric:

a) Symptoms of West syndrome in three infants resolved following treatment with low-dose lamotrigine. Spas following the initiation of lamotrigine therapy (1.25 milligrams (mg) one to three times daily) after unsuccessfu ACTH). The infants remained seizure-free at maintenance doses of lamotrigine 1.25 mg/day to 2.5 mg twice

4.6 Comparative Efficacy / Evaluation With Other Therapies

Carbamazepine

Gabapentin

Lithium

Topiramate

4.6.A Carbamazepine

4.6.A.1 Seizure

a) Carbamazepine and lamotrigine are equally effective as monotherapy in patients with newly diagnosed ep randomly assigned to a fixed dosage titration of either carbamazepine or lamotrigine. After four weeks, all pa lamotrigine or 600 mg/day of carbamazepine; for the next 24 weeks, doses were adjusted according to effica patients who were seizure-free for the last 6 months of the study were 39% and 38% for lamotrigine and carb was better tolerated, and more patients were able to complete the study period than patients treated with carb common with carbamazepine than lamotrigine (22% versus 12%, respectively) (Brodie et al, 1995).

b) As initial monotherapy in elderly patients newly diagnosed with epilepsy, lamotrigine demonstrated a supe carbamazepine. Subjects (n=150) were randomized in a double-blinded 2:1 ratio to lamotrigine 25 milligrams medications were titrated slowly upward over 6 weeks to 50 mg twice daily and 200 mg twice daily, respectiv duration. The median doses of lamotrigine and carbamazepine in study completers were 100 mg/day and 40 concentrations at week 24 were 2.3 mg/liter (L) and 6.9 mg/L, respectively. Somnolence (29% versus 12%) a often in the carbamazepine versus lamotrigine groups, respectively. The corresponding withdrawal rates wer 42% and 18% of discontinuations, respectively. The hazard ratio for withdrawal with carbamazepine compare to 4). Efficacy measures were considered secondary endpoints in this trial. While no between-group differenc significantly more lamotrigine recipients remained seizure-free over the last 16 weeks of the study (39% vers

4.6.B Gabapentin

4.6.B.1 Mood disorder

a) Preliminary results from a cross-over study (randomized, double- blinded) suggest that LAMOTRIGINE m the improvement of refractory mood disorders (n=31) (Frye et al, 2000). Study subjects included bipolar I (11 23 were rapid-cycling); all had tried other mood stabilizing agents previously. Percentages of those who had for gabapentin, and 23% for placebo based on the Clinical Global Impression (CGI) scale modified for bipolar

responders were defined as those who were much or very much improved on the CGI scale. Both agents we
developed a rash caused by lamotrigine; the rash progressed to toxic epidermal necrolysis, requiring treatme
trend showed that subjects tended to lose weight on lamotrigine relative to the weight gained on gabapentin.
(mg) daily in week 1, titrated to 50 mg/day in week 2, 50 to 100 mg/day in week 3, 150 to 300 mg for weeks 4
was given at an initial daily dose of 900 mg, titrated to 1500 mg by the end of week 1, 2700 mg by the end of
and 4800 mg by week 5 to 6. Mean daily doses as of week 6 were 274 mg for lamotrigine and 3987 mg for ga

DRUGDEX® Evaluations

ESCITALOPRAM

0.0 Overview

1) Class
- **a)** This drug is a member of the following class(es):
  Antianxiety
  Antidepressant
  Serotonin Reuptake Inhibitor

2) Dosing Information
- **a)** Escitalopram Oxalate
  - **1)** Adult
    - **a)** Generalized anxiety disorder
      1) initial, 10 mg/day ORALLY as a single dose in the morning or ev
      Info LEXAPRO(R) Oral solution, Oral tablets, 2009)
      2) maintenance, 10 mg/day ORALLY, may increase to 20 mg/day (
      after a minimum of one week (Prod Info LEXAPRO(R) Oral solution
      2009)
    - **b)** Major depressive disorder
      1) initial, 10 mg/day ORALLY as a single dose in the morning or ev
      Info LEXAPRO(R) Oral solution, Oral tablets, 2009)
      2) maintenance, 10 mg/day ORALLY, may increase to 20 mg/day (
      after a minimum of one week (Prod Info LEXAPRO(R) Oral solution
      2009)
  - **2)** Pediatric
    a) safety and effectiveness in children for the acute treatment of genera
    disorder have not been established (Prod Info LEXAPRO(R) Oral solutic
    tablets, 2009)
    b) safety and effectiveness in children under the age of 12 years for the
    maintenance treatment of major depressive disorder have not been esta
    Info LEXAPRO(R) Oral solution, Oral tablets, 2009)
    - **1)** Major depressive disorder
      a) age 12 years and older: initial, 10 mg/day ORALLY as a sin
      morning or evening (Prod Info LEXAPRO(R) Oral solution, Oral
      2009)
      b) age 12 years and older: maintenance, 10 mg/day ORALLY,
      to 20 mg/day ORALLY only after a minimum of 3 weeks (Prod I
      LEXAPRO(R) Oral solution, Oral tablets, 2009)

3) Contraindications
- **a)** Escitalopram Oxalate
  1) concomitant use of pimozide or monoamine oxidase inhibitors (MAOIs) (F
  Lexapro(R) oral tablets, solution, 2009)
  2) hypersensitivity to citalopram, escitalopram, or any other component of th
  (Prod Info Lexapro(R) oral tablets, solution, 2009)

4) Serious Adverse Effects
- **a)** Escitalopram Oxalate
  1) Depression, worsening
  2) Diabetes mellitus
  3) Grand mal seizure
  4) Heart failure
  5) Myocardial infarction
  6) Neuroleptic malignant syndrome
  7) Pancreatitis

8) Prolonged QT interval
9) Rectal hemorrhage
10) Serotonin syndrome
11) Suicidal thoughts
12) Suicide
13) Syndrome of inappropriate antidiuretic hormone secretion
14) Torsades de pointes

5) Clinical Applications
a) Escitalopram Oxalate
1) FDA Approved Indications
a) Generalized anxiety disorder
b) Major depressive disorder

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referri
Tradename List (Product Index)
B) Synonyms
Escitalopram
Escitalopram Oxalate
C) Physicochemical Properties
1) Molecular Weight
a) 414.40 (Prod Info Lexapro™, 2002a)
2) Solubility
a) Systemic: Escitalopram is freely soluble in methanol and dimethylsulf
(DMSO), sparingly soluble in water and in ethanol, slightly soluble in eth
and insoluble in heptane.(Prod Info Lexapro™, 2002a)

1.2 Storage and Stability

A) Escitalopram Oxalate
1) Preparation
a) Oral route
1) Allow at least 14 days between the discontinuation of an MAOI a
escitalopram or the discontinuation of escitalopram and initiation of
MAO inhibitors (Prod Info LEXAPRO(R) Oral solution, Oral tablets,
2) Administer without regard to meals (Prod Info LEXAPRO(R) Ora
tablets, 2009).
B) Oral route
1) Tablets should be stored at 77 degrees Fahrenheit (25 degrees Celsius);
permitted to 59 to 86 degrees Fahrenheit (15 to 30 degrees Celsius)(Prod In
(TM), 2002g).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Geriatric Patients

Dosage in Other Disease States

1.3.1 Normal Dosage

1.3.1.A Escitalopram Oxalate

1.3.1.A.1 Oral route

Generalized anxiety disorder

Major depressive disorder

1.3.1.A.1.a Generalized anxiety disorder

1) The initial recommended dose in the acute treatment of gen
anxiety disorder in adults is escitalopram 10 milligrams (mg) or
(morning or evening). After one week, the dose may be increas
orally once daily. The efficacy of escitalopram in the treatment
anxiety disorder for longer than 8 weeks has not been establish
on long-term treatment should be reevaluated periodically to de
long term usefulness of escitalopram (Prod Info LEXAPRO(R)
Oral tablets, 2009).

1.3.1.A.1.b Major depressive disorder

1) The initial recommended dose in the acute and maintenanc
major depressive disorder in adults is escitalopram 10 milligram
once daily (morning or evening). After one week the dose may
to 20 mg once daily; however, there were no statistically signific
improvements in efficacy at the higher dose, and higher rates o
effects were reported (Prod Info LEXAPRO(R) Oral solution, O
2009; Wade et al, 2002; Gorman, 2001a).

1.3.1.A.2 Switching To Or From a Monoamine Oxidase Inhibitor

a) Because of a potential interaction, at least 14 days should elaps
discontinuation of a monoamine oxidase inhibitor (MAOI) and the in
escitalopram therapy or between the cessation of escitalopram and
of MAOI therapy (Prod Info LEXAPRO(R) Oral solution, Oral tablets

1.3.2 Dosage in Renal Failure

A) Escitalopram Oxalate

1) In patients with mild to moderate renal impairment, there is no dose a
recommended. Caution should be used in patients with severe renal imp
Info LEXAPRO(R) Oral solution, Oral tablets, 2009).

1.3.3 Dosage in Hepatic Insufficiency

A) Escitalopram Oxalate

1) Escitalopram is extensively metabolized in the liver. The recommend
patients with hepatic impairment is 10 milligrams (mg) orally once daily (
LEXAPRO(R) Oral solution, Oral tablets, 2009).

1.3.4 Dosage in Geriatric Patients

A) Escitalopram Oxalate

1) In pharmacokinetic studies, escitalopram half-life was increased by a
50% in elderly patients as compared with young patients. The recomme
elderly patients is 10 milligrams (mg) of escitalopram once daily (Prod In
(R) Oral solution, Oral tablets, 2009).

1.3.6 Dosage in Other Disease States

A) Escitalopram Oxalate

1) Discontinuation of Treatment

a) Patients should be monitored for withdrawal symptoms when dis
escitalopram treatment and a gradual tapering of the dose, rather th
discontinuation, is recommended whenever possible. If intolerable s
occur after a dose reduction or upon cessation of treatment, the pre
prescribed dose may be reinstated and then the dose may be reduc
gradual rate (Prod Info LEXAPRO(R) Oral solution, Oral tablets, 20

2) Pregnancy

a) Neonates exposed to escitalopram and other selective serotonin

inhibitors (SSRI) or selective noradrenaline reuptake inhibitors (SNR
third trimester have developed complications requiring prolonged ho
tube feeding, and respiratory support. The potential risks and benef
carefully considered when treating pregnant women with escitalopra
third trimester. Tapering escitalopram in the third trimester may be c
(Prod Info LEXAPRO(R) Oral solution, Oral tablets, 2009).

1.4 Pediatric Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Other Disease States

1.4.1 Normal Dosage

1.4.1.A Escitalopram Oxalate

1.4.1.A.1 Oral route

1.4.1.A.1.a Major depressive disorder

1) The initial recommended dose in the acute and maintenanc
major depressive disorder in adolescents age 12 years and old
escitalopram 10 milligrams (mg) orally once daily (morning or e
3 weeks the dose may be increased to 20 mg once daily; howe
were no statistically significant improvements in efficacy at the
and higher rates of adverse effects were reported (Prod Info LE
Oral solution, Oral tablets, 2009).

2) The safety and effectiveness in children for the acute treatment of ge
anxiety disorder have not been established (Prod Info LEXAPRO(R) Ora
Oral tablets, 2009).

3) The safety and effectiveness in children under the age of 12 years fo
and maintenance treatment of major depressive disorder have not been
(Prod Info LEXAPRO(R) Oral solution, Oral tablets, 2009).

1.4.2 Dosage in Renal Failure

A) Escitalopram Oxalate

1) In patients with mild to moderate renal impairment, there is no dose a
recommended. Caution should be used in patients with severe renal imp
Info LEXAPRO(R) Oral solution, Oral tablets, 2009).

1.4.3 Dosage in Hepatic Insufficiency

A) Escitalopram Oxalate

1) Escitalopram is extensively metabolized in the liver. The recommend
patients with hepatic impairment is 10 milligrams (mg) orally once daily (
LEXAPRO(R) Oral solution, Oral tablets, 2009).

1.4.5 Dosage in Other Disease States

A) Escitalopram Oxalate

1) Discontinuation of Treatment

a) Patients should be monitored for withdrawal symptoms when dis
escitalopram treatment and a gradual tapering of the dose, rather th
discontinuation, is recommended whenever possible. If intolerable s
occur after a dose reduction or upon cessation of treatment, the pre
prescribed dose may be reinstated and then the dose may be reduc
gradual rate (Prod Info LEXAPRO(R) Oral solution, Oral tablets, 20

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Initial Response

a) DEPRESSION, ORAL: 1 to 2 weeks (Montgomery et al, 2001; Wade Burke, 2001a).

1) Indicates time to a significant antidepressant effect compared to doses of 10 or 20 mg daily.

b) ANXIETY IN DEPRESSION, ORAL: 1 week (Lydiard, 2001b).

2.2 Drug Concentration Levels

A) Therapeutic Drug Concentration

1) Not established.

B) Time to Peak Concentration

1) ORAL, TABLET: 3 to 6 hours (single 20-mg dose) (Prod Info Lexapro(TM Drewes et al, 2001; Gutierrez et al, 2001).

a) In healthy subjects, a mean peak plasma level of 18.8 ng/mL was ob hours after single oral doses of escitalopram 20 mg in healthy subjects. its major metabolite, S(+)-desmethylcitalopram, occurred in 14 hours (m ng/mL) (Drewes et al, 2001). After 40-mg oral doses of racemic citalopra study, nearly identical peak levels and times to peak levels of escitalopra in 3.2 hours) and S(+)-desmethylcitalopram (3.5 ng/mL in 14.2 hours) w other pharmacokinetic parameters were also very similar (eg, AUC, half- excretion). These data collectively suggest that 20 mg escitalopram is bi 40 mg citalopram with respect to escitalopram and S(+)-desmethylcitalo

b) Duration: Following single oral doses of escitalopram 20 mg, plasma fallen from a peak of about 19 ng/mL to approximately 1 ng/mL at 120 h et al, 2001).

C) Area Under the Curve

1) 600 to 635 hr x ng/mL (20-mg single dose) (Drewes et al, 2001); (Gutierre

a) AUC (infinity) values for both escitalopram and S(+)-desmethylcitalop similar after oral doses of escitalopram 20 mg and citalopram 40 mg in c S(+)-desmethylcitalopram specifically, the mean AUC was approximatel ng/mL after 20 mg escitalopram (Drewes et al, 2001).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Bioavailability

1) ORAL, TABLET: 80% for citalopram; no data available for escitalopra Lexapro(TM), 2002h)

a) Escitalopram 20 mg and citalopram 40 mg appear bioequivalent escitalopram and S(+)-desmethylcitalopram (peak plasma levels ac to peak levels, other pharmacokinetic parameters) (Drewes et al, 20

B) Effects of Food

1) None (Prod Info Lexapro(TM), 2002h)

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding
a) 56% (Prod Info Lexapro(TM), 2002h).
B) Distribution Kinetics
1) Volume of Distribution
a) approximately 1330 L (single 20-mg oral dose) (Drewes et al, 20
1) Similar to the value for escitalopram after 40 mg of oral cital (Drewes et al, 2001).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics
1) LIVER, extensive (Prod Info Lexapro(TM), 2002h; Greenblatt et al, 2(Moltke et al, 2001; Greenblatt et al, 2000); (Gutierrez et al, 2001).
a) Escitalopram (S(+)-citalopram) is metabolized to S(+)-desmethyl which is mediated by cytochrome P450 isozymes 2D6, 2C19, and 3 metabolism of S(+)-desmethylcitalopram to S(+)-didesmethylcitalop via cytochrome P450-2D6 (von Moltke et al, 2001; Greenblatt et al, Greenblatt et al, 2000).
b) Studies with human liver microsomes (Greenblatt et al, 2001) ha that escitalopram and S(+)-desmethylcitalopram are only weak or n inhibitors of cytochrome P450 isozymes 1A2, 2C19, 2C9, 2D6, 2E1 (+)-Didesmethylcitalopram was also only a weak inhibitor of 1A2, 2D 3A, although moderate inhibition of the 2C9 and 2C19 isozymes wa with this metabolite; these latter effects do not appear clinically relev the low plasma levels of S(+)-didesmethylcitalopram observed after escitalopram.
c) There is no apparent in vivo interconversion from S-enantiomers enantiomers following oral doses of escitalopram (Drewes et al, 200
B) Metabolites
1) S(+)-Desmethylcitalopram (active in vitro) (von Moltke et al, 2001).
a) Major metabolite; 7 times less potent than escitalopram. Despite evidence of serotonin reuptake inhibition, the contribution of this me clinical activity of escitalopram is considered minimal (Prod Info Lex 2002h).
2) S(+)-Didesmethylcitalopram (active in vitro) (Greenblatt et al, 2001).
a) Twenty-seven times less potent than escitalopram. Despite evid serotonin reuptake inhibition, the contribution of this metabolite to th activity of escitalopram is doubtful as it is present in very low concer plasma (Prod Info Lexapro(TM), 2002h).

2.3.4 Excretion

A) Kidney
1) Renal Clearance (rate)
a) 2.7 L/hr (single 20-mg oral dose) (Drewes et al, 2001).
1) Similar to the value for escitalopram after oral citalopram 40
2) For S(+)-desmethylcitalopram, a value of 6.9 L/hr was repor mg oral escitalopram (Drewes et al, 2001); this was similar to th (+)-desmethylcitalopram after oral citalopram 40 mg.
2) Renal Excretion (%)
a) 8% unchanged (single 20-mg oral dose) (Drewes et al, 2001).
1) Identical to the escitalopram value observed after oral doses 40 mg.
2) Approximately 10% of an oral dose of escitalopram 20 mg is S(+)-desmethylcitalopram (Drewes et al, 2001). This is similar t S(+)-desmethylcitalopram excretion after oral citalopram 40 mg
B) Total Body Clearance
1) 600 mL/min (Prod Info Lexapro(TM), 2002h).
a) Similar to the value for escitalopram clearance after oral doses c 40 mg (Drewes et al, 2001).

2.3.5 Elimination Half-life

A) Parent Compound
1) ELIMINATION HALF-LIFE
a) 22 to 32 hours (single 20-mg oral dose) (Prod Info Lexapro(TM), (Gutierrez et al, 2001)(Drewes et al, 2001).
1) Escitalopram half-life is increased by approximately 50% in patients as compared with young patients. (Prod Info Lexapro(T
2) Similar to the value for escitalopram after oral citalopram 40

et al, 2001).

B) Metabolites

1) S(+)-Desmethylcitalopram, 59 hours (Drewes et al, 2001).

a) Represents value after 20 mg oral escitalopram.

b) This value is similar to that observed for the metabolite following citalopram 40 mg (Drewes et al, 2001).

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING

1) Escitalopram Oxalate

a) Oral (Tablet; Solution)

Suicidality and Antidepressant Drugs

Antidepressants increased the risk compared to placebo of suicidal think behavior (suicidality) in children, adolescents, and young adults in short- of major depressive disorder (MDD) and other psychiatric disorders. Any considering the use of escitalopram oxalate or any other antidepressant adolescent, or young adult must balance this risk with the clinical need. studies did not show an increase in the risk of suicidality with antidepres compared to placebo in adults beyond age 24; there was a reduction in antidepressants compared to placebo in adults aged 65 and older. Depr certain other psychiatric disorders are themselves associated with increa of suicide. Patients of all ages who are started on antidepressant therap monitored appropriately and observed closely for clinical worsening, suic unusual changes in behavior. Families and caregivers should be advise for close observation and communication with the prescriber. Escitalopra not approved for use in pediatric patients (Prod Info Lexapro(R) oral tabl 2009).

3.1 Contraindications

A) Escitalopram Oxalate

1) concomitant use of pimozide or monoamine oxidase inhibitors (MAOIs) (P Lexapro(R) oral tablets, solution, 2009)

2) hypersensitivity to citalopram, escitalopram, or any other component of th (Prod Info Lexapro(R) oral tablets, solution, 2009)

3.2 Precautions

A) Escitalopram Oxalate

1) suicidal ideation and behavior or worsening depression; increased risk, pa children, adolescents, and young adults, during the first few months of therap changes in dosage (Prod Info Lexapro(R) oral tablets, solution, 2009)

2) abnormal bleeding has been reported, including life-threatening hemorrha Info Lexapro(R) oral tablets, solution, 2009)

3) abrupt withdrawal; serious discontinuation symptoms have been reported Lexapro(R) oral tablets, solution, 2009)

4) bipolar disorder; increased risk of precipitation of a mixed/manic episode Lexapro(R) oral tablets, solution, 2009)

5) concomitant use of NSAIDs, aspirin, or other drugs that affect coagulation bleeding, particularly the gastrointestinal tract, may occur (Prod Info Lexapro tablets, solution, 2009)

6) concomitant serotonergic drug use (serotonin precursors (tryptophan), SS serotonin-norepinephrine reuptake inhibitors); monitoring recommended duri escitalopram initiation and discontinuation (Prod Info Lexapro(R) oral tablets, 2009)

7) diseases or conditions that produce altered metabolism or hemodynamic

(Prod Info Lexapro(R) oral tablets, solution, 2009)
8) hepatic impairment; reduced drug clearance; lower or less frequent dose required (Prod Info Lexapro(R) oral tablets, solution, 2009)
9) mania history; risk of activation of mania/hypomania (Prod Info Lexapro(F solution, 2009)
10) seizure disorder, history (Prod Info Lexapro(R) oral tablets, solution, 200
11) serotonin syndrome has been reported, including cases that are life-thre that resemble neuroleptic malignant syndrome; monitoring recommended (Pr Lexapro(R) oral tablets, solution, 2009)
12) use of escitalopram within 14 days of MAOI discontinuation (Prod Info L tablets, solution, 2009)
13) use of MAOIs within 14 days after escitalopram discontinuation (Prod Int oral tablets, solution, 2009)
14) volume-depleted, elderly, or concurrent diuretic therapy; hyponatremia, s inappropriate antidiuretic hormone secretion (SIADH) has occurred; discontir symptoms develop (Prod Info Lexapro(R) oral tablets, solution, 2009)

3.3.1 Cardiovascular Effects

3.3.1.A Escitalopram Oxalate

Bradyarrhythmia

Heart failure

Hypertension

INR raised

Myocardial infarction

Palpitations

Prolonged QT interval

Sudden cardiac death

Torsades de pointes

3.3.1.A.1 Bradyarrhythmia

a) Incidence: 1% or less (Prod Info LEXAPRO(R), 2008)

b) No significant effects on blood pressure, heart rate, or the ECG v observed with therapeutic doses in studies monitoring these parame Info LEXAPRO(R), 2008; Burke, 2001; Burke, 2000).

c) A 60-year-old post-stroke female experienced severe bradycardi consciousness and respiratory failure within 45 minutes of escitalop Upon admission to the stroke unit 3 days prior, neurological examin a left brachiofacial hemiparesis and ECG was normal. Acute ischem the right temporo-insular cortex was confirmed by MRI, while dopple ultrasonography and cerebral angiography revealed 90% stenosis o internal carotid artery and complete occlusion of the right internal ca Because she had a history of depression (untreated at the time) tha after her stroke, she was treated with escitalopram. The episode of (20-30 beats/min) was successfully treated and the patient survived retrospectively remembered experiencing dizziness and fainting foll of citalopram 20 mg several years prior. The exact cause of the life- bradycardia is unclear, but stroke involving the insular cortex has be to induce ECG abnormalities, increasing the risk for cardiac abnorm death (Beyenburg & Schonegger, 2007).

3.3.1.A.2 Heart failure

a) Cardiac failure has been reported in postmarketing spontaneous trials (Prod Info LEXAPRO(R), 2008).

3.3.1.A.3 Hypertension

a) Incidence: 1% (Prod Info LEXAPRO(R), 2008)

b) Hypertension has been reported in at least 1% of patients follow escitalopram treatment (Prod Info LEXAPRO(R), 2008).

c) No significant effects on blood pressure, heart rate, or the ECG v with therapeutic doses in studies monitoring these parameters (Proc LEXAPRO(R), 2008; Burke, 2001; Burke, 2000).

3.3.1.A.4 INR raised

a) Increased INR has been reported in postmarketing spontaneous trials (Prod Info LEXAPRO(R), 2008).

3.3.1.A.5 Myocardial infarction

a) Myocardial infarction has been reported in postmarketing sponta clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.1.A.6 Palpitations

a) Incidence: 1% (Prod Info LEXAPRO(R), 2008)

b) Palpitations have been reported in at least 1% of patients followi escitalopram treatment (Prod Info LEXAPRO(R), 2008).

c) No significant effects on blood pressure, heart rate, or the ECG v with therapeutic doses in studies monitoring these parameters (Proc LEXAPRO(R), 2008; Burke, 2001; Burke, 2000).

3.3.1.A.7 Prolonged QT interval

a) Electrocardiogram QT prolongation has been reported in postma spontaneous and clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.1.A.8 Sudden cardiac death

a) In a large cohort study including 481,744 persons and 1487 case cardiac death occurring in a community setting, the use of selective reuptake inhibitors was not associated with an increased risk of sud death (rate ratio, 0.95; 95% CI, 0.42 to 2.15). In contrast, users of tr antidepressants in doses of 100 mg or higher (amitriptyline or its eq a 41% increased rate of sudden cardiac death (rate ratio, 1.41; 95% 1.95) (Ray et al, 2004).

3.3.1.A.9 Torsades de pointes

a) Torsades de pointes has been reported in postmarketing sponta clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.2 Dermatologic Effects

3.3.2.A Escitalopram Oxalate

Diaphoresis

Erythroderma

Rash

3.3.2.A.1 Diaphoresis

a) Incidence: 4% to 5% (Prod Info Lexapro(R) oral tablets, solution,
b) Increased sweating was observed in 4% to 5% of patients during treatment compared with 1% to 2% in matched placebo groups (Pro Lexapro(R) oral tablets, solution, 2009; Montgomery et al, 2001a).

3.3.2.A.2 Erythroderma

a) A 49-year-old female reported a case of photo-induced erythrode escitalopram therapy. The patient was initiated on escitalopram 10 r reactive depression. She was exposed to UV rays for 15 minutes in tanning bed about 4 hours following her first dose. Thirty-six hours l developed a skin rash which covered her face and body. Escitalopra discontinued 5 days later. Examination revealed diffuse erythema, c sparing only medallion, and string. Skin biopsy results revealed sing necrosis of keratinocytes with mild infiltrate of lymphocytes in the su dermis. Immunological evaluation was unremarkable. Photo-induce erythroderma was diagnosed and a regimen of betamethasone dipr 0.05% was initiated. The rash resolved within 3 weeks but with cont pigmentation (Ram-Wolf et al, 2008).

3.3.2.A.3 Rash

a) Incidence: at least 1% (Prod Info Lexapro(R) oral tablets, solutio
b) Rash has been reported in at least 1% of patients treated with es (Prod Info Lexapro(R) oral tablets, solution, 2009; Montgomery et al

3.3.3 Endocrine/Metabolic Effects

3.3.3.A Escitalopram Oxalate

Diabetes mellitus

Hyponatremia

Syndrome of inappropriate antidiuretic hormone secretion

Weight increased

3.3.3.A.1 Diabetes mellitus

a) Diabetes mellitus has been reported in postmarketing spontaneo

clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.3.A.2 Hyponatremia

a) Individual case reports have described development of hyponatr initiation of escitalopram therapy (Grover et al, 2007; Nirmalani et al Nahshoni et al, 2004). The incidence of hyponatremia associated w SSRI therapy ranges between 0.5% to 25%. Risk factors for the dev hyponatremia include older age, female gender, low body weight, hi SSRI, and concomitant use of diuretics, antipsychotics, narcotics, a hypoglycemic agents. Routine monitoring of electrolyte levels espec elderly during the first 2 to 4 weeks of therapy may be warranted (G 2007).

b) A case report described development of hyponatremia following therapy in a 67-year-old female. The patient, who had a history of h diabetes mellitus, and late-onset bipolar affective disorder, had pres acute-onset, severe depression without psychotic symptoms of 4 m duration. Escitalopram was initiated at 10 mg/day and after 3 weeks escalated to 15 mg/day. The patient had normal electrolyte levels pr of escitalopram, and concomitant drug therapy included sodium valp hydrochlorothiazide, gliclazide, aspirin, losartan, and metoprolol. Wi of the escalated escitalopram dose, the patient became delirious, ar to have serum sodium levels of 127 mEq/L and increased urine sod concentration 160 mmol/L. Following discontinuation of escitaloprar thiazides, and provision of supportive therapy, the patient level and consciousness gradually improved (Grover et al, 2007).

c) Hyponatremia occurred in a 65-year-old male patient subsequer of escitalopram. The patient, who had a history of generalized anxie and hypertension was initiated on escitalopram 10 mg/day after he p anxiety symptoms. Concurrent medications included amlodipine and Within 10 days of initiating escitalopram, the patient experienced on generalized tonic-clonic seizures and was found to have a serum so 126 mEq/L. Following discontinuation of escitalopram and provision care, the patient gradually improved over the next 2 weeks (Grover

d) A 50-year-old black male experienced the syndrome of inapprop antidiuretic hormone (SIADH) within 4 weeks of initiating escitalopra depression. Upon admission to the hospital, he was on no other me physical exam was normal, and all diagnostic tests for acute illness Serum sodium was within the normal range at 138 mmol/L. Escitalo at bedtime and olanzapine 10 mg at bedtime were begun on hospita the doses increased over the next 3 weeks. The patient was taking escitalopram by day 13. Due to lack of efficacy, olanzapine was disc day 23, and risperidone 2 mg/day was initiated. Over the next week patient's depression improved, but by day 28, he complained of wea dizziness, and appeared diaphoretic. The results of a complete mec were unremarkable except for serum sodium of 121 mmol/L, serum mmol/L, and serum osmolality of 254 mOsm/kg (normal 275-300 m Urine osmolality was 617 mOsm/kg (normal 50-1,200 mOsm/kg) an sodium was 115 mmol/L. Following a diagnosis of SIADH, the patie on fluid restriction. Escitalopram 20 mg/day and risperidone 2 mg/da continued. By day 32 the patient's sodium rose to 130 mmol/L, but b had again decreased to 124 mmol/L. The escitalopram was then dis and the patient improved by day 39. Sodium returned to normal at 1 day 41. Depression was successfully treated with mirtazapine 30 m risperidone 2 mg/day and the patient was discharged on day 46 (Ni 2006).

e) The syndrome of inappropriate antidiuretic hormone (SIADH) an hyponatremia was reported in a 62-year-old female patient 3 weeks initiation of escitalopram 10 mg/day for depression. She was admitt hospital following a syncopal fall resulting in head trauma. Upon adr serum sodium level was 110 mmol/L, serum osmolality was 261 mn sodium was 53 mmol/L, and urine osmolality was 286 mmol/kg. The identified for possible causes of SIADH was the use of escitalopram was discontinued. The patient was treated with intravenous normal her sodium levels slowly normalized. At discharge her serum sodiur mmol/L; one week later it was stabilized at 135 mmol/L and serum a osmolality returned to normal levels. The patient's depression was s treated with mirtazapine 30 mg/day without recurrence of hyponatre

(Nahshoni et al, 2004).

3.3.3.A.3 Syndrome of inappropriate antidiuretic hormone secretic

a) A 50-year-old black male experienced the syndrome of inapprop antidiuretic hormone (SIADH) within 4 weeks of initiating escitalopra depression. Upon admission to the hospital, he was on no other me physical exam was normal, and all diagnostic tests for acute illness Serum sodium was within the normal range at 138 mmol/L. Escitalo at bedtime and olanzapine 10 mg at bedtime were begun on hospita the doses increased over the next 3 weeks. The patient was taking escitalopram by day 13. Due to lack of efficacy, olanzapine was disc day 23, and risperidone 2 mg/day was initiated. Over the next week patient's depression improved, but by day 28, he complained of wea dizziness, and appeared diaphoretic. The results of a complete mec were unremarkable except for serum sodium of 121 mmol/L, serum mmol/L, and serum osmolality of 254 mOsm/kg (normal 275-300 m Urine osmolality was 617 mOsm/kg (normal 50-1,200 mOsm/kg) an sodium was 115 mmol/L. Following a diagnosis of SIADH, the patie on fluid restriction. Escitalopram 20 mg/day and risperidone 2 mg/da continued. By day 32 the patient's sodium rose to 130 mmol/L, but b had again decreased to 124 mmol/L. The escitalopram was then dis and the patient improved by day 39. Sodium returned to normal at 1 day 41. Depression was successfully treated with mirtazapine 30 m risperidone 2 mg/day and the patient was discharged on day 46 (Ni 2006).

b) The syndrome of inappropriate antidiuretic hormone (SIADH) an hyponatremia was reported in a 62-year-old female patient 3 weeks initiation of escitalopram 10 mg/day for depression. She was admitt hospital following a syncopal fall resulting in head trauma. Upon adr serum sodium level was 110 mmol/L, serum osmolality was 261 mn sodium was 53 mmol/L, and urine osmolality was 286 mmol/kg. The identified for possible causes of SIADH was the use of escitalopram was discontinued. The patient was treated with intravenous normal her sodium levels slowly normalized. At discharge her serum sodiur mmol/L; one week later it was stabilized at 135 mmol/L and serum a osmolality returned to normal levels. The patient's depression was s treated with mirtazapine 30 mg/day without recurrence of hyponatre (Nahshoni et al, 2004).

3.3.3.A.4 Weight increased

a) Incidence: 1% (Prod Info LEXAPRO(R), 2008)

b) Increased weight has been reported in at least 1% of patients re escitalopram therapy (Prod Info LEXAPRO(R), 2008).

3.3.4 Gastrointestinal Effects

3.3.4.A Escitalopram Oxalate

Abdominal pain

Constipation

Diarrhea

Gastroenteritis

Gastrointestinal hemorrhage

Heartburn

Indigestion

Nausea

Pancreatitis

Rectal hemorrhage

Vomiting

Xerostomia

3.3.4.A.1 Abdominal pain

a) Incidence: 1% to 2% (Prod Info LEXAPRO(R), 2008)

b) Abdominal pain has been reported in 1% to 2% of patients recei escitalopram therapy (Prod Info LEXAPRO(R), 2008; Wade et al, 2(2000; Montgomery et al, 2001a; Gorman, 2001; Burke, 2001) (Lepo 2001).

3.3.4.A.2 Constipation

a) Incidence: 3% to 6% (Prod Info LEXAPRO(R), 2008)

b) Constipation has been reported in 3% to 6% of patients receivin (10 to 20 mg) therapy, at a greater incidence than placebo (Prod Inf (R), 2008; Wade et al, 2001; Burke, 2000; Montgomery et al, 2001a 2001; Burke, 2001) (Lepola et al, 2001).

3.3.4.A.3 Diarrhea

a) Incidence: 6% to 14% (Prod Info LEXAPRO(R), 2008)

b) Diarrhea has been reported in 6% to 14% of patients receiving e (10 to 20 mg) therapy, at a greater incidence than placebo (Prod Inf (R), 2008; Wade et al, 2001; Burke, 2000; Montgomery et al, 2001a 2001; Burke, 2001) (Lepola et al, 2001).

3.3.4.A.4 Gastroenteritis

a) Incidence: 1% (Prod Info LEXAPRO(R), 2008)

b) Gastroenteritis has been reported in at least 1% patients receivi escitalopram therapy (Prod Info LEXAPRO(R), 2008; Wade et al, 2(2000; Montgomery et al, 2001a; Gorman, 2001; Burke, 2001) (Lepo 2001).

3.3.4.A.5 Gastrointestinal hemorrhage

See Drug Consult reference: CONCOMITANT USE OF SSRIs AND INCREASED RISK OF GASTROINTESTINAL BLEEDING

3.3.4.A.6 Heartburn

a) Incidence: 1% (Prod Info LEXAPRO(R), 2008)

b) Heartburn has been reported in at least 1% patients receiving es therapy (Prod Info LEXAPRO(R), 2008; Wade et al, 2001; Burke, 2(Montgomery et al, 2001a; Gorman, 2001; Burke, 2001) (Lepola et a

3.3.4.A.7 Indigestion

a) Incidence: 2% to 6% (Prod Info LEXAPRO(R), 2008)

b) Indigestion has been reported in 2% to 6% of patients receiving (10 to 20 mg) therapy, at a greater incidence than placebo (Prod Inf (R), 2008; Wade et al, 2001; Burke, 2000; Montgomery et al, 2001a 2001; Burke, 2001) (Lepola et al, 2001).

3.3.4.A.8 Nausea

a) Incidence: 15% to 18% (Prod Info LEXAPRO(R), 2008)

b) Nausea has been reported in 15% to 18% of patients receiving e (10 to 20 mg) therapy, at a greater incidence than placebo (Prod Inf (R), 2008; Wade et al, 2001; Burke, 2000; Montgomery et al, 2001a 2001; Burke, 2001) (Lepola et al, 2001).

3.3.4.A.9 Pancreatitis

a) Pancreatitis has been reported in postmarketing spontaneous ar trials (Prod Info LEXAPRO(R), 2008).

3.3.4.A.10 Rectal hemorrhage

a) Rectal hemorrhage has been reported in postmarketing spontan clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.4.A.11 Vomiting

a) Incidence: 3% (Prod Info LEXAPRO(R), 2008)

b) Vomiting has been reported in 3% of patients receiving escitalop mg) therapy, at a greater incidence than placebo (Prod Info LEXAP Wade et al, 2001; Burke, 2000; Montgomery et al, 2001a; Gorman, 2001) (Lepola et al, 2001).

3.3.4.A.12 Xerostomia

a) Incidence: 6% to 9% (Prod Info LEXAPRO(R), 2008)

b) Dry mouth has been reported in 6% to 9% of patients receiving e (10 to 20 mg) therapy, at a greater incidence than placebo (Prod Inf (R), 2008; Wade et al, 2001; Burke, 2000; Montgomery et al, 2001a 2001; Burke, 2001) (Lepola et al, 2001).

3.3.5 Hematologic Effects

3.3.5.A Escitalopram Oxalate

Anemia

Contusion

Epistaxis

Hematoma

3.3.5.A.1 Anemia

a) Incidence: 1% or less (Prod Info LEXAPRO(R), 2008)

b) Anemia has been reported in less than 1% of patients receiving therapy (Prod Info LEXAPRO(R), 2008).

3.3.5.A.2 Contusion

a) Incidence: 1% or less (Prod Info LEXAPRO(R), 2008)

b) Bruising has been reported in less than 1% of patients receiving therapy (Prod Info LEXAPRO(R), 2008).

3.3.5.A.3 Epistaxis

a) Incidence: 1% or less (Prod Info LEXAPRO(R), 2008)

b) Nosebleed has been reported in 1% or less of patients receiving therapy, and has been associated with SSRI and serotonin norepine reuptake inhibitor (SNRI) therapy in general (Prod Info LEXAPRO(F

3.3.5.A.4 Hematoma

a) Incidence: 1% or less(Prod Info LEXAPRO(R), 2008)

b) Hematoma has been reported in 1% or less of patients receiving therapy (Prod Info LEXAPRO(R), 2008).

3.3.6 Hepatic Effects

3.3.6.A Escitalopram Oxalate

Fulminant hepatitis

Hepatic necrosis

Liver failure

3.3.6.A.1 Fulminant hepatitis

a) Fulminant hepatitis has been reported in postmarketing spontan clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.6.A.2 Hepatic necrosis

a) Hepatic necrosis has been reported in postmarketing spontaneo trials (Prod Info LEXAPRO(R), 2008).

3.3.6.A.3 Liver failure

a) Hepatic failure has been reported in postmarketing spontaneous trials (Prod Info LEXAPRO(R), 2008).

3.3.7 Immunologic Effects

3.3.7.A Escitalopram Oxalate

3.3.7.A.1 Anaphylaxis

a) Oculogyric crisis with mixed anaphylactic features developed in female after ingestion of 20 milligrams (mg) of escitalopram in addit mg daily dose. The patient experienced a dystonic upward deviatior eye along with diaphoresis, dyspnea, palpitations, and swelling of th tongue. She self-administered a 0.3-mg dose of intramuscular epine autoinjector and symptoms temporarily resolved, but recurred after Resolution of all symptoms was achieved with administration of lora hydroxyzine. The patient had previously reported an episode of ana being treated with sertraline 50 mg daily. It is unclear if the dystonic symptoms of anaphylaxis are related (Patel & Simon, 2006).

3.3.8 Musculoskeletal Effects

3.3.8.A Escitalopram Oxalate

Arthralgia

Fracture of bone

Fracture of bone, Nonvertebral

Myalgia

Rhabdomyolysis

3.3.8.A.1 Arthralgia

a) Incidence: 1% (Prod Info LEXAPRO(R), 2008)

b) Arthralgia has been reported in at least 1% of patients following treatment (Prod Info LEXAPRO(R), 2008).

3.3.8.A.2 Fracture of bone

a) In a population-based, randomly selected, prospective cohort stu for potential covariates, an increased risk of fragility fracture was re 5-year follow-up in patients 50 years of age and older who used dai (n=137; mean age of 65.1 years), including citalopram (escitalopran in this study), compared with those who did not use an SSRI (n=487 of 65.7 years). Daily SSRI use was associated with a significant 2.1 increased risk of fragility fracture (95% confidence interval (CI), 1.3 dose of SSRI use was associated with a 1.5-fold increased risk of fr (95% CI, 1.1 to 2.1). Daily SSRI users who were recurrent (ie, treate at baseline and at 5-year follow-up) had a significant 2.1-fold increa fragility fracture (95% CI, 1.1 to 4). Fractures were reported at the fo forearm (40%), ankle and foot (21%), hip (13%), rib (13%), femur (9 (4%). None were reported at the skull, toes, or fingers (Richards et increased risk of fragility fracture has been reported in a prospective of SSRIs, including citalopram (Richards et al, 2007). Escitalopram included in this study

3.3.8.A.3 Fracture of bone, Nonvertebral

a) In a prospective, population-based, cohort study (n=7983) with a up of 8.4 years, there was an increased risk of nonvertebral fracture participants older than 55 years of age (mean age of 77.5 years) wh currently using an SSRI (citalopram, escitalopram, fluoxetine, fluvox paroxetine, or sertraline) compared to those who were not exposed antidepressants. Current SSRI use was associated with an increase nonvertebral fracture (adjusted hazard ratio (HR), 2.35; 95% confide (CI), 1.32 to 4.18) compared with no antidepressant use. Current SS also associated with an increased risk of nonvertebral fracture (adju 2.07; 95% CI, 1.23 to 3.5) compared with past antidepressant use (addition, duration of SSRI use showed a 9% increase in fracture risk month on an SSRI (95% CI, 3% to 16%; p for trend=0.004). Fractur (most frequent), wrist, humerus, and pelvis were reported (Ziere et a

3.3.8.A.4 Myalgia

a) Incidence: 1% (Prod Info LEXAPRO(R), 2008)

b) Myalgia has been reported in at least 1% of patients following es treatment (Prod Info LEXAPRO(R), 2008).

3.3.8.A.5 Rhabdomyolysis

a) Rhabdomyolysis has been reported in postmarketing spontaneo trials (Prod Info LEXAPRO(R), 2008).

3.3.9 Neurologic Effects

3.3.9.A Escitalopram Oxalate

Agitation

Dizziness

Feeling nervous

Grand mal seizure

Headache

Insomnia

Lightheadedness

Neuroleptic malignant syndrome

Restless legs syndrome

Serotonin syndrome

Somnolence

Tremor

3.3.9.A.1 Agitation

a) Incidence: 1% or less (Lydiard, 2001a)

b) Agitation has occurred in less than 1% of patients treated with es placebo (Lydiard, 2001a).

3.3.9.A.2 Dizziness

a) Incidence: 4% to 7%(Prod Info LEXAPRO(R), 2008)

b) Dizziness has been reported in 4% to 7% of patients receiving e

(10 to 20 mg) therapy, at a greater incidence than placebo (Prod Inf (R), 2008; Wade et al, 2001; Montgomery et al, 2001b; Montgomery Burke, 2001; Gorman, 2001).

3.3.9.A.3 Feeling nervous

a) Incidence: 1% or less (Lydiard, 2001a)

b) Nervousness has occurred in less than 1% of patients treated w escitalopram or placebo (Lydiard, 2001a).

3.3.9.A.4 Grand mal seizure

a) Grand mal seizures have been reported in postmarketing sponta clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.9.A.5 Headache

a) Incidence: 24% (Prod Info LEXAPRO(R), 2008)

b) Headache has been reported in 24% of patients receiving escita 20 mg) therapy, at a greater incidence than placebo (Prod Info LEX 2008; Wade et al, 2001; Montgomery et al, 2001b; Montgomery et a Burke, 2001; Gorman, 2001).

3.3.9.A.6 Insomnia

a) Incidence: 7% to 14% (Prod Info LEXAPRO(R), 2008)

b) Insomnia has been reported in 7% to 14% of patients receiving e (10 to 20 mg) therapy, at a greater incidence than placebo (Prod Inf (R), 2008; Wade et al, 2001; Montgomery et al, 2001b; Montgomery Burke, 2001; Gorman, 2001).

3.3.9.A.7 Lightheadedness

a) Incidence: 1% (Prod Info LEXAPRO(R), 2008)

b) Lightheadedness has been reported in at least 1% of patients re escitalopram therapy (Prod Info LEXAPRO(R), 2008).

3.3.9.A.8 Neuroleptic malignant syndrome

a) Neuroleptic malignant syndrome has been reported in postmarke spontaneous and clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.9.A.9 Restless legs syndrome

a) In a prospective, naturalistic study of patients (median age, 46 y 18 to 87 years) treated with antidepressants, 24 of 271 (9%) subjec experienced new-onset restless leg syndrome (RLS) or worsening o RLS as a side effect related to treatment. Antidepressants included paroxetine, citalopram, sertraline, escitalopram, venlafaxine, duloxe reboxetine, and mirtazapine. Mirtazapine led to a marked decline of of subjects compared with reboxetine which had none. The other ar showed RLS symptoms (newly occurred or deteriorated) at the rate 10%. Subjects stated symptoms occurred early in treatment (media range 1 to 23 days) (Rottach et al, 2008).

3.3.9.A.10 Serotonin syndrome

a) Serotonin syndrome has been reported in postmarketing sponta clinical trials (Prod Info LEXAPRO(R), 2008).

3.3.9.A.11 Somnolence

a) Incidence: 4% to 13% (Prod Info LEXAPRO(R), 2008)

b) Somnolence has been reported in 4% to 13% of patients receivi escitalopram (10 to 20 mg) therapy, at a greater incidence than plac Info LEXAPRO(R), 2008; Wade et al, 2001; Montgomery et al, 2001 Montgomery et al, 2001a; Burke, 2001; Gorman, 2001).

3.3.9.A.12 Tremor

a) Incidence: 1% or less (Lydiard, 2001a)

b) Tremors have occurred in less than 1% of patients treated with e or placebo (Lydiard, 2001a).

3.3.10 Ophthalmic Effects

3.3.10.A Escitalopram Oxalate

Angle-closure glaucoma

Oculogyric crisis

3.3.10.A.1 Angle-closure glaucoma

a) A case of acute bilateral angle closure glaucoma with choroidal e occurred in a 41-year-old woman following escitalopram use. The w had a history of depression and seasonal allergies, was placed on e 20 mg/day. Four weeks later, she presented with blurry vision in bot had lasted several hours. Ophthalmic examinations revealed elevat pressures of 47 and 45 millimeters of mercury in both eyes and a be visual acuity of 20/40 in both eyes, with a myopic shift of approxima from her current spectacle prescription. In addition, bilaterally shallo chambers and closed angles for 360 degrees in both eyes were not treatments, which consisted of topical timolol, dorzolamide, brimonic acetazolamide, and glycerin, followed by a laser peripheral iridotom eye, were not successful. The patient's corneas became edematous acuity declining from 20/40 to 20/400 in both eyes, over the next 3 h Additional testing confirmed the presence of choroidal effusions with detachments and diffuse choroidal thickening in each eye. Subsequ treatment was initiated oral prednisone (1 mg/kg), topical prednisolc and cycloplegic drops, and escitalopram was discontinued. Over the the patient's clinical symptoms resolved as evidenced by 20/20 visic eyes, normal intraocular pressures, and deepening of anterior cham postulated that escitalopram induced bilateral uveal effusions which angle closure in the patient (Zelefsky et al, 2006).

3.3.10.A.2 Oculogyric crisis

a) Oculogyric crisis with mixed anaphylactic features developed in a female after ingestion of 20 milligrams (mg) of escitalopram in addit mg daily dose. The patient experienced a dystonic upward deviation eye along with diaphoresis, dyspnea, palpitations, and swelling of th tongue. She self-administered a 0.3-mg dose of intramuscular epine autoinjector and symptoms temporarily resolved, but recurred after Resolution of all symptoms was achieved with administration of lora hydroxyzine. The patient had previously reported an episode of ana being treated with sertraline 50 mg daily. It is unclear if the dystonic symptoms of anaphylaxis are related (Patel & Simon, 2006).

3.3.12 Psychiatric Effects

3.3.12.A Escitalopram Oxalate

Depression, exacerbation

Depression, worsening

Psychotic disorder, acute

Suicidal thoughts

Suicide

3.3.12.A.1 Depression, exacerbation

a) Adult and pediatric patients who experience symptoms of anxiety panic attacks, insomnia, irritability, hostility (aggressiveness), impuls akathisia (psychomotor restlessness), hypomania, or mania may be worsening of their depression. This same concern applies to treating other psychiatric and nonpsychiatric disorders. If these symptoms a therapy should be reevaluated and it may be necessary to discontin medications when symptoms are severe, sudden in onset, or were n patient's initial symptoms (Prod Info LEXAPRO(R) Oral solution, Or

2009; Anon, 2004; Prod Info LEXAPRO(R), 2008).

3.3.12.A.2 Depression, worsening

a) Incidence: rare

b) Clinical worsening of depression has been reported in patients r escitalopram therapy, particularly during the initial few months of tre during dose adjustments. It may persist until significant remission oc patients treated with antidepressants for any indication should be m signs of clinical worsening (Prod Info LEXAPRO(R) Oral solution, O 2009).

3.3.12.A.3 Psychotic disorder, acute

a) Acute psychosis has been reported during postmarketing use of (Prod Info LEXAPRO(R) Oral solution, Oral tablets, 2009).

3.3.12.A.4 Suicidal thoughts

a) Incidence: rare

b) Adult and pediatric patients being treated with antidepressants f depressive disorder who experience symptoms of anxiety, agitation attacks, insomnia, irritability, hostility (aggressiveness), impulsivity, (psychomotor restlessness), hypomania, or mania may be at risk of ideation and behavior (suicidality). This same concern applies to tre with other psychiatric and nonpsychiatric disorders. If these sympto observed, therapy should be reevaluated and it may be necessary t medications when symptoms are severe, sudden in onset, or were n patient's initial symptoms. Patients and their caregivers should be p the Medication Guide that is available for this drug. Closely monitor especially during the initial few months of therapy or at times of dos (Prod Info LEXAPRO(R) Oral solution, Oral tablets, 2009; Anon, 20 2004).

c) A causal role for antidepressants in inducing suicidality has beer in pediatric patients. Anyone considering the use of antidepressants adolescent must balance this risk with the clinical need. In pooled a short-term, placebo-controlled trials of nine antidepressants (citalop fluoxetine, fluvoxamine, paroxetine, sertraline, bupropion, mirtazapi nefazodone, and venlafaxine extended-release) including over 440 patients with major depressive disorder (MDD), obsessive compulsi (OCD), or other psychiatric disorders, a greater risk of suicidal beha ideation during the first few months of therapy was demonstrated in receiving antidepressants as compared with placebo (4% vs 2%). T suicidality was most consistently observed in the trials that included MDD, but there were signs of risk emerging from trials in other psyc indications, such as obsessive compulsive disorder and social anxie (Anon, 2004).

1) In a pooled analyses of placebo-controlled trials in adults wi other psychiatric disorders including 295 short-term trials (medi 2 months) of 11 antidepressant drugs in greater than 77,000 pa of suicidality varied among the drugs studied. However, for alm studied, there was a tendency toward increasing suicidality in y patients. The risk difference (drug versus placebo in the numbe suicidality per 1000 patients treated) was 14 additional cases ir than 18 years of age, 5 additional cases in patients 18 to 24 ye case in patients 25 to 64 years, and 6 fewer cases in patients 6 older. No suicides occurred in the pediatric trials. Suicides did o adult trials; however, the number of suicides was insufficient to causality. The risk of suicidality during longer-term use (ie, beyo months) in pediatric patients is not known. However, evidence placebo-controlled, maintenance trials in adults with depressior substantiate a delay in the recurrence of depression with antide (Prod Info LEXAPRO(R) Oral solution, Oral tablets, 2009; Anor

3.3.12.A.5 Suicide

a) Incidence: rare

b) Suicide has been reported in adult patients receiving escitalopra clinical trials; however, the number of suicides was insufficient to de causality (Prod Info LEXAPRO(R) Oral solution, Oral tablets, 2009).

3.3.13 Renal Effects

3.3.13.A Escitalopram Oxalate

3.3.13.A.1 Urogenital finding

a) EJACULATION DISTURBANCES (primary ejaculatory delay) ha
reported in 9% to 14% of patients during escitalopram treatment in
studies compared with 2% to less than 1% in matched placebo grou
DECREASED LIBIDO (7%) and ANORGASMIA (6%) have also bee
following treatment with escitalopram (Prod Info Lexapro(TM), 2004
Gorman, 2001; Wade et al, 2001; Montgomery et al, 2001a).

3.3.15 Respiratory Effects

3.3.15.A Escitalopram Oxalate

3.3.15.A.1 Respiratory finding

a) BRONCHITIS, SINUS CONGESTION, COUGH, NASAL CONGI
SINUS HEADACHE have occurred in at least 1% of patients treatec
escitalopram (Prod Info Lexapro(TM), 2004).

3.3.16 Other

3.3.16.A Escitalopram Oxalate

Drug withdrawal

Fatigue

Serotonin syndrome

3.3.16.A.1 Drug withdrawal

See Drug Consult reference: WITHDRAWAL SYNDROME OF SEL
SEROTONIN REUPTAKE INHIBITORS

3.3.16.A.2 Fatigue

a) Incidence: 2% to 8% (Prod Info LEXAPRO(R), 2008)

b) Fatigue has been reported in 2% to 8% of patients receiving esc
to 20 mg) therapy, at a greater incidence than placebo (Prod Info LE
2008; Wade et al, 2001; Montgomery et al, 2001b; Montgomery et a
Burke, 2001; Gorman, 2001).

3.3.16.A.3 Serotonin syndrome

a) Serotonin syndrome, including life-threatening cases, or neurole
syndrome (NMS)-like reactions have been reported with the use of
alone. Signs and symptoms of serotonin syndrome include mental s
(eg, agitation, hallucination, coma), autonomic instability (eg, tachyc
blood pressure, hyperthermia), neuromuscular aberrations (eg, hyp
incoordination) and/or gastrointestinal symptoms (eg, nausea, vomi
Severe serotonin syndrome can resemble NMS with symptoms incl
hyperthermia, muscle rigidity, autonomic instability with possible rap
of vital signs, and mental status changes. Serotonin syndrome occu
commonly with the concomitant use of serotonergic drugs, including
drugs that impair metabolism of serotonin, including MAOIs, or with
or other dopamine antagonists (Prod Info Lexapro(R) oral tablets, s

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (P
LEXAPRO(R) oral tablets, solution, 2007) (All Trimesters)

a) Either studies in animals have revealed adverse effects on the fetus
embryocidal or other) and there are no controlled studies in women or st
women and animals are not available. Drugs should be given only if the
benefit justifies the potential risk to the fetus.

2) Australian Drug Evaluation Committee's (ADEC) Category: C (Australian Department of Health and Ageing Therapeutic Goods Administration, 2006)

a) Drugs which, owing to their pharmacological effects, have caused or suspected of causing harmful effects on the human fetus or neonate witl malformations. These effects may be reversible. Accompanying texts sh consulted for further details.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

3) Crosses Placenta: Yes

4) Clinical Management

a) There are no data on the use of escitalopram, the S(+)-enantiomer o during human pregnancy at this time. However, complications have bee neonates exposed to other SSRIs or serotonin and norepinephrine reupt (SNRIs) in the third trimester. Nonteratogenic effects (pulmonary hyperte newborn (PPHN) and clinical findings consistent with serotonin syndrom increased special or intensive unit care of the infant were demonstrated maternal use of SSRIs during the third trimester of pregnancy (Chamber One study revealed that women who discontinued antidepressant medic pregnancy had a greater likelihood of relapse compared with those who antidepressant therapy throughout the pregnancy (Prod Info LEXAPRO(tablets, solution, 2007). Animal studies of escitalopram and citalopram u gestation have shown adverse effects only with doses much higher than to humans. When deciding whether to treat a pregnant woman with esci during the third trimester, evaluate the potential risk to the fetus and the benefit to the mother. Consider tapering the escitalopram dose during th trimester of pregnancy (Prod Info LEXAPRO(R) oral tablets, solution, 20

5) Literature Reports

a) Neonates exposed to escitalopram and other SSRIs or serotonin-nor reuptake inhibitors (SNRIs) late in the third trimester have developed co some arising immediately upon delivery, including respiratory distress, s vomiting, tremor, and irritability, that were consistent with either direct S selective SNRI toxicity or a possible drug discontinuation syndrome. In s clinical findings were consistent with serotonin syndrome (Prod Info LEX tablets, solution, 2007).

b) In a case control study of women who delivered infants with pulmona hypertension of the newborn (PPHN; n=377) and women who delivered infants (n=836), the risk for developing PPHN was approximately six-fol infants exposed to SSRIs after week 20 of gestation compared with infa exposed to SSRIs during gestation. This study demonstrates a potential of PPHN, associated with considerable neonatal morbidity and mortality exposed to SSRIs later in the pregnancy. Because this is the first study PPHN with SSRI use during pregnancy and there are not enough cases to individual SSRIs, it can not be determined if all SSRIs posed similar le risk. In the general population, PPHN occurs in 1 to 2 per 1000 live birth LEXAPRO(R) oral tablets, solution, 2007; Chambers et al, 2006).

c) In a prospective longitudinal study of 201 women with a history of ma depression and no signs of depression at the beginning of pregnancy, th greater likelihood of relapse of major depression in those who discontinu antidepressant drugs during pregnancy compared with those who contin antidepressant drugs throughout the pregnancy (Prod Info LEXAPRO(R solution, 2007).

d) Fetal structural abnormalities, reduced fetal body weight, growth reta death were reported in the offspring of rats and rabbits treated with eithe escitalopram or racemic citalopram during pregnancy at doses considera than the maximum recommended human dose. Mild maternal toxicity wa reported in rat studies of escitalopram use during pregnancy (Prod Info L oral tablets, solution, 2007).

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk has been demonstrated.

a) Evidence and/or expert consensus has demonstrated harmful infant used during breastfeeding. An alternative to this drug should be prescrib should be advised to discontinue breastfeeding.

2) Clinical Management

a) Escitalopram is the S(+)-enantiomer of citalopram. Citalopram is sec human breast milk and has been associated with some adverse effects infants. Although there is no specific data on escitalopram, effects can b be similar to that seen with citalopram. Bottle feeding is suggested durin escitalopram therapy, and for at least 5 days after therapy discontinuatic

1998). The American Academy of Pediatrics considers antidepressants
that warrant concern in the nursing infant, particularly if used for long pe
2001). A decision should be made whether to discontinue nursing or dis
drug, taking into consideration the potential risks of citalopram exposure
and the benefits of treatment for the mother (Prod Info LEXAPRO(R) ora
solution, 2007). If the use of escitalopram in a nursing mother is necessa
monitoring the infant for unusual sleepiness, changes in appetite, and w
The long-term effects of exposure to SSRIs via breast milk on the cognit
development of the infant have not been determined.

3) Literature Reports

a) In a study describing 8 lactating women treated with an escitalopram
daily dose of 10 mg (range, 10 to 20 mg) that began 55 days before the
the infant plasma concentrations of escitalopram and its active metabolit
demethylescitalopram, were undetectable (n=4), low (n=1), or not measu
The total relative infant dose for escitalopram and its metabolite was a m
(95% confidence interval (CI), 4.2% to 6.2%) of the maternal weight-adju
and the absolute doses were 7.6 mcg/kg/day (95% CI, 5.2 to 10) and 3 m
(95% CI, 2.4 to 3.6) for escitalopram and demethylescitalopram, respect
mean milk/plasma ratio was 2.2 for both escitalopram (95% confidence i
to 2.4) and demethylescitalopram (95% CI, 1.9 to 2.5). The authors sugg
escitalopram is safe for use in nursing mothers; however, individual case
decided based on a risk/benefit analysis (Rampono et al, 2006).

b) Although specific data are not available for escitalopram, racemic cita
appears in breast milk. There have been two case reports of excessive s
weight loss, and decreased feeding in nursing infants whose mothers we
citalopram. One infant reportedly recovered completely upon maternal c
discontinuation; follow-up information was not available for the other infa

3.5.1.B Aceclofenac

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and th
potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi
upper gastrointestinal bleeding were searched among 26,005 users
antidepressant medications and compared with the number of hosp

those patients who did not receive prescriptions for antidepressants
of upper GI bleeding episodes was 3.6 times more than expected (9
confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA
dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1
5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of
demonstrate an increased risk of upper GI bleeding during the use
Combined use of SSRIs and NSAIDs or low-dose aspirin increased
further (Dalton et al, 2003).

b) Coadministration of ketorolac with psychoactive drugs (such as
been associated with hallucinations in some patients (Prod Info TOF
oral tablets, 2007).

3.5.1.C Acemetacin

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

8) Literature Reports

further (Dalton et al, 2003).

b) Coadministration of ketorolac with psychoactive drugs (such as
been associated with hallucinations in some patients (Prod Info TOF
oral tablets, 2007).

3.5.1.D Acenocoumarol

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk of
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R
solution, 2008). Bleeding events reported have included epistaxis, ecchy
hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra
with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table
2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When escitalopram and an anticoagulant are g
concurrently, monitor patients for signs of increased bleeding. Patients v
warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).

7) Probable Mechanism: unknown

8) Literature Reports

a) According to a retrospective cohort study (n=234), there was an
of clinically relevant bleeding (hospital admission due to bleeding) ir

receiving warfarin for atrial fibrillation during concomitant SSRI thera
weeks following SSRI therapy termination. Patients with a mean ag
years receiving warfarin plus SSRI (n=117) were matched with ranc
patients who received warfarin only (n=117). SSRI included fluoxeti
citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin
experienced 11 bleeding episodes during 213.9 treatment years in t
plus SSRI group, and 10 patients experienced 14 bleedings during
treatment years in the warfarin-only group. The corresponding total
bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel
ratio for first bleedings during treatment with warfarin plus SSRI was
CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI ir
patients experiencing bleeding at the time of concomitant administra
sertraline or citalopram. The addition of an SSRI was not associatec
change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T
the study may be limited by earlier bleeding events, unknown patier
and exclusion of clopidogrel, dipyridamol, corticosteroids and antico
other than warfarin in the model (Wallerstedt et al, 2009).

b) A population-based, case-controlled study of new coumarin user
(acenocoumarol and phenprocoumon) with concomitant selective se
reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali
nongastrointestinal bleeding. Using national pharmacy and hospitali
records, Netherlands researchers identified 1848 cases that were a
abnormal bleeding and compared them with 5818 control subjects a
coumarins. Median duration of treatment in patients was 220 days (
4690 days). Patients on SSRIs showed greater risk for hospitalizatic
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.E Alclofenac

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and th
potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi
upper gastrointestinal bleeding were searched among 26,005 users
antidepressant medications and compared with the number of hosp
those patients who did not receive prescriptions for antidepressants
of upper GI bleeding episodes was 3.6 times more than expected (9
confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA
dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1
5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of
demonstrate an increased risk of upper GI bleeding during the use
Combined use of SSRIs and NSAIDs or low-dose aspirin increased
further (Dalton et al, 2003).

b) Coadministration of ketorolac with psychoactive drugs (such as
been associated with hallucinations in some patients (Prod Info TOF
oral tablets, 2007).

3.5.1.F Almotriptan

1) Interaction Effect: an increased risk of serotonin syndrome

2) Summary: Concomitant use of almotriptan and selective serotonin re
inhibitors (SSRI's) has been reported to cause weakness, hyperreflexia,
incoordination (Prod Info Axert(TM), 2001). Concurrent use of a triptan a

may result in serotonin syndrome which may be life-threatening. Sympto
serotonin syndrome may include restlessness, hallucinations, loss of co
heart beat, rapid changes in blood pressure, increased body temperatur
overreactive reflexes, nausea, vomiting, and diarrhea. Clinicians should
triptans may be commonly used intermittently and that either the triptan
may be prescribed by a different physician. Discuss the risks of serotoni
with patients who are prescribed this combination and monitor them clos
symptoms of serotonin syndrome (US Food and Drug Administration, 20
3) Severity: major
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of a triptan, such as almotript
SSRI may result in a life-threatening condition called serotonin syndrom
that triptans may be commonly used intermittently and that either the trip
SSRI may be prescribed by a different physician. If these agents are use
discuss the risks of serotonin syndrome with the patient and monitor clos
symptoms of serotonin syndrome (restlessness, hyperthermia, hyperrefl
incoordination).
7) Probable Mechanism: additive pharmacologic effects resulting in exc
serotonergic stimulation
8) Literature Reports
a) Concomitant administration of fluoxetine and almotriptan is well
fluoxetine has only a modest effect on almotriptan maximum plasma
concentration (Cmax). Other almotriptan pharmacokinetics are not s
affected. A randomized, open-label, two-way crossover study involv
volunteers has been conducted. Subjects received each of the follo
treatments with a minimum 3-week washout between periods: (1) th
fluoxetine capsules on day 1 to 8 and one dose almotriptan 12.5 mg
one dose of almotriptan 12.5 mg on day 8 with no treatment on days
Peak almotriptan concentrations were 18% higher following concom
administration of fluoxetine than after almotriptan administration alo
difference was statistically significant (p equal 0.023). Mean almotrip
under the concentration-time curve (AUC) and oral clearance were
statistically different between treatment groups. Mean half-life was n
different between the treatment groups. During fluoxetine coadminis
was shorter, suggesting that the absorption rate of almotriptan may
increased by fluoxetine. The author concludes that based on the res
study and the lack of effect of fluoxetine on almotriptan pharmacoki
almotriptan and fluoxetine can be safely used concomitantly in migr
management (Fleishaker et al, 2001).

3.5.1.G Anagrelide

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and antiplatelet agents has been associated with an increased ris
Bleeding events reported have included epistaxis, ecchymosis, hematon
and life-threatening hemorrhages (Prod Info PAXIL(R) oral tablets, susp
Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are g
concurrently, monitor patient for signs of increased bleeding (Prod Info P
tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed
capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.H Ancrod

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk of
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(P
solution, 2008). Bleeding events reported have included epistaxis, ecchy
hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra

with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When escitalopram and an anticoagulant are g concurrently, monitor patients for signs of increased bleeding. Patients v warfarin should be monitored closely for altered anticoagulant effects, in increased bleeding, when escitalopram therapy is initiated or discontinue LEXAPRO(R) oral tablets, solution, 2008).
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an of clinically relevant bleeding (hospital admission due to bleeding) ir receiving warfarin for atrial fibrillation during concomitant SSRI thera weeks following SSRI therapy termination. Patients with a mean ag years receiving warfarin plus SSRI (n=117) were matched with rand patients who received warfarin only (n=117). SSRI included fluoxeti citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin experienced 11 bleeding episodes during 213.9 treatment years in t plus SSRI group, and 10 patients experienced 14 bleedings during treatment years in the warfarin-only group. The corresponding total bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel ratio for first bleedings during treatment with warfarin plus SSRI was CI; 1.37 to 8.91, p=0.009) compared with warfarin only. 4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an antiplatelet agent are g concurrently, monitor patient for signs of increased bleeding (Prod Info F tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed capsules, solution, 2008)

7) Probable Mechanism: unknown

3.5.1.M Benoxaprofen

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint hemostasis. Case-control and cohort studies have shown that the combi SSRIs and NSAIDs has been associated with an increased risk of bleed events have included epistaxis, ecchymosis, hematoma, petechiae, and threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension, Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and th potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi upper gastrointestinal bleeding were searched among 26,005 users antidepressant medications and compared with the number of hosp those patients who did not receive prescriptions for antidepressants of upper GI bleeding episodes was 3.6 times more than expected (9 confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1 5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of demonstrate an increased risk of upper GI bleeding during the use Combined use of SSRIs and NSAIDs or low-dose aspirin increased further (Dalton et al, 2003).

b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOR oral tablets, 2007).

3.5.1.N Bivalirudin

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint hemostasis. Case-control and cohort studies have shown that the combi SSRIs and anticoagulants has been associated with an increased risk of (Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R solution, 2008). Bleeding events reported have included epistaxis, ecchy hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa (including increased bleeding) have been reported with the coadministra with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When escitalopram and an anticoagulant are g concurrently, monitor patients for signs of increased bleeding. Patients v

warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an
of clinically relevant bleeding (hospital admission due to bleeding) ir
receiving warfarin for atrial fibrillation during concomitant SSRI thera
weeks following SSRI therapy termination. Patients with a mean ag
years receiving warfarin plus SSRI (n=117) were matched with ranc
patients who received warfarin only (n=117). SSRI included fluoxeti
citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin
experienced 11 bleeding episodes during 213.9 treatment years in t
plus SSRI group, and 10 patients experienced 14 bleedings during
treatment years in the warfarin-only group. The corresponding total
bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel
ratio for first bleedings during treatment with warfarin plus SSRI was
CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI ir
patients experiencing bleeding at the time of concomitant administra
sertraline or citalopram. The addition of an SSRI was not associated
change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T
the study may be limited by earlier bleeding events, unknown patier
and exclusion of clopidogrel, dipyridamol, corticosteroids and antico
other than warfarin in the model (Wallerstedt et al, 2009).
b) A population-based, case-controlled study of new coumarin user
(acenocoumarol and phenprocoumon) with concomitant selective se
reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali
nongastrointestinal bleeding. Using national pharmacy and hospitali
records, Netherlands researchers identified 1848 cases that were a
abnormal bleeding and compared them with 5818 control subjects a
coumarins. Median duration of treatment in patients was 220 days (
4690 days). Patients on SSRIs showed greater risk for hospitalizatio
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.O Bromfenac
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,

The findings of demonstrate an increased risk of upper GI bleeding during the use Combined use of SSRIs and NSAIDs or low-dose aspirin increased further (Dalton et al, 2003).

b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOF oral tablets, 2007).

3.5.1.Q Cannabis

1) Interaction Effect: manic symptoms

2) Summary: One case of mania following use of marijuana with fluoxet has been reported (Stoll et al, 1991a). Although an interaction is propose authors also state the manic symptoms could have resulted from the fluo marijuana alone. Caution is advised for patients using marijuana and tak or other serotonin reuptake inhibitors.

3) Severity: moderate

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: Caution patients taking selective serotonin reu inhibitors to avoid concomitant use of marijuana.

7) Probable Mechanism: additive serotonergic stimulation

8) Literature Reports

a) A 21-year-old female presented with mania, agitation, and grand delusions following use of marijuana with fluoxetine therapy. She ha fluoxetine 20 mg daily for 4 weeks and reported smoking 2 "joints" o hour period. Over the next 24 hours, she developed increased ener hypersexuality, pressured speech, and grandiose delusions. Loraze perphenazine were given for agitation and excitement which gradua over 4 days. She remained hospitalized for 36 days. Fluoxetine 20 m other day was reintroduced one week prior to discharge. One week discharge, she discontinued fluoxetine due to insomnia and feeling These symptoms resolved rapidly upon discontinuation of fluoxetine rapid switch to mania after smoking marijuana with fluoxetine, the m symptoms were associated with the concomitant use of fluoxetine a though mania could have developed from either fluoxetine or mariju (Stoll et al, 1991).

3.5.1.R Carprofen

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi

SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,

7) Probable Mechanism: unknown

3.5.1.Y Clorgyline

1) Interaction Effect: CNS toxicity and/or serotonin syndrome (hypertens
hyperthermia, myoclonus, mental status changes)
2) Summary: Concurrent administration or overlapping therapy with esc
a monoamine oxidase (MAO) inhibitor may result in CNS toxicity or sero
syndrome, a hyperserotonergic state characterized by symptoms such a
restlessness, myoclonus, changes in mental status, hyperreflexia, diaph
shivering, and tremor. Serious, even fatal, reactions have been reported

Lexapro(TM), 2002b). Concomitant use is contraindicated.
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of escitalopram and clorgyline contraindicated. Wait at least two weeks after discontinuing a MAO inhib initiating escitalopram therapy. In addition, wait at least five weeks after escitalopram before initiating therapy with a MAO inhibitor.
7) Probable Mechanism: inhibition of serotonin metabolism by monoam

3.5.1.Z Cyclobenzaprine
1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: Clinical symptoms of serotonin syndrome have been repo concurrent use of cyclobenzaprine with escitalopram. (Day & Jeanmono Caution is advised if cyclobenzaprine and escitalopram are coadminister patients for signs and symptoms of serotonin syndrome.
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: A case of serotonin syndrome was reported wi concomitant use of cyclobenzaprine and escitalopram, and therefore, co is discouraged (Day & Jeanmonod, 2008).
7) Probable Mechanism: additive serotonergic effects
8) Literature Reports
a) A 27-year-old female admitted to the hospital for possible overdo experienced serotonin syndrome following coadministration of cyclo and escitalopram. The patient stated she had taken "5 or 6" 10 mg cyclobenzaprine tablets and 2 rum beverages the previous evening currently being treated with escitalopram 10 mg daily for mild depre Lortab(R) and cyclobenzaprine as needed for lower back pain. The initially responsive, but quickly became stuporous, marked by eye o pain, nonsensical speech, and localization to painful stimuli. Her ten 101.7, pulse of 140, blood pressure of 159/76, respirations of 24, ar oximetry of 94% on 6 L. Physical exam showed skin flushing, diaph tremors, rigidity in lower extremities, horizontal nystagmus and hype the patella. Laboratory results showed a respiratory acidosis (7.29/5 creatinine kinase fraction of 3862 units/L, serum ethanol of 44 mg/d positive tricyclic and opiate screens. An ECG showed tachycardia w morphology or interval changes. A diagnosis of serotonin syndrome and the patient was treated accordingly. Over the next 12 hours, the temperature, tachycardia, tremors, and creatinine kinase fraction de mental status improved and she was oriented. After a psychiatric ev was discharged with direction to discontinue cyclobenzaprine while escitalopram (Day & Jeanmonod, 2008).

3.5.1.AA Dalteparin
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and anticoagulants has been associated with an increased risk of (Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R solution, 2008). Bleeding events reported have included epistaxis, ecchy hematoma, petechiae, and life-threatening hemorrhages. change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T
the study may be limited by earlier bleeding events, unknown patier
and exclusion of clopidogrel, dipyridamol, corticosteroids and antico
other than warfarin in the model (Wallerstedt et al, 2009).

b) A population-based, case-controlled study of new coumarin user
(acenocoumarol and phenprocoumon) with concomitant selective se
reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali
nongastrointestinal bleeding. Using national pharmacy and hospitali
records, Netherlands researchers identified 1848 cases that were a
abnormal bleeding and compared them with 5818 control subjects a
coumarins. Median duration of treatment in patients was 220 days (
4690 days). Patients on SSRIs showed greater risk for hospitalizatio
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.AC Defibrotide

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk of
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R
solution, 2008). Bleeding events reported have included epistaxis, ecchy
hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra
with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table
2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When escitalopram and an anticoagulant are g
concurrently, monitor patients for signs of increased bleeding. Patients v
warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).

7) Probable Mechanism: unknown

8) Literature Reports

a) According to a retrospective cohort study (n=234), there was an
of clinically relevant bleeding (hospital admission due to bleeding) ir
receiving warfarin for atrial fibrillation during concomitant SSRI thera
weeks following SSRI therapy termination. Patients with a mean age
years receiving warfarin plus SSRI (n=117) were matched with rand
patients who received warfarin only (n=117). SSRI included fluoxeti
citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin
experienced 11 bleeding episodes during 213.9 treatment years in t
plus SSRI group, and 10 patients experienced 14 bleedings during 5
treatment years in the warfarin-only group. The corresponding total
bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel
ratio for first bleedings during treatment with warfarin plus SSRI was
CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI ir
patients experiencing bleeding at the time of concomitant administra
sertraline or citalopram. The addition of an SSRI was not associated
change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T
the study may be limited by earlier bleeding events, unknown patier
and exclusion of clopidogrel, dipyridamol, corticosteroids and antico
other than warfarin in the model (Wallerstedt et al, 2009).

b) A population-based, case-controlled study of new coumarin user
(acenocoumarol and phenprocoumon) with concomitant selective se
reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali
nongastrointestinal bleeding. Using national pharmacy and hospitali
records, Netherlands researchers identified 1848 cases that were a
abnormal bleeding and compared them with 5818 control subjects a
coumarins. Median duration of treatment in patients was 220 days (
4690 days). Patients on SSRIs showed greater risk for hospitalizatio
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir

OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka 2008).

3.5.1.AD Dehydroepiandrosterone

1) Interaction Effect: development of manic symptoms

2) Summary: A case has been reported in which concomitant dehydroepiandrosterone (DHEA) and sertraline use was suggested to p manic episode in a patient with a history of bipolar disorder (Dean, 2000 also noted to cause mania in a patient with no previous personal or fami bipolar disorder (Markowitz et al, 1999). Elevated DHEA levels have bee patients with mental disorders; DHEA suppression has lead to improvem psychotic symptoms (Howard, 1992). DHEA possesses proserotonergic may predispose patients to manic episodes (Majewska, 1995). DHEA is androgenic steroids, which in high doses may precipitate mania (Markov 1999). Patients taking medication for bipolar disorder or patients with a p and/or family history of bipolar disorder should not take DHEA until furth available to characterize this drug-herb interaction. Concomitant use of D selective serotonin reuptake inhibitors (SSRIs) should be avoided due to additive precipitation of mania.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Avoid concomitant use of dehydroepiandroster and selective serotonin reuptake inhibitors. If patients present with mani (i.e. agitation, anger, irritability, aggressive behavior), determine if the pa DHEA and discontinue DHEA.

7) Probable Mechanism: serotonergic activity of dehydroepiandrosteron increased androgen levels

8) Literature Reports

a) A 31-year-old male was admitted following threats to commit sui family members. He had self-initiated sertraline 100 milligrams (mg) previous 2 to 3 weeks for depression. Sertraline had been prescribe prior when he was diagnosed with bipolar disorder, which he discon weeks. He had also taken dehydroepiandrosterone (DHEA) 300 mg daily for the previous 2 months apparently for weight training. Follov DHEA for a short time, he became more irritable, was not sleeping v began threatening a female friend and family members. He also dra occasionally and reportedly had difficulty controlling his anger when Sertraline was stopped and the patient was treated with valproic aci dose titrated to 500 mg twice daily. The combination of DHEA, sertr alcohol was suggested responsible for the developing of the manic (Dean, 2000).

3.5.1.AE Dermatan Sulfate

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and anticoagulants has been associated with an increased risk of (Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R solution, 2008). Bleeding events reported have included epistaxis, ecchy hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa (including increased bleeding) have been reported with the coadministra with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When escitalopram and an anticoagulant are g concurrently, monitor patients for signs of increased bleeding. Patients v warfarin should be monitored closely for altered anticoagulant effects, in increased bleeding, when escitalopram therapy is initiated or discontinue LEXAPRO(R) oral tablets, solution, 2008).

7) Probable Mechanism: unknown

8) Literature Reports

a) According to a retrospective cohort study (n=234), there was an of clinically relevant bleeding (hospital admission due to bleeding) ir receiving warfarin for atrial fibrillation during concomitant SSRI thera

weeks following SSRI therapy termination. Patients with a mean ag
years receiving warfarin plus SSRI (n=117) were matched with ranc
patients who received warfarin only (n=117). SSRI included fluoxeti
citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin
experienced 11 bleeding episodes during 213.9 treatment years in t
plus SSRI group, and 10 patients experienced 14 bleedings during
treatment years in the warfarin-only group. The corresponding total
bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel
ratio for first bleedings during treatment with warfarin plus SSRI was

interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.AF Desipramine

1) Interaction Effect: increase in the bioavailability and plasma concentr
desipramine

2) Summary: Desipramine plasma concentration and area under the co
time curve increased by 40% and 100%, respectively, when a single dos
desipramine 50 milligrams (mg) was administered concurrently with a 21
of escitalopram 20 mg/day (Prod Info LEXAPRO(R) Oral Tablet, Oral Sc

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Caution is indicated in the coadministration of
and escitalopram due to the risk for increased desipramine plasma conc

7) Probable Mechanism: escitalopram inhibition of cytochrome P450-2D
desipramine metabolism

3.5.1.AG Desirudin

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk of
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R
solution, 2008). Bleeding events reported have included epistaxis, ecchy
hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra
with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table
2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When escitalopram and an anticoagulant are g
concurrently, monitor patients for signs of increased bleeding. Patients v
warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).

7) Probable Mechanism: unknown

coumarins. Median duration of treatment in patients was 220 days (
4690 days). Patients on SSRIs showed greater risk for hospitalizatic
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.AH Desvenlafaxine

1) Interaction Effect: increased risk of serotonin syndrome (hypertensio
hyperthermia, myoclonus, mental status changes)

2) Summary: Concurrent use of desvenlafaxine and a selective seroton
inhibitor (SSRI) may result in serotonin syndrome, which may be life-thre
Symptoms of serotonin syndrome may include restlessness, hallucinatio
coordination, fast heart beat, rapid changes in blood pressure, increasec
temperature, overreactive reflexes, nausea, vomiting, and diarrhea (Proc
PRISTIQ(TM) oral extended-release tablets, 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Coadministration of desvenlafaxine and an SS
in a life-threatening condition called serotonin syndrome. If these agents
together, discuss the risks of serotonin syndrome with the patient and m
for symptoms of serotonin syndrome (restlessness, hyperthermia, hyper
incoordination), especially during treatment initiation and dose increases
PRISTIQ(TM) oral extended-release tablets, 2008).

7) Probable Mechanism: additive serotonergic effect

3.5.1.AI Dexketoprofen

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and th

potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi
upper gastrointestinal bleeding were searched among 26,005 users
antidepressant medications and compared with the number of hosp
those patients who did not receive prescriptions for antidepressants
of upper GI bleeding episodes was 3.6 times more than expected (9
confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA
dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1
5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of
demonstrate an increased risk of upper GI bleeding during the use

b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOR oral tablets, 2007).

3.5.1.AP Duloxetine

1) Interaction Effect: an increased risk of serotonin syndrome

2) Summary: Duloxetine is a selective serotonin and norepinephrine reu inhibitor. The concomitant use of duloxetine with escitalopram, a selectiv reuptake inhibitor, is not recommended due to the potential for serotonin (Prod Info CYMBALTA(R) delayed-release oral capsules, 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concomitant use of duloxetine and escitalo recommended due to the potential for development of serotonin syndron CYMBALTA(R) delayed-release oral capsules, 2008).

7) Probable Mechanism: additive serotonergic effects

3.5.1.AQ Eletriptan

1) Interaction Effect: an increased risk of serotonin syndrome

2) Summary: There have been case reports of weakness, hyperreflexia incoordination following concomitant use of sumatriptan, a 5-hydroxytryp (5HT-1) agonist, and a serotonin specific reuptake inhibitor (SSRI) (Proc (R) Nasal Spray, 2003). Because eletriptan is a 5HT 1B/1D agonist, a si interaction between SSRIs and eletriptan may occur (Prod Info Relpax(R Concurrent use of a triptan and an SSRI may result in serotonin syndron be life-threatening. Symptoms of serotonin syndrome may include restle hallucinations, loss of coordination, fast heart beat, rapid changes in blo increased body temperature, overreactive reflexes, nausea, vomiting, ar Clinicians should be aware that triptans may be commonly used intermit either the triptan or the SSRI may be prescribed by a different physician risks of serotonin syndrome with patients who are prescribed this combi monitor them closely for symptoms of serotonin syndrome (US Food and Administration, 2006).

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Coadministration of a triptan, such as eletriptan SSRI may result in a life-threatening condition called serotonin syndrom that triptans may be commonly used intermittently and that either the trip SSRI may be prescribed by a different physician. If these agents are use discuss the risks of serotonin syndrome with the patient and monitor clos symptoms of serotonin syndrome (restlessness, hyperthermia, hyperrefl incoordination).

7) Probable Mechanism: additive pharmacologic effects resulting in exc serotonergic stimulation

3.5.1.AR Enoxaparin

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and anticoagulants has been associated with an increased risk of (Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R solution, 2008). Bleeding events reported have included epistaxis, ecchy hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa (including increased bleeding) have been reported with the coadministra with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table 2008).

3) Severity: major

4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When escitalopram and an anticoagulant are g concurrently, monitor patients for signs of increased bleeding. Patients v warfarin should be monitored closely for altered anticoagulant effects, in increased bleeding, when escitalopram therapy is initiated or discontinue LEXAPRO(R) oral tablets, solution, 2008).
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an of clinically relevant bleeding (hospital admission due to bleeding) ir receiving warfarin for atrial fibrillation during concomitant SSRI thera weeks following SSRI therapy termination. Patients with a mean ag years receiving warfarin plus SSRI (n=117) were matched with ranc patients who received warfarin only (n=117). SSRI included fluoxeti citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin experienced 11 bleeding episodes during 213.9 treatment years in t plus SSRI group, and 10 patients experienced 14 bleedings during treatment years in the warfarin-only group. The corresponding total bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel ratio for first bleedings during treatment with warfarin plus SSRI was CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI ir patients experiencing bleeding at the time of concomitant administra sertraline or citalopram. The addition of an SSRI was not associated change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T the study may be limited by earlier bleeding events, unknown patier and exclusion of clopidogrel, dipyridamol, corticosteroids and antico other than warfarin in the model (Wallerstedt et al, 2009).
b) A population-based, case-controlled study of new coumarin user (acenocoumarol and phenprocoumon) with concomitant selective se reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali nongastrointestinal bleeding. Using national pharmacy and hospitali records, Netherlands researchers identified 1848 cases that were a abnormal bleeding and compared them with 5818 control subjects a coumarins. Median duration of treatment in patients was 220 days (4690 days). Patients on SSRIs showed greater risk for hospitalizatio nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka 2008).

3.5.1.AS Epoprostenol
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and antiplatelet agents has been associated with an increased ris Bleeding events reported have included epistaxis, ecchymosis, hematon and life-threatening hemorrhages (Prod Info PAXIL(R) oral tablets, susp Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are g concurrently, monitor patient for signs of increased bleeding (Prod Info P tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.AT Eptifibatide
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and antiplatelet agents has been associated with an increased ris Bleeding events reported have included epistaxis, ecchymosis, hematon and life-threatening hemorrhages (Prod Info PAXIL(R) oral tablets, susp Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution
3) Severity: major

4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are g
concurrently, monitor patient for signs of increased bleeding (Prod Info F
tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayec
capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.AU Etodolac

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and th
potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi
upper gastrointestinal bleeding were searched among 26,005 users
antidepressant medications and compared with the number of hosp
those patients who did not receive prescriptions for antidepressants
of upper GI bleeding episodes was 3.6 times more than expected (9
confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA
dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1
5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of
demonstrate an increased risk of upper GI bleeding during the use
Combined use of SSRIs and NSAIDs or low-dose aspirin increased
further (Dalton et al, 2003).
b) Coadministration of ketorolac with psychoactive drugs (such as
been associated with hallucinations in some patients (Prod Info TOF
oral tablets, 2007).

3.5.1.BE Fondaparinux

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk o
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R
solution, 2008). Bleeding events reported have included epistaxis, ecchy

hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra
with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table
2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When escitalopram and an anticoagulant are g
concurrently, monitor patients for signs of increased bleeding. Patients v
warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an
of clinically relevant bleeding (hospital admission due to bleeding) ir
receiving warfarin for atrial fibrillation during concomitant SSRI thera
weeks following SSRI therapy termination. Patients with a mean ag
years receiving warfarin plus SSRI (n=117) were matched with rand
patients who received warfarin only (n=117). SSRI included fluoxeti
citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin
experienced 11 bleeding episodes during 213.9 treatment years in t
plus SSRI group, and 10 patients experienced 14 bleedings during
treatment years in the warfarin-only group. The corresponding total
bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel
ratio for first bleedings during treatment with warfarin plus SSRI was
CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI ir
patients experiencing bleeding at the time of concomitant administra
sertraline or citalopram. The addition of an SSRI was not associated
change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T
the study may be limited by earlier bleeding events, unknown patier
and exclusion of clopidogrel, dipyridamol, corticosteroids and antico
other than warfarin in the model (Wallerstedt et al, 2009).
b) A population-based, case-controlled study of new coumarin user
(acenocoumarol and phenprocoumon) with concomitant selective se
reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali
nongastrointestinal bleeding. Using national pharmacy and hospitali
records, Netherlands researchers identified 1848 cases that were a
abnormal bleeding and compared them with 5818 control subjects a
coumarins. Median duration of treatment in patients was 220 days (
4690 days). Patients on SSRIs showed greater risk for hospitalizatio
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.BF Frovatriptan
1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: There have been case reports of weakness, hyperreflexia
incoordination following concomitant use of sumatriptan, a 5-hydroxytryp
(5HT-1) agonist, and a serotonin specific reuptake inhibitor (SSRI) (Proc
(R) Nasal Spray, 2003). Because frovatriptan is a 5HT 1B/1D agonist, a
interaction between SSRIs and frovatriptan may occur (Prod Info Frova(
Concurrent use of frovatriptan and an SSRI may result in serotonin synd
may be life-threatening. Symptoms of serotonin syndrome may include r
hallucinations, loss of coordination, fast heart beat, rapid changes in blo
increased body temperature, overreactive reflexes, nausea, vomiting, ar
Clinicians should be aware that triptans may be commonly used intermit
either the triptan or the SSRI may be prescribed by a different physician.
risks of serotonin syndrome with patients who are prescribed this combi
monitor them closely for symptoms of serotonin syndrome (US Food and
Administration, 2006).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Coadministration of a triptan, such as frovatrip
SSRI may result in a life-threatening condition called serotonin syndrom

that triptans may be commonly used intermittently and that either the trip
SSRI may be prescribed by a different physician. If these agents are use
discuss the risks of serotonin syndrome with the patient and monitor clos
symptoms of serotonin syndrome (restlessness, hyperthermia, hyperrefl
incoordination).
7) Probable Mechanism: additive pharmacologic effects resulting in exc
serotonergic stimulation

3.5.1.BG Furazolidone

1) Interaction Effect: weakness, hyperreflexia, and incoordination
2) Summary: Although not its primary mechanism of action, furazolidon
monoamine oxidase inhibitor activity. Cases of serious sometimes fatal r
been reported in patients receiving selective serotonin reuptake inhibitor
combination with monoamine oxidase inhibitors (MAOIs). Hyperthermia,
myoclonus, autonomic instability with possible rapid fluctuations of vital s
mental status changes that include extreme agitation progressing to deli
coma have been reported. Furazolidone should not be used in combinat
SSRI, or within a minimum of 14 days of discontinuing therapy with a MA
Furoxone(R), 1999).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If concurrent therapy with furazolidone and a s
serotonin reuptake inhibitor (SSRI) is deemed to be necessary, closely r
patient for signs of serotonergic excess (mental status changes, diaphor
weakness, hyperreflexia, incoordination).
7) Probable Mechanism: additive pharmacologic effects resulting in exc
serotonergic stimulation

3.5.1.BH Ginkgo

1) Interaction Effect: increased risk of serotonin syndrome (hypertensio
hyperthermia, myoclonus, mental status changes)
2) Summary: The addition of Ginkgo biloba and/or St. John's Wort to th
buspirone and fluoxetine may have precipitated a hypomanic episode in
(Spinella & Eaton, 2002a). It is unclear if Ginkgo or St. John's Wort, the
both, or other patient factors, contributed to the effect. Theoretically, Gin
increase the risk of serotonin syndrome when taken with selective seroto
inhibitors (SSRIs). Caution is advised, especially when ginkgo is taken to
sexual dysfunction associated with SSRIs. Ginkgo may inhibit monoamin
(Sloley et al, 2000; White et al, 1996), and has demonstrated serotonerg
animals (Ramassamy et al, 1992) which might increase the risk of seroto
when ginkgo is combined with SSRIs. The potential MAO inhibitory activ
is questionable. A human study did not show MAO inhibition in the brain
consumption (Fowler et al, 2000). Ginkgo biloba extract inhibited MAO-A
the rat brain in vitro (Sloley et al, 2000; White et al, 1996) and MAO-B in
platelets in vitro (White et al, 1996). No significant MAO inhibition was fo
following oral consumption (Porsolt et al, 2000).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients closely for symptoms of seroto
if ginkgo is combined with selective serotonin reuptake inhibitors (SSRIs
7) Probable Mechanism: additive pharmacologic effects resulting in exc
serotonergic stimulation
8) Literature Reports

3.5.1.BI Heparin

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint hemostasis. Case-control and cohort studies have shown that the combi SSRIs and anticoagulants has been associated with an increased risk of (Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R solution, 2008). Bleeding events reported have included epistaxis, ecchy hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa (including increased bleeding) have been reported with the coadministra with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When escitalopram and an anticoagulant are g concurrently, monitor patients for signs of increased bleeding. Patients v warfarin should be monitored closely for altered anticoagulant effects, in increased bleeding, when escitalopram therapy is initiated or discontinue LEXAPRO(R) oral tablets, solution, 2008).

7) Probable Mechanism: unknown

8) Literature Reports

a) According to a retrospective cohort study (n=234), there was an of clinically relevant bleeding (hospital admission due to bleeding) ir receiving warfarin for atrial fibrillation during concomitant SSRI thera weeks following SSRI therapy termination. Patients with a mean ag years receiving warfarin plus SSRI (n=117) were matched with ranc patients who received warfarin only (n=117). SSRI included fluoxeti citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin experienced 11 bleeding episodes during 213.9 treatment years in t plus SSRI group, and 10 patients experienced 14 bleedings during 5 treatment years in the warfarin-only group. The corresponding total bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel ratio for first bleedings during treatment with warfarin plus SSRI was CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI ir patients experiencing bleeding at the time of concomitant administra sertraline or citalopram. The addition of an SSRI was not associated change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T the study may be limited by earlier bleeding events, unknown patier and exclusion of clopidogrel, dipyridamol, corticosteroids and antico other than warfarin in the model (Wallerstedt et al, 2009).

b) A population-based, case-controlled study of new coumarin user (acenocoumarol and phenprocoumon) with concomitant selective se reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali nongastrointestinal bleeding. Using national pharmacy and hospitali records, Netherlands researchers identified 1848 cases that were a abnormal bleeding and compared them with 5818 control subjects a coumarins. Median duration of treatment in patients was 220 days (4690 days). Patients on SSRIs showed greater risk for hospitalizatio nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka 2008).

3.5.1.BJ Hydrocodone

1) Interaction Effect: an increased risk of serotonin syndrome (tachycard hyperthermia, myoclonus, mental status changes)

2) Summary: Coadministration of escitalopram and hydrocodone has re development of visual hallucinations in a 90-year-old woman. While no c symptoms suggestive of serotonin syndrome were reported for this patie symptoms such as visual hallucinations are usually reported less commo serotonin syndrome (approximately 10% of cases). Clinical symptoms of syndrome have been reported with concurrent use of escitalopram with c (Gnanadesigan et al, 2005). Caution is advised if escitalopram and hydr coadministered. Monitor patients for signs and symptoms of serotonin sy

(tachycardia, hyperthermia, myoclonus, mental status changes).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concomitant administration of escitalopram an hydrocodone may increase the risk of developing serotonin syndrome. If are coadministered, monitor patients for symptoms of serotonin syndrom (tachycardia, hyperthermia, myoclonus, mental status changes).
7) Probable Mechanism: additive pharmacologic effects resulting in exc serotonergic stimulation
8) Literature Reports
a) Visual hallucinations developed in an 90-year-old woman followi administration of hydrocodone and escitalopram. The woman was b with hydrocodone and citalopram 10 mg/day. Citalopram was chang escitalopram 10 mg once daily and a few weeks later, the patient be experiencing visual hallucinations. Improvement in pain symptoms c hydrocodone to be subsequently discontinued. One month later, the hallucinations had resolved. Prior to escitalopram therapy, the patie treated with paroxetine and later, citalopram along with the same hy dose. However, this had not resulted in any hallucinations or any se syndrome-related symptoms (Gnanadesigan et al, 2005).

3.5.1.BK Hydroxytryptophan

1) Interaction Effect: an increased risk of serotonin syndrome (hyperten hyperthermia, myoclonus, mental status changes)
2) Summary: Hydroxytryptophan (5-HTP) may potentiate the serotonerg selective serotonin reuptake inhibitors (SSRIs) (Meltzer et al, 1997a). Si increases serotonin levels, when combined with an SSRI, the serotonin increased sufficiently to produce serotonin syndrome. Caution is advised concomitant use of 5-HTP and SSRIs.
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: No cases have been reported of serotonin syn resulting from this combination. Caution is advised if hydroxytryptophan selective serotonin reuptake inhibitor (SSRI) are used concomitantly. Mo patient for early signs of serotonin syndrome such as anxiety, confusion, disorientation.
7) Probable Mechanism: additive serotonergic effect
8) Literature Reports
a) Hydroxytryptophan (5-HTP) (200 milligrams (mg) orally) as a sin increased plasma cortisol and prolactin levels in both medicated and unmedicated patients with major depression or obsessive compulsiv (OCD). These responses were greater if the patient was also taking = 16) (p less than 0.0001). Mean fluoxetine dose for depressed pati mg/day,and for OCD patients it was 60 mg/day. Cortisol or prolactin in patients taking 5-HTP with tricyclic antidepressants (n = 14) or the no medication (n = 83) were not significantly different from each oth measurement of serotonergic effects of antidepressants can be eva measuring hypothalamic-pituitary-adrenal (HPA) axis or PRL respon clinical manifestations of serotonin syndrome were reported in patie HTP concomitantly with fluoxetine (Meltzer et al, 1997).

3.5.1.BL Ibuprofen

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and NSAIDs has been associated with an increased risk of bleed events have included epistaxis, ecchymosis, hematoma, petechiae, and threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension, Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora solution, 2005).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concu monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and th potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi upper gastrointestinal bleeding were searched among 26,005 users antidepressant medications and compared with the number of hosp those patients who did not receive prescriptions for antidepressants of upper GI bleeding episodes was 3.6 times more than expected (9 confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1 5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of demonstrate an increased risk of upper GI bleeding during the use Combined use of SSRIs and NSAIDs or low-dose aspirin increased further (Dalton et al, 2003).
b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOR oral tablets, 2007).

3.5.1.BM Iloprost
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and antiplatelet agents has been associated with an increased ris Bleeding events reported have included epistaxis, ecchymosis, hematon and life-threatening hemorrhages (Prod Info PAXIL(R) oral tablets, susp Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are g concurrently, monitor patient for signs of increased bleeding (Prod Info F tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.BN Indomethacin
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and NSAIDs has been associated with an increased risk of bleed events have included epistaxis, ecchymosis, hematoma, petechiae, and threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension, Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora solution, 2005).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concu monitor patient for signs of increased bleeding.
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and th potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi upper gastrointestinal bleeding were searched among 26,005 users antidepressant medications and compared with the number of hosp those patients who did not receive prescriptions for antidepressants of upper GI bleeding episodes was 3.6 times more than expected (9 confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1 5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of demonstrate an increased risk of upper GI bleeding during the use Combined use of SSRIs and NSAIDs or low-dose aspirin increased further (Dalton et al, 2003).
b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOR oral tablets, 2007).

3.5.1.BO Indoprofen

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and NSAIDs has been associated with an increased risk of bleed events have included epistaxis, ecchymosis, hematoma, petechiae, and threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension, Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and th potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi upper gastrointestinal bleeding were searched among 26,005 users antidepressant medications and compared with the number of hosp those patients who did not receive prescriptions for antidepressants of upper GI bleeding episodes was 3.6 times more than expected (9 confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1 5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of demonstrate an increased risk of upper GI bleeding during the use Combined use of SSRIs and NSAIDs or low-dose aspirin increased further (Dalton et al, 2003).

b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOR oral tablets, 2007).

3.5.1.BP Isocarboxazid

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, myoclonus, mental status changes)

2) Summary: Concurrent administration or overlapping therapy with esc a monoamine oxidase (MAO) inhibitor may result in CNS toxicity or sero syndrome, a hyperserotonergic state characterized by symptoms such a restlessness, myoclonus, changes in mental status, hyperreflexia, diaph shivering, and tremor. Serious, even fatal, reactions have been reported Lexapro(TM), 2002a). Concomitant use is contraindicated.

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: Concurrent use of escitalopram and isocarbox contraindicated. Wait at least two weeks after discontinuing a MAO inhib initiating escitalopram therapy. In addition, wait at least five weeks after escitalopram before initiating therapy with a MAO inhibitor.

7) Probable Mechanism: inhibition of serotonin metabolism by monoam

3.5.1.BQ Isoxicam

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and NSAIDs has been associated with an increased risk of bleed events have included epistaxis, ecchymosis, hematoma, petechiae, and threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension, Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and th

potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi
upper gastrointestinal bleeding were searched among 26,005 users
antidepressant medications and compared with the number of hosp

further (Dalton et al, 2003).

b) Coadministration of ketorolac with psychoactive drugs (such as
been associated with hallucinations in some patients (Prod Info TOF
oral tablets, 2007).

3.5.1.BR Ketoconazole

1) Interaction Effect: decreased ketoconazole bioavailability

2) Summary: Concomitant administration of escitalopram 40 milligrams
ketoconazole 200 mg induced reductions in ketoconazole maximum plas
concentrations and area under the concentration-time curve by 21% and
respectively; escitalopram pharmacokinetics were unaffected by coadmi
(Prod Info LEXAPRO(R) Oral Tablet, Oral Solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: If concurrent therapy is required, a dosage adj
be required for ketoconazole in order to achieve and maintain a consiste
effect.

7) Probable Mechanism: unknown

3.5.1.BS Ketoprofen

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOR oral tablets, 2007).

3.5.1.BU Lamifiban

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and antiplatelet agents has been associated with an increased ris Bleeding events reported have included epistaxis, ecchymosis, hematon and life-threatening hemorrhages (Prod Info PAXIL(R) oral tablets, susp Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are g concurrently, monitor patient for signs of increased bleeding (Prod Info P tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.BV Lamotrigine

1) Interaction Effect: an increased risk of myoclonus
2) Summary: Myoclonus occurred in 2 patients receiving escitalopram a lamotrigine concomitantly, where symptoms resolved following withdraw escitalopram in 1 patient. There was no evidence of a metabolic enzyme with lamotrigine, and the interaction was believed to be due to an additiv effect of lamotrigine and escitalopram on the 5-HT1A receptors, or by ar inhibition of voltage-gated calcium channels by both agents (Rosenhage Exercise caution when using both drugs concurrently and monitor for sig symptoms of myoclonus including involuntary twitching and jerking.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Use caution if escitalopram and lamotrigine are concurrently as this resulted in myoclonus in 2 patients. In one patient, n resolved after escitalopram was withdrawn (Rosenhagen et al, 2006). M signs and symptoms of myoclonus including involuntary twitching and je
7) Probable Mechanism: additive inhibition of voltage-gated calcium cha additive or synergistic effects on the 5-HT1A receptor
8) Literature Reports
a) Myoclonus occurred in 2 patients following concomitant treatmer escitalopram and lamotrigine. The first patient, a 22-year-old woma escitalopram 30 mg/day for depression, developed daytime and nig

myoclonus after 8 weeks of receiving lamotrigine (titrated to 100 mg treatment of bipolar type II disorder. Serum levels of both drugs, me the onset of myoclonus, were within the expected drug reference ra escitalopram levels remained stable compared to a baseline level d starting lamotrigine therapy. Neither drug was discontinued and the continued to have myoclonus while on escitalopram and lamotrigine Further analysis revealed that the patient was a normal metabolizer CYP2C19, and CYP2D6 enzymes. The second patient, a 28-year-o taking lamotrigine 300 mg/day for a seizure disorder, developed day nighttime myoclonus after 2 weeks of receiving escitalopram (titrate mg/day) for generalized anxiety disorder. For 6 months, the patient the same frequency of myoclonus while on both therapies; however myoclonus resolved 2 weeks after escitalopram was withdrawn. Lar serum levels, measured at the onset and after the myoclonus resolv change. Although escitalopram is metabolized by hepatic enzymes CYP2C19, and CYP2D6, there was no evidence of a metabolic enz interaction with lamotrigine. It was postulated that the myoclonus ma caused by an additive or synergistic effect of lamotrigine and escital 5-HT1A receptors, or by an additive inhibition of voltage-gated calci by both agents (Rosenhagen et al, 2006).

3.5.1.BW Lazabemide

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, myoclonus, mental status changes)

2) Summary: Concurrent administration or overlapping therapy with esc a monoamine oxidase (MAO) inhibitor may result in CNS toxicity or sero syndrome, a hyperserotonergic state characterized by symptoms such a restlessness, myoclonus, changes in mental status, hyperreflexia, diaph shivering, and tremor. Serious, even fatal, reactions have been reported Lexapro(TM), 2002d). Concomitant use is contraindicated.

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: Concurrent use of escitalopram and lazabemic contraindicated. Wait at least two weeks after discontinuing a MAO inhib initiating escitalopram therapy. In addition, wait at least five weeks after escitalopram before initiating therapy with a MAO inhibitor.

7) Probable Mechanism: inhibition of serotonin metabolism by monoam

3.5.1.BX Lexipafant

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint hemostasis. Case-control and cohort studies have shown that the combi SSRIs and antiplatelet agents has been associated with an increased ris Bleeding events reported have included epistaxis, ecchymosis, hematon and life-threatening hemorrhages (Prod Info PAXIL(R) oral tablets, susp Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an antiplatelet agent are g concurrently, monitor patient for signs of increased bleeding (Prod Info P tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed capsules, solution, 2008)

7) Probable Mechanism: unknown

3.5.1.BY Linezolid

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, myoclonus, mental status changes)

2) Summary: Linezolid is a reversible, nonselective inhibitor of monoam Concurrent administration or overlapping therapy with escitalopram and oxidase (MAO) inhibitor may result in CNS toxicity or serotonin syndrom hyperserotonergic state characterized by symptoms such as restlessnes changes in mental status, hyperreflexia, diaphoresis, shivering, and trem even fatal, reactions have been reported. There have been spontaneous serotonin syndrome associated with concomitant use of linezolid and se agents (Prod Info ZYVOX(R) IV injection, oral tablets, oral suspension, 2

Info Lexapro(R), 2002). If escitalopram and linezolid are used concomita
closely for symptoms of serotonin syndrome. Serotonin syndrome can b
threatening. If serotonin syndrome develops, discontinue the offending a
provide supportive care and other therapy as necessary (Boyer & Shanr
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Unless carefully monitored for serotonin syndr
should not be administered to patients taking escitalopram (Prod Info ZY
injection, oral tablets, oral suspension, 2008) If escitalopram and linezoli
concomitantly, monitor closely for symptoms of serotonin syndrome such
neuromuscular abnormalities (including hyper-reflexia, tremor, muscle ri
peripheral hypertonicity, and shivering), autonomic hyperactivity (includi
tachycardia, mydriasis, diaphoresis, and diarrhea), and mental status ch
(including agitation and delirium). Serotonin syndrome can be life-threate
serotonin syndrome develops, discontinue the offending agents and pro
supportive care and other therapy as necessary (Boyer & Shannon, 200
7) Probable Mechanism: inhibition of serotonin metabolism by monoam

3.5.1.BZ Lithium

1) Interaction Effect: possible increased lithium concentrations and/or a
risk of SSRI-related serotonin syndrome (hypertension, hyperthermia, m
mental status changes)
2) Summary: Concomitant use of lithium and various SSRIs has been a
enhanced side effects of either or both drugs, and with or without elevat
levels. The combination has resulted in neurotoxicity and increased lithi
one case report (Salama & Shafey, 1989a). Signs and symptoms of lithi
and serotonin syndrome have also been reported in patients who demor
therapeutic serum lithium levels while on concurrent fluoxetine and lithiu
1993a; Noveske et al, 1989a). Two studies have failed to identify a phar
interaction between lithium and citalopram (Gram et al, 1993a; Baumann
1996a). Combined administration of citalopram (40 mg daily for 10 days)
(30 mmol/day for 5 days) had no significant effect on the pharmacokinet
citalopram or lithium. However, plasma lithium levels should be monitore
appropriate adjustment to the lithium dose in accordance with standard c
practice. Lithium may enhance the serotonergic effects of citalopram, the
caution should be exercised when citalopram and lithium are coadminist
Info Celexa(R), 2004). Concurrent use of fluvoxamine and lithium has le
reports of increased lithium levels and neurotoxicity, serotonin syndrome
somnolence, and mania (Salama & Shafey, 1989a; Ohman & Spigset, 1
& Marwick, 1990; Burrai et al, 1991a). No pharmacokinetic interference
during a multiple-dose study of coadministered lithium and paroxetine (P
CR(TM), 2003). If these two agents are to be given concomitantly, the m
suggests that caution be used until more clinical experience is available.
interactions leading to lithium toxicity have been reported when lithium w
coadministered with fluoxetine and fluvoxamine (both in the same pharm
class as paroxetine, eg, selective serotonin reuptake inhibitors) (Ohman
1993a; Salama & Shafey, 1989a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: Monitor patients on concurrent lithium and sele
serotonin reuptake inhibitor therapy for increased plasma concentrations
addition, monitor patients for signs and symptoms associated with seroto
(hypertension, hyperthermia, myoclonus, mental status changes).
7) Probable Mechanism: unknown
8) Literature Reports
a) Concomitant administration of oral lithium carbonate and oral flu
resulted in increased lithium serum levels with lithium toxicity in a 4
woman with a bipolar affective disorder (Salama & Shafey, 1989). F
mg daily was added to a regimen of lithium 1200 mg daily following
complaints of weakness, tiredness, decreased concentration, and e
awakening. Lithium serum levels increased to 1.7 mEq/L from a ran
1.15 mEq/L prior to fluoxetine. Fluoxetine was discontinued and the
lithium decreased; this resulted in a decrease in the lithium serum le
hours to 1.2 mEq/L. The neurologic symptoms subsided within seve
lithium serum level decreased to 0.9 mEq/L. The contribution of fluo

lithium toxicity in this patient was obscured by the fact that the lithiu
reduced at the time of fluoxetine withdrawal.
b) A 53-year old woman who had been taking fluoxetine 20 mg dail
lorazepam 0.5 mg four times daily for a major depressive disorder h
mg per day added to her regimen in order to augment her response
Within 48 hours, the patient became confused, ataxic, and develope
tremor in her right arm. Vital signs showed a rectal temperature of 1
and laboratory values were normal except for an elevated leukocyte
slightly elevated bilirubin level. After discontinuation of lithium and fl
patient's symptoms resolved over the next four days. At no point dic
levels reach a toxic level, suggesting that the patient's symptoms w
toxic reaction between fluoxetine and lithium (Noveske et al, 1989).
c) Serotonin syndrome was precipitated when lithium 300 mg twice
added to a three-month regimen of fluoxetine 40 mg per day. Five d
patient's lithium level was measured at 0.65 mEq/L and the dose wa
to 300 mg three times daily. Two days after this dosage change, the
experienced akathisia, myoclonus, hyperreflexia, shivering, tremor,
incoordination. After discontinuation of lithium and initiation of cypro
therapy, the patient's symptoms began to improve. The patient was
on a regimen of fluoxetine 40 mg per day without further symptoms
syndrome (Muly et al, 1993).
d) Eight healthy male volunteers completed three phases of an inte
to determine the effects of coadministered lithium and citalopram. A
were extensive metabolizers of sparteine, indicating normal cytochr
2D6 enzyme activity. Although lithium is not influenced by drug oxid
citalopram metabolites are excreted by the kidney, as is lithium. Eac
received citalopram 40 mg alone as a single daily dose for 10 days,
mmol (1980 mg) alone daily for five days, and lithium coadministere
citalopram on days 3-7. At least two weeks separated each treatme
Results showed that the concurrent administration of citalopram and
not significantly alter the pharmacokinetics of lithium (Gram et al, 19
e) Twenty-four patients experiencing depression (DSM III criteria) v
randomized under double-blind conditions to receive citalopram (40
daily) and lithium carbonate (800 mg daily) or placebo. All of the sub
failed to respond to four weeks of citalopram monotherapy. Lithium
coadministered on days 29 to 42. No evidence of a pharmacokinetic
between lithium and citalopram was noted, and cotherapy was well
(Baumann et al, 1996).
f) Serotonin syndrome was described in a 53-year-old patient who
on lithium 1400 mg daily (serum level 0.71 mmol/L) and was given f
50 mg daily. Over a 10-day period the fluvoxamine dose was increa
daily; tremor and difficulty with fine hand movements developed. Aft
tremor, impaired motor function coordination, marked bilateral hype
biceps and knee jerks, and clonus in both ankles were seen. After 1
continued therapy, during which time no further deterioration occurr
nortriptyline 100 mg daily replaced fluvoxamine, and the neuromusc
symptoms abated over a 2-week period. After four weeks the patier
neurological exam was normal (Ohman & Spigset, 1993).
g) Three cases of mania were reported in patients who were treate
and fluvoxamine. The mania appeared 10 days, four weeks, and fiv
respectively, after cotherapy was begun. Fluvoxamine was discontir
two of the three patients, the mania resolved, and successful treatm
depression occurred with lithium alone. The third patient improved,
depression reappeared within a month of fluvoxamine discontinuatic
al, 1991).
h) In an open-labeled, placebo-controlled study, lithium 600 mg wa
administered to 16 subjects orally twice daily on days one through e
in the morning on day nine. In addition, oral sertraline 100 mg or pla
given twice, ten hours and two hours prior to lithium dosing on day r
steady-state lithium level was only decreased by 1.4% (0.01 mEq/L)
lithium renal clearance increased by 6.9% (0.11 L/hour) when sertra
coadministered. Seven subjects experienced side effects, mainly tre
receiving lithium and sertraline, whereas no subjects who ingested p
lithium experienced side effects (Wilner et al, 1991).

3.5.1.CA Lornoxicam

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and th
potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi
upper gastrointestinal bleeding were searched among 26,005 users
antidepressant medications and compared with the number of hosp
those patients who did not receive prescriptions for antidepressants
of upper GI bleeding episodes was 3.6 times more than expected (9
confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA
dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1
5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of
demonstrate an increased risk of upper GI bleeding during the use
Combined use of SSRIs and NSAIDs or low-dose aspirin increased
further (Dalton et al, 2003).
b) Coadministration of ketorolac with psychoactive drugs (such as
been associated with hallucinations in some patients (Prod Info TOF
oral tablets, 2007).

3.5.1.CB Meclofenamate

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maint
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,

b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOF oral tablets, 2007).

3.5.1.CE Methylphenidate

1) Interaction Effect: increased selective serotonin reuptake inhibitor pla concentrations
2) Summary: Human pharmacologic studies have demonstrated that me may inhibit the metabolism of selective serotonin reuptake inhibitors (SS Downward dose adjustments of the SSRI may be necessary when it is u concurrently with methylphenidate. Additionally, when initiating or discor methylphenidate, the SSRI dose may need to be adjusted as needed (P

METADATE CD(R) extended-release oral capsules, 2007).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Use caution when prescribing methylphenidate who take an selective serotonin reuptake inhibitor (SSRI). Concomitant u methylphenidate and an SSRI may cause elevated SSRI plasma concer Consider a decrease in the dose of SSRI when these agents are coadm Additionally, consider adjusting the SSRI dose if necessary when initiatir discontinuing methylphenidate therapy (Prod Info METADATE CD(R) ex release oral capsules, 2007).
7) Probable Mechanism: inhibition of selective serotonin reuptake inhibi metabolism by methylphenidate

3.5.1.CF Metoprolol
1) Interaction Effect: increased metoprolol plasma concentrations and p metoprolol cardioselectivity
2) Summary: Administration of a single dose of metoprolol 100 milligran following administration of escitalopram 20 mg daily for 21 days produce 50% and 82% in metoprolol maximum plasma concentrations and area u concentration-time curve, respectively. No clinically significant changes i pressure or heart rate were observed; however, increased metoprolol pl have been associated with decreased cardioselectivity (Prod Info LEXAI Tablet, Oral Solution, 2005).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Patients stabilized on metoprolol who are adm escitalopram should be observed for signs of increased beta blockade s bradycardia, hypotension or heart failure. At higher metoprolol concentra cardioselectivity may be diminished; monitor appropriate measures of di when escitalopram and metoprolol are used concomitantly.
7) Probable Mechanism: unknown

3.5.1.CG Milnacipran
1) Interaction Effect: increased risk of serotonin syndrome (hypertensio hyperthermia, myoclonus, mental status changes)
2) Summary: Concurrent use of milnacipran and an SSRI or a serotonir norepinephrine reuptake inhibitor (SNRI) may result in hypertension, cor vasoconstriction or serotonin syndrome, which may be life-threatening. S serotonin syndrome may include restlessness, hallucinations, loss of coo heart beat, rapid changes in blood pressure, increased body temperatur overreactive reflexes, nausea, vomiting, and diarrhea (Prod Info SAVEL tablets, 2009).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of milnacipran and an SSRI o norepinephrine reuptake inhibitor (SNRI) may result in hypertension and artery vasoconstriction through the additive serotonergic effects. If these used together, discuss the risks of serotonin syndrome with the patient a closely for symptoms of serotonin syndrome (restlessness, hyperthermia hyperreflexia, incoordination), especially during treatment initiation and o increases (Prod Info SAVELLA(R) oral tablets, 2009).
7) Probable Mechanism: additive serotonergic effect

3.5.1.CH Moclobemide
1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, myoclonus, mental status changes)
2) Summary: Concurrent administration or overlapping therapy with esc a monoamine oxidase (MAO) inhibitor may result in CNS toxicity or sero syndrome, a hyperserotonergic state characterized by symptoms such a restlessness, myoclonus, changes in mental status, hyperreflexia, diaph shivering, and tremor. Serious, even fatal, reactions have been reported Lexapro(TM), 2002e). Concomitant use is contraindicated.
3) Severity: contraindicated
4) Onset: rapid

5) Substantiation: theoretical
6) Clinical Management: Concurrent use of escitalopram and moclobem contraindicated. Wait at least two weeks after discontinuing a MAO inhib initiating escitalopram therapy. In addition, wait at least five weeks after escitalopram before initiating therapy with a MAO inhibitor.
7) Probable Mechanism: inhibition of serotonin metabolism by monoam

3.5.1.CI Morniflumate

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and NSAIDs has been associated with an increased risk of bleed events have included epistaxis, ecchymosis, hematoma, petechiae, and threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension, Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora solution, 2005).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concu monitor patient for signs of increased bleeding.
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and th potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi upper gastrointestinal bleeding were searched among 26,005 users antidepressant medications and compared with the number of hosp those patients who did not receive prescriptions for antidepressants of upper GI bleeding episodes was 3.6 times more than expected (9 confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1 5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of demonstrate an increased risk of upper GI bleeding during the use Combined use of SSRIs and NSAIDs or low-dose aspirin increased further (Dalton et al, 2003).
b) Coadministration of ketorolac with psychoactive drugs (such as been associated with hallucinations in some patients (Prod Info TOF oral tablets, 2007).

3.5.1.CJ Nabumetone

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main hemostasis. Case-control and cohort studies have shown that the combi SSRIs and NSAIDs has been associated with an increased risk of bleed events have included epistaxis, ecchymosis, hematoma, petechiae, and threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension, Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora solution, 2005).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concu monitor patient for signs of increased bleeding.
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and th potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi upper gastrointestinal bleeding were searched among 26,005 users antidepressant medications and compared with the number of hosp those patients who did not receive prescriptions for antidepressants of upper GI bleeding episodes was 3.6 times more than expected (9 confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1 5.2 (95% confidence interval, 3.2 to 8), respectively. b) Coadministration of ketorolac with psychoactive drugs (such as t
been associated with hallucinations in some patients (Prod Info TOF
oral tablets, 2007).

3.5.1.CK Nadroparin

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk of
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R
solution, 2008). Bleeding events reported have included epistaxis, ecchy
hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra
with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table
2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When escitalopram and an anticoagulant are g
concurrently, monitor patients for signs of increased bleeding. Patients v
warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).

7) Probable Mechanism: unknown

8) Literature Reports

a) According to a retrospective cohort study (n=234), there was an
of clinically relevant bleeding (hospital admission due to bleeding) in
receiving warfarin for atrial fibrillation during concomitant SSRI thera
weeks following SSRI therapy termination. Patients with a mean age
years receiving warfarin plus SSRI (n=117) were matched with rand
patients who received warfarin only (n=117). SSRI included fluoxeti
citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin
experienced 11 bleeding episodes during 213.9 treatment years in t
plus SSRI group, and 10 patients experienced 14 bleedings during 5
treatment years in the warfarin-only group. The corresponding total
bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel
ratio for first bleedings during treatment with warfarin plus SSRI was
CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI in
patients experiencing bleeding at the time of concomitant administra
sertraline or citalopram. The addition of an SSRI was not associated
change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T
the study may be limited by earlier bleeding events, unknown patien
and exclusion of clopidogrel, dipyridamol, corticosteroids and antico
other than warfarin in the model (Wallerstedt et al, 2009).

b) A population-based, case-controlled study of new coumarin user
(acenocoumarol and phenprocoumon) with concomitant selective se
reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali
nongastrointestinal bleeding. Using national pharmacy and hospitali
records, Netherlands researchers identified 1848 cases that were a
abnormal bleeding and compared them with 5818 control subjects a
coumarins. Median duration of treatment in patients was 220 days (
4690 days). Patients on SSRIs showed greater risk for hospitalizatio
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedi
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.CL Naproxen

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maint
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).

3) Severity: moderate

4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.
7) Probable Mechanism: unknown
8) Literature Reports

oral tablets, 2007).

3.5.1.CQ Oxycodone

1) Interaction Effect: an increased risk of serotonin syndrome (tachycar
hyperthermia, myoclonus, mental status changes)

2) Summary: Coadministration of oxycodone and escitalopram resulted
development of serotonin syndrome in an 88-year-old woman (Gnanade
2005). Caution is advised if escitalopram and oxycodone are coadminist
patients for signs and symptoms of serotonin syndrome (tachycardia, hy
myoclonus, mental status changes).

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Concomitant administration of escitalopram an
may increase the risk of developing serotonin syndrome. If these agents
coadministered, monitor patients for symptoms of serotonin syndrome (t
hyperthermia, myoclonus, mental status changes).

7) Probable Mechanism: additive pharmacologic effects resulting in exc
serotonergic stimulation

8) Literature Reports

a) Symptoms of serotonin syndrome developed in an 88-year-old w
following concurrent administration of oxycodone and escitalopram.
was taking escitalopram 10 mg/day and extended-release oxycodor
twice daily. Approximately 5 weeks prior to the current presentation,
extended-release oxycodone had been doubled. She presented to t
room with acutely elevated blood pressure (200/90 millimeters of m
frequent myoclonic jerks in the lower extremities. Both escitalopram
oxycodone were stopped and the patient was treated with intraveno
which led to resolution of the myoclonic jerks and a return to baselir
pressure in less than a day. Subsequent re-initiation of extended-re
oxycodone (20 mg twice daily), but not escitalopram, did not result i
or blood pressure elevation (Gnanadesigan et al, 2005).

3.5.1.CR Parecoxib

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for main
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and NSAIDs has been associated with an increased risk of bleed
events have included epistaxis, ecchymosis, hematoma, petechiae, and
threatening hemorrhages (Prod Info PAXIL(R) oral tablets, suspension,
Info Lexapro(TM), 2003a; Dalton et al, 2003a; Prod Info CELEXA (R) ora
solution, 2005).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concu
monitor patient for signs of increased bleeding.

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and th
potentiated by concurrent use of NSAIDs or low-dose aspirin. Hospi
upper gastrointestinal bleeding were searched among 26,005 users
antidepressant medications and compared with the number of hosp
those patients who did not receive prescriptions for antidepressants
of upper GI bleeding episodes was 3.6 times more than expected (9
confidence interval, 2.7 to 4.7). Combined use of an SSRI and NSA
dose aspirin increased the risk to 12.2 (95% confidence interval, 7.1
5.2 (95% confidence interval, 3.2 to 8), respectively. The findings of

demonstrate an increased risk of upper GI bleeding during the use c
Combined use of SSRIs and NSAIDs or low-dose aspirin increased
further (Dalton et al, 2003).
b) Coadministration of ketorolac with psychoactive drugs (such as f
been associated with hallucinations in some patients (Prod Info TOF
oral tablets, 2007).

3.5.1.CS Parnaparin

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maint
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk of
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R
solution, 2008). Bleeding events reported have included epistaxis, ecchy
hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra
with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table
2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When escitalopram and an anticoagulant are g
concurrently, monitor patients for signs of increased bleeding. Patients v
warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an
of clinically relevant bleeding (hospital admission due to bleeding) ir
receiving warfarin for atrial fibrillation during concomitant SSRI thera
weeks following SSRI therapy termination. Patients with a mean age
years receiving warfarin plus SSRI (n=117) were matched with rand
patients who received warfarin only (n=117). SSRI included fluoxeti
citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin
experienced 11 bleeding episodes during 213.9 treatment years in t
plus SSRI group, and 10 patients experienced 14 bleedings during 5
treatment years in the warfarin-only group. The corresponding total
bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel
ratio for first bleedings during treatment with warfarin plus SSRI was
CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI ir
patients experiencing bleeding at the time of concomitant administra
sertraline or citalopram. The addition of an SSRI was not associated
change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T
the study may be limited by earlier bleeding events, unknown patier
and exclusion of clopidogrel, dipyridamol, corticosteroids and antico
other than warfarin in the model (Wallerstedt et al, 2009).
b) A population-based, case-controlled study of new coumarin user
(acenocoumarol and phenprocoumon) with concomitant selective se
reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali
nongastrointestinal bleeding. Using national pharmacy and hospitali
records, Netherlands researchers identified 1848 cases that were a
abnormal bleeding and compared them with 5818 control subjects a
coumarins. Median duration of treatment in patients was 220 days (
4690 days). Patients on SSRIs showed greater risk for hospitalizatio
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.CT Pentosan Polysulfate Sodium

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maint
hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk of
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R
solution, 2008). Bleeding events reported have included epistaxis, ecchy

hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra
with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table
2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When escitalopram and an anticoagulant are g
concurrently, monitor patients for signs of increased bleeding. Patients v
warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an
of clinically relevant bleeding (hospital admission due to bleeding) ir
receiving warfarin for atrial fibrillation during concomitant SSRI thera
weeks following SSRI therapy termination. Patients with a mean ag
years receiving warfarin plus SSRI (n=117) were matched with rand
patients who received warfarin only (n=117). SSRI included fluoxeti
citalopram, paroxetine, sertraline, fluvoxamine, or escitalopram. Nin
experienced 11 bleeding episodes during 213.9 treatment years in t
plus SSRI group, and 10 patients experienced 14 bleedings during
treatment years in the warfarin-only group. The corresponding total
bleedings were 51.4 and 23.9 per 1000 treatment years, respectivel
ratio for first bleedings during treatment with warfarin plus SSRI was
CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI ir
patients experiencing bleeding at the time of concomitant administra
sertraline or citalopram. The addition of an SSRI was not associated
change in warfarin dose or INR (p=0.48 and p=0.31 respectively). T
the study may be limited by earlier bleeding events, unknown patier
and exclusion of clopidogrel, dipyridamol, corticosteroids and antico
other than warfarin in the model (Wallerstedt et al, 2009).
b) A population-based, case-controlled study of new coumarin user
(acenocoumarol and phenprocoumon) with concomitant selective se
reuptake inhibitors (SSRIs) resulted in an increased risk of hospitali
nongastrointestinal bleeding. Using national pharmacy and hospitali
records, Netherlands researchers identified 1848 cases that were a
abnormal bleeding and compared them with 5818 control subjects a

4690 days). Patients on SSRIs showed greater risk for hospitalizatio
nongastrointestinal bleeding (adjusted odds ratio (OR) 1.7, 95% cor
interval (CI), 1.1 to 2.5), however, the rate of gastrointestinal bleedir
OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schaleka
2008).

3.5.1.CU Phenelzine
1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension,
myoclonus, mental status changes)
2) Summary: Concurrent administration or overlapping therapy with esc
a monoamine oxidase (MAO) inhibitor may result in CNS toxicity or sero
syndrome, a hyperserotonergic state characterized by symptoms such a
restlessness, myoclonus, changes in mental status, hyperreflexia, diaph
shivering, and tremor. Serious, even fatal, reactions have been reported
Lexapro(TM), 2002f). Concomitant use is contraindicated.
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of escitalopram and phenelzin
contraindicated. Wait at least two weeks after discontinuing a MAO inhib
initiating escitalopram therapy. In addition, wait at least five weeks after
escitalopram before initiating therapy with a MAO inhibitor.
7) Probable Mechanism: inhibition of serotonin metabolism by monoam

3.5.1.CV Phenindione
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for main

hemostasis. Case-control and cohort studies have shown that the combi
SSRIs and anticoagulants has been associated with an increased risk o
(Wallerstedt et al, 2009; Schalekamp et al, 2008; Prod Info LEXAPRO(R
solution, 2008). Bleeding events reported have included epistaxis, ecchy
hematoma, petechiae, and life-threatening hemorrhages. Altered anticoa
(including increased bleeding) have been reported with the coadministra
with warfarin (Schalekamp et al, 2008; Prod Info LEXAPRO(R) oral table
2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When escitalopram and an anticoagulant are g
concurrently, monitor patients for signs of increased bleeding. Patients v
warfarin should be monitored closely for altered anticoagulant effects, in
increased bleeding, when escitalopram therapy is initiated or discontinue
LEXAPRO(R) oral tablets, solution, 2008).

7) Probable Mechanism: unknown
