Carbamazepine plasma levels were increased by 99.4% to 16.6 mg/L (4-12), and his phenytoin concentı by 32.7% to 7 mg/L (10-20). Carbamazepine concentration returned to the therapeutic range two days a dosage was reduced to 200 mg three times daily, ritonavir was discontinued and nelfinavir 1000 mg twic initiated. Symptoms of toxicity disappeared as well. The author concludes that blood concentrations of a be monitored during the first 24-48 hours when ritonavir is added to carbamazepine and phenytoin treatr Reduction of the carbamazepine dose may prevent toxicity (Mateu-de Antonio et al, 2001).

3.5.1.EV Rocuronium

1) Interaction Effect: decreased duration of rocuronium-induced neuromuscular blockade
2) Summary: One case report has described a resistance to rocuronium in a patient maintained on chronic c therapy. This resistance is similar to that seen during therapy with other neuromuscular blockers and carbam precise mechanism of this interaction is not known, but may involve both pharmacodynamic and pharmacoki (Baraka & Idriss, 1996a). A study involving 22 healthy individuals undergoing neurosurgical procedures also duration of the rocuronium-induced neuromuscular block is significantly shortened by chronic carbamazepine et al, 1999a).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Monitor patients for an appropriate clinical response to the neuromuscular blocker. intervals or higher doses of rocuronium may be needed in patients receiving carbamazepine.
7) Probable Mechanism: induction of rocuronium metabolism via cytochrome P450 enzyme system
8) Literature Reports

a) A 61-year old epileptic male who had been maintained on oral carbamazepine 200 mg three times da underwent cataract surgery. Anesthesia was induced with thiopental and fentanyl prior to the administrat intravenous bolus dose of rocuronium 0.6 mg/kg. This dose of rocuronium is twice the 95% effective dos Rocuronium caused a partial neuromuscular block and was followed by rapid recovery to T1 to 25% of th within five minutes. This response suggests that long-term therapy with carbamazepine causes a resista nondepolarizing neuromuscular blocking effects of rocuronium (Baraka & Idriss, 1996).

b) Twenty-two healthy individuals scheduled for neurosurgical procedures were studied to determine the carbamazepine therapy on the duration of rocuronium-induced neuromuscular blockade. Eleven patients treated with carbamazepine for a minimum of four weeks prior to surgery, while the other eleven patients controls. All patients received oral diazepam one hour prior to surgery, and anesthesia was induced with thiopental. A single bolus dose of rocuronium 0.6 mg/kg, which is two times the ED95, was given intrave the two groups, the lag time and the onset time did not differ significantly. However, when comparing the carbamazepine groups, the time to 10% recovery was 29.2 min vs. 19.8 min, 25% recovery was 36.1 mi 50% recovery was 43.5 min vs. 30.4 min, and 75% recovery was 57.0 min vs. 36.5 min, respectively. Th calculated as the time required for the response to the first stimulus to recover from 25% to 75% of base decreased from 20.8 min in the control group to 10.9 min in the carbamazepine group (Spacek et al, 199

3.5.1.EW Rufinamide

1) Interaction Effect: decreased carbamazepine and rufinamide plasma concentrations
2) Summary: Concomitant administration of carbamazepine and rufinamide may result in rufinamide concen of 19% to 26% (dependent on the carbamazepine dose) and carbamazepine concentration decreases of 7% Carbamazepine decreases are dependent on the concentration of rufinamide, so maximum changes will mos children and other patients who achieve significantly higher levels of rufinamide (Prod Info BANZEL(TM) oral
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Caution is advised if carbamazepine and rufinamide are coadministered as this ma decreased carbamazepine or rufinamide plasma concentrations. Risk of carbamazepine concentration reduc children and in other patients who achieve significantly higher levels of rufinamide (Prod Info BANZEL(TM) o
7) Probable Mechanism: induction of carboxylesterase-mediated rufinamide metabolism by carbamazepine

3.5.1.EX Sabeluzole

1) Interaction Effect: reduced sabeluzole efficacy
2) Summary: In epileptic patients receiving a variety of anticonvulsants (primarily carbamazepine or phenyto combinations), sabeluzole plasma concentrations have been reduced compared to data from healthy subject al, 1995a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Higher doses of sabeluzole may be required during combined therapy with carbam therapeutic plasma levels of sabeluzole are unknown, dose titration is necessarily empirical.
7) Probable Mechanism: induction by carbamazepine of sabeluzole metabolism
8) Literature Reports

a) In one study, a target minimal trough sabeluzole concentration of 50 ng/mL was not achieved in most receiving anticonvulsants (primarily carbamazepine and/or phenytoin) and sabeluzole in doses of up to 6 (Aldenkamp et al, 1995). In contrast, prior sabeluzole pharmacokinetic studies have consistently demons

levels of 40 to 50 ng/mL with 10-mg twice daily doses (De Deyn et al, 1992). Unpublished data from the (Janssen) also provide evidence of enhanced elimination of sabeluzole when combined with antiepileptic levels of anticonvulsants were unaffected by sabeluzole (Aldenkamp et al, 1995). However, these data n preliminary and are based predominantly on indirect observations; a formal kinetic study in epileptic patie ascertain the magnitude of the interaction with specific anticonvulsants.

3.5.1.EY Saquinavir

1) Interaction Effect: reduced saquinavir effectiveness
2) Summary: Coadministration of carbamazepine and saquinavir may result in reduced saquinavir serum cor Info Invirase(R), 2003). The mechanism of action is thought to be induction by carbamazepine of the cytochro isoenzyme, the enzyme primarily responsible for saquinavir metabolism. The effectiveness of saquinavir is lik decreased in patients receiving carbamazepine-saquinavir therapy due to reduced saquinavir bioavailability.
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Clinicians may want to consider using alternative medication to carbamazepine in p saquinavir therapy. However, if it becomes necessary to give these agents concurrently, upward adjustments dosing may be needed to maintain antiviral effectiveness.
7) Probable Mechanism: P450 induction of saquinavir metabolism

3.5.1.EZ Selegiline

1) Interaction Effect: an increase in selegiline concentrations
2) Summary: Concomitant administration of carbamazepine and MAO inhibitors, such as selegiline, is contra Info EMSAM(R) transdermal patch, 2006; Prod Info Tegretol(R), 1998). Simultaneous use may theoretically r hyperpyrexia, excitation, and seizure activity (Prod Info Parnate(R), 1995; Prod Info Tegretol(R), 1998; Thwe minimum of 14 days should elapse after discontinuing selegiline before initiating therapy with carbamazepine EMSAM(R) transdermal patch, 2006). However, there is preliminary evidence that the combination of carbam MAOI may be safe and efficacious, even in some refractory cases (Ketter et al, 1995a; Barker & Eccleston, 1 controlled studies are needed.
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of carbamazepine and monoamine oxidase inhibitors contraindicated. Selegiline should be discontinued for a minimum of 14 days, or longer if the clinical situation carbamazepine therapy is initiated.
7) Probable Mechanism: unknown
8) Literature Reports

a) A double-blind study was conducted in ten inpatients with depression that had proved refractory to m therapies (electroconvulsive therapy, tricyclic antidepressants, monoamine oxidase inhibitors, lithium, ca benzodiazepines, and antipsychotics) (Ketter et al, 1995). In addition to their regular carbamazepine and four patients received phenelzine (mean maximum dose 67.5 mg daily) and six patients received tranylc maximum dose 55 mg daily) for a mean duration combination therapy of 52.2 days. During MAOI coadm concentrations of carbamazepine and lithium did not change significantly from baseline values. Self-rate not substantially different. Four patients (three on phenelzine and one on tranylcypromine) responded to were subsequently discharged.

b) A 60-year-old woman who had an atypical endogenous, depressive illness of psychotic intensity was intermittently with cyclic antidepressants and intermittent electroconvulsive therapy. Following an acute v illness, she was treated successfully with a combination of phenelzine and L-tryptophan. Following a few improvement, her situation worsened and she was subsequently treated with zimelidine and lithium. Faili placed on a regimen of tranylcypromine with doses increasing progressively up to 30 mg daily in conjunc and tryptophan. Subsequently, carbamazepine was added in small doses with increments to achieve a p approximately 5 mg/L. This regimen proved successful, and she was discharged home and had remaine two months of follow up at the time of publication (Barker & Eccleston, 1984).

c) Addition of tranylcypromine to carbamazepine therapy did not significantly affect carbamazepine seru case (Joffe et al, 1985). Conversely, five patients on tranylcypromine needed a mean daily dose of carba mg to achieve a carbamazepine blood level of 8.0-11.1 mcg/mL (Barklage et al, 1992). Four other patien phenelzine only required a mean daily dose of carbamazepine 450 mg to attain a blood level of 8.7-10.9

d) In subjects who had received carbamazepine (400 mg/day) for 14 days, slightly increased levels of s metabolites were seen after a single application of selegiline transdermal patch, Emsam (R), 6 mg/24 ho the selegiline plasma levels were nearly 2 fold and variable across the subject population (Prod Info EMS transdermal patch, 2006).

3.5.1.FA Sertraline

1) Interaction Effect: an increased risk of carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vo seizures, coma)
2) Summary: Coadministration of sertraline and carbamazepine may cause reduced carbamazepine clearan carbamazepine toxicity manifesting in blurred vision, dizziness, tremor, and possibly blood dyscrasias (Joblin Similar interactions have been reported between carbamazepine and two other selective serotonin reuptake i

fluoxetine and fluvoxamine (Pearson, 1990; Fritze et al, 1991). However, in two separate in vivo studies, coad sertraline and carbamazepine under steady-state conditions did not increase the plasma concentrations of ca (Prod Info Zoloft(R), 2002). Two case reports of coadministration of carbamazepine and sertraline resulted in expected levels as well as lack of efficacy of sertraline (Khan et al, 2000).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Due to the potential for elevated carbamazepine levels, patients should be closely f evidence of carbamazepine toxicity when sertraline is added to therapy. Consider measuring carbamazepine concentrations within two to three weeks of adding or discontinuing sertraline, with dosage adjustments as ne cytochrome P450 3A4-mediated metabolism of sertraline, sertraline levels may be lower than expected, whic lack of efficacy of sertraline when carbamazepine is coadministered.

7) Probable Mechanism: inhibition of carbamazepine metabolism, increase in sertraline CYP3A4-mediated n

8) Literature Reports

a) A 24-year-old woman received maintenance carbamazepine 600 mg daily and flecainide 100 mg dail beginning sertraline 100 mg daily, her carbamazepine trough level increased from 4.7 to 8.5 mg/L (norm mg/L), and her blood counts were normal. Two months later, in routine testing before elective surgery, he platelet, and red and white blood cell counts were abnormally low. Postoperatively her blood counts rem blood transfusions, and on day 3 her trough carbamazepine was 11.9 mg/L, although she had missed or On bone marrow examination, erythroid hyperplasia with megaloblastic characteristics and reduced meg numbers were observed. Her hematologic counts began to improve five days after withdrawal of sertralir carbamazepine; she was not rechallenged. Suggested mechanisms of action were reduced carbamazep due to inhibition of cytochrome P450 isoenzymes and carbamazepine protein binding displacement (Job 1994).

b) Sertraline is suspected of inhibiting cytochrome P450IIIA4 (CYP3A4) enzyme activity (DeVane, 1994 carbamazepine is known to be a CYP3A4 substrate, carbamazepine might have a potentially significant sertraline. Conversely, carbamazepine is also a known potent inducer of CYP3A4 and may stimulate the sertraline, resulting in decreased sertraline concentrations (Spina et al, 1996).

c) Two cases have been reported in which concomitant use of sertraline and carbamazepine resulted in efficacy. The first such case describes a 33-year-old female with schizoaffective disorder who had been treated with haloperidol and carbamazepine for 3 years. After a depressive episode, sertraline had been titrated slowly to 300 mg/day. A plasma level for carbamazepine and sertraline was obtained after sertral Sertraline was undetectable with levels below 10 ng/ml. Another case describes a 25-year-old male diag posttraumatic stress disorder who had been successfully treated with carbamazepine for 13 years. Sertr after the patient developed major depressive disorder. Plasma levels were obtained for sertraline and ca during therapy. Sertraline levels were undetectable with carbamazepine doses of 400 mg/day and sertra mg/day (Kahn et al, 2000).

3.5.1.FB Simvastatin

1) Interaction Effect: reduced simvastatin exposure

2) Summary: Concurrent administration of carbamazepine with simvastatin significantly reduced maximum s concentration, serum half-life, and area under the concentration-time curve for both simvastatin and its active simvastatin acid (Ucar et al, 2004).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor cholesterol levels in patients receiving concomitant therapy with carbamaze simvastatin. Simvastatin dose may need to be adjusted.

7) Probable Mechanism: induction of CYP3A4-mediated first-pass metabolism of simvastatin by carbamazep

8) Literature Reports

a) Concurrent administration of carbamazepine with simvastatin significantly reduced simvastatin expos randomized, crossover study with a 2-week wash out period, healthy subjects (n=12) received either no carbamazepine 200 milligrams (mg) once daily for 2 days, after which the active drug group received car mg twice daily for the next 12 days. On day 15 (12 hours after the last carbamazepine dose), subjects fa prior to receiving a single dose of simvastatin 80 mg. Serial blood samples were obtained immediately pr hours after simvastatin administration. Carbamazepine co-administration significantly reduced the mean concentration for both simvastatin and its active metabolite simvastatin acid (from 18.7 nanograms/millili ng/mL and from 3.5 ng/mL to 1.1 ng/mL, respectively; p less than 0.01, both values). Simvastatin and sir mean areas under the concentration-time curves (AUC, 0-infinity) declined from 88.8 ng/mL x hour to 22 and from 33.5 ng/mL x hour to 6.8 ng/mL x hour, respectively (p less than 0.001, both values). Concurre with carbamazepine also significantly reduced simvastatin acid serum mean half-life (from 5.9 hours to 3 than 0.01) (Ucar et al, 2004).

3.5.1.FC Sirolimus

1) Interaction Effect: decreased plasma sirolimus concentration

2) Summary: Sirolimus is extensively metabolized by cytochrome P450 3A4 (CYP3A4) enzymes in the gut w such as carbamazepine, which are cytochrome P450 3A4 inducers, may increase the metabolism of sirolimu decreased sirolimus plasma concentrations. Caution should be used when these two agents are used concor

Rapamune(R), 2005).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Monitor sirolimus levels and adjust sirolimus dosage accordingly. Monitor the patier perform additional tests to determine effectiveness of sirolimus.
7) Probable Mechanism: induction of cytochrome P450-mediated sirolimus metabolism

3.5.1.FD Sorafenib
1) Interaction Effect: decreased sorafenib concentrations
2) Summary: Sorafenib is primarily metabolized by the cytochrome P450 3A4 (CYP3A4) enzymes in the live carbamazepine, which are inducers of CYP3A4, may increase the metabolism of sorafenib, thus decreasing concentrations. Although no drug studies have been conducted between carbamazepine and sorafenib, cauti when these two agents are coadministered (Prod Info NEXAVAR(R) oral tablets, 2005).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of carbamazepine and sorafenib may result in decreased sorafeni due to induction of cytochrome P450-mediated sorafenib metabolism by carbamazepine. Use caution if carba sorafenib are administered concurrently. Monitor patients for clinical response to sorafenib.
7) Probable Mechanism: induction of cytochrome P450-mediated sorafenib metabolism

3.5.1.FE St John's Wort
1) Interaction Effect: altered carbamazepine blood concentrations
2) Summary: An open trial involving 8 healthy volunteers taking St. John's Wort (300 milligrams (mg) three ti carbamazepine (400 mg once daily) concomitantly for 14 days demonstrated no alterations of mean carbama (Burstein et al, 2000a). This trial found some individual variability in carbamazepine clearance, indicating that have differing sensitivity to enzyme induction, which may be clinically significant. It is unknown if longer thera days as used in this trial) with St. John's Wort may affect carbamazepine levels due to a more slowly accumu which may induce cytochrome P450 enzymes. Carbamazepine is metabolized by the cytochrome P450 syste CYP3A4, and is capable of autoinduction of its own metabolism by these enzymes. St. John's Wort has been CYP3A4 in human subjects (Durr et al, 2000a; Moore et al, 2000a; Roby et al, 2000a), which suggests that a between St. John's Wort and drugs metabolized by CYP3A4 such as carbamazepine is possible. St. John's W significantly alter the cytochrome P450 system once it has already been induced by carbamazepine, which m of effect in this trial (Burstein et al, 2000a). Carbamazepine may also be capable of inducing the clearance of and its metabolites, specifically hyperforin which has been found to induce CYP3A4 transcription and expres activation of pregnane X receptors (Burstein et al, 2000a; Moore et al, 2000a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Caution is advised if St. John's Wort and carbamazepine are taken concomitantly. a consistent dose of St. John's Wort with a reputable product containing a consistent amount of active ingred Wort. Carbamazepine concentrations should be monitored if patients report the loss of seizure control or new taking St. John's Wort concomitantly. When patients discontinue St. John's Wort, carbamazepine levels and carbamazepine toxicity (e.g. drowsiness, ataxia, slurred speech, nystagmus, dystonic reactions, hallucination should be monitored.
7) Probable Mechanism: induction of cytochrome P450 3A4 by St. John's Wort
8) Literature Reports
a) St. John's Wort had no effect on steady state carbamazepine and carbamazepine-10,11-epoxide pha Eight volunteers participated in an unblinded study in which subjects received immediate release carbam days. A dose titration upward from carbamazepine 200 mg daily to carbamazepine 400 mg daily occurre therapy. From days 22 through 35 subjects received 1 tablet of St. John's Wort (300 mg reagent grade ta hypericin) 3 times daily with food concomitantly with the once daily dose of carbamazepine 400 mg. No c carbamazepine or the carbamazepine-10,11-epoxide concentration-time profiles before and after St. Joh noted. None of the pharmacokinetic parameters for carbamazepine and carbamazepine-10,11-epoxide w concomitant administration of St. John's Wort. The data in this study suggest that the potential for a phar interaction is minimal and that the two agents can be given safely in combination. However, interindividu enzyme induction may be clinically important. Carbamazepine concentrations should be monitored if pat loss of seizure control or new side effects while taking St. John's Wort concomitantly (Burstein et al, 200
b) In 8 healthy male volunteers, St. John's Wort significantly induced intestinal P-glycoprotein/MDR1 an cytochrome P450 3A4. Subjects were nonsmokers, aged 23-35 years, and abstained from caffeine, alco and medications for 5 days prior to and during the study. Biopsy specimens of the duodenal intestinal mu obtained to determine P-gycoprotein/MDR1, CYP3A4 expression, and villin content at baseline and on d Erythromycin breath test was performed on days 2, 15 and 16 to determine effect on CYP3A4 function. D milligrams (mg) was given orally on day 2 for pharmacokinetic analysis. St. John's Wort extract (LI 160, L AG, Berlin) was given as 300 mg three times daily for 14 days, digoxin 0.5 mg was given again on day 1 bioavailability was increased by 18% after St. John's Wort administration. Mean intestinal P-glycoprotein increased 1.37 +/- 0.31 times following St. John's Wort (p = 0.025). One subject demonstrated a decreas

glycoprotein/villin ratio, indicating that interindividual variability is possible. Mean CYP3A4/villin ratios inc
0.17 times following St. John's Wort (p = 0.012). Induction of CYP3A4 was further evidenced by increase
erythromycin, 1.44 +/- 0.28 times over baseline, by the erythromycin breath test (Durr et al, 2000).
c) St. John's Wort has been reported to induce cytochrome P450 isoenzyme 3A4 as measured by urina
hydroxycortisol to cortisol ratios in a study of 13 healthy volunteers treated with St. John's Wort for 2 wee
baseline, mean urinary 6-beta hydroxycortisol to cortisol ratios increased from 7.1 to 13.0 (p=0.003). One
experienced an unexplained 25% decrease in urinary 6-beta hydroxycortisol to cortisol ratio. The results
recommended doses of St. John's Wort induce CYP3A4 activity (Roby et al, 2000).
d) Hyperforin was shown to activate the pregnane X receptor (PXR), which regulates expression of CYP
human hepatocytes. Levels of hyperforin in humans taking standard doses of St. John's Wort (300 mg th
are well above those required for hyperforin to activate PXR. All three St. John's Wort extracts tested act
extent comparable to that of rifampicin, which is a known activator of PXR and CYP3A4 expression (Moo

3.5.1.FF Sunitinib

1) Interaction Effect: decreased plasma concentrations of sunitinib and its active metabolite
2) Summary: Sunitinib is primarily metabolized by the cytochrome P450 3A4 (CYP3A4) enzyme to its active
is also further metabolized by CYP3A4. Coadministration of sunitinib with a CYP3A4 inducer, such as carban
result in decreased plasma concentrations of sunitinib and its active metabolite. Selection of an alternative to
with no or minimal enzyme induction potential is advised. However, if carbamazepine is used concurrently, a
sunitinib is recommended. The dose may be increased in 12.5 milligrams (mg) increments, depending on ind
tolerability, to a maximum daily dose of 87.5 mg (Prod Info SUTENT(R) oral capsules, 2006).
3) Severity: major
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Due to induction of the cytochrome P450-mediated sunitinib metabolism, concomita
of sunitinib and carbamazepine may result in decreased plasma concentrations of sunitinib and its active met
of an alternative to carbamazepine, with no or minimal enzyme induction potential is advised. However, if car
used concurrently, consider increasing sunitinib dose in increments of 12.5 milligrams (mg), based on individ
tolerability, to a maximum daily dose of 87.5 mg.
7) Probable Mechanism: induction of cytochrome P450-mediated sunitinib metabolism

3.5.1.FG Tacrolimus

1) Interaction Effect: decreased tacrolimus efficacy
2) Summary: Tacrolimus, an immunosuppressant agent, is principally metabolized by the CYP3A hepatic en
Coadministered drugs known to induce this enzyme system could be expected to reduce plasma concentrati
Carbamazepine is one of the agents known to induce the cytochrome P-450 system. Patients receiving carba
concomitantly with tacrolimus may exhibit decreased plasma and whole blood levels of tacrolimus. When the
concurrently, monitor patients for reduced tacrolimus plasma concentrations and reduced tacrolimus efficacy.
tacrolimus doses may need to be increased (Prod Info PROGRAF(R) oral capsules, IV injection, 2006).
3) Severity: major
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If carbamazepine and tacrolimus are used concurrently, monitor patient for reduced
plasma concentrations and reduced tacrolimus efficacy. Additionally, tacrolimus doses may need to be increa
7) Probable Mechanism: increased CYP3A-mediated tacrolimus metabolism

3.5.1.FH Tadalafil

1) Interaction Effect: decreased tadalafil plasma concentrations
2) Summary: Although the carbamazepine/tadalafil interaction has not been studied, concomitant use of rifar
CYP3A4 inducer) 600 mg/day, and tadalafil (a CYP3A4 substrate) as a 10-mg single dose resulted in decrea
Cmax and AUC by 88% and 46% compared with tadalafil 10 mg alone. Therefore, tadalafil use should be avo
chronically treated with potent inducers of CYP3A4, such as carbamazepine (Prod Info ADCIRCA (TM) oral t
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of carbamazepine, a CYP3A4 inducer, and tadalafil, a CYP3A4 su
resulted in significantly decreased tadalafil bioavailability. Therefore, tadalafil use should be avoided in patier
chronic treatment with a potent CYP3A4 inducer, such as carbamazepine (Prod Info ADCIRCA (TM) oral tabl
7) Probable Mechanism: induction of CYP3A4-mediated metabolism of tadalafil by carbamazepine

3.5.1.FI Telithromycin

1) Interaction Effect: subtherapeutic telithromycin concentrations and/or elevated serum levels of carbamaze
2) Summary: Concomitant administration of carbamazepine, a cytochrome P450 3A4 inducer, is likely to res
subtherapeutic levels of telithromycin and loss of effect. Elevation of serum levels of drugs metabolized by th
P450 system, such as carbamazepine, may be observed when coadministered with telithromycin, a cytochro
inhibitor. As a result, increases or prolongation of the therapeutic and/or adverse effects of carbamazepine m
(Prod Info Ketek(TM), 2004).
3) Severity: moderate

4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Concomitant treatment of telithromycin and carbamazepine is not recommended. W and carbamazepine are coadministered, monitor carbamazepine concentrations and monitor for telithromycin
7) Probable Mechanism: induction of cytochrome P450 3A4-mediated metabolism of telithromycin by carban of cytochrome P450-mediated phenytoin metabolism by telithromycin

3.5.1.FJ Temsirolimus

1) Interaction Effect: decreased maximum concentration of sirolimus, the active metabolite of temsirolimus
2) Summary: Temsirolimus is primarily metabolized by the CYP3A4 isozyme into 5 metabolites, of which sirc principal active metabolite. Sirolimus is also primarily metabolized by CYP3A4 (Prod Info RAPAMUNE(R) ora tablets, 2007). Although not studied with carbamazepine, coadministration of rifampin, a potent CYP3A4 indu intravenous temsirolimus decreased the Cmax and AUC of sirolimus by 65% and 56%, respectively, compare alone. Therefore, avoid using carbamazepine and temsirolimus concurrently. If concurrent use of temsirolimu CYP3A4 inducer is clinically warranted, the temsirolimus dose may be increased from 25 mg/week up to 50 r discontinuation of the inducer, the temsirolimus dose should be returned to its original dose used prior to initia (Prod Info TORISEL(TM) KIT IV injection, 2007).
3) Severity: major
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Avoid using carbamazepine and temsirolimus concurrently as coadministration may substantially decreased exposure and maximum concentration of sirolimus (active metabolite of temsirolimus of temsirolimus with a strong CYP3A4 inducer, such as carbamazepine, is clinically warranted, consider increa temsirolimus dose from 25 mg/week up to 50 mg/week. Upon discontinuation of the inducer, reduce the tems to its original dose used prior to initiation of the inducer (Prod Info TORISEL(TM) KIT IV injection, 2007).
7) Probable Mechanism: induction of CYP3A4-mediated metabolism of sirolimus (active metabolite of temsir

3.5.1.FK Terfenadine

1) Interaction Effect: carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vomiting, apnea, seizur
2) Summary: A case report indicates that terfenadine may displace carbamazepine from protein binding sites free carbamazepine levels and toxicity when terfenadine is added to carbamazepine therapy (Hirschfeld & Ja
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Monitor serum concentrations of carbamazepine when terfenadine is added or disc therapy. Patients should be followed for any symptoms of carbamazepine toxicity.
7) Probable Mechanism: carbamazepine displacement from protein binding sites by terfenadine
8) Literature Reports
a) An 18-year-old female displayed confusion, disorientation, visual hallucinations, nausea, and ataxia. began shortly after terfenadine 60 mg twice daily was added to her regular regimen of carbamazepine (d unspecified) which resulted in an excess of free (unbound) carbamazepine (6 mg/L). The free carbamaz returned to 2.1 mg/L (normal, 1.6 to 2.2 mg/L) and the symptoms resolved after terfenadine was disconti may have displaced carbamazepine from protein binding sites, leading to the high free carbamazepine le Jarosinski, 1993).

3.5.1.FL Theophylline

1) Interaction Effect: decreased theophylline effectiveness
2) Summary: The concurrent use of theophylline and carbamazepine could lead to decreased theophylline le et al, 1983a). Carbamazepine induces hepatic cytochrome P450 activity and would be expected to affect theo metabolized in the liver (Prod Info Tegretol(R) carbamazepine chewable tablets, 2002). An increase in theopl be necessary with concomitant use. One report of decreased carbamazepine levels and efficacy suggests tha both drugs is necessary (Mitchell et al, 1986a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Carbamazepine and theophylline serum concentrations should be closely monitored carbamazepine is added, discontinued, or when dosing changes of either drug occur. Dosing adjustments of be necessary.
7) Probable Mechanism: increased theophylline metabolism
8) Literature Reports
a) A single case was reported in which a short course of theophylline appeared to cause a mild reductio of carbamazepine in close temporal relationship to a brief generalized tonic-clonic seizure. During hospit trough serum carbamazepine levels were reduced by about 50% after six doses of theophylline every 6 l seizure occurred shortly after the seventh dose (Mitchell et al, 1986).
b) An asthmatic child was receiving theophylline 10 mg/kg/day and phenobarbital. The phenobarbital wa carbamazepine, resulting in subtherapeutic theophylline levels and markedly decreased half-life after 3 w concurrent use. Within 3 weeks of changing carbamazepine to ethotoin, the half-life of theophylline had i asthma controlled (Rosenberry et al, 1983).

3.5.1.FM Tiagabine

1) Interaction Effect: decreased tiagabine efficacy

2) Summary: Concurrent use of tiagabine and carbamazepine had no effect on the steady-state plasma conc carbamazepine or its epoxide metabolite in epileptic patients. However, it has been shown in population phar studies that tiagabine clearance is 60% greater in patients taking carbamazepine than in patients not receivin inducing agents. Tiagabine is metabolized primarily by the cytochrome P450 3A isoform subfamily of enzyme is known to induce these enzymes, therefore causing an increase in the metabolism of tiagabine (Prod Info G

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor patients for tiagabine efficacy. It may be useful to obtain tiagabine plasma l after the addition or withdrawal of carbamazepine.

7) Probable Mechanism: induction of tiagabine metabolism by carbamazepine

3.5.1.FN Ticlopidine

1) Interaction Effect: an increased risk of carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vor seizures, coma)

2) Summary: Carbamazepine toxicity developed in a patient one week after ticlopidine therapy was initiated. carbamazepine is mediated through the cytochrome P450 3A4 enzyme system, and ticlopidine appears to be pathway (Brown & Cooper, 1997a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor patients for signs of carbamazepine toxicity if ticlopidine is added to their th A carbamazepine plasma level may be useful if toxicity is suspected and downward dosing adjustments may carbamazepine dose may need to be increased when ticlopidine is discontinued.

7) Probable Mechanism: inhibition of cytochrome P450-mediated carbamazepine metabolism by ticlopidine

8) Literature Reports

a) A 67-year-old male scheduled to undergo elective coronary stenting was started on ticlopidine 250 m week prior to the procedure. Other medications included aspirin , diltiazem 180 mg daily, a nitroglycerin p carbamazepine 600 mg twice daily. Shortly after ticlopidine therapy was initiated, the patient experienced ataxia that resulted in his inability to walk. These symptoms would resolve five to six hours after his ticlop Although the patient's carbamazepine level had been 43 mol/L (therapeutic range 25 to 50 mol/L) five we carbamazepine was 75 mol/L on admission to the hospital. The carbamazepine dose was decreased to and his symptoms resolved. One week after the dose decrease, the carbamazepine level was 53 mol/L. the discontinuation of ticlopidine, the carbamazepine level had fallen to 42 mol/L (Brown & Cooper, 1997

3.5.1.FO Tipranavir

1) Interaction Effect: decreased tipranavir concentrations

2) Summary: Tipranavir is a CYP3A substrate. Concomitant use of tipranavir and carbamazepine, a CYP3A cause decreased tipranavir plasma concentrations (Prod Info APTIVUS(R) oral capsules, solution, 2008).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Use caution when prescribing carbamazepine to patients who are taking tipranavir decreased tipranavir plasma concentrations (Prod Info APTIVUS(R) oral capsules, solution, 2008).

7) Probable Mechanism: induction of CYP3A-mediated tipranavir metabolism

3.5.1.FP Toloxatone

1) Interaction Effect: hypertensive urgency, hyperpyrexia, and seizures

2) Summary: Concomitant MAO inhibitor and carbamazepine therapy is contraindicated (Prod Info Tegretol(Simultaneous use may theoretically result in hyperpyrexia, excitation, and seizure activity (Prod Info Parnate(Info Tegretol(R), 1998h; Thweatt, 1986h). However, there is preliminary evidence that the combination of car an MAOI may be safe and efficacious, even in some refractory cases (Ketter et al, 1995q; Barker & Ecclestor controlled studies are needed.

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of carbamazepine and monoamine oxidase inhibitors contraindicated by the manufacturer. Monoamine oxidase inhibitors should be discontinued for a minimum of if the clinical situation permits, before carbamazepine therapy is initiated.

7) Probable Mechanism: unknown

8) Literature Reports

a) A double-blind study was conducted in ten inpatients with depression that had proved refractory to m therapies (electroconvulsive therapy, tricyclic antidepressants, monoamine oxidase inhibitors, lithium, ca benzodiazepines, and antipsychotics). In addition to their regular carbamazepine and lithium doses, four phenelzine (mean maximum dose 67.5 mg daily) and six patients received tranylcypromine (mean maxir

daily) for a mean duration combination therapy of 52.2 days. During MAOI coadministration, serum conc carbamazepine and lithium did not change significantly from baseline values. Self-rated side effects were different. Four patients (three on phenelzine and one on tranylcypromine) responded to this therapy and discharged (Ketter et al, 1995p).

b) A 60-year-old woman who had an atypical endogenous, depressive illness of psychotic intensity was intermittently with cyclic antidepressants and intermittent electroconvulsive therapy. Following an acute v illness, she was treated successfully with a combination of phenelzine and L-tryptophan. Following a few improvement, her situation worsened and she was subsequently treated with zimelidine and lithium. Faili placed on a regimen of tranylcypromine with doses increasing progressively up to 30 mg daily in conjunc and tryptophan. Subsequently, carbamazepine was added in small doses with increments to achieve a p approximately 5 mg/L. This regimen proved successful, and she was discharged home and had remaine two months of follow up at the time of publication (Barker & Eccleston, 1984p).

c) Addition of tranylcypromine to carbamazepine therapy did not significantly affect carbamazepine seru (Joffe et al, 1985h). Conversely, five patients on tranylcypromine need a mean daily dose of carbamazep achieve a carbamazepine blood level of 8.0-11.1 mcg/mL. Four other patients receiving phenelzine only daily dose of carbamazepine 450 mg to attain a blood level of 8.7-10.9 mcg/mL (Barklage et al, 1992h).

3.5.1.FQ Topiramate

1) Interaction Effect: decreased topiramate concentrations

2) Summary: In controlled, clinical pharmacokinetic studies, patients with epilepsy showed a 40% decrease i concentrations when carbamazepine was added to topiramate therapy (Prod Info TOPAMAX(R) oral tablets, capsules, 2008). Topiramate oral and nonrenal clearance is twofold to threefold higher during concurrent carl therapy. The renal clearance of topiramate, however, is not affected by concomitant carbamazepine therapy. changes in carbamazepine pharmacokinetic parameters were evident upon coadministration with topiramate 1996a). In another study, addition of topiramate to existing carbamazepine regimens in epileptic patients resu significant pharmacokinetic changes in either drug (Wilensky et al, 1989a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Upon the addition of carbamazepine to a drug regimen involving topiramate, the do may need to be increased to accommodate for the decreased concentration of topiramate that occurs with co (Prod Info TOPAMAX(R) oral tablets, oral sprinkle capsules, 2008).

7) Probable Mechanism: unknown

8) Literature Reports

a) Twelve patients with partial epilepsy receiving chronic stable doses of carbamazepine were enrolled i determine the steady-state pharmacokinetic profile of topiramate and the effects of comedication with ca subjects were receiving carbamazepine in doses of 300 mg to 800 mg every eight hours. Topiramate wa doses were increased at approximately two week intervals until the highest tolerated dose was reached. was then tapered off over the next four weeks, and topiramate was maintained as monotherapy for two r Results showed that the mean topiramate area under the concentration-time curve (AUC), Cmax, Cmin, were all approximately 40% lower during carbamazepine treatment as compared to topiramate monother suggest that the metabolic clearance of topiramate increases when carbamazepine is coadministered. T significant changes in the carbamazepine pharmacokinetic profile during topiramate administration (Sach

b) The interaction between carbamazepine and topiramate was assessed in eight epileptic patients. Pha profiles were evaluated after a single dose of topiramate, after two weeks at three different doses of topir each subject had taken topiramate at its highest tolerated dose for two months. No significant changes ir carbamazepine, or carbamazepine metabolite pharmacokinetics were observed at any dose level (Wilen

3.5.1.FR Tramadol

1) Interaction Effect: decreased tramadol efficacy and increased seizure risk

2) Summary: Chronic carbamazepine therapy increases the metabolism of tramadol by the cytochrome P45(which may significantly reduce the analgesic effect of tramadol. Due to the seizure risk involved with tramadc administration of tramadol and carbamazepine is not recommended (Prod Info ULTRAM(R)ER extended-rele 2005).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Concomitant administration of carbamazepine and tramadol is not recommended, a may reduce tramadol efficacy and tramadol may increase the risk of seizure.

7) Probable Mechanism: induction of CYP3A4 metabolism of tramadol by carbamazepine

3.5.1.FS Tranylcypromine

1) Interaction Effect: hypertensive urgency, hyperpyrexia, and seizures

2) Summary: Concomitant tranylcypromine and carbamazepine therapy is contraindicated (Prod Info Tegretc Simultaneous use may theoretically result in hyperpyrexia, excitation, and seizure activity (Prod Info Parnate(Info Tegretol(R), 1998c; Thweatt, 1986c). However, there is preliminary evidence that the combination of carl an MAOI may be safe and efficacious, even in some refractory cases (Ketter et al, 1995g; Barker & Eccleston controlled studies are needed.

3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of carbamazepine and monoamine oxidase inhibitors contraindicated by the manufacturer. Monoamine oxidase inhibitors should be discontinued for a minimum of if the clinical situation permits, before carbamazepine therapy is initiated.
7) Probable Mechanism: unknown
8) Literature Reports
a) A double-blind study was conducted on ten inpatients with depression that had proved refractory to m therapies (electroconvulsive therapy, tricyclic antidepressants, monoamine oxidase inhibitors, lithium, ca benzodiazepines, and antipsychotics). In addition to their regular carbamazepine and lithium doses, four phenelzine (mean maximum dose 67.5 mg daily) and six patients received tranylcypromine (mean maxir daily) for a mean duration combination therapy of 52.2 days. During MAOI coadministration, serum conc carbamazepine and lithium did not change significantly from baseline values. Self-rated side effects were different. Four patients (three on phenelzine and one on tranylcypromine) responded to this therapy and discharged (Ketter et al, 1995f).
b) A 60-year-old woman who had an atypical endogenous, depressive illness of psychotic intensity was intermittently with cyclic antidepressants and intermittent electroconvulsive therapy. Following an acute v illness, she was treated successfully with a combination of phenelzine and L-tryptophan. Following a few improvement, her situation worsened and she was subsequently treated with zimeldine and lithium. Faili placed on a regimen of tranylcypromine with doses increasing progressively up to 30 mg daily in conjunc and tryptophan. Subsequently, carbamazepine was added in small doses with increments to achieve a p approximately 5 mg/L. This regimen proved successful, and she was discharged home and had remaine two months of follow up at the time of publication (Barker & Eccleston, 1984f).
c) Addition of tranylcypromine to carbamazepine therapy did not significantly affect carbamazepine seru (Joffe et al, 1985c). Conversely, five patients on tranylcypromine needed a mean daily dose of carbamaz achieve a carbamazepine blood level of 8.0-11.1 mcg/mL. Four other patients receiving phenelzine only daily dose of carbamazepine 450 mg to attain a blood level of 8.7-10.9 mcg/mL (Barklage et al, 1992c).

3.5.1.FT Trazodone

1) Interaction Effect: decreased trazodone plasma concentrations
2) Summary: An increase in carbamazepine concentration/dose ratio was reported when trazodone was add although the patient did not exhibit any signs of carbamazepine toxicity (Romero et al, 1999a). Trazodone se have been decreased during coadministration with carbamazepine. Patients should be closely monitored to s need for an increased dose of trazodone when taking both drugs (Prod Info Desyrel(R), 2003).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When given concurrently with carbamazepine, trazodone serum concentrations sho monitored and trazodone dose adjustments made as needed.
7) Probable Mechanism: induction of trazodone CYP3A4-mediated metabolism
8) Literature Reports
a) A 53-year-old male diagnosed with generalized partial epilepsy was receiving carbamazepine 700 mg corresponding serum concentration of 7.9 mg/L. The concentration/dose ratio, calculated by dividing the concentration (mg/L) by the dose (mg/kg), was 0.89. Trazodone therapy was initiated for depression, and the carbamazepine serum concentration had increased to 10.0 mg/L with a corresponding concentration The serum concentration of the main pharmacologically active metabolite of carbamazepine, carbamaze epoxide, was not measured. Although this patient did not show any signs or symptoms of carbamazepin interaction may be clinically significant in patients stabilized at a higher carbamazepine steady-state con et al, 1999).

3.5.1.FU Trimipramine

1) Interaction Effect: decreased trimipramine effectiveness
2) Summary: The concomitant use of carbamazepine and antidepressants has been reported to decrease se antidepressant levels (Leinonen et al, 1991b; Brown et al, 1990). Although not reported for trimipramine, a sir could occur.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor for clinical efficacy of the trimipramine therapy and for any signs of toxicity Serum levels of both agents should be considered when either agent is added or discontinued, with appropria adjustments made accordingly.
7) Probable Mechanism: increased trimipramine metabolism
8) Literature Reports
a) Concomitant administration of imipramine and carbamazepine to children with attention deficit disorde reported to result in a 50% decrease in the total plasma concentration of imipramine plus desipramine (E Carbamazepine probably enhances the hepatic microsomal metabolism of imipramine and other tricyclic by inducing hepatic enzymes (Moody et al, 1977). Although not reported specifically for trimipramine, be

potential for a similar interaction exists. Patients on chronic carbamazepine therapy may require increase tricyclic antidepressants.

3.5.1.FV Troleandomycin

1) Interaction Effect: carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vomiting, apnea, seizur
2) Summary: Concurrent administration of carbamazepine and troleandomycin has resulted in increased pla carbamazepine levels and signs of toxicity (Dravet et al, 1977; Mesdjian et al, 1980a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: The combination of carbamazepine and macrolide antibiotics should be avoided an given to an alternative antibiotic. If the combination is necessary, carbamazepine levels should be obtained w adding or discontinuing troleandomycin and dosage adjustments made accordingly.
7) Probable Mechanism: decreased carbamazepine metabolism
8) Literature Reports

a) Seventeen epileptic patients receiving troleandomycin concurrently with carbamazepine alone or in c other anticonvulsants experienced symptoms of acute intoxication (dizziness, drowsiness, nausea, vomi Troleandomycin was given a second time to 3 patients who experienced similar symptoms. Six patients increase in carbamazepine plasma levels after administration of troleandomycin; when the antibiotic was carbamazepine levels returned to normal (Mesdjian et al, 1980).

3.5.1.FW Valnoctamide

1) Interaction Effect: carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vomiting, apnea, seizur
2) Summary: One study in six epileptic patients demonstrated that concurrent administration of valnoctamide carbamazepine (CBZ) resulted in a significant increase in carbamazepine epoxide serum concentrations. Fou experienced clinical symptoms of carbamazepine intoxication. Carbamazepine epoxide serum levels returned discontinuation of valnoctamide, and all signs of toxicity abated (Pisani et al, 1993).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concurrent use of carbamazepine and valnoctamide is best avoided; however, if th necessary, careful monitoring for signs of carbamazepine toxicity is needed with dosage adjustments made a
7) Probable Mechanism: inhibition of carbamazepine metabolism
8) Literature Reports

a) If phenytoin or carbamazepine (or any prodrugs) is used in pregnant women, there is a substantially i teratogenicity with many combinations of other anticonvulsants. The teratogenicity of these drugs is large related to the levels of the reactive epoxide metabolites (Buehler et al, 1990e; Van Dyke et al, 1991e; Fir The epoxide/parent drug ratio is generally increased when phenytoin or carbamazepine is combined with other drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide hyc valproic acid, progabide, and lamotrigine (Bianchetti et al, 1987e; Ramsay et al, 1990e; Spina et al, 1996 combinations increase the risk of major birth defects 3- to 4-fold over monotherapy and about 10-fold ov rates.

3.5.1.FX Valproic Acid

1) Interaction Effect: carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vomiting, apnea, seizur decreased valproic acid effectiveness
2) Summary: The literature contains conflicting data regarding the effects of combined carbamazepine and v Carbamazepine may decrease valproic acid levels by 15% to 25% while increasing clearance by up to 30% (1979a; Rimmer & Richens, 1985a; Mahaly et al, 1979a; Jann et al, 1988a). Furthermore, the conversion of va ene-VPA (thought to be the most toxic metabolite with potential for hepatotoxicity and teratogenicity) is signifi with coadministration of carbamazepine (Kondo et al, 1990a). Valproic acid may increase, decrease, or caus carbamazepine concentrations (Mattson et al, 1982a; Levy et al, 1984a; Pisani et al, 1990a; Anderson et al,
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients for signs of carbamazepine toxicity such as nausea, vomiting, drov when valproic acid is added. Serum carbamazepine concentrations should also be measured, though clinicia aware of the increase in the concentration of the active metabolite, carbamazepine-epoxide, which is not rout but does contribute to the efficacy and toxicity of the drug. If carbamazepine is added to valproic acid therapy acid levels; increased valproic acid dosage may be required.
7) Probable Mechanism: increased valproic acid clearance; variable effects on carbamazepine metabolism
8) Literature Reports

a) Significant increases (59%) in valproic acid serum concentrations have been reported following the w carbamazepine in six epileptic patients. A new plateau for the valproic acid serum level was observed at weeks after withdrawal of the carbamazepine (Jann et al, 1988).

b) Several reports have indicated conflicting effects of valproic acid on carbamazepine serum levels (Ri 1985; Flachs et al, 1979; Adams et al, 1978). In an in vitro study of protein binding, valproic acid compet carbamazepine plasma protein binding sites, resulting in significant increases in free carbamazepine (Ma

Concurrent therapy of valproic acid and carbamazepine in seven patients was found to decrease levels c by 3% to 59% and protein binding decreased. The plasma concentration ratio of carbamazepine-10,11-e carbamazepine increased in all patients by 11% to 500% (Levy et al, 1984; Pisani et al, 1990) probably c epoxide hydroxylase by valproic acid (Robbins et al, 1990). In addition, carbamazepine may cause a red valproic acid half-life with increased clearance secondary to enzyme induction and increased hepatic me et al, 1979; Rimmer & Richens, 1985; Mahaly et al, 1979). Infrequent reports have indicated symptoms c nausea, or confusion when valproic acid was added to carbamazepine therapy (Lhermitte et al, 1978; Ha A single case of psychosis following the addition of carbamazepine to valproic acid has been reported in refractory epilepsy (McKee et al, 1989).

c) Select patients with suspected genetic deficiencies may tolerate poorly the effects of valproic acid on certain amino and fatty acids, which may impact anticonvulsant therapy based on carbamazepine-valpro these individuals (Anderson et al, 1994).

d) The pharmacokinetics of valproic acid and its metabolites when coadministered with carbamazepine epileptic patients. The ratio of valproic acid concentration to dose was significantly lower in those patient acid with carbamazepine compared with those receiving only valproic acid. Additionally, the ratio of 4-en concentration to valproic acid concentration was significantly higher in those receiving combined carbam acid compared with those on valproic acid monotherapy. 4-ene-VPA, reported to be the most toxic of val metabolites, may manifest as hepatotoxicity and teratogenicity (Kondo et al, 1990).

e) If phenytoin or carbamazepine (or any prodrug) is used in pregnant women, there is a substantially in teratogenicity with many combinations of other anticonvulsants. The teratogenicity of these drugs is large related to the levels of the reactive epoxide metabolites (Buehler et al, 1990; Van Dyke et al, 1991; Finne epoxide/parent drug ratio is generally increased when phenytoin or carbamazepine is combined with eac drugs that induce cytochrome P450 enzymes (3A4, 2C9, 2C19), or drugs which inhibit epoxide hydrolase acid, progabide, and lamotrigine (Bianchetti et al, 1987; Ramsay et al, 1990; Spina et al, 1996a). Such c increase the risk of major birth defects 3- to 4-fold over monotherapy and about 10-fold over background

3.5.1.FY Vecuronium

1) Interaction Effect: decreased vecuronium duration of action

2) Summary: Patients on carbamazepine maintenance therapy required significantly higher doses of vecuror similar neuromuscular blocking effects as controls (Whalley & Ebrahim, 1994a; Norman, 1993a). This may be pharmacokinetic interaction between carbamazepine and vecuronium, although a pharmacodynamic interact ruled out (Alloul et al, 1996a).

3) Severity: moderate

4) Onset: rapid

5) Substantiation: established

6) Clinical Management: Monitor patients for an appropriate clinical response to the neuromuscular blocker. intervals or higher doses of vecuronium may be needed in patients receiving carbamazepine.

7) Probable Mechanism: increased clearance of vecuronium

8) Literature Reports

a) Twenty-four surgical patients were evaluated, of which eight were receiving carbamazepine (along wi other drugs) and 16 were using several different drugs but not carbamazepine (Whalley & Ebrahim, 199 vecuronium required for 50%, 90%, and 95% depression of first twitch were 29, 52, and 64 mcg/kg, resp carbamazepine group, compared with 21, 36, and 44 mcg/kg, respectively, for the non-carbamazepine g 40% higher dose of vecuronium was required in study subjects using carbamazepine.

b) A case report describes a 19-year old epileptic female who underwent a sigmoid colectomy (Norman, patient had been maintained on carbamazepine 700 mg daily. The first bolus dose of vecuronium 6 mg p for only 18 minutes. A continuous infusion of vecuronium at an average of 6.67 mg/hr was needed to sus neuromuscular block. This is higher than the average of vecuronium 4 mg/hr that is needed to produce b patients not treated with carbamazepine.

c) The pharmacokinetic and pharmacodynamic effects of a bolus intravenous dose of vecuronium were carbamazepine-treated subjects and in ten control subjects (Alloul et al, 1996). No changes in onset time distribution at steady-state were observed. However, the carbamazepine group had a shorter mean reco (T1 25%) compared to controls (28.1 minutes vs. 47.3 minutes). The T1 25% to T1 75% recovery index v the carbamazepine group compared to 21.9 minutes in controls. Clearance of vecuronium was 9.0 mL/kg carbamazepine group and only 3.8 mL/kg/min in the control group. This two-fold increase in the clearanc provides evidence of a pharmacokinetic origin to the interaction with carbamazepine, although the possib concurrent pharmacodynamic interaction cannot be ruled out.

d) Long-term phenytoin or carbamazepine therapy accelerates recovery from vecuronium-induced paral The patients were assigned to one of 3 groups: control (n=10; no history of epilepsy and not receiving ch affecting neurotransmission), children receiving phenytoin (n=10) or carbamazepine (n=10). The eliminat significantly shorter for the phenytoin and carbamazepine groups compared with control. A statistically si in clearance of vecuronium occurred in the carbamazepine groups compared with control. Increased clea vecuronium in the phenytoin group also occurred but was not statistically significant. The recovery indice vecuronium-induced block for the children on antiepileptic drugs were significantly faster than those for th The author concludes that resistance to vecuronium in children on chronic anticonvulsant therapy is part increased metabolism. The contribution of altered pharmacodynamics to the resistance to vecuronium co determined in this study (Soriano et al, 2001).

3.5.1.FZ Verapamil

1) Interaction Effect: increased carbamazepine plasma concentrations and risk of toxicity (ataxia, nystagmus headache, vomiting, apnea, seizures, coma)

2) Summary: Concomitant administration of carbamazepine and verapamil has resulted in increased carbam increasing the risk of toxicity (Summers et al, 2004; Prod Info Covera HS(R), 2003; Brodie & Macphee, 1986l 1986a; Eimer & Carter, 1987b; Bahls et al, 1991a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for clinical signs of carbamazepine toxicity along with carbamazepine serur dose accordingly. Nifedipine does not appear to interact with carbamazepine and may be considered as an a verapamil.

7) Probable Mechanism: decreased carbamazepine metabolism and inhibition of p-glycoprotein-mediated ef

8) Literature Reports

a) Concomitant administration of verapamil 120 mg orally 3 times a day in patients receiving carbamaze partial epilepsy was reported to result in carbamazepine neurotoxicity in all of 6 patients treated (MacPhe Increase in free and total carbamazepine levels were observed in 5 patients (mean increases of 33 and associated with a concurrent decrease by 36% in the ratio of carbamazepine-10,11 epoxide to carbamaz resolved after several days following withdrawal of verapamil in all patients. Rechallenge in 2 patients re neurotoxic symptoms. These data suggest that verapamil inhibits carbamazepine metabolism. Reductior carbamazepine may be required when verapamil is administered, and increased when verapamil is witho exacerbation of epileptic seizures. Seizure aggravation occurred in one patient in this series following ab verapamil.

b) The concurrent use of verapamil with carbamazepine was effective in suppressing p-glycoprotein-me carbamazepine transport and clearance in a 24-year-old woman with intractable epilepsy. The patient's c seizures had been refractory to multiple anticonvulsants, partial temporal lobectomy, and vagal nerve sti resulted in intermittent hospitalization a mean of every 55 days for management of complex partial status Verapamil 180 milligrams (mg)/day was added to an anticonvulsant regimen comprising carbamazepine in addition to levetiracetam, topiramate, and clonazepam. Baseline carbamazepine plasma concentratior low end of the therapeutic range (4.2 mg/milliliter (mL). At 1-month follow up, carbamazepine plasma cor mg/L, and the patient reported subjective improvement in seizure control. Verapamil dose was titrated in 480 mg daily, resulting in an increase in carbamazepine plasma concentration to 13.3 mg/L, without repo effects, and with an extension of between-hospitalization time to approximately 4 months between admis et al, 2004).

3.5.1.GA Vigabatrin

1) Interaction Effect: carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vomiting, apnea, seizur

2) Summary: In a study of sixty-six epileptic patients, when vigabatrin was added to carbamazepine therapy carbamazepine serum concentrations increased 24.2%. A strong negative correlation between the value of th the initial level of carbamazepine concentration after vigabatrin addition also was revealed in this study (Jedrz 2000a).

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: When vigabatrin is added to carbamazepine therapy, concentration of carbamazepi monitored and the dose of carbamazepine should be adjusted accordingly.

7) Probable Mechanism: decreased carbamazepine metabolism

8) Literature Reports

a) Sixty-six epileptic patients were evaluated for the changes in carbamazepine concentration following All patients had simple or complex partial seizures, and all were drug-resistant. Vigabatrin was added as after long-term (at least 3 months) carbamazepine monotherapy and was administered in increasing dos Carbamazepine concentrations prior to vigabatrin addition was 9.41 mcg/ml (range 4.33 to 13.05 mcg/m vigabatrin the mean carbamazepine concentration increased to 11.31 mcg/ml (range 6.88 to 18.57 mcg/ increase in carbamazepine concentration was 24.2%. An increase in carbamazepine concentration by at occurred in 46 out of 66 patients, i.e. 69.7%, after vigabatrin therapy. Twenty-four patients (36.4%) respo carbamazepine level of at least 12 mcg/ml. Carbamazepine concentration in this group ranged from 11.9 whereas the carbamazepine concentration before vigabatrin therapy was 10.57 mcg/ml (range 6.59 to 1 significant relationship was found between vigabatrin dosage and the percentile change in carbamazepir after the addition of vigabatrin. There was a strong negative correlation between the percentile increase concentration and initial carbamazepine concentration (Jedrzejczak et al, 2000).

b) Vigabatrin produces a statistically significant increase in the plasma clearance of carbamazepine (CE drugs are given simultaneously. Fifteen patients with refractory partial epilepsy and receiving vigabatrin a were studied. Treatment 1 consisted of an initial period with CBZ monotherapy. Treatment 2 consisted o combination with vigabatrin. CBZ monotherapy was given for 3-12 months with monitoring of CBZ plasm After an initial period, patients received open add-on treatment with vigabatrin 1500 mg/day in two divide 1500 mg daily dose of vigabatrin was increased up to a maximum of 4000 mg. The final daily dose of vig 2150+/-900 mg, with a range of 1500-4000 mg. The steady-state trough plasma concentration of CBZ w the presence of vigabatrin, with a mean value of 7.9+/-1.4 vs 6.5+/-2.0 mcg/mL (p less than 0.03), respe

ratio of CBZ was significantly decreased from 0.59 +/- 0.20 in monotherapy to 0.45+/-0.15 in combinatior less than 0.05). CBZ plasma clearances in monotherapy ranged from 40 to 128 mL/h/kg, with a mean va mL/h/kg. When CBZ was combined with vigabatrin there was a marked increase in the plasma clearance mL/h/kg) with a mean value of 105.8 +/- 38.9 mL/h/kg (P less than 0.01). The plasma clearance of CBZ i 35% in the presence of vigabatrin. Dosing of CBZ and vigabatrin in combination is best adjusted by indiv drug monitoring (Sanchez-Alcaraz et al, 2002).

3.5.1.GB Viloxazine

1) Interaction Effect: carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vomiting, apnea, seizur
2) Summary: Viloxazine administered concurrently with carbamazepine increased carbamazepine steady-sta significantly (Pisani et al, 1984a; Pisani et al, 1986aa). These increased serum levels were associated with sy carbamazepine toxicity (dizziness, ataxia, fatigue, drowsiness) in five of seven patients and four of seven pat aformentioned studies, respectively. The concentration of the active metabolite, carbamazepine-10,11-epoxic increased (Pisani et al, 1986aa). In another study by (Pisani et al, 1986ba), viloxazine pharmacokinetics were the administration of carbamazepine.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Downward adjustment of carbamazepine dosage may be necessary when adding v therapy. Monitor serum carbamazepine concentrations closely.
7) Probable Mechanism: inhibition of carbamazepine hepatic metabolism by viloxazine
8) Literature Reports

a) The possibility of a drug interaction between viloxazine and carbamazepine was studied in seven epil stabilized on carbamazepine therapy. Viloxazine 100 mg three times daily was added to drug therapy for significantly increased steady-state carbamazepine serum levels from an average of 8.1 mcg/mL before to an average of 12.1 mcg/mL during the second and third weeks of viloxazine therapy (p less than 0.005 increased levels were associated with mild symptoms of carbamazepine toxicity (dizziness, ataxia, fatigu five patients. Serum carbamazepine levels returned to normal and symptoms abated after discontinuing et al, 1984).

b) Significant increases in serum carbamazepine and carbamazepine-10,11-epoxide levels during viloxa investigated. The study was performed in six epileptic patients stabilized on carbamazepine. After three viloxazine administration, steady-state plasma carbamazepine levels increased by 55% (p less than 0.00 carbamazepine-10,11-epoxide levels increased by 16% (p less than 0.001). Three of the six patients suf symptoms of carbamazepine intoxication. In a seventh patient, viloxazine had to be discontinued after tw severe carbamazepine intoxication (Pisani et al, 1986a).

c) The pharmacokinetics of viloxazine and whether chronic anticonvulsant therapy has any affect on vilo pharmacokinetics were studied in six epileptic patients taking one or two anticonvulsants (carbamazepin or phenytoin) and six drug-free control subjects. One oral viloxazine 200 mg dose followed by a single in of viloxazine 200 mg at least one week later were administered to each patient and control subject. Term not affected by anticonvulsant therapy (4.3 +/- 1.5 hours for the patients and 4.3 +/- 1.8 hours for the cor Absolute oral availability was 85% +/- 14%. Clearance and volume of distribution calculated from the intr the patients were 124 +/- 11 mL/kg/hr and 0.73 +/-0.28 L/kg, respectively. The authors concluded that vil pharmacokinetics did not appear to be significantly altered by carbamazepine, phenobarbital, or phenyto 1986b).

3.5.1.GC Voriconazole

1) Interaction Effect: reduced systemic exposure to voriconazole
2) Summary: Although not studied clinically, plasma voriconazole concentrations may be significantly reduce administration of carbamazepine (Prod Info VFEND(R) IV injection, oral tablets, suspension, 2008).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of voriconazole and carbamazepine is contraindicated (Prod Info injection, oral tablets, suspension, 2008).
7) Probable Mechanism: induction by carbamazepine of cytochrome P450-mediated voriconazole metabolis

3.5.1.GD Warfarin

1) Interaction Effect: decreased anticoagulant effectiveness
2) Summary: Concomitant carbamazepine and warfarin therapy has been reported to result in a decreased a effect, secondary to the induction of hepatic metabolism of the anticoagulant (Massey, 1983; Cohen & Armstr Weser & Koch-Weser, 1975; Kendall & Boivin, 1981; Hansen et al, 1971).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When carbamazepine is added or deleted from oral anticoagulant therapy with warf coumarin anticoagulant, intensified monitoring of the prothrombin time ratio or international normalized ratio (undertaken. It is often necessary to increase the dose of warfarin with the addition of carbamazepine, while a warfarin dose is frequently required upon the discontinuation of carbamazepine. Stabilization of the warfarin d

anticoagulant effect may require four to six weeks after the addition or deletion of carbamazepine.
7) Probable Mechanism: increased warfarin metabolism
8) Literature Reports
a) A patient taking carbamazepine 300 mg to 600 mg daily and warfarin 6 mg daily was stable at 2 to 3 i experienced a PT increase to 5 times the control value within four weeks of discontinuation of carbamaz dosage was reduced to 4 mg daily. Carbamazepine was reinstituted, and five weeks were required for re steady-state warfarin level at a dose of 5.5 mg daily (Ross & Beeley, 1980).

3.5.1.GE Yohimbine
1) Interaction Effect: increased risk of manic episodes in patients taking carbamazepine for bipolar disorder
2) Summary: Yohimbine may exacerbate bipolar disorder by precipitating manic episodes. This effect has be reports, generally within one to two hours of yohimbine administration. The authors concluded that patients w diathesis are predisposed to the psychogenic effect of yohimbine (Price et al, 1984a). Yohimbine appears to alpha2-adrenergic receptors on sympathetic nerve endings, increasing noradrenergic output through negative Alpha2-adrenoceptors may be involved in the pathogenesis of psychiatric disorders (Price et al, 1984a). Theo taking carbamazepine for bipolar disorder may experience a return of manic symptoms if they take yohimbine
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Avoid yohimbine use in patients taking carbamazepine for treatment of bipolar diso
7) Probable Mechanism: increased norepinephrine release by yohimbine
8) Literature Reports
a) Yohimbine challenges were administered to 55 patients with major depression, 39 patients with agora disorder, and 20 normal control subjects. Three patients developed manic-like symptoms, 2 of which hac bipolar disorder and one with manic symptoms which developed on withdrawal of desipramine. Normal s experienced either mild anxiety or no effect after yohimbine. Yohimbine increases anxiety in patients with disorder (Price et al, 1984).
b) A 41-year-old male with a 3 year history of bipolar disorder presented with depressive symptoms of 1 unresponsive to a 6 month trial of desipramine 250 mg/day and lithium 2100 mg/day. Lithium was discor given a 10 mg yohimbine challenge upon hospital admission. One hour after receiving yohimbine, the pa tremulousness, restlessness, giddiness, pressured speech, and feelings of increased energy and eupho after receiving yohimbine, he began to return to his baseline state. He continued to experienced increase decreased hopelessness, and decreased depression 4 hours after the yohimbine challenge. His full depr returned by the next morning. Following a 4 week period during which desipramine was discontinued and given, the patient's depression resolved. A second challenge of yohimbine 10 mg led to chills within 60 m 90 minutes he reported feeling euphoric. After 2 hours he returned to his baseline state (Price et al, 1984
c) A 20-year-old female with melancholic major depression with mood-congruent psychosis during her s was treated with desipramine 250 mg and perphenazine 40 mg daily with partial response. Perphenazine 6 weeks postpartum and desipramine was tapered off and discontinued 5 days prior to hospital admissio placebo washout period, she reported hearing voices telling her to kill herself. She was given a 20 mg yo challenge. Within one hour she experienced tremor, lacrimation, rhinorrhea, and became talkative. In the her affect brightened, her speech became increasingly clear and loud, and her hallucinations stopped. D symptoms gradually returned over the next several hours. Bupropion was initiated at doses up to 600 mg depression and intermittent hallucinations continued. A second challenge of yohimbine 20 mg led to mild tremulousness within 30 minutes, which resolved over an hour. Her affect improved and remained bright after which she returned to her baseline state (Price et al, 1984).
d) A 43-year-old woman with a 26-year history of bipolar disorder was discontinued from all medications admission (thioridazine, lithium, l-triiodothyronine, methylphenidate, and lorazepam) with the exception o was tapered off over 5 days following admission. One hour after receiving yohimbine 20 mg orally, she b voluble, and expansive. She experienced diaphoresis, palpitations, and tremors. Her elation progressed loud hysterical, inappropriate laughter. The intense manic symptoms persisted for 40 minutes. Her affect for the remainder of the day (Price et al, 1984).

3.5.1.GF Zaleplon
1) Interaction Effect: reduced zaleplon plasma concentrations
2) Summary: Zaleplon is partially metabolized by the CYP3A4 isozyme. Concomitant use of rifampin, a poter inducer, and zaleplon reduced zaleplon exposure and plasma concentrations by approximately 80%. Althoug carbamazepine, also a potent CYP3A4 inducer, a similar interaction can be expected. An alternative hypnotic substrate of CYP3A4 should be considered in patients receiving rifampin (Prod Info SONATA(R) oral capsule
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of carbamazepine, a potent CYP3A4 inducer, and zaleplon may r zaleplon levels and efficacy. Consider using an alternative hypnotic agent that is not a substrate of CYP3A4 i receiving rifampin (Prod Info SONATA(R) oral capsules, 2007).
7) Probable Mechanism: induction of CYP3A4-mediated zaleplon metabolism by carbamazepine

3.5.1.GG Ziprasidone

1) Interaction Effect: decreased ziprasidone plasma concentrations
2) Summary: Ziprasidone is metabolized primarily by CYP3A4. The concomitant use of carbamazepine (a C
200 mg twice daily for 21 days decreased the ziprasidone AUC by approximately 35%. Therefore, caution sh
carbamazepine and ziprasidone are coadministered due to the potential for reduced ziprasidone plasma con
Info GEODON(R) oral capsules, IM injection, 2008).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Use caution when prescribing carbamazepine to a patient who takes ziprasidone. C
carbamazepine and ziprasidone has resulted in decreased ziprasidone plasma concentrations (Prod Info GE
capsules, IM injection, 2008).
7) Probable Mechanism: induction of CYP3A4-mediated ziprasidone metabolism by carbamazepine

3.5.1.GH Zotepine

1) Interaction Effect: decreased zotepine plasma concentrations
2) Summary: Carbamazepine enhances the metabolism of zotepine by induction of the hepatic microsomal e
This may result in lower plasma levels of zotepine (Prod Info Nipolept(R), 1994).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor the patient carefully and increase the dose of zotepine if necessary.
7) Probable Mechanism: hepatic microsomal enzyme induction

3.5.2 Drug-Food Combinations

3.5.2.A Grapefruit Juice

1) Interaction Effect: increased carbamazepine bioavailability
2) Summary: Grapefruit juice increased the peak concentration, trough concentration, and area under the co
curve of carbamazepine by 40.4%, 39.2%, and 40.8%, respectively, during a randomized crossover study. C
metabolized in the liver to the active metabolite 10,11-epoxide by cytochrome P450 3A4 enzymes. Grapefruit
metabolic pathway, causing an increase in the bioavailability of carbamazepine. Because of the narrow thera
carbamazepine, patients should be advised to avoid the consumption of grapefruit juice (Garg et al, 1998a).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Patients receiving carbamazepine therapy should be instructed to avoid grapefruit j
7) Probable Mechanism: inhibition by grapefruit juice of cytochrome P450 3A-mediated carbamazepine meta
8) Literature Reports
a) Ten hospitalized epileptic patients who had been receiving carbamazepine 200 mg three times daily f
three to four weeks received 300 mL of grapefruit juice or water with their morning dose of carbamazepir
maximum concentration (Cmax) and minimum concentration (Cmin) values of carbamazepine increased
to 9.2 mcg/mL and from 4.51 mcg/mL to 6.28 mcg/mL, respectively, in the presence of grapefruit juice. T
concentration-time curve (AUC) from 0 to 8 hours also increased from 43.99 mcg/h/mL to 61.95 mcg/h/m
indicate that grapefruit juice does inhibit the metabolism of carbamazepine in epileptic patients (Garg et a

3.5.3 Drug-Lab Modifications

Perphenazine measurement

Tricyclic antidepressant measurement

3.5.3.A Perphenazine measurement

1) Interaction Effect: false increases in perphenazine levels
2) Summary: Carbamazepine was reported to cause false increases in perphenazine levels when measured
Beckman Ultrasphere ODS 3 mcm particle, 4.6 x 75 mm column using the method of Larson (with modificatic
patient (Spigset et al, 1994). Retention times were indistinguishable for the two drugs, resulting in a greater th
overestimation of the perphenazine concentration. Serendipitous changing of the column to a Nucelosil C18 5
x 150 mm column adequately resolved the two peaks. All HPLC perphenazine assay methods should be eva
carbamazepine interference.
3) Severity: minor
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: All HPLC perphenazine assay methods should be evaluated for carbamazepine int
7) Probable Mechanism: perphenazine assay interference

3.5.3.B Tricyclic antidepressant measurement

1) Interaction Effect: false positive tricyclic antidepressant assay results with serum fluorescence-polarized ir
2) Summary: Because carbamazepine is structurally similar to tricyclic antidepressants (TCAs), it can interfe fluorescence-polarized immunoassays for TCAs, causing falsely positive results. Carbamazepine does not in enzyme-linked immunoassays for TCAs, as they are much less sensitive than the serum assays. In the event assay with no history of TCA use, gas chromatography/mass spectrometry (GC/MS) should be considered to TCA toxicity (Saidinejad et al, 2007).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: established
6) Clinical Management: The molecular structural similarity of carbamazepine to tricyclic antidepressants (TC falsely positive results with the serum fluorescence-polarized immunoassay but not the less sensitive urine er immunoassay. When an assay is positive for TCAs and there is no history of TCA use, gas chromatography/r (GC/MS) should be considered, as they are specific enough to differentiate between TCAs and structurally si (Saidinejad et al, 2007).
7) Probable Mechanism: molecular structural similarity of carbamazepine to the tricyclic antidepressant class
8) Literature Reports

a) A cross-sectional study of pediatric patients (n=52) taking carbamazepine or oxcarbazepine showed carbamazepine significantly interferes with the serum fluorescence-polarized immunoassay for tricyclic a (TCAs), but does not interfere with the urine enzyme-linked immunoassay for TCAs. Patients aged 3 to 1 been prescribed carbamazepine or oxcarbazepine and needed routine laboratory testing were enrolled ir were also excluded if they had used TCAs or a structurally similar compound other than the medications week prior to the study. The investigators used the TCA screening serum and urine assays, measured s carbamazepine or oxcarbazepine metabolite levels, and then performed gas chromatography/mass spec to confirm or rule out the presence of TCAs in the serum. Thirteen of 33 patients on carbamazepine had the serum assay, which had a positive cutoff of 50 micrograms per liter (mcg/L). All of the patients had a level within therapeutic range (4 to 12 mcg/L), but 12 of the 13 patients with carbamazepine levels of 8 m positive serum assay results. Linear regression showed a significant dose-dependent relationship betwe carbamazepine levels and the quantity of TCAs detected (p less than 0.0001). The investigators estimate mcg/L of carbamazepine present in the serum, the assay detected 4.2 mcg/L of TCAs. Urine assays had 150 mcg/L, as recommended by the manufacturer, and there were no positive results in patients taking e carbamazepine or oxcarbazepine.(Saidinejad et al, 2007).

4.0 Clinical Applications

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters

A) Therapeutic

1) Laboratory Parameters

a) Monitor blood concentrations of carbamazepine is recommended to optimize therapeutic effect and reduc (Prod Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007; Prod Info TEGRETOL(R)-XR ext tablets, 2007).
b) The usual adult therapeutic levels are between 4 and 12 micrograms/milliliter (Warner et al, 1998; Yukawa
c) Levels drawn during the first few weeks of therapy should be cautiously interpreted, due to induction of en
d) Routine monitoring of the epoxide metabolite may also be required during carbamazepine therapy, as ser carbamazepine levels alone may not be adequate to detect toxicity in some patients. Total serum carbamaze epoxide serum levels above 9 micromol/L are associated with greater side effects than lower levels (Patsalos
e) Therapeutic levels for therapy of neuralgias have been reported to be 2 to 7 micrograms/milliliter (HPLC) (1993).

2) Physical Findings

a) EPILEPSY

1) Monitor patients for reduction in seizure frequency.

b) NEUROLOGICAL PAIN SYNDROMES

1) Monitor patients for improvement in pain of trigeminal neuralgia and other neurological syndromes.

B) Toxic

1) Laboratory Parameters

a) High-resolution human leukocyte antigen-B*1502 (HLA-B*1502) typing in Asian patients including South A should be performed due to a strong correlation between the risk of developing serious and sometimes fatal c reactions (including Stevens-Johnson syndrome and toxic epidermal necrolysis) and the presence of HLA-B* Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007; Prod Info TEGRETOL(R)-XR extended tablets, 2007; US Food and Drug Administration, 2007).

1) Prevalence of HLA-B*1502 allele

a) Human leukocyte antigen-B*1502 (HLA-B*1502) allele is common in Asians including South Asia prevalence of HLA-B*1502 is not known for all regions of Asia. The following are known HLA-B*150 prevalence rates in some regions of Asia: greater than 15% in Hong Kong, Thailand, Malaysia, and Philippines; about 10% in Taiwan; 4% in North China; 2% to 4% in South Asians, including Indians b in some groups; and less than 1% in Japan and Korea. Individuals not of Asian origin (eg, Caucasia Americans, Hispanics, and Native Americans) generally are not HLA-B*1502 positive (Prod Info TE chewable tablets, tablets, suspension, 2007; Prod Info TEGRETOL(R)-XR extended-release oral tab Food and Drug Administration, 2007).

b) Perform complete blood counts including platelets, and possibly reticulocytes and serum iron before thera periodically (Prod Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007; Prod Info TEGRETO release oral tablets, 2007).

1) If significant bone marrow depression develops, the manufacturer recommends the following (Prod In oral chewable tablets, tablets, suspension, 2007; Prod Info TEGRETOL(R)-XR extended-release oral tab

a) Stop drug

b) Perform daily CBC, platelet, and reticulocyte counts

c) Do bone marrow aspiration and trephine biopsy and repeat as necessary to monitor recovery

d) Other specific studies that might help include: white cell and platelet antibodies, (59)Fe-ferrokine peripheral blood cell typing, cytogenetic studies on marrow and peripheral blood, bone marrow cultu colony-forming units, hemoglobin electrophoresis for A(2) and F hemoglobin, and serum folic acid a

c) Hepatic function tests (AST, alkaline phosphatase) should be conducted prior to and periodically during th TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007; Prod Info TEGRETOL(R)-XR extended-rele 2007).

d) Baseline and periodic monitoring of renal function tests (complete urinalysis and BUN) is recommended d renal dysfunction (Prod Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007; Prod Info TEGI extended-release oral tablets, 2007).

e) Monitor serum sodium due to the risk of hyponatremia (Prod Info TEGRETOL(R) oral chewable tablets, ta 2007).

f) Conduct periodic thyroid function tests at the physician's discretion during therapy as thyroid levels may be Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007; Prod Info TEGRETOL(R)-XR extended tablets, 2007)

2) Physical Findings

a) Observe patients for hypersensitivity reactions who previously experienced this reaction to anticonvulsant phenytoin and phenobarbital (Prod Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007; Pro (R)-XR extended-release oral tablets, 2007).

b) Due to the potential of serious and sometimes fatal dermatologic reactions, carefully observe patients for symptoms of Stevens-Johnson syndrome and toxic epidermal necrolysis (Prod Info TEGRETOL(R) oral chew tablets, suspension, 2007; Prod Info TEGRETOL(R)-XR extended-release oral tablets, 2007).

c) Baseline and periodic eye examinations, including slit-lamp, funduscopy, and tonometry, are recommende phenothiazines and related drugs have been shown to cause eye changes (Prod Info TEGRETOL(R) oral ch tablets, suspension, 2007; Prod Info TEGRETOL(R)-XR extended-release oral tablets, 2007).

d) Monitor patients with a mixed seizure disorder, including atypical absence seizures, for the potential incre generalized convulsion (Prod Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007; Prod Info XR extended-release oral tablets, 2007).

e) Activation of latent psychosis is a possibility due to the relationship between carbamazepine and tricyclic c Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007).

f) Confusion or agitation in the elderly is a possibility due to the relationship between carbamazepine and tric (Prod Info TEGRETOL(R) oral chewable tablets, tablets, suspension, 2007).

g) Data reviewed by the US Food and Drug Administration suggest an increased risk of suicidal behavior or in patients receiving therapy with antiepileptic drugs (AEDs). The increased risk of suicidality was noted at 1 an AED and continued to at least 24 weeks. Patients treated for epilepsy, psychiatric disorders, or other conc an increased risk for suicidality compared to placebo. Closely monitor patients treated with AEDs for emerge of depression, suicidality, and other unusual changes in behavior, which may include symptoms such as anxi hostility, mania, and hypomania (US Food and Drug Administration, 2008).

4.2 Patient Instructions

A) Carbamazepine (By mouth)

Carbamazepine

Treats different types of seizures. Also used to treat nerve pain and bipolar disorder, also known as manic-depres

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to carbamazepine or to certain medicines fo
as amitriptyline, desipramine, imipramine, protriptyline, and nortriptyline. You should not use this medicine if you h
bone marrow depression (low blood counts). Do not use this medicine if you are using nefazodone (Serzone®) or
MAO inhibitor (MAOI) such as selegiline (Eldepryl®), isocarboxazid (Marplan®), phenylzine (Nardil®), or tranylcyp
(Parnate®) within the past 14 days. Do not use this medicine if you are pregnant.

How to Use This Medicine:
Long Acting Capsule, Liquid, Tablet, Chewable Tablet, Long Acting Tablet
Your doctor will tell you how much of this medicine to use and how often. Do not use more medicine or use it
your doctor tells you to.
It is best to take this medicine with food or milk.
Swallow the extended-release tablet or extended-release capsule whole. Do not crush, break, or chew it. Do
extended-release tablet that is cracked or chipped.
If you cannot swallow the extended-release capsule, you may open it and pour the medicine into a small amo
such as pudding, yogurt, or applesauce. Stir this mixture well and swallow it without chewing.
The chewable tablet must be chewed before you swallow it.
Measure the oral liquid medicine with a marked measuring spoon, oral syringe, or medicine cup.

If a Dose is Missed:
If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next d
then to use the medicine and skip the missed dose. Do not use extra medicine to make up for a missed dose

How to Store and Dispose of This Medicine:
Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after
your treatment. You will also need to throw away old medicine after the expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a
products.
There are many other drugs that can interact with carbamazepine. Make sure your doctor knows about all oth
are using. Some medicines that can interact include heart medicines, blood pressure medicines, seizure mec
antidepressants, pain medicines, cancer medicines, steroids, and medicines to treat infections, including HIV
medicines. Also tell your doctor if you are using cimetidine (Tagamet®), haloperidol (Haldol®), levothyroxine
nicotinamide, praziquantel (Biltricide®), risperidone (Risperdal®), theophylline (Theo-Dur®), ziprasidone (Ge
thinner such as warfarin (Coumadin®).
Birth control pills, implants, or shots will not work while you are using this medicine. To keep from getting pre
form of birth control such as condoms or a diaphragm with contraceptive foam or jelly.
Do not eat grapefruit or drink grapefruit juice while you are using this medicine.
Tell your doctor if you are using any medicines that make you sleepy. These include sleeping pills, cold and a
narcotic pain relievers, and sedatives.
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:
Using this medicine while you are pregnant can harm your unborn baby. Use an effective form of birth contro
getting pregnant. If you think you have become pregnant while using the medicine, tell your doctor right away
Make sure your doctor knows if you are breastfeeding, or if you have glaucoma, liver disease, kidney disease
heart or heart rhythm problems, or if you have ever had a mental illness or an inherited disease such as porp
doctor if you have had an allergic reaction to any other medicines (especially seizure medicines).
Do not stop using this medicine suddenly without asking your doctor. You may need to slowly decrease your
stopping it completely.
Your doctor will need to check your blood or urine at regular visits while you are using this medicine. Be sure
appointments.
Make sure any doctor or dentist who treats you knows that you are using this medicine. This medicine may a
certain medical tests.
This medicine may make you dizzy or drowsy. Avoid driving, using machines, or doing anything else that cou
you are not alert.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, d
trouble breathing.
Blistering, peeling, red skin rash.
Change in how much or how often you urinate.
Chest pain, fast or uneven heartbeat.

Dark-colored urine or pale stools.
Fever, sore throat, or sores in your mouth.
Lightheadedness or fainting.
Nausea, vomiting, loss of appetite, or pain in your upper stomach.
Problems with balance, walking, or speech.
Shortness of breath, cold sweat, and bluish-colored skin.
Swelling in your hands, ankles, or feet.
Unusual bleeding, bruising, or weakness.
Yellowing of your skin or the whites of your eyes.

If you notice these less serious side effects, talk with your doctor:
Anxiety, confusion, depression, restlessness, or agitation.
Diarrhea, constipation, or upset stomach.
Dizziness, drowsiness or unsteady on your feet.
Dry mouth.
Headache or back pain.
Vision changes.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Carbamazepine is considered the drug of first choice with the least toxicity for treating partial seizures with or witho generalization (Herman & Pedley, 1998). Carbamazepine should not be used for absence seizure since an exacerbati occur (Parker et al, 1998).
B) In comparison with phenobarbital, phenytoin, and primidone, carbamazepine appears to have the least effect on c and behavioral disturbances (Trimble, 1988).
C) Carbamazepine is the drug of choice for trigeminal neuralgia and is considered a drug of choice for bipolar disorde
D) Carbamazepine should be included on the hospital formulary.

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION
1) SUMMARY
a) Carbamazepine is an anticonvulsant chemically related to imipramine; its mechanism of action in preventi remains unclear but may involve reduction of polysynaptic responses and blocking the post-tetanic potentiati models, carbamazepine reduces pain by stimulation of the infraorbital nerve. In addition, the drug may depre potential and bulbar and polysynaptic reflexes (Prod Info Tegretol(R), 2002a).
2) Carbamazepine is a dibenzoazepine iminostilbene derivative, which has shown to be an effective anticonvulsa patients not responding to other anticonvulsant therapy. Carbamazepine has been shown effective in <GENERAL CLONIC SEIZURES>, COMPLEX PARTIAL SEIZURES, and SIMPLE PARTIAL SEIZURES, as well as those rep secondary generalization (Troupin et al, 1974; Penovich & Morgan, 1976; Anon, 1975). True ABSENCE SEIZURE SPASMS have not responded well although atypical absence seizures have been more responsive (Troupin et al
3) Carbamazepine possesses psychotropic effects. Carbamazepine is less sedating than most anticonvulsants (1974). The drug elevates mood in some depressed patients with epilepsy and is considered a drug of choice for b
4) Although effective in psychiatric disorders, carbamazepine does not have a neurochemical profile resembling t antipsychotics. Data suggest, however, that carbamazepine may decrease dopamine turnover without directly blo receptors (Post et al, 1986).
B) REVIEW ARTICLES
1) The treatment of seizures have been reviewed; these include treatment of first seizure and status epilepticus (treatment of the elderly (Rowan, 1998), and management of epilepsy in adults (Feely, 1999; Mattson, 1998). Pedi management has also been reviewed (Wolf et al, 1998; Pellock, 1998).
2) With the addition of the newer antiepileptic drugs, polypharmacy in epilepsy is being revisited (Schneiderman, 1998).
3) Carbamazepine prophylaxis for bipolar disorder has been reviewed (Keck et al, 1998; Post et al, 1997).
4) A review of the metabolism of carbamazepine is presented (Eichelbaum et al, 1985c).
5) Reviews of the use of carbamazepine in children are available (Gilman, 1991; Seetharam & Pellock, 1991).
6) The treatment and prophylaxis of facial neuralgias has been reviewed (Diener et al, 1994).
7) Drug-interactions of antidepressants are reviewed in German language (Zapotoczky & Simhandl, 1995).

4.5 Therapeutic Uses

Aggressive behavior

Agitation - Brain injury

Agitation - Dementia

Alcohol withdrawal syndrome

Apraxia

Behavioral syndrome - Mental retardation

Benzodiazepine withdrawal

Bipolar I disorder, acute manic and mixed episodes

Chorea

Chronic paroxysmal hemicrania - Tic disorder

Cocaine dependence

Dementia

Depression

Diabetes insipidus

Diaphragmatic tic

Dystonia

Encephalitis due to human herpes simplex virus; Adjunct

Epilepsy, Partial, generalized, and mixed types

Erythrodermic psoriasis

Facial spasm

Glossopharyngeal neuralgia

Hiccoughs, Intractable

Huntington's disease

Migraine; Prophylaxis

Multiple sclerosis, Sensory symptoms

Myoclonus

Myokymia

Neuralgia

Neurogenic pain

Neuropathy, General

Obsessive-compulsive disorder

Obsessive compulsive personality disorder

Pain

Panic disorder

Phantom limb syndrome

Polyradiculoneuropathy

Postherpetic neuralgia

Posttraumatic stress disorder

Psychotic disorder

Restless legs syndrome

Schwartz-Jampel syndrome

Subacute sclerosing panencephalitis

Tabes dorsalis

Temporal lobectomy behavior syndrome

Tinnitus

Trigeminal neuralgia

Trigeminal trophic syndrome

Uremic neuropathy

4.5.A Aggressive behavior

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Possibly effective for aggression (Coons, 1992; Yatham & McHale, 1988)

3) Adult:

a) Case reports of CARBAMAZEPINE 300 to 800 milligrams daily were reported effective in the treatment of BEHAVIOR (Coons, 1992; Yatham & McHale, 1988).

4.5.B Agitation - Brain injury

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

May be safe and effective for the treatment of post-traumatic agitation, but the response is inconsistent (

3) Adult:

a) Post-traumatic agitated behaviors, particularly irritability and disinhibition, were effectively treated with car patients severe CLOSED-HEAD INJURY. In this prospective, open trial, patients (mean age 34 years) receiv

200 milligrams (mg) per day, increased by 200 mg increments until 600 to 1200 mg/day was reached. Behav including the Neurobehavioral Rating Scale-revised (NRS-R) and the Agitated Behavior Scale (ABS) were pe baseline and every 2 weeks during treatment. Significant improvement in scores of both tools was observed a assessment (p=0.02 for both), but considerable interindividual variability was observed. Five patients demons than 50% improvement in NRS- R score, while 3 showed a 25% to 43% improvement, and 2 patients showed during the study period. Adverse effects consisted of drowsiness, for which the dose was reduced, and 1 cas allergic cutaneous reaction requiring drug withdrawal (Azouvi et al, 1999).

4.5.C Agitation - Dementia

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in the treatment of hyperactivity, psychomotor restlessness, and agitation associated with deme

3) Adult:

a) In a 6-week, randomized, parallel-group study, carbamazepine was more effective than placebo in patient and aggression associated with dementia (Tariot et al, 1998); however following DRUG WITHDRAWAL, agita aggressive behavior returned to baseline levels (Tariot et al, 1999). At multiple nursing home sites, patients r carbamazepine (n=27) or placebo (n=24). The modal carbamazepine dose at 6 weeks was 300 milligrams/da serum level of 5.3 micrograms/milliliter was achieved. Mean total Brief Psychiatric Rating Scale decreased by carbamazepine group and 0.9 for the placebo group. The Clinical Global Impression ratings showed improve patients taking carbamazepine and 21% of those taking placebo. Staff perception of the extra time required t behavioral problems also significantly decreased in the carbamazepine group as compared to placebo. The s terminated after a planned interim analysis showed that carbamazepine provided more benefit than placebo (An additional open treatment period of 12 weeks was undertaken to examine long-term efficacy and safety a patterns of behavioral response. Behaviors were assessed at 6, 9, 15, and 21 weeks. Evaluations performed washout period demonstrated that scores for agitation and aggression were no different from untreated basel those assessing anxiety, depression, psychosis, and cognitive function were similar to those following 6 week carbamazepine treatment. Longer treatment with carbamazepine produced similar benefits regarding aggres behaviors, as well as improvements in other psychopathologic behaviors. Over the 21 weeks of study, 26 pat from participation for the following reasons: adverse effects (11), administrative reasons (12), lack of efficacy oral medications (1). Only 1 adverse effect, ataxia, was possibly related to carbamazepine treatment. Ongoin generally well tolerated (Tariot et al, 1999).

b) CARBAMAZEPINE 200 to 1000 milligrams daily was useful in the treatment of agitation in 6 of 9 patients disease (Gleason & Schneider, 1990). Corresponding serum concentrations ranged from 2.3 to 9.6 micrograi Overall improvement was greatest in agitation and hostility; some improvement was also seen in tension and uncooperativeness. Clinical improvement was generally seen within 2 to 4 weeks following the start of treatm

c) CARBAMAZEPINE was reported effective in the treatment of assaultive and aggressive behavior in patier DEMENTIA in a small study involving 8 ambulatory male patients (Patterson, 1987). The drug was given in d milligrams (mg) 3 times daily for 1 day, followed by 200 mg orally 4 times daily for the second day; subseque administered to achieve serum levels of 8 to 12 micrograms/milliliter. The number of assaults decreased sign CARBAMAZEPINE therapy (by more than 50%); assaultive behavior was also considered to be less intense duration.

4.5.D Alcohol withdrawal syndrome

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

May prove useful in the treatment of anxiety, dysphoria, somatization, and other signs of alcohol abstine (Flygenring et al, 1984; Agricola et al, 1982; Wilbur & Kulik, 1981).

See Drug Consult reference: DRUG THERAPY OF ETHANOL WITHDRAWAL

3) Adult:

a) In an open trial of approximately 100 patients, CARBAMAZEPINE was found to be effective in relieving ar associated with acute alcohol withdrawal syndromes (Poutanen, 1979).

4.5.E Apraxia

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Apraxia may respond to carbamazepine therapy (Naqvi et al, 1998)

3) Pediatric:

a) In a case series, carbamazepine was useful in treating 3 patients with apraxia and new-onset partial seizu 1998). Seven children (2 to 12 years old) with either oral motor apraxia or ocular motor apraxia received carb milligrams/kilogram/day. Responders had interictal epileptiform discharges on EEG while non-responders (n= seizures and had non-epileptiform EEG findings.

4.5.F Behavioral syndrome - Mental retardation

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in the treatment of overactive, severely mentally handicapped patients (Reid et al, 1981)

3) Adult:

a) CARBAMAZEPINE was used for behavioral disorders including aggression, self-injurious behavior, hyper tantrums in 76 chronically institutionalized mentally retarded individuals previously unresponsive to other mec patients demonstrated nearly complete resolution of symptoms and 10 showed some improvement. Previous seizure disorders or underlying electroencephalogram abnormalities were noted in 27 of the 30 responders. T study is limited due to the lack of psychiatric diagnosis and the failure to distinguish among "behavior disorde 1989).

4.5.G Benzodiazepine withdrawal

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Possibly useful in the treatment of benzodiazepine withdrawal (Ries et al, 1989; Klein et al, 1986)

3) Adult:

a) CARBAMAZEPINE in doses of 400 to 800 milligrams daily was reported effective in treating withdrawal fr benzodiazepines (CHLORDIAZEPOXIDE, ALPRAZOLAM, DIAZEPAM, CLONAZEPAM) in a small open stuc 1989; Klein et al, 1986). Controlled studies are required to confirm these findings.

4.5.H Bipolar I disorder, acute manic and mixed episodes

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes (Extended release formulation); Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Indicated for the treatment of acute manic and mixed episodes associated with bipolar I disorder (Prod Ir extended release capsules, 2004)
Effective in the acute and prophylactic treatment of bipolar affective disorder
Effective in bipolar patients who have shown no response to LITHIUM therapy
In combination with LITHIUM may be effective when either or both agents alone have failed

3) Adult:

a) Therapy with carbamazepine extended-release (ER) capsules was more effective than placebo in the trea manic and mixed episodes in patients with bipolar disorder. In two randomized, double-blind, multicenter, flex patients diagnosed with bipolar I disorder with manic or mixed episodes received carbamazepine ER (titrated of 400 to 1600 milligrams (mg)/day, given twice daily in divided doses) or placebo for 3 weeks. The mean car dose during the last week of treatment was 952 mg/day in the first study and 726 mg/day in the second study Young Mania Rating Scale scores from baseline to endpoint were significantly more reduced in carbamazepi patients as compared with those who received placebo (Prod Info Equetro(TM) extended release capsules, 2

b) In a double-blind study in 52 bipolar patients, lithium and carbamazepine had a roughly equal but less tha prophylactic efficacy in overall bipolar illness (Denicoff et al, 1997a). Patients were randomly assigned to 1 ye with lithium or carbamazepine, and then crossed over to the other drug in the second year. During a third yea received a combination of the 2 drugs. A marked or moderate improvement occurred in 33% of patients recei 31% of patients receiving carbamazepine and 55% of those receiving the combination. Lithium, however, wa prophylaxis of mania (no mania experienced by 11% on lithium, 4% on carbamazepine, and 33% on combina

less than 0.01). The combination of lithium and carbamazepine was better than monotherapy in rapid cyclers
c) The addition of LITHIUM CARBONATE (plasma levels, 0.7 to 1.2 milliequivalents/liter) to CARBAMAZEPI
to 1500 milligrams daily) was reported effective in improving MANIA in 6 of 7 patients previously refractory to
alone. These patients were also refractory to several weeks of CARBAMAZEPINE therapy (Kramlinger & Pos
data support previous studies suggesting that some manic patients may respond to a combination of LITHIU
CARBAMAZEPINE, but not to each agent alone (Woods, 1986).
d) CARBAMAZEPINE was effective as an adjunctive medication in the treatment of 11 of 13 patients with tre
affective disorders including LITHIUM nonresponders. CARBAMAZEPINE was used in combination with neu
as well as with LITHIUM CARBONATE. Four patients were judged to have had markedly effective responses
effective response and in 4 there was a slightly effective response. The mean daily dose varied from 300 to 1
(Kwamie et al, 1984).

4.5.I Chorea

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category C; Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in the treatment of chorea

3) Adult:

a) CARBAMAZEPINE 15 to 24 milligrams/kilogram/day orally (plasma levels, 6.5 to 8.8 micrograms/milliliter)
be effective in the treatment of NONHEREDITARY CHOREA in 5 patients (Roig et al, 1988). Chorea was ca
streptococcal infection in 2 patients and head injury in 1 other; the cause in the remaining 2 patients could no
Clinical improvement was observed within 4 to 15 days after initiation of CARBAMAZEPINE treatment. Side e
observed in 4 patients during 3 months to 36 months therapy. In one patient, withdrawal of the drug was requ
an allergic cutaneous reaction after 17 days. More studies are required to evaluate the efficacy of CARBAMA
b) CARBAMAZEPINE has been reported to be effective in the treatment of benign dominant hereditary chor
mother and daughter). Both showed decreased involuntary movements and functional improvement and felt s
quieter. Doses of CARBAMAZEPINE were 250 milligrams (mg) (3.5 mg/kilogram) daily in the child and 400 m
mother (Roulet & Deonna, 1989).

4) Pediatric:

a) Carbamazepine was found to be safe and effective in the treatment of choreic movements in 17 pediatric
female; 10.9 +/- 2.4 years-old) with SYDENHAM'S CHOREA in an open-label trial. The children received 15 m
kilogram per day of carbamazepine. Onset of clinical improvement was 7.4 +/- 8.2 days; time to complete rem
movements was 6.7 +/- 6.3 weeks; and the duration of treatment was 5.0 +/- 2.4 months. There was a recurr
and no adverse drug events were reported during the trial (Genel et al, 2002).
b) A prospective case series of 10 children with RHEUMATIC CHOREA found low-dose CARBAMAZEPINE
effective (Harel et al, 2000). Ages of the children ranged from 7 to 16 years; 9 children in the cohort had Syde
with concomitant carditis and 1 child had antiphospholipid antibody syndrome that evolved to systemic lupus
Dosing of carbamazepine was 4 to 10 milligrams/kilogram daily (associated plasma concentrations were 2.8
micrograms/milliliter). Initial improvement was observed within 2 to 14 days. Chorea disappeared in 7 childre
and in all patients within 12 weeks. Treatment duration was 1 to 15 months. Symptoms recurred in 3 patients
retreatment. One patient experienced a treatment-related side effect, a maculopapular rash that responded to

4.5.J Chronic paroxysmal hemicrania - Tic disorder

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

INDOMETHACIN and CARBAMAZEPINE may be beneficial for treatment of chronic paroxysmal hemicra
based on anecdotal evidence (Martinez-Salio et al, 2000)

3) Adult:

a) A 52-year-old man suffering from chronic paroxysmal hemicrania- tic syndrome (CPS-tic) was successfull
INDOMETHACIN and CARBAMAZEPINE . The patient initially presented with a 2-month history of headache
severe, sharp, or stabbing pain behind the right eye and temporal area, with attacks occurring 5 to 8 times a
to 15 minutes. During the attacks, he also experienced ipsilateral lacrimation, nasal congestion, and rhinorrhe
PAROXYSMAL HEMICRANIA (CPH) was diagnosed. Indomethacin 25 milligrams (mg) 3 times a day brough
complete relief. Some months later (indomethacin had been terminated after 6 months), he developed brief e
pains spreading from his right jaw to his right ear, that were triggered by talking, chewing, or touching the affe
shock-like pains were diagnosed as TRIGEMINAL NEURALGIA. Indomethacin was tried unsuccessfully. CA
200 mg 3 times a day brought complete relief in 24 hours. Two months later (with continuing use of carbama
type of headache (CPH) returned. Again indomethacin provided complete response. One month later, he suc
discontinued indomethacin, and carbamazepine was slowly tapered off. At 3-months follow-up, the patient wa

(Martinez-Salio et al, 2000).

4.5.K Cocaine dependence

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in reducing cocaine craving and assisting in maintaining cocaine abstinence

3) Adult:

a) In a 12-week, randomized, double-blind, placebo-controlled study, carbamazepine reduced the duration a craving episodes but had little impact on frequency of urges (Halikas et al, 1997). Patients (n=183) were ranc placebo, carbamazepine 400 milligrams (mg), or 800 mg daily (31% of patients randomized completed the st carbamazepine levels were associated with lower rates of positive cocaine urinalysis (p=0.004), fewer days c cocaine use (p=0.014), shorter craving duration (p less than 0.001), and greater overall therapeutic effect (p=

b) CARBAMAZEPINE 200 to 400 milligrams daily was reported to be effective in reducing COCAINE craving maintaining COCAINE abstinence in 1 small study (Halikas et al, 1989). Similar results were reported in place crossover studies for the treatment of crack cocaine use (Halikas et al, 1992; Halikas et al, 1991). CARBAMA more than 4 micrograms/milliliter were associated with greater improvement.

4.5.L Dementia

See Drug Consult reference: BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA

4.5.M Depression

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Carbamazepine was effective in unipolar depressed patients who had not previously been treated with a other psychotherapeutic treatments in a double-blind, randomized, placebo-controlled study (n=89) (Zha
Carbamazepine was effective in the prophylaxis of unipolar depression in an open-label study involving
(Stuppaeck et al, 1994)
Carbamazepine was effective in patients with depression resistant to other treatment, but the high rate o may limit its utility (Cullen et al, 1991)

3) Adult:

a) Carbamazepine was effective in unipolar depressed patients who had not previously been treated with an other psychotherapeutic treatments in a double-blind, randomized, placebo-controlled study (n=89). Patients with a history 2 or more episodes of major depression, no history of mania or hypomania, and currently exper episode of depression with a duration of at least 2 weeks, were randomized to immediate release carbamaze placebo (n=38) for 12 weeks. Carbamazepine was started at 300 milligrams/day (mg/day) in 2 divided doses (within 2 weeks) to a maximum of 800 mg/day based on patient response and tolerability. The mean final car was 461.6 +/- 87.7 mg/day. The primary efficacy analysis was based on a modified-intention-to-treat (MITT) p as all patients who completed at least one post baseline evaluation utilizing the last observation carried forwa method. Measures of primary efficacy included the Hamilton Rating Scale for Depression (HAMD), the Montg Depression Rating Scale (MADRS), and the Clinical Global Impression-Severity (CGI-S). Clinical response w greater than or equal to a 50% reduction in score on the HAMD from baseline to endpoint. Patients in both ar symptomatic improvements by week 8 (p less than 0.05 vs baseline), but significant separation in HAMD, MA results occurred between treatment groups (p less than 0.05). Mean HAMD score improved from 25 at baseli 8 in the carbamazepine arm compared with an improvement from 24 to 13.1 in the placebo arm (p less than (endpoint clinical response rate of carbamazepine-treated patients was 73.9% (34/46) compared to 45.9% (17 patients (p=0.018). The most frequently reported adverse event was benign leucopenia (30.4%) in the carbar Four carbamazepine patients discontinued treatment due to intolerable adverse events (3 rash, 1 blurred visi 2008).

b) Carbamazepine was effective in the prophylaxis of unipolar depression in an open-label study involving 15 study, patients received an initial dose of carbamazepine of 200 milligrams/day (mg/day), slowly increasing to final dose was adjusted to maintain a serum level in the lower end of the therapeutic range of 5 to 12 microgr Patients were followed for a period of 5 years. Carbamazepine was beneficial in 11 of 15 (73%) treated patie patients were completely free of depressive episodes (Stuppaeck et al, 1994).

c) Carbamazepine was effective in patients with depression resistant to other treatment, but the high rate of may limit its utility. In a retrospective study, 7 of 16 patients. demonstrated moderate to marked improvement included those with both psychotic and nonpsychotic depression as well as patients with organic brain diseas responders discontinued medication because of rash, hyponatremia, or hepatotoxicity (Cullen et al, 1991).

d) Relapse of depression was prevented with carbamazepine prophylaxis in a single patient. Recurrence of

appeared within 2 to 4 months of carbamazepine discontinuation. No significant side effects were noted durir (Kobayashi et al, 1988).

4.5.N Diabetes insipidus

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Induces antidiuresis by releasing antidiuretic hormone

3) Adult:

a) Seven of 9 patients with diabetes insipidus (1 to 23 years' duration) were successfully treated with CARBA to 1200 milligrams daily in divided doses for 7 to 10 days in a controlled study. In 7 patients, there was satisfa urine output and fluid intake. Plasma osmolality significantly decreased after 7 days. Upon substituting placeb symptoms of diabetes insipidus recurred (Wales, 1975).

b) Carbamazepine therapy successfully treated a patient's NEPHROGENIC DIABETES INSIPIDUS induced drug was also effective in the treatment of the patient's affective psychosis (Brook & Lessin, 1983).

c) Successful use of CARBAMAZEPINE was described in a 19-year-old black pituitary dwarf with diabetes ir age of 6 (Dindar & Cooper, 1974). Doses of 100 milligrams (mg) twice daily to 200 mg three times daily resul urinary output from 3 to 4 liters/day (L/day) to 1.5 L/day. Upon discontinuing therapy, urinary volume increase successfully maintained at 100 mg twice daily. The patient had previously failed to respond to pituitary snuff, and CHLORPROPAMIDE.

d) One study investigating the mechanism of ANTIDIURETIC ACTION showed that CARBAMAZEPINE in dc milligrams orally increased plasma ADH from 0.4 micrograms/milliliter (mcg/mL) to 3.8 mcg/mL and increasec from 0.4 to 1.7. Water loading did not inhibit the effects of CARBAMAZEPINE (Kimura et al, 1974).

4.5.O Diaphragmatic tic

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Successfully treated with carbamazepine in 3 patients (Vantrappen et al, 1992)

3) Adult:

a) High frequency diaphragmatic flutter characterized by esophageal belching, hiccups, and retching was tre CARBAMAZEPINE 200 to 400 milligrams 3 times daily in 3 patients with long-standing symptoms. All patient complete remission or significant improvement in symptoms and reductions in flutter as demonstrated by elec (Vantrappen et al, 1992).

4.5.P Dystonia

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Limited data suggests efficacy of CARBAMAZEPINE in dystonia (Geller et al, 1976)

3) Adult:

a) Successful use of CARBAMAZEPINE in 8 of 8 patients with dystonic symptoms (hereditary torsion dyston dystonia, 4) has been reported. The drug was given in doses of 300 to 1200 milligrams daily for a period of 4 was noted that brief episodes of dystonia responded most dramatically and completely, but returned the soor discontinuation of the drug. More sustained tension in dystonia responded more slowly to CARBAMAZEPINE completely, and required higher doses than brief dystonic episodes. Effectiveness of the dystonias was maint for periods of 4 to 12 months. Although symptoms remained improved for some time after withdrawal in 2 pat eventually relapsed following discontinuation of therapy or when placebo was substituted (Geller et al, 1976).

4.5.Q Encephalitis due to human herpes simplex virus; Adjunct

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Stabilized psychiatric sequelae of herpes simplex encephalitis (Vallini & Burns, 1987)
3) Adult:
a) In 1 case report, carbamazepine 200 milligrams 3 to 4 times daily was effective in stabilizing psychiatric se simplex ENCEPHALITIS in a 62-year-old male. It is unclear if beneficial effects observed were secondary to s mesial temporal seizure activity observed in this patient, or to mood-stabilizing effects of the drug (Vallini & B

4.5.R Epilepsy, Partial, generalized, and mixed types
FDA Labeled Indication
1) Overview
FDA Approval: Adult, yes; Pediatric, yes
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS
2) Summary:
Indicated for the following seizure types (Prod Info Tegretol(R), 2002):
Partial seizures with complex symptomatology (psychomotor, temporal lobe)
Generalized tonic-clonic seizures (grand mal)
Mixed seizure patterns which include the above or other partial or generalized seizures
Not effective against absence seizures (petit mal)
3) Adult:
a) GENERAL INFORMATION
1) Carbamazepine is the drug of choice for the initial treatment of partial seizures with or without seconc (Herman & Pedley, 1998a). The drug is ineffective for absence seizures (may actually exacerbate these only minimally effective for atonic and myoclonic seizures (Parker et al, 1998a; Troupin et al, 1974a). CA as single-agent therapy has been effective in controlling seizures in over 75% of outpatients, reducing se more than 75% (Dodson, 1987; Andersen et al, 1983a). Other studies report that CARBAMAZEPINE is a PHENYTOIN as initial seizure therapy in adults with partial and generalized seizures (Mattson et al, 198 1983b). The sustained-release formulation of carbamazepine provides less peak-related adverse effects control, and greater compliance (Herman & Pedley, 1998a).
b) Following temporal lobectomy for treatment of medically intractable temporal lobe epilepsy, carbamazepir has been shown to be as effective as multidrug therapy (Kuzniecky et al, 1992). In this study, patients were r either carbamazepine or continued on their same multidrug antiepileptic regimen that they were on prior to su to monotherapy was achieved by discontinuing other antiepileptic drugs postoperatively. Carbamazepine ser maintained in the range of 6 to 10 micrograms/milliliter.
4) Pediatric:
a) CARBAMAZEPINE was effective in the treatment of grand mal seizures and psychomotor seizures, and w against absence seizures. Carbamazepine therapy was evaluated in 106 children and adolescents with vario disorders (Fischel & Heyer, 1970). Average doses of 15 to 20 milligrams/kilogram/day (mg/kg/d) (100 to 120(administered for an average of 45 months. In 40 patients with grand mal seizures alone, good to excellent re in 21 patients with no response in 14 patients and worsening of seizure control in 5. In 20 patients with psych alone, good to excellent results were obtained in 16 patients. The drug was not effective in absence seizures patients treated, 71 exhibited good to excellent results. Only 6 patients worsened during therapy with CARBA this group, 44 patients received other anticonvulsants concurrently with CARBAMAZEPINE. The main side e were initial fatigue, headache, and abdominal pains.
b) In 45 patients with chronic complex partial seizures or secondarily generalized tonic-clonic seizures, CAR monotherapy significantly improved complex-partial seizures regardless of the site of the EEG focus. In patie secondarily generalized seizures, seizures were better controlled in patients with a left-sided vs right-sided E et al, 1991).
c) Although CARBAMAZEPINE has generally been considered ineffective in absence seizures, one study re of CARBAMAZEPINE in a case of absence seizures unresponsive to ETHOSUXIMIDE or VALPROIC ACID (1988).
d) The successful use of a combination of benzodiazepines and CARBAMAZEPINE in controlling refractory myoclonic-astatic seizures in 24 children was reported (Tatzer et al, 1987). During the 5-year follow-up perioc infantile spasms and 4 children with myoclonic seizures became seizure-free; 6 additional children demonstra reduction in seizure frequency. Further controlled studies are required in this area.
e) In one study, carbamazepine controlled seizures in 22 of 58 children not adequately controlled on other m (Gamstorp, 1970). An additional 8 children experienced a 75% reduction in seizure frequency. After follow-up 19 of the 22 complete responders still remained seizure-free and 5 of the 8 patients maintained a 75% reduct frequency. Follow-up after 2 to 6.5 years revealed that 13 of 22 patients remained seizure-free, and in 3 of 22 carbamazepine was successfully withdrawn after 5 years.

4.5.S Erythrodermic psoriasis
1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb

Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Effective in one case of psoriatic erythroderma (Smith & Skelton, 1996)

3) Adult:
a) A 29-year-old HIV-1-positive man with a CD4+ T-cell count below 10 cells per cubic millimeter was succes carbamazepine for psoriatic erythroderma. This patient's skin disease had become progressively more difficu EXFOLIATIVE ERYTHRODERMA developed. He has continued to take carbamazepine for 1 year without re disease and with no changes in his laboratory values (Smith & Skelton, 1996). Other practitioners have been duplicate this response (Redondo & Vazquez-Doral, 1998).

4.5.T Facial spasm

1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Effective in the treatment of HEMIFACIAL SPASM in uncontrolled studies (Alexander & Moses, 1982)

3) Adult:
a) Efficacy of CARBAMAZEPINE in hemifacial spasm was reported in 3 patients receiving doses of 600 to 1 daily. These authors reviewed previous reports indicating the efficacy of the drug in over 50% of patients trea controlled trials are required to establish the efficacy of the drug as compared to surgical therapies or other m (Alexander & Moses, 1982).

4.5.U Glossopharyngeal neuralgia

FDA Labeled Indication

1) Overview
FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Indicated for glossopharyngeal neuralgia (Prod Info Tegretol(R), 1998)

3) Adult:
a) CARBAMAZEPINE 600 milligrams daily was effective in the treatment of paroxysms of pain and associate symptoms in an 83-year-old woman with glossopharyngeal neuralgia (Saviolo & Fiasconaro, 1987). It is sugg CARBAMAZEPINE may be an alternative to surgical resection of the glossopharyngeal nerve in these patien studies are required to fully evaluate the efficacy of CARBAMAZEPINE in glossopharyngeal neuralgia.
b) The efficacy of CARBAMAZEPINE 1200 milligrams daily in controlling paroxysmal pain associated with gl neuralgia in a 53-year-old man was reported (Johnston & Redding, 1990).

4.5.V Hiccoughs, Intractable

1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Effective in 1 patient with INTRACTABLE HICCUPS due to multiple sclerosis (McFarling & Susac, 1974)

4.5.W Huntington's disease

1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
May alleviate micturitional disturbances in some patients with Huntington's disease (Cochen et al, 2000)

3) Adult:
a) CARBAMAZEPINE 200 milligrams (mg)/day resolved PRECIPITATE MICTURITIONS and DIURNAL or N INCONTINENCE in 3 male patients (aged 42 to 50 years) with genetically confirmed Huntington's disease (H patients with severe HD, dementia, and incontinence not characterized as precipitate micturition were not hel carbamazepine therapy. For those benefiting from carbamazepine, micturition difficulties ceased within 2 to 7

carbamazepine 200 mg/day. Two of these 3 patients failed on 100 mg/day, but were successful when the dos
to 200 mg/day. None of the patients who responded to carbamazepine had demonstrated seizures. The auth
that carbamazepine may have a direct action on the control center of micturition and defecation (Cochen et a

4.5.X Migraine; Prophylaxis

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category C; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Carbamazepine has been used for migraine headache prophylaxis
Studies on the effectiveness of carbamazepine for migraine prophylaxis have produced mixed results

3) Adult:

a) Carbamazepine was moderately effective in the prophylactic treatment of 51 adult patients with symptoms
(Anthony et al, 1972). Carbamazepine 600 milligrams/day was effective in reducing the frequency of migraine
patients. Fifty-three percent of patients experienced side effects (giddiness, ataxia, drowsiness, nausea) and
discontinued in 24% of these patients.

b) CARBAMAZEPINE was more effective than placebo in a double-blind study of 48 patients with migraine h
CARBAMAZEPINE treatment resulted in improvement in 84.4% of patients as compared to 27.1% of patients
placebo. Doses of CARBAMAZEPINE were not specified (Rompel & Bauermeister, 1970).

4) Pediatric:

a) Carbamazepine 10 to 20 milligrams/kilogram/day divided into 2 doses has been used in children for migra
prophylaxis (Hamalainen, 1998). The dosage should be increased slowly and the patient monitored every 3 r
monitoring the usual lab values, height and body weight should also be monitored.

4.5.Y Multiple sclerosis, Sensory symptoms

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in a few patients with PAROXYSMAL DYSARTHRIA and ATAXIA associated with multiple scle

3) Adult:

a) CARBAMAZEPINE was effective 100 milligrams three times daily in a 41-year-old male with multiple scler
loss of control of right arm and leg with burning sensations around the left eye and dysarthria. These attacks
following administration of the drug and recurred when the drug was discontinued. Three other patients with r
(including 1 PHENYTOIN failure) experienced suppression of attacks when CARBAMAZEPINE was administ
Walker, 1967).

b) Two patients with multiple sclerosis and paroxysmal dysarthria and ataxia were treated with CARBAMAZE
milligrams twice daily (Miley & Forster, 1974). Paroxysmal episodes decreased in both patients within 2 days
patient, the drug was discontinued after 1 month of therapy with no recurrences seen at a 5 month follow-up.

c) CARBAMAZEPINE 400 milligrams daily was effective in alleviating both spontaneous and TONIC SPASM
hyperventilation and pain in a 31-year-old man with multiple sclerosis (Honig et al, 1991).

4.5.Z Myoclonus

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

ACTION MYOCLONUS secondary to acute hypoxia has responded to CARBAMAZEPINE therapy (Hiros

4.5.AA Myokymia

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective for the treatment of myokymia based on 1 case report (Kinnett & Keebler, 2001)

3) Pediatric:

a) Oral CARBAMAZEPINE successfully prevented painful cramping of the anterior thigh muscles in a 12-yea diagnosed with HEREDITARY MYOKYMIA. Her condition received medical attention when she declined to pa physical education classes due to recurrent cramping. The patient was started on carbamazepine 200 milligra daily. Compared with test results before carbamazepine, endurance time on a treadmill without cramping was after she began receiving carbamazepine. Strength testing showed improvement in only the hamstring muscl reports of sedation, the dose of carbamazepine was reduced to 100 mg twice a day and gradually increased twice a day. After 2 years, she was slowly weaned off of carbamazepine over 8 weeks, without symptom recu later, she was using prednisone for an exacerbation of asthma and the cramping returned. Reintroduction of brought relief. She received a 2-week course of carbamazepine 100 mg twice daily while being weaned off pr patient continued to do well without carbamazepine (Kinnett & Keebler, 2001).

4.5.AB Neuralgia

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in treating a variety of neuralgias

3) Adult:

a) Two patients with SUNCT SYNDROME (short-lasting, unilateral, neuralgi-form, headache attacks with cor and tearing) received relief with carbamazepine therapy (Raimondi & Gardella, 1997). The first patient was a whose moderately painful episodes in the medial right supraciliary area lasted between 15 and 20 seconds a times per day. Treatment with carbamazepine 600 milligrams (mg) provided a decrease in intervals between months. After 3 months the medication was discontinued with only 2 attacks per week. The second patient wa woman with 6 or 7 attacks of right orbitofrontal area pain which peaked in intensity after 30 seconds followed lesser pain for 35 to 120 minutes. She was treated with prednisolone 60 mg for 6 days and then 20 mg for 10 carbamazepine 800 mg/day for 11 weeks. She eventually received complete relief from this regimen.

b) CARBAMAZEPINE 200 milligrams (mg) at bedtime was effective in treating the pain associated with MOR NEURALGIA in a 79-year-old woman. Similarly, 200 mg 3 to 4 times daily effectively controlled pain in a 46-y (Guiloff, 1979).

4.5.AC Neurogenic pain

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in some types of neurogenic pain

3) Adult:

a) Carbamazepine effectively reduced NEURITIC PAIN and OPIOID REQUIREMENTS in 12 patients recove GUILLAIN-BARRE SYNDROME. In a prospective, double-blind, crossover study, mechanically ventilated pat 54 years with moderate to severe body and back aches requiring increasing doses of opioids were randomize placebo or carbamazepine 100 milligrams via a nasogastric feeding tube every 8 hours for 3 days. Carbamaz associated with significantly reduced pain scores, meperidine requirements, and less sedation (p less than 0. groups). It is suggested that these effects may benefit patients with Guillain-Barre syndrome who are candida weaning (Tripathi & Kaushik, 2000).

b) CARBAMAZEPINE 400 milligrams (mg) to 1200 mg daily was effective in the treatment of intractable neu 7 patients (Rapeport et el, 1984). However, of 16 patients entering the study, 9 withdrew due to side effects o the 7 patients completing the protocol were used for efficacy evaluation. Controlled studies are required to de the drug in neurogenic pain.

c) CARBAMAZEPINE 200 milligrams 3 times daily was effectively used in combination with HYDROMORPH old patient with PANCOAST SYNDROME who had suffered severe, unrelieved pain for approximately 10 mo combination therapy, the patient was able to remain pain-free until the time of death (Tanelian & Cousins, 19

4.5.AD Neuropathy, General

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category C; Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in some types of neuropathic pain

3) Adult:

a) Reduced pain was noted in patients (n=12) with THIAMINE-DEFICIENCY NEUROPATHY treated with PH milligrams (mg) at bedtime or CARBAMAZEPINE 200 mg at bedtime (Skelton & Skelton, 1991). Two patients were unable to tolerate the side effects of these medications. Of the remaining patients, similar effects were r treatment groups with significant reductions in pain noted in all patients. Two patients treated with PHENYTC treated with CARBAMAZEPINE reported complete relief.

4) Pediatric:

a) Two 14-year-old boys experienced relief of their painful neuropathy secondary to MERCURY POISONING carbamazepine 20 milligrams/kilogram/day (Karagol et al, 1997). Both had distal extremity pain with severe a along with, excessive sweating, weight loss, fatigue, photophobia and diarrhea. Urine mercury levels were 70 micrograms/liter (mcg/L) (normal 2 to 26 mcg/L). Both experience continued pain after 2 days of N-acetyl-D,L therapy. After 2 days of carbamazepine and pyridoxine therapy the pain subsided.

4.5.AE Obsessive-compulsive disorder

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Mixed results have been obtained when assessing carbamazepine in the use of obsessive-compulsive d

3) Adult:

a) The addition of carbamazepine to clomipramine therapy was effective in the treatment of refractory obses disorder (OCD) in a 27-year-old woman. The patient had been unresponsive to clomipramine treatment since Coadministration of numerous medications (haloperidol, thioridazine, bromazepam, sulpiride, oxazepam, diaz risperidone) with clomipramine failed to improve her condition. After adding carbamazepine 500 milligrams (m (plasma level=6.1 mg/milliliter) to clomipramine 200 mg/day, her OCD symptoms dramatically improved withi improvement was sustained for at least 5 months (Iwata et al, 2000).

b) CARBAMAZEPINE in mean doses of 1088 mg daily was ineffective in the treatment of obsessive-compuls uncontrolled study involving 9 patients (Joffe & Swinson, 1987). No effects on mood or behavior were observ of treatment.

c) A small population of patients with obsessive-compulsive symptoms might respond to CARBAMAZEPINE anticonvulsant effects. The use of CARBAMAZEPINE 600 to 1000 milligrams daily in 7 patients meeting diag obsessive-compulsive disorder was reported (Khanna, 1988). Blood levels were maintained in the range of 8 micrograms/milliliter during the 12-week study. Only 2 patients reported a greater than 50% reduction in obse symptoms; in both cases, there was a history of a seizure disorder likely to respond to CARBAMAZEPINE.

4.5.AF Obsessive compulsive personality disorder

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Improved symptoms in one case (Greve & Adams, 2002)

3) Adult:

a) Carbamazepine reduced irritable and agitated behavior of a 61- year-old man with Obsessive-Compulsive Disorder (OCPD). The man presented with mild cognitive impairment, including reduced attention, concentrat motivation, which had been worsening over the preceding 3 years. He had a life-long rigid, perfectionistic, an personality style and became easily irritated and agitated. He was diagnosed with OCPD with features of Obs Compulsive Disorder. One month after starting carbamazepine 100 milligrams (mg) twice daily, he reported f less prone to excessive reactions. The dosage was raised to 200 mg twice daily, and he developed a rash. T discontinued. Eight months later he reported some return of symptoms, including problems with self- regulatc & Adams, 2002).

4.5.AG Pain

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Possibly effective for pain associated with depression (Kudoh et al, 1998)

3) Adult:

a) Carbamazepine demonstrated both analgesic and antidepressant effects in depressed patients who had f adequate pain relief with tricyclic or tetracyclic antidepressants or nonsteroidal analgesics. After a central me

a clinically significant organic disorder were ruled out, carbamazepine 450 milligrams/day was started. Doses every 2 weeks until satisfactory pain relief and then maintained for 3 weeks. Thereafter, placebo was adminis followed by an additional 3 weeks of carbamazepine at the same dose that previously produced satisfactory p of 15 patients completed the study, 3 patients were unable to tolerate the initial dose. On a visual analog scal significantly improved from 8.2 to 4.0 on the first round of carbamazepine therapy (p less than 0.05), increase during placebo, and decreased to 4.1 with the second carbamazepine trial (p less than 0.05). Hamilton depre improved from 27.4 to 20.2 with carbamazepine therapy (Kudoh et al, 1998).

4.5.AH Panic disorder

1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Results were mixed in the treatment of panic disorder (Uhde et al, 1988)

3) Adult:
a) Mixed results were obtained when 14 patients with panic disorder were treated with CARBAMAZEPINE 2(milligrams daily (median 800 milligrams) during a 3-week, placebo-controlled trial. Although a statistically sign overall anxiety was noted on several rating scales, only 1 patient demonstrated sustained clinical improveme panic attacks was noted in 40% of patients as compared with an increase in 50% of patients (Uhde et al, 198

4.5.AI Phantom limb syndrome

1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Total abatement of phantom limb pain has been achieved (Patterson, 1988)

3) Adult:
a) The successful use of CARBAMAZEPINE 200 milligrams four times a day in the treatment of phantom lim year-old male was reported. The drug was given in increasing doses to achieve serum levels of 8 to 12 micro resulted in total abatement of pain. Controlled studies are required to more fully evaluate the efficacy of CARI phantom limb pain (Patterson, 1988).

4.5.AJ Polyradiculoneuropathy

1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Effective in one case report (Winspur, 1970)

3) Adult:
a) A case of POLYRADICULONEUROPATHY with severe shooting pains in both legs was successfully treat CARBAMAZEPINE 400 milligrams (mg) at bedtime initially, followed by 200 mg three times daily in combinat PREDNISONE 60 mg daily. Further investigations are required to determine the efficacy of CARBAMAZEPIN polyradiculoneuropathy (Winspur, 1970).

4.5.AK Postherpetic neuralgia

1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Variable results in POSTHERPETIC NEURALGIA (Thompson & Bones, 1985)

3) Adult:
a) Limited response was seen with carbamazepine 400 to 1200 milligrams/day in 4 patients with intractable (associated with post-herpetic neuralgia. A favorable response (greater than 50% reduction in subjective pain attained in 1 patient. The response was limited by side effects, especially neurotoxicity (drowsiness, diplopia, ataxia), as only 7 of a total of 16 patients in the study were able to complete the entire 6-week protocol (Rape
b) Carbamazepine has been reported to be ineffective for preventing post-hepatic neuralgia. Forty otherwise

over 50 years of age with early, severe painful herpes zoster were randomly grouped to receive either predni daily for 10 days with gradual reduction over 3 weeks or carbamazepine 400 milligrams daily. Thirteen (65%) given carbamazepine developed post-herpetic neuralgia lasting up to 2 years whereas three (15%) of 20 pre patients had post-herpetic neuralgia lasting up to 5 months only (Keczkes & Basheer, 1980).

4.5.AL Posttraumatic stress disorder

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Symptomatic improvement has been seen with the use of carbamazepine for posttraumatic stress disorc 1986)

3) Adult:

a) In a preliminary study of CARBAMAZEPINE in 10 patients with post-traumatic stress disorder, 7 patients marked to moderate improvement as measured by the Clinical Global Impression Scale. Symptomatic impro in reduced frequency and intensity of flashbacks, intrusive memories and nightmares. CARBAMAZEPINE do to maintain levels at 5 to 10 micrograms/milliliter (Lipper et al, 1986).

4.5.AM Psychotic disorder

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

May augment neuroleptic therapy in psychotic patients with aggression (Neppe et al, 1991)
In case reports, provides neuroleptic-augmentation of CANNABIS-INDUCED PSYCHOTIC DISORDER
In case reports, relieves sensory-induced psychotic symptoms

3) Adult:

a) Two patients with cannabis-induced psychotic symptoms benefited from adding carbamazepine to their n (Leweke & Emrich, 1999). These young patients (19 and 22 years old) developed a schizophrenia-like psych term cannabis use. They were both treated with perazine up to 400 milligrams. One patient had also failed h risperidone trials. Symptoms improved over the next 2 weeks as measured on the Brief Psychiatric Rating Sc

b) Eight women with violent episodic outbursts ranging from murder to serious assaults, with EEGs revealin were successfully treated with CARBAMAZEPINE 400 to 800 milligrams/day (mg/day). Patients were also re doses of neuroleptics (mean 2040 mg/day in CHLORPROMAZINE equivalents). CARBAMAZEPINE therapy 2 months to 11 years (mean 2.7 years). Violent behavior disappeared almost completely in all 8 patients and schizophrenic symptoms decreased markedly. By the end of the trial, the neuroleptic dosage had been reduc of 1310 mg/day in CHLORPROMAZINE equivalents. It appears that the combination of CARBAMAZEPINE a therapy successfully controls violent schizophrenia and allows reduced doses of the neuroleptics (Hakola & L

c) One study reported CARBAMAZEPINE efficacy in 9 schizophrenic patients with episodic hostility and agg suggested that the presence of these target features may be predictive of CARBAMAZEPINE responsivenes 1991).

d) The combination of CARBAMAZEPINE plus HALOPERIDOL was superior to haloperidol plus placebo in involving 43 patients with EXCITED PSYCHOSES. Combination therapy was reported superior to HALOPER clinical benefits being as apparent in excited SCHIZOPHRENIA as in mania (Klein et al, 1984a).

e) Carbamazepine therapy was effective for MUSICAL HALLUCINATIONS with temporal lobe abnormalities woman (Terao & Tani, 1998). The woman's musical hallucinations had lasted for at least 2 years. Alpha wave predominately in the occipital area were evident on electroencephalography (EEG). Carbamazepine 300 milli softened, slowed and decreased the duration of the music. The mild spike activity on EEG disappeared.

f) A 40-year-old man with PALINOPSIA (the recurrence of visual images after the stimulus is removed) was treated with carbamazepine. This man's diagnoses included DSM-IV diagnostic criteria for psychosis not othe anxiety disorder not otherwise specified, and some of the symptoms of post-traumatic stress disorder. He des abnormalities as unrelated to his combat experiences and as perseverations of images or objects he had pre He was treated with imipramine 200 milligrams (mg) and trifluoperazine 10 mg daily. This decreased his flash and insomnia; however, the palinopsia continued. Carbamazepine 400 mg/day was started and within 48 hou had decreased. After 6 days of carbamazepine 800 mg, his palinoptic experiences disappeared (Silva et al, 1

4.5.AN Restless legs syndrome

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Short-term efficacy for restless legs syndrome

See Drug Consult reference: RESTLESS LEG SYNDROME - DRUGS OF CHOICE

3) Adult:

a) CARBAMAZEPINE in doses of 200 milligrams at bedtime initially, increasing to maximum doses of 200 m morning and 400 milligrams at bedtime, was effective in reducing the number of attacks of restless legs (EKE SYNDROME) in a placebo-controlled study (Lundvall et al, 1983).

b) An additional report of the efficacy of CARBAMAZEPINE in restless legs (Ekbom's syndrome) was reporte 1984). In this study, the placebo response was remarkable, although response to CARBAMAZEPINE was su daily dose was 236 milligrams CARBAMAZEPINE.

4.5.AO Schwartz-Jampel syndrome

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence favors efficacy
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Possibly beneficial for Schwartz-Jampel syndrome (Topaloglu et al, 1993)

3) Pediatric:

a) Three cases of MYOTONIC CHONDRODYSTROPHY (Schwartz-Jampel syndrome) were reported to ber with carbamazepine. The three children were placed on carbamazepine 20 milligrams/kilogram/day. Symptor gradually improved over several months (Topaloglu et al, 1993).

4.5.AP Subacute sclerosing panencephalitis

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in 1 case report (Kertesz et al, 1970)

3) Adult:

a) CARBAMAZEPINE effectively reduced the number and intensity of akinetic attacks secondary to subacute PANENCEPHALITIS in 1 patient with doses of 200 milligrams three times daily. Symptoms were ameliorated initiation of therapy (Kertesz et al, 1970).

4.5.AQ Tabes dorsalis

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective for lightning pains of tabes dorsalis (Ekbom, 1972; Alarcon-Segovia & Lazcano, 1968; Ekbom,

3) Adult:

a) Three uncontrolled studies have revealed the beneficial effects of carbamazepine in 10 of 10 patients with tabes dorsalis (Ekbom, 1972; Alarcon-Segovia & Lazcano, 1968; Ekbom, 1966). In all patients, pain symptom 1 to 3 days and attempts to withdraw medication led to reappearance of pain. During long-term therapy, mild sporadic pain was usually exacerbated by infections with fever or by consumption of ETHANOL. Also, during larger doses were required in some patients to maintain adequate analgesia.

4.5.AR Temporal lobectomy behavior syndrome

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Effective in one case of posttraumatic Kluver-Bucy syndrome (Stewart, 1985)

3) Adult:

a) In one case, CARBAMAZEPINE blood levels of 8 to 11 micrograms/milliliter were effective in controlling ra affective blunting, hypersexuality, hyperorality and hypermetamorphosis in a 20-year-old man with post-traun

syndrome. His bulimia was unaffected by drug therapy (Stewart, 1985).

4.5.AS Tinnitus

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Ineffective in the general treatment of tinnitus (Hulshof & Vermeij, 1985)
Effective in case reports of ear clicking and HYPERACUSIS

See Drug Consult reference: DRUG THERAPY OF TINNITUS

3) Adult:

a) Two women with hyperacusis due to Lyme disease benefited from carbamazepine therapy (Nields et al, 1 had other central nervous system effects which remitted after treatment with cefotaxime. After cefotaxime, bo remained so sensitive to sound that they wore ear plugs, rifle range headphones, or airport headphones to pr kindling-like phenomenon occurred in each woman where repeated subthreshold sound lowered their toleran hours or days. This led to a trial of carbamazepine titrated to a blood level of 4 to 6 micrograms/milliliter. Both experienced an increase in baseline sound tolerance. Symptoms again worsened in each patient after a trial

b) Although an early study (Rahko & Akkinen, 1979) demonstrated CARBAMAZEPINE to have considerable treatment of clicking tinnitus (clicks almost totally disappeared in 3 patients, with symptoms reappearing whe discontinued), a double-blind study involving 78 patients failed to show a statistically significant difference in t patient's tinnitus when taking CARBAMAZEPINE or placebo (Donaldson, 1981a).

c) In an anecdotal report, benefits were reported with CARBAMAZEPINE 200 milligrams orally three times a treatment of ear-clicking tinnitus. Withdrawal of CARBAMAZEPINE resulted in return of tinnitus and reinstituti again produced symptom resolution. In this case report, a caffeine-free diet was also reported helpful in allev when the patient was not receiving CARBAMAZEPINE. More studies are required to fully evaluate the efficac CARBAMAZEPINE in this form of tinnitus (Mardini, 1987).

4.5.AT Trigeminal neuralgia

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class I
Strength of Evidence: Adult, Category A

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:

Indicated for pain associated with trigeminal neuralgia
Drug of choice

3) Adult:

a) CARBAMAZEPINE has been used effectively in patients with trigeminal neuralgia for many years and is n drug of choice (Voorhies & Patterson, 1981; Tomson et al, 1980; Daly & Sajor, 1973; Lewis, 1969; Killian, 19 Sachdev, 1969; Marotta, 1969; Sturman & O'Brien, 1969; Killian & Fromm, 1968a; Walsh & Smith, 1968). Eff these studies range from 100 to 800 milligrams daily resulting in blood levels of 6 to 12 micrograms/milliliter. can be used over long periods of time for the treatment of trigeminal neuralgia without loss of efficacy.

b) The results of 143 patients with trigeminal neuralgia who had received CARBAMAZEPINE over a 16-year reviewed (Taylor et al, 1981). Fifty-six males and 87 female patients received a starting dose of CARBAMAZ 200 milligrams (mg) 3 or 4 times daily. The dose was increased until the pain was controlled or side effects d then continued to receive the minimum dose needed to prevent pain and were instructed to stop the drug dur Forty-six (32%) of the patients were completely or well-controlled by CARBAMAZEPINE and 53 (37%) were p acceptably, controlled. Ten patients experienced mild side effects, but did not stop treatment. Of these 99 pa good initial response, 19 developed a late resistance in that pain recurred and did not respond to CARBAMA Resistance developed anywhere from 2 months to 10 years after treatment began. Sixty-three of the original required alternate treatment. Thirty-six of the patients failed to respond to CARBAMAZEPINE initially, eight p intolerant and 9 responded initially, but developed resistance.

c) A synergistic effect between BACLOFEN and CARBAMAZEPINE was shown in the treatment of trigemina 57-year-old patient. The patient had a history of paroxysmal jaw pain unresponsive to CARBAMAZEPINE alo eventually controlled with BACLOFEN 60 milligrams (mg) per day plus CARBAMAZEPINE 800 mg per day (E

4.5.AU Trigeminal trophic syndrome

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

2) Summary:
Successfully treated a case of trigeminal trophic syndrome (Bhushan et al, 1999)
3) Adult:
a) Carbamazepine was effective in the treatment of trigeminal trophic syndrome in a 58-year-old male. This i
caused by damage to the trigeminal nerve and is associated with facial dysesthesias and ulceration. Carbam
milligrams twice daily effectively reduced the patient's sensory symptoms within 48 hours of initiation (Bhusha

4.5.AV Uremic neuropathy
1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS
2) Summary:
Antidepressant actions may contribute to analgesic effectiveness
Further data is needed to evaluate this mode of therapy
3) Adult:
a) CARBAMAZEPINE was effective in relieving pain in 5 patients with severe UREMIC NEUROPATHY (Zar
1976). Doses of 100 milligrams (mg) twice daily were given initially, followed by maintenance doses of 200 to
daily for several weeks. In all patients, pain relief was noted within 1 to 2 weeks. However, motor weakness,
other symptoms remained unchanged in all patients.

4.6 Comparative Efficacy / Evaluation With Other Therapies

Amitriptyline

Baclofen

Clonazepam

Haloperidol

Lamotrigine

Lithium

Lorazepam

Oxazepam

Oxcarbazepine

Phenobarbital

Phenytoin

Primidone

Progabide

Propranolol

Tiapride

Topiramate

Valproic Acid

Vigabatrin

Zonisamide

4.6.A Amitriptyline

4.6.A.1 Neurogenic pain

a) Carbamazepine 800 mg daily was compared with amitriptyline 75 mg daily in a 4-week, randomized, doub over trial in 15 patients with central post-stroke pain. Amitriptyline produced a statistically significant reductior weeks of the start of treatment. Five of the patients treated with carbamazepine obtained pain relief but it was significant as compared with placebo. Carbamazepine produced a greater number of side effects which requi reduction in 4 patients (Leijon & Boivie, 1989).

4.6.B Baclofen

4.6.B.1 Trigeminal neuralgia

a) Baclofen reduced the number of trigeminal neuralgic attacks in patients resistant to carbamazepine but ef significant when the drug was combined with carbamazepine. This was a double-blind trial (Parekh et al, 198

4.6.C Clonazepam

4.6.C.1 Psychomotor epilepsy

a) Clonazepam and carbamazepine were equally effective in the treatment of newly diagnosed and previous psychomotor epilepsy. In a double-blind, randomized study, 36 patients were maintained on either clonazepa or carbamazepine 900 milligrams/day for a period of 6 months. Plasma levels for each drug remained within t range throughout treatment. Both drugs were equally effective in controlling epilepsy. Side effects were simila (Mikkelsen et al, 1981).

4.6.D Haloperidol

4.6.D.1 Drug-induced psychosis, Inhalant

a) Carbamazepine demonstrated comparable efficacy to haloperidol in the treatment of inhalant-induced psy (Hernandez- Avila et al, 1998). Patients received either 1 capsule of carbamazepine 200 milligrams (mg) 3 tir 1 capsule of haloperidol 5 mg 3 times daily (n=20) for 5 weeks. Doses were increased at weekly intervals by patient failed to show a 25% decrease in the Brief Psychiatric Rating Scale (BPRS). At the end of the study, r were carbamazepine 920 mg (serum level of 10.8 micrograms/liter) and haloperidol 21.7 mg. Similar improve in both groups with 48.3% improvement in the carbamazepine group and 52.7% improvement in the haloperi

4.6.E Lamotrigine

4.6.E.1 Seizure

a) Carbamazepine and lamotrigine are equally effective as monotherapy in patients with newly diagnosed ep double-blind manner, patients were randomly assigned to a fixed dosage titration of either carbamazepine or four weeks, all patients were receiving either 150 milligrams/day (mg) of lamotrigine or 600 mg/day of carbam next 24 weeks, doses were adjusted according to efficacy, tolerance, and drug serum levels. The percentage were seizure-free for the last 6 months of the study were 39% and 38% for lamotrigine and carbamazepine g respectively. However, lamotrigine was better tolerated, and more patients were able to complete the study p treated with carbamazepine. Sleepiness was significantly more common with carbamazepine than lamotrigin 12%, respectively) (Brodie et al, 1995).

b) As initial monotherapy in elderly patients newly diagnosed with epilepsy, lamotrigine demonstrated a supe tolerability profile compared to carbamazepine. Subjects (n=150) were randomized in a double-blinded 2:1 ra 25 milligrams/day (mg/day) or carbamazepine 100 mg/day. Both medications were titrated slowly upward ove mg twice daily and 200 mg twice daily, respectively, with adjustments as needed over the 24-week study dura doses of lamotrigine and carbamazepine in study completers were 100 mg/day and 400 mg/day, respectively serum concentrations at week 24 were 2.3 mg/liter (L) and 6.9 mg/L, respectively. Somnolence (29% versus (25% versus 9%) occurred significantly more often in the carbamazepine versus lamotrigine groups, respecti corresponding withdrawal rates were 58% and 29%, with adverse events accounting for 42% and 18% of dis respectively. The hazard ratio for withdrawal with carbamazepine compared to lamotrigine was 2.4 (95% con 1.4 to 4). Efficacy measures were considered secondary endpoints in this trial. While no between-group differ respect to time to first seizure, significantly more lamotrigine recipients remained seizure-free over the last 16 study (39% versus 21%, p=0.03) (Brodie et al, 1999).

4.6.F Lithium

Bipolar disorder

Depression

Mania

4.6.F.1 Bipolar disorder

a) SUMMARY: Comparisons of prophylactic use of lithium and carbamazepine for bipolar disorder have proc results for superiority of one agent over the other, with both agents showing only modest efficacy rates.

b) In treatment-naive bipolar patients, lithium was superior to carbamazepine for preventing recurrence of m depressive episodes. Based upon analyses of 94 patients who had been randomized to blinded treatment eit blood levels 0.6 to 1.0 millimoles/liter) or carbamazepine (target blood levels 6 to 10 milligrams/liter), 27% an on lithium and carbamazepine, respectively, experienced relapse within the 2-year study period. Among relap almost all on lithium had initially experienced a hypomanic episode, and had recurrent episodes within the firs therapy. In contrast, patients relapsing during carbamazepine had episodes that were more evenly distributed entire study period. Notably, patients randomized during an acute episode showed different results from thos during the prophylactic treatment phase; the authors speculated that differences may be attributed to the dise which randomization occurred or to characteristics of bipolar disease. Post hoc analysis of subgroup characte to clarify these differences (Hartong et al, 2003).

c) In an open, randomized, controlled clinical trial, lithium was superior to carbamazepine for maintenance th with bipolar disorder. Patients received lithium (n=86) and carbamazepine (n=85) in average doses of 26.8 m per day (serum concentration 0.61 +/- 0.12 mmol/liter) and 635 milligrams per day (serum concentration 6.12 micrograms per milliliter), respectively, for 2.5 years. Outcomes measured included inter-episodic morbidity, a average severity of affective symptoms during outpatient treatment, as well as drop-out rate, and rate of reho Although rates of rehospitalization were similar for both treatment groups, more patients demonstrated a goo (low inter-episodic morbidity without rehospitalization or drop-out) with lithium than during carbamazepine tre versus 24%; p=0.03). This difference was largely due to a difference in drop-out rate in patients without rehos versus 42%). Drop-outs were primarily related to the development of adverse effects. Overall, inter-episodic r similar. However, in lithium-treated patients, average inter-episodic morbidity declined by about 50% during th months and remained at this level for the rest of the observation period, while in those treated with carbamaz was not observed (Kleindienst et al, 2002)

d) Lithium appeared superior to carbamazepine in the treatment of classic bipolar symptoms (Bipolar Type I) carbamazepine may have been more useful in patients with nonclassic symptoms (Greil et al, 1998). Patients depressive symptoms or schizoaffective disorder requiring prophylactic therapy were categorized as having e symptoms (bipolar type I) or nonclassic symptoms, and randomized to receive either lithium or carbamazepir during the 2.5-year study were lithium 26.8 millimoles (mmol)/day with a serum level of 0.61 mmol/liter (L) an 190 milligrams/day with a level of 6.12 micrograms/milliliter. Prevention of hospitalization was the primary out with classic symptoms (n=67), lithium use was associated with significantly fewer hospitalizations than carba (p=0.005). In the non- classic bipolar patients (n=104), there was a trend favoring carbamazepine (p=0.075). group, hospitalizations correlated significantly with the number of nonclassic features (p=0.035). In the carba negative association was found between hospitalization rate and number of nonclassic features (p=0.033). D in both groups with fewer occurrences in the lithium group (p=0.004).

e) In a retrospective chart review, younger patients with rapid cycling affective disorder had their manic symp controlled with carbamazepine while older-onset patients had their symptoms better controlled with lithium (F 1998). Early-onset cases were defined as affective disorder beginning at 25 years of age or younger (n=14) v disorder was defined as beginning after the age of 25 (n=21). Further controlled studies are needed.

f) In a double-blind study of 52 bipolar patients, lithium and carbamazepine had a roughly equal but less thar prophylactic efficacy in overall bipolar illness (Denicoff et al, 1997). Patients were randomly assigned to 1 yea lithium or carbamazepine, and then crossed over to the other drug in the second year. During a third year, pa combination of the 2 drugs. A marked or moderate improvement occurred in 33%, 31%, and 55% of patients carbamazepine, and the combination, respectively. Lithium, however, was superior in the prophylaxis of man experienced by 11% on lithium, 4% on carbamazepine, and 33% on combination therapy; p less than 0.01). T lithium and carbamazepine was better than monotherapy in rapid cyclers (p less than 0.05).

4.6.F.2 Depression

a) In an controlled study, 15 depressed patients who did not respond to treatment with carbamazepine were Eight of the 15 patients responded to the addition of lithium therapy (0.8 +/= 0.2 mmol/L) within 4.1 +/- 2.4 da responders tended to be more rapid cyclers (ie, 6.9 +/- 4.1 affective episodes/year versus 3.4 +/- 2.4 year) (K 1989a). A controlled study comparing the two drugs in patients unresponsive to lithium may be useful in disce characteristics of patients most likely to respond to carbamazepine.

4.6.F.3 Mania

a) Lithium and carbamazepine were similarly effective in the treatment of manic patients in a controlled study 1987). However, results suggested that lithium is more effective than carbamazepine in a heterogenous popu patients. A more consistent beneficial effect was observed in lithium-treated patients with regard to Clinical G the Brief Psychiatric Rating Scale and the Beigel- Murphy Manic State Rating Scale. It is suggested that carb antimanic potential in specific types of bipolar patients whose characteristics must be defined in further clinica in this study suggested that carbamazepine may be useful in the "brittle" lithium non- responsive bipolar patie affective relapses.

b) The combination of lithium plus carbamazepine was more effective than lithium alone in reducing depress

episodes in patients with bipolar disorder. Lithium concentrations were maintained between 0.6 and 1 milliequ
those taking carbamazepine concurrently maintained carbamazepine concentrations 4.6 to 8.8 milligrams/mil
was limited in that there were only 8 patients per group (Di Costanzo & Schifano, 1991).
c) Efficacy of carbamazepine and lithium carbonate was compared in a randomized trial of 52 patients with r
previously failed other courses of treatment (Small et al, 1991). Following a two-week drug withdrawal period
assessments were performed for 8 weeks with long term follow-up in responders for up to 2 years. Dosages
titrated to obtain therapeutic plasma levels. One third of the patients showed a positive response with no stati
differences noted between the two treatment groups. Carbamazepine-treated patients demonstrated better c
during the first 3 weeks of therapy although the drop-out rate was higher in this group.

4.6.F.4 Adverse Effects

a) In a comparative efficacy trial for bipolar disorder, adverse effects occurred more often with lithium than w
despite therapeutic blood levels in the majority of each group. Effects that occurred more often with lithium in
vision, difficulties concentrating, feeling thirsty, decreased appetite, hand tremor, muscle weakness. Increase
occurred more often with carbamazepine, however (Hartong et al, 2003).

4.6.G Lorazepam

4.6.G.1 Alcohol withdrawal syndrome

a) Carbamazepine and lorazepam were equally efficacious for the treatment of symptoms associated with al
but carbamazepine was superior for preventing rebound withdrawal symptoms and for reducing post-treatme
especially in those patients with a history of multiple withdrawals. In a randomized, double-blind trial, 136 trea
patients with alcohol dependence were stratified according to number of previous withdrawal experiences (2
than 2) prior to randomization to treatment with carbamazepine on a 5-day fixed dose taper, starting with 600
(mg) on day 1 and tapering to 200 mg as a single dose on day 5, or lorazepam, 6 to 8 mg on day 1 and taper
mg dose on day 5. Prior research had determined the equivalency of the dosages of carbamazepine and lora
with 2 or more previous detoxifications had significantly higher scores on the CIWA-Ar (Clinical Institute Withd
Assessment for Alcohol-Revised) throughout treatment and during the post-treatment follow-up (days 7 to 12
with fewer than 2 previous detoxifications. The mean number of drinks per day during post-treatment was sim
carbamazepine-treated and lorazepam-treated patients who had 0 or 1 prior detoxifications, whereas, among
than 2 prior detoxifications, the average daily consumption was 5 drinks for the lorazepam group and 1 for the
group (p=0.004). The relative risk of having a first drink was 3 times higher for the lorazepam group than for t
group. Twenty percent of carbamazepine-treated patients and 1.3% of lorazepam-treated patients complaine
not with rash). Seven percent of the carbamazepine group and 23% of the lorazepam group showed signs of
incoordination, light-headedness, and drowiness, which they themselves did not recognize (Malcolm et al, 20

4.6.H Oxazepam

4.6.H.1 Alcohol withdrawal syndrome

a) Carbamazepine (CBZ) and oxazepam were equally effective in the treatment of alcohol withdrawal in a 7-
study in 60 inpatients (Stuppaeck et al, 1992). Oxazepam 120 milligrams (n=30) or CBZ 800 milligrams (n=30
days 1 to 3; on days 4 through 7, the doses were reduced to 90 milligrams and 600 milligrams, respectively; a
the 7-day trial, all patients received CBZ 200 milligrams twice a day on day 8 and 200 milligrams/d on day 9.
Institute Withdrawal Scale-Alcohol (CIWA-A), Clinical Global Impression Scale (CGI), and self-rating scores s
improvement of symptom severity throughout the trial. CBZ was superior to oxazepam on days 6 and 7 as m
A (p less than 0.05) and on day 7 as measured by CGI (p less than 0.05). Three patients from each group dr
of side effects, and 1 patient in each group withdrew consent and left treatment. The authors conclude that C
treatment in non-delirious patients with alcohol withdrawal syndrome.
b) Carbamazepine 200 milligrams orally 4 times daily was as effective as oxazepam 30 milligrams orally 4 ti
treatment of severe alcohol withdrawal during a 7-day, double-blind study involving 86 alcoholic men (Malcol
Both drugs were equally effective in reducing alcohol withdrawal symptoms, and adverse effects were also si
carbamazepine was more effective with regard to improving psychiatric symptoms and is therefore recomme
rehabilitation phase of alcoholism therapy.

4.6.I Oxcarbazepine

Epilepsy

Trigeminal neuralgia

4.6.I.1 Epilepsy

a) SUMMARY: Oxcarbazepine appears to be as effective as carbamazepine in the treatment of epilepsy; se
effects have occurred to a lesser degree with oxcarbazepine in some studies. Further studies are needed to i
enzyme-inducing effects, particularly at higher doses.
b) Oxcarbazepine is similar in efficacy to carbamazepine as monotherapy or add-on therapy in epileptic pati
1989; Reinikainen et al, 1987); (Bulau et al, 1987)(Houtkooper et al, 1987; Houtkooper et al, 1984; Dam, 199

1986; Anon, 1990; Jensen, 1990). There is some evidence of efficacy in patients unresponsive to carbamaze associated with therapeutic equivalency in some studies have been 200 mg carbamazepine and 300 to 400 r (Houtkooper et al, 1987), however the ratio has been closer to 1:1 in others (Bulau et al, 1987).

c) Oxcarbazepine is at least as effective as carbamazepine in patients receiving polytherapy, and oxcarbaze tolerated in some patients. The efficacy of oxcarbazepine and carbamazepine was compared in 48 epileptic i controlled on polytherapy, including carbamazepine, in a double- blind, crossover study (Houtkooper et al, 19 seizures were generalized (9 patients), partial (10 patients), or both generalized and partial (29 patients); all p least 2 seizures/week despite therapy with 2 to 4 antiepileptic agents. Patients were randomly allocated to ox mg/day or carbamazepine 200 mg/day. Following a titration period, where the dose of each was increased to seizure control, therapy was continued for 12 weeks (steady- state) in each trial period. As compared to carb therapy with oxcarbazepine reduced the total number of seizures by 9%; tonic-clonic and tonic seizures were 20% and 31%, respectively. In 5 patients, a shift from complex partial to simple partial seizures or atypical ab was observed during oxcarbazepine therapy. Other differences reported during oxcarbazepine therapy were alertness and greater ability to concentrate in 5 patients and remission of carbamazepine related allergic skin Serum levels of valproic acid and phenytoin were higher in oxcarbazepine treated patients, and serum sodiur were lower. Other adverse effects were similar with each agent.

d) In a double-blind study, the efficacy of oxcarbazepine and carbamazepine in 16 epileptic patients inadequ at least 1 anticonvulsant (other than carbamazepine) was evaluated (Bulau et al, 1987). Each patient had exp 1 tonic-clonic or complex partial seizure per month. Oxcarbazepine or carbamazepine were added sequentia fashion during a 1 month titration period; therapy was continued for an additional 3 months. Mean doses were mg daily for oxcarbazepine and carbamazepine, respectively. Concomitant anticonvulsants were continued th frequency was reduced by 90% during therapy with both agents, with 28% of all patients becoming seizure-fr effects were less in oxcarbazepine treated patients. Increases in serum levels of valproic acid, phenytoin, and observed in the oxcarbazepine group, presumably secondary to a lesser degree of enzyme induction as com carbamazepine.

4.6.I.2 Trigeminal neuralgia

a) Oxcarbazepine and its 10-hydroxy-metabolite (10-hydroxy-carbazepine; 10,11-dihydro-10-hydroxy carbar compared with carbamazepine in 24 patients with trigeminal neuralgia (Farago, 1987). All patients had either trigeminal neuralgia or other idiopathic facial neuralgias for at least 2 weeks. Fourteen patients had been trea carbamazepine. Oxcarbazepine was administered to 13 of the 24 patients for a mean of 11 months (mean m 1100 milligrams daily), resulting in an adequate clinical response in 10 and a moderate response in 3. Sympt however, was seen in 1 patient after 6 months of treatment. Eleven patients were treated with the 10-hydroxy oxcarbazepine (GP 47779) for a mean of 3.5 months (mean maximal dose, 1100 milligrams daily), with 7 ach of symptoms and 4 noticing definite improvement. However, recurrence of symptoms occurred in 2 patients a months of treatment, respectively. In the 14 patients treated previously with carbamazepine, therapy with eith or its metabolite was reported to be more effective than carbamazepine in 12; efficacy was considered equiva worse in another. These overall results suggest the potential superiority of oxcarbazepine over carbamazepir neuralgia. However, placebo-controlled trials are required to confirm these findings.

4.6.I.3 Efficacy

a) The primary difference between oxcarbazepine and carbamazepine is in regard to pharmacokinetic prope affect the propensity of these agents to elicit adverse effects. Following absorption, oxcarbazepine is rapidly converted via reduction to 10-hydroxy-carbazepine, the active metabolite, which is excreted in the urine as th conjugate. A portion of the 10-hydroxy-metabolite is hydroxylated to isomeric 10,11-diols, the trans-diol predo (Theisohn & Heimann, 1982; Schutz et al, 1986; Anon, 1989).

b) In contrast, carbamazepine is oxidized to the active carbamazepine-10,11-epoxide; a portion of this metal converted to the inactive 10,11-diol (Eichelbaum et al, 1985d; Anon, 1989; Anon, 1990). The 10,11-epoxide r carbamazepine is responsible for dose-dependent adverse effects (Anon, 1990; Anon, 1989). Because an ep produced during oxcarbazepine metabolism, this drug is expected to be better tolerated than carbamazepine

4.6.I.4 Adverse Effects

a) A trend toward a lower incidence of severe adverse effects has been observed with oxcarbazepine as cor carbamazepine in some studies (Bulau et al, 1987)(Dam, 1990; Houtkooper et al, 1987), which at times reach significance (Dam, 1990).

b) Oxcarbazepine appears less likely than carbamazepine to influence oxidative processes, as the metabolis oxcarbazepine is facilitated primarily by reduction. Studies have reported that oxcarbazepine lacks autoinduc unlike carbamazepine, a feature which may decrease the incidence of breakthrough seizures (Anon, 1989; B Anon, 1990).

c) In some studies, oxcarbazepine has not influenced antipyrine kinetics, suggesting an advantage with rega interactions (Anon, 1989). However, dose-dependent enzyme induction has been reported by other investiga doses producing effects similar to carbamazepine (Patsalos et al, 1990). As the optimal dose of oxcarbazepir undefined, further studies will be needed to determine if the drug will offer a significant advantage in regard to and autoinduction.

4.6.J Phenobarbital

Epilepsy

Epilepsy, Children

4.6.J.1 Epilepsy

a) Phenobarbital in doses of 4 to 5 mg/kg/day proved to be more effective than carbamazepine 20 mg/kg/da day doses) in the treatment of recurrent febrile convulsions in a double-blind study. Nine of 19 carbamazepin (47%) had recurrent seizures despite therapeutic blood levels, however only two of the phenobarbital treated had recurrent seizures (Antony & Hawke, 1983).

b) The efficacy and toxicity of carbamazepine, phenobarbital, phenytoin and primidone were compared in 62 simple partial, complex partial and secondarily generalized seizures in a multicenter, randomized, double blin were treated with monotherapy and if treatment failure occurred, patients were randomly switched to an alter There was no significant difference among the drugs in the treatment of tonic-clonic seizures. Conversely, ca significantly more effective in controlling simple partial and complex partial seizures than were any of the othe rather than seizure control appeared to be the greatest differentiating factor among the four study drugs with primidone manifesting the highest incidence of side effects early in therapy with no significant differences afte Patient tolerance of the drugs as measured by retention rates were significantly better among carbamazepine treated patients. In studies of behavioral toxicity, carbamazepine-treated patients showed the least deteriorat of patients were successfully managed for 1 year on monotherapy, regardless of the drug chosen. The autho based on anticonvulsant activity and side effect profile, carbamazepine may be the preferred drug for initiatio adults with either generalized tonic-clonic, simple partial or complex partial seizures (Smith et al, 1987).

4.6.J.2 Epilepsy, Children

a) The efficacy and tolerability of phenobarbital, phenytoin, carbamazepine, and sodium valproate in the trea epilepsy were compared in a long-term, prospective, randomized trial (de Silva et al, 1996). Children aged 3 (n=167) with at least two previously untreated tonic-clonic or partial seizures were eligible for participation in drugs were equally efficacious with 20% of the patients remaining seizure-free and 73% achieving a 1-year re years. However, randomization to phenobarbital was discontinued early in the study period due to unaccepta Carbamazepine and sodium valproate were the best tolerated with only 4% of children discontinuing treatme 9% of children treated with phenytoin.

4.6.K Phenytoin

Epilepsy

Epilepsy, Children

Impaired cognition

Myotonia

4.6.K.1 Epilepsy

a) Carbamazepine is as effective an anticonvulsant as phenytoin (Simonsen et al, 1975; Ramsay et al, 1983 1975).

b) In a controlled study, carbamazepine was reported as effective as phenytoin as initial seizure therapy in 7 with either simple seizures, complex seizures, partial evolving to generalized seizures and generalized convu (Ramsay et al, 1983). Thirty-five patients were treated with each drug. Complete control of seizures was achi patients in each treatment group. Mean serum levels during weeks 8 to 24 of treatment were 9.1 to 11 mcg/m and 4.7 to 6.5 mcg/mL for carbamazepine. The incidence of side effects was similar in both groups. Carbama recommended as a major anticonvulsant to be given initially as single agent therapy in the management of th

c) The efficacy and toxicity of carbamazepine, phenobarbital, phenytoin and primidone were compared in 62 simple partial, complex partial and secondarily generalized seizures in a multicenter, randomized, double blin were treated with monotherapy with doses titrated to produce blood levels in the therapeutic range. If treatme (inadequate seizure control with the initial drug or unacceptable toxicity from the initial drug), patients were ra to an alternate study drug. Combined results with all four drugs suggested that full seizure control was signifi patients with generalized tonic-clonic seizures than for those with partial seizure disorders (56% vs 39%). Th significant difference among the drugs in treatment of tonic- clonic seizures. Conversely, carbamazepine was effective in controlling simple partial and complex partial seizures than were any of the other drugs. Toxicity a greatest differentiating factor among the 4 study drugs. Patients taking primidone exhibited the highest incide early in therapy, although there were no significant differences with chronic therapy. Patient tolerance of the d by retention rates were significantly better among carbamazepine- and phenytoin-treated patients. In studies toxicity, carbamazepine-treated patients showed the least deterioration. Overall, 80% of patients were succes 1 year on monotherapy, regardless of the drug chosen. The authors concluded that based on anticonvulsant carbamazepine may be the preferred drug for initiation of therapy in adults with either generalized tonic-clonic complex partial seizures (Smith et al, 1987a).

d) One hundred eighty-one patients with previously untreated epilepsy were randomized to receive valproic a carbamazepine as monotherapy and followed for 14 to 24 months (Callaghan et al, 1985). The oral drug dose phenytoin 300 milligrams/day (mg/day) (adults) and 5 to 10 milligrams/kilogram/day (children), carbamazepin (adults) and 5 to 10 mg/kg/day (children), and valproic acid 600 mg/day (adults) and 5 to 10 mg/kg/day (child were highly effective in the control of generalized seizures but less effective for partial seizures. There was no difference between the overall incidence of side effects between the 3 drugs.

4.6.K.2 Epilepsy, Children

a) The efficacy and tolerability of phenobarbital, phenytoin, carbamazepine, and sodium valproate in the trea epilepsy were compared in a long-term, prospective, randomized trial (de Silva et al, 1996a). Children aged 3 (n=167) with at least two previously untreated tonic-clonic or partial seizures were eligible for participation in t drugs were equally efficacious with 20% of the patients remaining seizure free and 73% achieving 1-year rem However, randomization to phenobarbital was discontinued early in the study period due to unacceptable side Carbamazepine and sodium valproate were the best tolerated with only 4% of children discontinuing treatmen 9% of children treated with phenytoin.

4.6.K.3 Impaired cognition

a) Most studies have found phenytoin to cause more cognitive impairment than carbamazepine, but there wa didn't find any clinically significant differences in cognitive adverse effects between phenytoin and carbamaze similar kinds of neuropsychological evaluations (Meador et al, 1991).

b) A study was conducted to compare the cognitive effects of phenytoin and carbamazepine during monothe controlled withdrawal in two groups of chronic epileptic patients who were seizure-free for at least two years. (mean age 28.5 +/- 7 years) who took phenytoin for a mean duration of 32.08 +/- 17.8 months and 13 patient +/- 8.9 years) receiving carbamazepine for a mean duration of 28.07 +/- 16.1 months were compared with 26 age 23.57 +/- 8.3 years). Neuropsychological baseline assessment included tests of intelligence, vigilance, at and visuomotor performance. The effects of drug withdrawal were assessed by further neuropsychological re months after a fifty percent dosage reduction and three months and one year following complete withdrawal o carbamazepine. Results of neuropsychological testing at baseline showed that patients taking phenytoin suffe impairments in attention, visuomotor, and intellectual abilities as well as in global performance. Patients who carbamazepine performed markedly worse only on tasks requiring attention. After discontinuation of phenytoi markedly worse performances on verbal digits span, three months after a fifty percent dosage reduction and performances on verbal learning three months after discontinuation of phenytoin. Following discontinuation of patients suffered no further impairments on neuropsychological testing. One year after complete withdrawal o carbamazepine, both groups were no different than controls on the neuropsychological exam, thus demonstra reversibility of cognitive effects (Gallassi et al, 1988).

c) The cognitive effects of phenytoin and carbamazepine during monotherapy were compared in two groups referrals with epilepsy and with an untreated control group of epileptic patients. Twenty-one patients were in e seizure activity well-controlled in the majority of patients for 2 to 3.5 years. Patients in the phenytoin-treated g phenytoin plasma concentrations of 9.5 microgram/milliliter (mcg/mL) (range 1 to 21 mcg/mL) and had been t duration of 5.8 years. Patients in the carbamazepine-treated group had mean carbamazepine plasma concer mcg/mL (range 0.5 to 10.6 mcg/mL) and had been treated for a mean duration of 3.6 years. Assessments of included tests of memory scanning, word list learning, memory (immediate recall and with a one-hour delay), (three subtasks of graduated difficulty), and the tracking task. The phenytoin group performed significantly wo two groups on the most demanding subtest of short-term memory scanning (p less than 0.05). Performance o memory tasks were significantly worse in the phenytoin-treated group (p less than 0.05). The phenytoin-treat demonstrated greater impairment on the prose recall test than the carbamazepine-treated group. Patients tre carbamazepine showed a trend to learn more rapidly than the phenytoin-treated patients. After a one-hour de carbamazepine-treated patients forgot significantly more than the phenytoin-treated patients (p less than 0.05 next list-learning task, the carbamazepine group relearned significantly more than the phenytoin group (p less significant difference was observed between the two treatment groups for the decision-making task or trackin et al, 1986).

d) In another clinical trial, patients receiving carbamazepine performed better than those receiving phenytoin tasks. The phenytoin group performed significantly worse (p less than 0.05) on short-term memory scanning t short-term memory task became more complex, the phenytoin group made more errors as compared with the treated group (p less than 0.06). Patients on carbamazepine performed significantly better than the phenytoin the tracking task (p less than 0.05) (Andrewes et al, 1984).

e) A randomized, double-blind, 10-month study, in 56 adult patients with chronic epilepsy was conducted to c cognitive effects of phenytoin and carbamazepine. Following a two-month stabilization period, patients were r to continue phenytoin or begin carbamazepine and then continue treatment for four months. All patients were to receive treatment for an additional four months. Mean phenytoin plasma concentrations were 31.2 +/- 2.13 microgram/milliliter (mcg/mL) for the entire study population, and the mean dose of phenytoin administered w milligrams/kilogram (mg/kg). Mean carbamazepine plasma concentrations were reported to be 9.3 +/- 0.55 m patients on mean doses of carbamazepine of 18.4 mg/kg. Twenty patients from each treatment group were ra from 47 patients who completed the 10 month study. No significant differences were reported on Halstead's r battery or the Weschler adult intelligence scale regardless of treatment; however, even though patients solve the same number of problems when receiving either phenytoin or carbamazepine, fewer errors were made on high cognitive component while taking carbamazepine. Patients reported feeling more alert during carbamaze than while taking phenytoin (Troupin et al, 1977).

f) A double-blind, crossover study compared the cognitive effects of four month trials of phenytoin and carba adult patients with chronic epilepsy. No significant differences were reported between phenytoin or carbamaz the Halstead battery or the Weschsler intelligence scale. Other neuropsychological tests showed significant i patients taking phenytoin on tasks requiring concentration and mental manipulation such as receptive aphasi 0.05), constructional dyspraxia (p less than 0.01), Stroop attention tasks (p less than 0.05), and Wonderlic pr tasks (p less than 0.05). Differences in performances on tasks requiring greater mental manipulation were mo patients being treated with phenytoin. As the task increased in complexity, the cognitive impairment effects o became more apparent as compared to carbamazepine. The investigators suggested that the impact of phen abilities may not be readily detectable when testing performance on routine tasks, but may require testing tas complexity to detect subtle cognitive impairment. The patients in this study reported feeling more alert when t treatment with carbamazepine compared to phenytoin (Dodrill & Troupin, 1977).

4.6.K.4 Myotonia

a) One study reported that phenytoin in doses of 200 to 300 milligrams (mg) daily and carbamazepine 600 to were similarly effective in the treatment of myotonia (Sechi et al, 1983). Carbamazepine is indicated as the a myotonia and Steinert's disease by virtue of its lesser long-term side effects.

4.6.L Primidone

4.6.L.1 Seizure

a) The efficacy and toxicity of carbamazepine, phenobarbital, phenytoin and primidone were compared in 62 simple partial, complex partial and secondarily generalized seizures in a multicenter, randomized, double blin were treated with monotherapy with doses titrated to produce blood levels in the therapeutic range. If treatme (inadequate seizure control with the initial drug or unacceptable toxicity from the initial drug), patients were ra to an alternate study drug. Combined results with all four drugs suggested that full seizure control was signifi patients with generalized tonic-clonic seizures than for those with partial seizure disorders (56% vs 39%). The significant difference among the drugs in treatment of tonic-clonic seizures. Conversely, carbamazepine was effective in controlling simple partial and complex partial seizures than were any of the other drugs. Toxicity r control appeared to be the greatest differentiating factor among the four study drugs with patients taking prim the highest incidence of side effects early in therapy although there were no significant differences with chron tolerance of the drugs as measured by retention rates were significantly better among carbamazepine- and p patients . In studies of behavioral toxicity, carbamazepine-treated patients showed the least deterioration. Ov patients were successfully managed for 1 year on monotherapy, regardless of the drug chosen. The authors based on anticonvulsant activity and side effect profile, carbamazepine may be the preferred drug for initiatio adults with either generalized tonic-clonic, simple partial or complex partial seizures (Smith et al, 1987b).

4.6.M Progabide

4.6.M.1 Epilepsy

a) There are no direct comparisons of progabide with carbamazepine in the treatment of any form of epilepsy comparisons of clinical studies suggest that adjunctive therapy with progabide in therapy-resistant partial seiz effective as other primary anticonvulsants such as phenytoin, phenobarbital, primidone, or carbamazepine wh adjunctive therapy to patients who have failed previous therapy (Schmidt, 1984; Schmidt, 1982).

4.6.N Propranolol

4.6.N.1 Intermittent explosive disorder

a) One study (Mattes, 1990) compared the efficacy of propranolol and carbamazepine in a randomized trial i diagnosed with intermittent explosive disorder. An additional 29 patients with rage outbursts secondary to res deficit disorder, alcohol or drug abuse, antisocial personality disorder, unsocialized conduct disorder and bord disorder; 27 of these patients received carbamazepine. Mean daily dosages were 486 mg and 860 mg for pro carbamazepine respectively. Both medications were equally well tolerated and were effective in reducing targ However, the absence of a placebo-control group makes the efficacy of either drug difficult to evaluate. Two f predict a differential benefit between the two drugs; these were diagnosis of attention deficit disorder, residua more effective) and age of onset of symptoms (again, propranolol more effective). Carbamazepine appeared patients with intermittent explosive disorder.

4.6.O Tiapride

4.6.O.1 Alcohol withdrawal syndrome, acute

a) Tiapride was as effective as carbamazepine in the treatment of acute alcohol withdrawal. Sixty patients w receive either tiapride 200 milligrams (mg) 3 times daily (n=30) or carbamazepine 200 mg 3 times daily (n=30 Withdrawal symptoms improved significantly in both groups. Symptoms such as frequent awakening, nightma palpitations decreased more quickly in the carbamazepine group while aggression and gastrointestinal disco more quickly in the tiapride group. Carbamazepine was more effective against fear and hallucinations, while t vertigo. No seizures occurred and both drugs were well tolerated. Overall, tiapride and carbamazepine demo efficacy for the treatment of acute alcohol withdrawal (Agricola et al, 1982).

4.6.P Topiramate

4.6.P.1 Epilepsy

a) In a double-blinded, randomized study, topiramate, carbamazepine and valproate monotherapy demonstr to study exit, times to first seizure and proportions of patients who were seizure-free during the final 6 months Newly diagnosed epilepsy patients were randomized to receive topiramate 100 milligrams (mg) daily (n=210) mg daily (n=199), or traditional therapy (n=204). Patients in the traditional therapy arm were prescribed either 600 mg/day or valproate 1250 mg/day depending on the prescribing physician's treatment choice. Patients w months after the final patient was enrolled. Of the total 285 patients, 46% completed the study. Adverse even 19% and 23% of discontinuations in the topiramate and traditional therapy arms, respectively. Ineffective trea for 11% and 12% of discontinuations in the topiramate and traditional therapy arms, respectively. The time to to first seizure between the arms did not differ (p=0.53 and 0.35, respectively). The proportion of patients who experience a seizure during the last 6 months of the study was 49% of topiramate-100 mg patients and 44% other arms. Dose related paresthesia (25 to 33%), difficulty with concentration or attention (4 to 11%), langua 7%), confusion (3 to 6%), nausea (7 to 14%) and abdominal pain (3 to 7%) were reported with topiramate. Ca valproate were associated with concentration and attention difficulty (4% and 1%), and language problems (6 Carbamazepine was also associated with confusion (3%) (Privitera et al, 2003a).

4.6.Q Valproic Acid

Epilepsy

Epilepsy, Children

Rheumatic chorea

4.6.Q.1 Epilepsy

a) One hundred eighty-one patients with previously untreated epilepsy were randomized to valproic acid, phe carbamazepine as monotherapy and followed for 14 to 24 months. All 3 drugs were highly effective in the cor seizures but less effective for partial seizures. There was no significant difference between the overall incider between the 3 drugs (Callaghan et al, 1985a).

b) Carbamazepine and sodium valproate were shown to be equally effective in controlling seizures in patient diagnosed primary generalized or partial seizures (Richens et al, 1994). In this large multicenter study patient randomized to either carbamazepine or valproate and followed for a period of three years. Although long-term similar in the two groups, significantly more patients in the carbamazepine group (15% vs 5%) discontinued t first six months due to adverse reactions (predominantly rash). Headache and dizziness were also reported n the carbamazepine group; weight gain was reported more often in patients receiving sodium valproate.

c) Results from a large multicenter trial comparing valproate with carbamazepine in the treatment of complex secondarily generalized tonic-clonic seizures indicate similar effectiveness of both drugs for control of seconc tonic-clonic seizures. However, for complex partial seizures, carbamazepine was more effective and was ass adverse reactions (Mattson et al, 1992). Long-term side effects associated with valproate therapy included w loss or change in texture, and tremor. Hypersensitivity, characterized by rash, occurred more frequently in tho carbamazepine.

d) Patients switched to high dose valproic acid (target serum level 80 to 150 micrograms/milliliter) demonstra improved seizure control versus treatment with their baseline antiepileptic drug. Participating patients had pa history of at least 2 complex partial seizures per month with or without secondarily generalized tonic-clonic se maintained on therapeutic levels of either carbamazepine, phenytoin, phenobarbital or primidone. A 30% mec complex partial seizures and a 70% median reduction for secondarily generalized tonic-clonic seizures over p occurred. The authors conclude that valproic acid is efficacious as monotherapy for partial-onset seizures an considered as first-line therapy (Beydoun et al, 1997).

e) In a double-blinded, randomized study, topiramate, carbamazepine and valproate monotherapy demonstr to study exit, times to first seizure and proportions of patients who were seizure-free during the final 6 months Newly diagnosed epilepsy patients were randomized to receive topiramate 100 milligrams (mg) daily (n=210) mg daily (n=199), or traditional therapy (n=204). Patients in the traditional therapy arm were prescribed either 600 mg/day or valproate 1250 mg/day depending on the prescribing physician's treatment choice. Patients w months after the final patient was enrolled. Of the total 285 patients, 46% completed the study. Adverse even 19% and 23% of discontinuations in the topiramate and traditional therapy arms, respectively. Ineffective trea for 11% and 12% of discontinuations in the topiramate and traditional therapy arms, respectively. The time to to first seizure between the arms did not differ (p=0.53 and 0.35, respectively). The proportion of patients who experience a seizure during the last 6 months of the study was 49% of topiramate-100 mg patients and 44% other arms. Dose related paresthesia (25 to 33%), difficulty with concentration or attention (4 to 11%), langua 7%), confusion (3 to 6%), nausea (7 to 14%) and abdominal pain (3 to 7%) were reported with topiramate. Ca valproate were associated with concentration and attention difficulty (4% and 1%), and language problems (6 Carbamazepine was also associated with confusion (3%) (Privitera et al, 2003).

4.6.Q.2 Epilepsy, Children

a) The efficacy and tolerability of phenobarbital, phenytoin, carbamazepine, and sodium valproate in the trea epilepsy were compared in a long-term, prospective, randomized trial (de Silva et al, 1996b). Children aged 3 (n=167) with at least two previously untreated tonic-clonic or partial seizures were eligible for participation in t drugs were equally efficacious with 20% of the patients remaining seizure free and 73% achieving 1-year rem However, randomization to phenobarbital was discontinued early in the study period due to unacceptable sid Carbamazepine and sodium valproate were the best tolerated with only 4% of children discontinuing treatme 9% of children treated with phenytoin.

4.6.Q.3 Rheumatic chorea

a) Carbamazepine and valproic acid were found to be safe and equally effective in the treatment of choreic r of clinical improvement, time to complete remission, duration of treatment, and recurrence rates in a group of patients with Sydenham's chorea. In this open-label trial, 7 children received 20 to 25 milligrams per kilogram sodium valproate and a matched group of 17 children received 15 mg/kg/day of carbamazepine. No adverse reported by either group.

Demographics and Response to Treatment

	Sodium valproate	Carbamazepine	P
Female sex (%)	71.4	58.8	0.56
Age (years)	12.4 +/- 1.5	10.9 +/- 2.4	0.13
Onset of improvement (days)	8.0 +/- 4.0	7.4 +/- 8.2	0.88
Time to remission (weeks)	10.1 +/- 8.5	6.7 +/- 6.3	0.36
Duration of treatment (months)	4.3 +/- 2.8	5.0 +/- 2.4	0.56
Recurrences (%)	14.3	17.6	0.84
Generalized chorea (%)	71.4	64.7	0.75

(Genel et al, 2002)

4.6.R Vigabatrin

4.6.R.1 Seizure

a) Time to withdrawal for lack of efficacy or adverse events did not differ in newly diagnosed epileptic patient carbamazepine (n=226) or vigabatrin (n=220) in a double-blind, randomized, monotherapy study (p=0.318) (However, patients treated with carbamazepine were more likely to withdraw sooner than vigabatrin patients, first 4 to 6 months of therapy. The total daily dose of vigabatrin was 1 gram (g) during the first 6 weeks after r Vigabatrin dose was increased to 2 g as an initial maintenance dose with a dose range from 1.5 g to 4 g daily dose of carbamazepine was 200 milligrams (mg) followed by an increase to 600 mg after 6 weeks. Maintena carbamazepine ranged from 400 mg to 1600 mg per day. No treatment differences between treatment groups throughout the study. After 12 months of double-blind therapy, 107 vigabatrin and 116 carbamazepine patien months of remission. The time to first seizure was significantly less for vigabatrin patients compared to carba (p=0.0003). Twenty-three vigabatrin and 9 carbamazepine patients withdrew from the study solely due to lac effect (p=0.0298). Drowsiness, fatigue, and headache were reported by more than 20% of patients with no di the two treatment groups observed.. Adverse events in the psychiatric system were reported significantly mo vigabatrin patients (25%) compared to carbamazepine patients (15%; p less than 0.05). Likewise, more patie vigabatrin experienced weight gain (11%) compared to those treated with carbamazepine (5%; p less than 0. Carbamazepine patients experienced significantly more adverse events in the skin and appendages system vigabatrin patients (14%; p less than 0.05). A decrease in white-cell counts, uric acid and bilirubin and an inc phosphatase were observed in carbamazepine patients.

b) Preliminary results from an open-label comparative trial (n=34) suggested the potential superiority of carb monotherapy over vigabatrin monotherapy in patients with newly diagnosed epilepsy (Grant & Heel, 1991). In patients treated with vigabatrin 50 milligrams/kilogram/day were considered non- responders; 1 of these patie failed to respond to carbamazepine. None of the patients treated with carbamazepine (plasma levels of 35 m considered non-responders. However, 3 carbamazepine-treated patients discontinued therapy due to hypers

c) Carbamazepine monotherapy was compared to vigabatrin monotherapy in patients with newly-diagnosed

generalized tonic-clonic seizures (Kalviainen et al, 1995). Sixty percent of patients (n=50) were considered su in both groups; however, significantly more patients were totally seizure free while receiving carbamazepine. resulted in fewer side effects that resulted in discontinuation of therapy. Vigabatrin monotherapy may be an a carbamazepine or other standard antiepileptic drugs in cases where patients are intolerant of toxic or cognitiv

4.6.S Zonisamide

4.6.S.1 Epilepsy

a) In a small study, zonisamide was as effective as carbamazepine in the treatment of refractory partial seizu week run-in period, 8 patient with a poor response to phenytoin (more than 4 seizures/month) received either zonisamide for 12 weeks, and then were switched to the other drug for an additional 12 weeks. Patients rece carbamazepine and zonisamide adjusted to maximal therapeutic response and minimal toxicity; phenytoin wa the 4 patients completing the study, 2 had the best response to carbamazepine, an intermediate response to poor response to phenytoin. Two patients responded best to zonisamide. Optimal seizure control and minima seen with serum zonisamide concentrations of 20 to 30 micrograms/milliliter (mcg/mL), and a high incidence were seen with serum levels exceeding 30 mcg/mL (Wilensky et al, 1985a).

874. Product Information: ADCIRCA (TM) oral tablets, tadalafil oral tablets. Eli Lilly and Company, Indianapolis, IN, 2009
875. Product Information: AFINITOR(R) oral tablets, everolimus oral tablets. Novartis Pharmaceutical Corporation, East 2009.
876. Product Information: APTIVUS(R) oral capsules, solution, tipranavir oral capsules, solution. Boehringer Ingelheim Pharmaceuticals,Inc., Ridgefield, CT, 2008.
877. Product Information: Adalat(R) CC Extended Release Tablets, nifedipine extended release tablets. Schering Corpo NJ, USA, 2004.
878. Product Information: Adenocard(R), adenosine injection. Fujisawa Healthcare, Inc., Deerfield, IL, 2002.
879. Product Information: Agenerase(R), amprenavir. Glaxo Wellcome Inc., Research Triangle Park, NC, 2000.
880. Product Information: Apo-Carbamazepine. Apotex, Canada, 1989.
881. Product Information: BANZEL(TM) oral tablets, rufinamide oral tablets. Novartis Pharma AG, Woodcliff Lake, NJ, 2
882. Product Information: Biaxin(R), clarithromycin. Abbott Laboratories, North Chicago, IL, 2000.
883. Product Information: CANCIDAS(R) IV infusion, caspofungin acetate IV infusion. Merck & Co,Inc, Whitehouse Stati
884. Product Information: CARBATROL(R) extended release capsules, carbamazepine extended release capsules. Shi 2005.
885. Product Information: Camptosar(R) Injection, Irinotecan hydrochloride injection. Pharmacia & Upjohn Company, Ka 2004.
886. Product Information: Carbamazepine Tablets USP,. Lederle, 86.
887. Product Information: Carbatrol(R), carbamazepine extended-release capsules. Shire Richwood Inc, Florence, KY,
888. Product Information: Carbatrol(R), carbamazepine extended-release capsules. Shire Richwood Inc, Florence, KY,
889. Product Information: Carbatrol. Shire, US, 97.
890. Product Information: Cerebyx(R), fosphenytoin sodium injection. Parke-Davis, Division of Warner-Lambert, Morris F
891. Product Information: Clozaril(R), clozapine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 2002.
892. Product Information: Covera HS(R), verapamil. Pharmacia Corporation, Chicago, IL, 2003.
893. Product Information: Crixivan(R), indinavir sulfate. Merck & Co., Inc., Whitehouse Station, NJ, 2004.
894. Product Information: DEPLIN(R) oral tablets, l-methylfolate oral tablets. Pamlab,LLC, Covington, LA, 2006.
895. Product Information: Desyrel(R), trazodone HCL. Bristol-Myers Squibb Company, Princeton, NJ, 2003.
896. Product Information: Doxil(R), doxorubicin hydrochloride liposome injection. SEQUUS Pharmaceuticals, Inc., Menlo
897. Product Information: Duragesic(R), fentanyl. Janssen Pharmaceitica Products, L.P., Titusville, NJ, 2001.
898. Product Information: EMEND(R) IV injection, fosaprepitant dimeglumine IV injection. Merck & Co,Inc, Whitehouse S
899. Product Information: EMEND(R) oral capsules, aprepitant oral capsules. Merck & Co Inc, Whitehouse Station, NJ,
900. Product Information: EMSAM(R) transdermal patch, selegiline transdermal patch. Bristol-Myers Squibb Company,

2006.
901. Product Information: EQUETRO(TM) Oral Extended Release Capsule, carbamazepine oral extended release capsı Newport, KY, 2004.
902. Product Information: EQUETRO(TM) oral extended release capsules, carbamazepine oral extended release capsu Wayne, PA, 2004.
903. Product Information: Equetro(TM) extended release capsules, carbamazepine extended release capsules. Shire US KY, 2004.
904. Product Information: Equetro™, carbamazepine. Shire US, Newport, KY, 2004.
905. Product Information: FOSAMAX PLUS D(TM) oral tablets, alendronate sodium, cholecalciferol oral tablets. Merck & Whitehouse Station, NJ, 2008.
906. Product Information: Felbatol(R), felbamate. Wallace Laboratories, Cranbury, NJ, 2000.
907. Product Information: Felbatol(R), felbamate. Wallace Laboratories, Cranbury, NJ, 2000a.
908. Product Information: GEODON(R) oral capsules, IM injection, ziprasidone HCl oral capsules, ziprasidone mesylate Inc, New York, NY, 2008.
909. Product Information: GLEEVEC(R) oral tablets, imatinib mesylate oral tablets. Novartis, East Hanover, NJ, 2005.
910. Product Information: Gabitril(TM), tiagabine hydrochloride. Abbott Laboratories, North Chicago, IL, 1998.
911. Product Information: INTELENCE(TM) oral tablets, etravirine oral tablets. Tibotec Therapeutics,Inc, Raritan, NJ, 20
912. Product Information: INVEGA(TM) extended-release oral tablets, paliperidone extended-release oral tablets. Janss NJ, 2007.
913. Product Information: IXEMPRA(TM) IV injection, ixabepilone IV injection. Bristol-Myers Squibb Company, Princetor
914. Product Information: Invirase(R), saquinavir mesylate. Roche Laboratories Inc., Nutley, NJ, 2003.
915. Product Information: KALETRA(R) oral capsule, oral solution, lopinavir/ritonavir oral capsule, oral solution. Abbott L Chicago, IL, 2005.
916. Product Information: KEPPRA(R) oral solution, tablets, levetiracetam oral solution, tablets. UCB Pharma,Inc, Roche
917. Product Information: Ketek(TM), telithromycin. Aventis Pharmaceuticals Inc., Kansas City, MO, 2004.
918. Product Information: LEVOTHYROXINE SODIUM(R) oral tablet, levothyroxine sodium oral tablet. Alara Pharmaceu Caguas, Puerto Rico, 2007.
919. Product Information: LEXIVA(R) oral solution, oral tablets, fosamprenavir calcium oral solution, oral tablets. GlaxoS Research Triangle Park, NC, 2009.
920. Product Information: Lamictal(R), lamotrigine. GlaxoSmithKline., Research Triangle Park, NC, 2003.
921. Product Information: Lariam(R), mefloquine. Roche Laboratories, Inc., Nutley, NJ, 2003.
922. Product Information: MIFEPREX(R) oral tablets, mifepristone oral tablets. Danco Laboratories,LLC, New York, NY,
923. Product Information: Marplan(R), isocarboxazid. Roche Laboratories Inc., Nutley, NJ, 1998.
924. Product Information: Miokacin(R), miocamycin. F.I.R.M.A., SpA, Florence, Italy, 1996.
925. Product Information: Miokacin(R), miocamycin. F.I.R.M.A., SpA, Florence, Italy, 1996a.
926. Product Information: NEXAVAR(R) oral tablets, sorafenib oral tablets. Bayer Pharmaceutical Corporation, West Ha
927. Product Information: NORVIR(R), ritonavir capsules, ritonavir oral solution. Abbott Laboratories, Abbott Park, IL, 20
928. Product Information: NUVIGIL(TM) oral tablets, armodafinil oral tablets. Cephalon,Inc, Frazer, PA, 2007.
929. Product Information: Nimbex(R), cisatracurium besylate injection. Glaxo Wellcome Inc., Research Triangle Park, N
930. Product Information: Nipolept(R), zotepine. Klinge Pharma GmbH, Munich, Germany, 1994.
931. Product Information: Novocarbamaz. Novopharm Limited, Canada, 88.
932. Product Information: Nuromax(R), doxacurium. Glaxo Wellcome Inc., Research Triangle Park, NC, 1994.
933. Product Information: Ortho Evra(TM), norelgestromin, ethinyl estradiol. Ortho-McNeil Pharmaceutical, Inc., Raritan,
934. Product Information: PRANDIN(R) oral tablets, repaglinide oral tablets. Novo Nordisk,Inc, Princeton, NJ, 2006.
935. Product Information: PREZISTA(R) film coated oral tablets, darunavir film coated oral tablets. Tibotec,Inc, Raritan,
936. Product Information: PROGRAF(R) oral capsules, IV injection, tacrolimus oral capsules, IV injection. Astellas Pharr Deerfield, IL, 2006.
937. Product Information: Parnate(R), tranylcypromine sulfate. SmithKline Beecham Pharmaceuticals, Philadelphia, PA,
938. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995.
939. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995a.
940. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995b.
941. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995c.
942. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995d.
943. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995e.
944. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995f.
945. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995g.
946. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995h.
947. Product Information: Parnate(R), tranylcypromine. SmithKline Beecham Pharmaceuticals, Philadelphia, PA, 1995i.
948. Product Information: Priftin(R), rifapentine. Aventis Pharmaceuticals, Inc., Kansas City, MO, 2000.
949. Product Information: ProSom(TM), estazolam tablets. Abbott Laboratories, North Chicago, IL, USA, 2004.
950. Product Information: Provigil(R) modafinil. Cephalon, Inc., West Chester, PA, 2004.
951. Product Information: RANEXA(R) extended-release oral tablets, ranolazine extended-release oral tablets. CV Ther Alto, CA, 2008.
952. Product Information: RAPAMUNE(R) oral solution, oral tablets, sirolimus oral solution, oral tablets. Wyeth Pharmac Philadelphia, PA, 2007.
953. Product Information: RESCRIPTOR(R) oral tablets, delavirdine mesylate oral tablets. Pfizer,Inc, New York, NY, 200
954. Product Information: Rapamune(R), sirolimus, oral solution and tablets. Wyeth Pharmaceuticals Inc., Philadelphia,
955. Product Information: Raplon(TM), rapacuronium bromide. Organon Inc., West Orange, NJ, 1999.

956. Product Information: Risperdal(R) Consta(TM), risperidone. Janssen Pharmaceutica Inc., Titusville, NJ, 2003a.
957. Product Information: Risperdal(R) Consta(TM), risperidone. Janssen Pharmaceutica Products, L.P., Titusville, NJ,
958. Product Information: SELZENTRY(R) oral tablets, maraviroc oral tablets. Pfizer Labs, New York, NY, 2007.
959. Product Information: SERZONE(R) oral tablets, nefazodone hcl oral tablets. Bristol-Myers Squibb Company, Prince
960. Product Information: SONATA(R) oral capsules, zaleplon oral capsules. Wyeth Pharmaceuticals Inc., Philadelphia,
961. Product Information: SPRYCEL(R) oral tablets, dasatinib oral tablets. Bristol-Myers Squibb, Princeton, NJ, 2008.
962. Product Information: SUSTIVA(R) oral capsules, tablets, efavirenz oral capsules, tablets. Bristol-Myers Squibb Con NJ, 2008.
963. Product Information: SUTENT(R) oral capsules, sunitinib malate oral capsules. Pfizer Labs, New York, NY, 2006.
964. Product Information: SYNTHROID(R) oral tablets, levothyroxine sodium oral tablets. Abbott Laboratories, North Ch
965. Product Information: Seroquel(R), quetiapine. AstraZeneca Pharmaceuticals LP, Wilmington, DE, 2001.
966. Product Information: Sporonox(R), itraconazole capsules. Janssen Pharmaceutica, Titusville, NJ, 2002.
967. Product Information: Synercid(R) I.V., quinupristin and dalfopristin. Rhone-Poulenc Rorer Pharmaceuticals Inc., Co 1999.
968. Product Information: Syprine(R), trientine hydrochloride. Merck & Co., Inc., West Point, PA, 2001.
969. Product Information: TARCEVA(R) oral tablets, erlotinib oral tablets. OSI Pharmaceuticals,Inc, Melville, NY, 2007.
970. Product Information: TASIGNA(R) oral capsules, nilotinib oral capsules. Novartis Pharmaceuticals Corporation, Eas 2007.
971. Product Information: TEGRETOL(R) chewable oral tablets, oral tablets, oral suspension, TEGRETOL(R) XR extenc tablets, carbamazepine chewable oral tablets, oral tablets, oral suspension, extended-release oral tablets. Novartis Corporation, East Hanover, NJ, 2003.
972. Product Information: TEGRETOL(R) chewable oral tablets, oral tablets, suspension, carbamazepine chewable oral tablets, suspension. Novartis, East Hanover, NJ, 2007.
973. Product Information: TEGRETOL(R) oral chewable tablet, tablet, suspension, TEGRETOL(R)-XR oral extended-rel carbamazepine oral chewable tablet, tablet, suspension, extended-release tablet. Novartis Pharmaceuticals Corpor Hanover, NJ, 2003.
974. Product Information: TEGRETOL(R) oral chewable tablets, tablets, suspension, carbamazepine oral chewable tabl suspension. Novartis, East Hanover, NJ, 2007.
975. Product Information: TEGRETOL(R) tablet, chewable tablet, suspension; TEGRETOL-XR(R) extended-release tab tablet, chewable tablet, extended-release tablet, suspension. Novartis Pharmaceuticals Corporation, East Hanover
976. Product Information: TEGRETOL(R)-XR extended-release oral tablets, carbamazepine extended-release oral table Hanover, NJ, 2007.
977. Product Information: TEGRETOL(R)-XR extended-release oral tablets, carbamazepine extended-release oral table Hanover, NJ, 2007a.
978. Product Information: TOPAMAX(R) oral tablets, oral sprinkle capsules, topiramate oral tablets, oral sprinkle capsule Neurologics,Inc, Titusville, NJ, 2008.
979. Product Information: TORISEL(TM) KIT IV injection, temsirolimus IV injection. Wyeth Pharmaceuticals,Inc, Philadel
980. Product Information: TRILEPTAL(R) oral tablets, oral suspension, oxcarbazepine oral tablets, oral suspension. Nov Pharmaceuticals Corporation, East Hanover, NJ, 2005.
981. Product Information: TYKERB(R) oral tablets, lapatinib oral tablets. GlaxoSmithKline, Research Triangle Park, NC,
982. Product Information: Tegretol suspension,. Geigy, US, 88.
983. Product Information: Tegretol tablets,. Geigy, US, 87.
984. Product Information: Tegretol and Tegretol-XR. Ciba, US, 96.
985. Product Information: Tegretol(R) carbamazepine chewable tablets. Novartis Pharmaceuticals Corporation, East Ha
986. Product Information: Tegretol(R), carbamazepine. Geigy Pharmaceuticals, Summit, NJ, 1990.
987. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1997.
988. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998.
989. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998a
990. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998b
991. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998c
992. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998c
993. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998e
994. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998f
995. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998g
996. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998h
997. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998i.
998. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 1998j.
999. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals, East Hanover, NJ, 2002a.
1000. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals, East Hanover, NJ, 2002b.
1001. Product Information: Tegretol(R), carbamazepine. Novartis Pharmaceuticals, East Hanover, NJ, 2002c.
1002. Product Information: Tegretol(R), carbamzepine chewable tablets. Novartis Pharmaceuticals Corp., East Hanover,
1003. Product Information: Tiazac(TM), diltiazem. Forest Pharmaceuticals, Inc., St. Louis, MO, 1996.
1004. Product Information: ULTRAM(R)ER extended-release oral tablets, tramadol hcl extended-release oral tablets. Pri 2005.
1005. Product Information: VELCADE(R) injection, bortezomib injection. Millennium Pharmaceuticals,Inc, Cambridge, MA
1006. Product Information: VFEND(R) IV injection, oral tablets, suspension, voriconazole IV injection, oral tablets, solutio York, NY, 2008.
1007. Product Information: Viracept(R), nelfinavir mesylate. Agouron Pharmaceuticals, Inc., La Jolla, CA, 1999.

1008. Product Information: Viramune(R), nevirapine. Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT, 2004.
1009. Product Information: Wellbutrin XL(TM), bupropion hydrochloride. Glaxo Wellcome Inc., Research Triangle Park, N
1010. Product Information: Zervalx(R) oral tablets, l-methylfolate oral tablets. Pamlab,LLC, Covington, LA, 2008.

DRUGDEX® Evaluations

IMIPRAMINE

0.0 Overview

1) Class

a) This drug is a member of the following class(es):
Antidepressant
Antidepressant, Tricyclic
Urinary Enuresis Agent

2) Dosing Information

a) Imipramine Hydrochloride

1) Adult

a) Depression

1) (hospitalized patients) 100 mg ORALLY per day in divided doses; may increase up to a MAX of 300 r TOFRANIL(R) tablets, 2005)

2) (outpatients) 75 mg ORALLY per day; may increase up to a MAX of 200 mg/day; usual maintenance mg/day (Prod Info TOFRANIL(R) tablets, 2005).

b) Panic disorder

1) 100-200 mg ORALLY in divided doses (1-3 doses per day), higher doses may be required if agoraph

c) Urinary incontinence

1) 25 mg ORALLY at bedtime, may increase in 25 mg increments to max dose of 150mg at bedtime

2) Pediatric

a) safety and effectiveness in children with nocturnal enuresis below the age of 6 years have not been estab effectiveness in pediatric patients for any other condition has not been established (Prod Info TOFRANIL(R) t

1) Nocturnal enuresis

a) (children 6 to 12 y) initial, 25 mg ORALLY 1 h before bedtime, may increase in 25 mg increments 50 mg/d or 2.5 mg/kg/d (Prod Info TOFRANIL(R) tablets, 2005)

b) (children over 12 y) initial, 25 mg ORALLY 1 h before bedtime, may increase in 25 mg increment 75 mg/d or 2.5 mg/kg/d (Prod Info TOFRANIL(R) tablets, 2005)

b) Imipramine Pamoate

1) Adult

a) Depression

1) (hospitalized patients) initial, 100 to 150 mg ORALLY once daily at bedtime; may increase up to MAX usual maintenance dose, 75 to 150 mg ORALLY once daily at bedtime (Prod Info TOFRANIL-PM(R) cap

2) (outpatients) 75 mg ORALLY once daily at bedtime; may increase up to a max of 200 mg/day; usual 75 to 150 mg ORALLY once daily at bedtime (Prod Info TOFRANIL-PM(R) capsules, 2005)

b) Panic disorder

1) 100-200 mg/day ORALLY in divided doses (1-3 doses per day), higher doses may be required if agor

2) Pediatric

a) safety and effectiveness have not been established in children (Prod Info TOFRANIL-PM(R) capsules, 20

3) Contraindications

a) Imipramine Hydrochloride

1) coadministration with a MAOI or use within 14 days of discontinuing a MAOI; may cause serious reactions (eg crisis, convulsive seizures, death) (Prod Info imipramine hcl oral tablets, 2007)

2) hypersensitivity to dibenzazepines; risk of cross-sensitivity reactions (Prod Info imipramine hcl oral tablets, 20

3) hypersensitivity to imipramine hydrochloride (Prod Info imipramine hcl oral tablets, 2007)

4) myocardial infarction, during the acute recovery period (Prod Info imipramine hcl oral tablets, 2007)

b) Imipramine Pamoate

1) coadministration with an MAOI or use within 14 days of discontinuing an MAOI; may cause serious reactions (crisis, severe convulsive seizures, death) (Prod Info TOFRANIL-PM(R) oral capsules, 2007)

2) hypersensitivity to dibenzazepines; risk of cross-sensitivity reactions (Prod Info TOFRANIL-PM(R) oral capsule

3) hypersensitivity to imipramine pamoate (Prod Info TOFRANIL-PM(R) oral capsules, 2007)

4) myocardial infarction, during the acute recovery period (Prod Info TOFRANIL-PM(R) oral capsules, 2007)

4) Serious Adverse Effects

a) Imipramine Hydrochloride

1) Agranulocytosis
2) Atrioventricular conduction pattern - finding
3) Cardiac dysrhythmia
4) Cerebrovascular accident
5) Decreased liver function
6) Depression, worsening
7) Heart block
8) Hypertension
9) Jaundice

10) Myocardial infarction
11) Orthostatic hypotension
12) Palpitations
13) Psychotic disorder
14) Seizure
15) Suicidal thoughts
16) Suicide
17) Syncope

b) Imipramine Pamoate
1) Agranulocytosis
2) Atrioventricular conduction pattern - finding
3) Cardiac dysrhythmia
4) Cardiac dysrhythmia
5) Cerebrovascular accident
6) Decreased liver function
7) Depression, worsening
8) Hypertension
9) Jaundice
10) Myocardial infarction
11) Orthostatic hypotension
12) Seizure
13) Suicidal thoughts
14) Suicide
15) Syncope

5) Clinical Applications
a) Imipramine Hydrochloride
1) FDA Approved Indications
a) Depression
b) Nocturnal enuresis
2) Non-FDA Approved Indications
a) Panic disorder
b) Urinary incontinence

b) Imipramine Pamoate
1) FDA Approved Indications
a) Depression
2) Non-FDA Approved Indications
a) Panic disorder

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms
Imipramine
Imipramine HCl
Imipramine Hydrochloride
Imipramine Pamoate

1.2 Storage and Stability

A) Oral route
1) Store between 59 and 86 degrees F (15 to 30 degrees C) (Prod Info Tofranil(R), 1995).

B) Parenteral route
1) Store between 59 to 86 degrees F (15 to 30 degrees C). Upon storing, minute crystals may form; this has no ir drug's therapeutic efficacy. Crystals will dissolve when the ampul is immersed in hot water (Prod Info Tofranil(R), al, 1994; Trissel, 1994).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Geriatric Patients

Dosage Adjustment During Dialysis

Dosage in Other Disease States

1.3.1 Normal Dosage

Imipramine Hydrochloride

Imipramine Pamoate

1.3.1.A Imipramine

1.3.1.A.1 Cataplexy - Narcolepsy

See Drug Consult reference: NARCOLEPSY AND CATAPLEXY - DRUG THERAPY

1.3.1.B Imipramine Hydrochloride

Intramuscular route

Oral route

1.3.1.B.1 Intramuscular route

1.3.1.B.1.a Depression

1) Initial intramuscular dose of up to 100 milligrams/day in divided doses. Lower dosages are recom
adolescents and for outpatients (Prod Info Tofranil(R), 1995b; Anon, 1983a; Trissel, 1994).

1.3.1.B.2 Oral route

Agoraphobia

Bulimia nervosa

Depression

Diabetic neuropathy

Panic disorder

Urinary incontinence

1.3.1.B.2.a Agoraphobia

1) Efficacy is dose related and may require doses of 150 milligrams/day or greater (Cohen et al, 19
(Mavissaakalian & Perel, 1985a)(Mavissakalian & Perel, 1994; Mavissakalian & Michelson, 1986).

1.3.1.B.2.b Bulimia nervosa

1) The doses used in the treatment of bulimia have ranged from the doses commonly used in the tr depression (75 to 275 milligrams/day) (Pope et al, 1983a; Pope et al, 1983; Rothschild et al, 1994).

1.3.1.B.2.c Depression

1) HOSPITALIZED PATIENTS

a) The recommended initial dose for hospitalized patients is 100 milligrams (mg) orally per day and gradually increased to 200 mg/day as required. If no response is seen after 2 weeks, then t increased up to 250 to 300 mg ORALLY per day in divided doses (Prod Info TOFRANIL(R) tabl as high as 750 milligrams/day maintenance in divided doses have been reported (Schuckit & Fe are not recommended.

2) OUTPATIENTS

a) The recommended initial dose for outpatients is 75 milligrams (mg) orally per day, increased day. Usual maintenance dose ranges from 50 to 150 mg daily. The recommended maximum do (Prod Info TOFRANIL(R) tablets, 2005).

b) Maintenance doses greater than 150 milligrams/day have been well tolerated and may be re patients to prevent relapses, but are associated with a higher incidence of persistent side effect headache, nausea, and vomiting) (Kupfer et al, 1989). The best method, other than experience, the optimal maintenance dose for a particular individual has not been established.

c) Patients with chronic depression that respond to imipramine may benefit from long-term mai (Kocsis et al, 1991).

1.3.1.B.2.d Diabetic neuropathy

1) Standard doses of 100 milligrams/day of imipramine may not be high enough to produce therape some patients with diabetic neuropathy. In one study, the therapeutic dose range was 125 milligram milligrams/day. The maximum therapeutic effect in neuropathy is reached within a week. Dosage titr started with a dose corresponding to a plasma level of 100 to 200 nmol/L for imipramine plus desipra should then be increased in a stepwise fashion (Sindrup et al, 1990a).

1.3.1.B.2.e Panic disorder

1) Based upon a dose-response study in patients with panic disorder with agoraphobia, IMIPRAMIN doses of 1.5 milligrams/kilogram/day (approximately 100 milligrams daily) may be effective in the tre some patients, whereas higher doses (3 milligrams/kilogram/day, approximately 200 milligrams daily for the agoraphobic dimension of this disorder (Mavissakalian & Perel, 1989); (Mavissakalian & Pera 1989a).

2) The suggested target dose is 2.25 milligrams/kilogram/day or a total (imipramine and N-desmeth plasma concentration of 110 to 140 nanograms/milliliter in the acute treatment of patients with panic agoraphobia. Higher doses were associated with good clinical response but a greater dropout rate s effects (Mavissakalian & Peral, 1995).

1.3.1.B.2.f Urinary incontinence

1) The dose used in the treatment of urinary incontinence is 75 to 150 milligrams/day. The dose car milligrams per day and titrated to clinical effect. Some patients may require the dose to be administe doses throughout the day instead of single dose administration (Rabey et al, 1979; Gilja et al, 1984) 1981)(Jarvis, 1981).

2) Imipramine 25 milligrams three times daily has been used in the treatment of females with urinar to detrusor instability (Jarvis, 1981).

1.3.1.C Imipramine Pamoate

1.3.1.C.1 Oral route

Agoraphobia

Bulimia nervosa

Depression

Diabetic neuropathy

Panic disorder

1.3.1.C.1.a Agoraphobia

1) Efficacy is dose related and may require doses of 150 milligrams/day or greater (Cohen et al, 19

(Mavissaakalian & Perel, 1985a)(Mavissakalian & Perel, 1994; Mavissakalian & Michelson, 1986).

1.3.1.C.1.b Bulimia nervosa

1) The doses used in the treatment of bulimia have ranged from the doses commonly used in the tr depression (75 to 275 milligrams/day) (Pope et al, 1983a; Pope et al, 1983; Rothschild et al, 1994).

1.3.1.C.1.c Depression

1) HOSPITALIZED PATIENTS

a) The initial oral dose for hospitalized patients is usually 100 to 150 milligrams (mg) once daily may be increased to 200 mg/day as required. If no response is seen after 2 weeks, then the dos increased up to 250 to 300 mg/day. Doses greater than 150 mg daily may be administered once optimum dosage and tolerance have been determined. The usual maintenance dose ranges fro once daily at bedtime (Prod Info TOFRANIL-PM(R) capsules, 2005). Doses as high as 750 milli maintenance in divided doses have been reported (Schuckit & Feighner, 1972) but are not reco

2) OUTPATIENTS

a) The usual initial oral dose for outpatients is 75 milligrams (mg) once daily at bedtime and ma to 200 mg/day. Doses greater than 75 mg daily may be administered once a day after the optim tolerance have been determined. The usual maintenance dose ranges from 75 to 150 mg once (Prod Info TOFRANIL-PM(R) capsules, 2005).

b) Maintenance doses greater than 150 milligrams/day have been well tolerated and may be re patients to prevent relapses, but are associated with a higher incidence of persistent side effect headache, nausea, and vomiting) (Kupfer et al, 1989). The best method, other than experience the optimal maintenance dose for a particular individual has not been established.

c) Patients with chronic depression that respond to imipramine may benefit from long-term mai (Kocsis et al, 1991).

1.3.1.C.1.d Diabetic neuropathy

1) Standard doses of 100 milligrams/day of imipramine may not be high enough to produce therape some patients with diabetic neuropathy. In one study, the therapeutic dose range was 125 milligram milligrams/day. The maximum therapeutic effect in neuropathy is reached within a week. Dosage titr started with a dose corresponding to a plasma level of 100 to 200 nmol/L for imipramine plus desipra should then be increased in a stepwise fashion (Sindrup et al, 1990a).

1.3.1.C.1.e Panic disorder

1) Based upon a dose-response study in patients with panic disorder with agoraphobia, IMIPRAMIN doses of 1.5 milligrams/kilogram/day (approximately 100 milligrams daily) may be effective in the tre some patients, whereas higher doses (3 milligrams/kilogram/day, approximately 200 milligrams daily for the agoraphobic dimension of this disorder (Mavissakalian & Perel, 1989); (Mavissakalian & Pera 1989a).

2) The suggested target dose is 2.25 milligrams/kilogram/day or a total (imipramine and N-desmeth plasma concentration of 110 to 140 nanograms/milliliter in the acute treatment of patients with panic agoraphobia. Higher doses were associated with good clinical response but a greater dropout rate s effects (Mavissakalian & Peral, 1995).

1.3.2 Dosage in Renal Failure

A) Imipramine Hydrochloride

1) No specific dosage adjustment is necessary (Bennett et al, 1994).

B) Imipramine Pamoate

1) No specific dosage adjustment is necessary (Bennett et al, 1994).

1.3.4 Dosage in Geriatric Patients

A) Imipramine Hydrochloride

1) GENERAL INFORMATION

a) Dosage reduction is recommended in elderly patients since this patient population is reported to have incidence of confusional-type reactions and other central nervous system symptoms while on tricyclic an therapy (Davies et al, 1971). A one-third to one-half reduction in tricyclic antidepressant dosage is sugge An increase in age is correlated with elevated steady-state serum levels of imipramine, desipramine and (Hicks et al, 1981a; Benetello et al, 1990).

2) DEPRESSION

a) The initial recommended dose for depression in geriatric patients is 30 to 40 milligrams orally daily; it necessary to exceed 100 milligrams/day (Prod Info TOFRANIL(R) tablets, 2005).

3) URINARY INCONTINENCE

a) In elderly patients with urinary incontinence associated with spontaneous unstable detrusor contractio imipramine is started at 25 milligrams at bedtime and increased by 25 milligrams, until the patient is cont side effects, or reaches 150 milligrams/day (Castleden et al, 1981).

b) A review for utilizing antidepressants in the treatment of depression in geriatric patients has been pub 1985).

B) Imipramine Pamoate

1) GENERAL INFORMATION

a) Dosage reduction is recommended in elderly patients since this patient population is reported to have incidence of confusional-type reactions and other central nervous system symptoms while on tricyclic an therapy (Davies et al, 1971). A one-third to one-half reduction in tricyclic antidepressant dosage is sugge An increase in age is correlated with elevated steady-state serum levels of imipramine, desipramine and (Hicks et al, 1981a; Benetello et al, 1990).

b) It is recommended that therapy in geriatric patients is initiated with imipramine hydrochloride tablets (orally per day (Prod Info TOFRANIL(R) tablets, 2005)) since lower dosages should be used. Imipramine may be used once a total daily dosage of 75 mg or higher is established (Prod Info TOFRANIL-PM(R) ca

1.3.5 Dosage Adjustment During Dialysis

A) Imipramine Hydrochloride

1) HEMODIALYSIS

a) No dosage supplementation is required following hemodialysis or peritoneal dialysis (Bennett et al, 19

2) PERITONEAL DIALYSIS

a) No dosage supplementation is required following hemodialysis or peritoneal dialysis (Bennett et al, 19

B) Imipramine Pamoate

1) HEMODIALYSIS

a) No dosage supplementation is required following hemodialysis or peritoneal dialysis (Bennett et al, 19

2) PERITONEAL DIALYSIS

a) No dosage supplementation is required following hemodialysis or peritoneal dialysis (Bennett et al, 19

1.3.6 Dosage in Other Disease States

A) Imipramine Hydrochloride

1) DIABETES

a) Studies in mice have shown that imipramine stimulates insulin secretion in the presence of low glucos whereas it inhibits insulin secretion in the presence of high glucose levels. Imipramine should be adminis to type II diabetic patients (El-Dakhakhny et al, 1996).

B) Imipramine Pamoate

1) DIABETES

a) Studies in mice have shown that imipramine stimulates insulin secretion in the presence of low glucos whereas it inhibits insulin secretion in the presence of high glucose levels. Imipramine should be adminis to type II diabetic patients (El-Dakhakhny et al, 1996).

1.4 Pediatric Dosage

Normal Dosage

Dosage in Renal Failure

Dosage Adjustment During Dialysis

1.4.1 Normal Dosage

Imipramine

Imipramine Hydrochloride

Imipramine Pamoate

1.4.1.A Imipramine

1.4.1.A.1 Anorexia nervosa

See Drug Consult reference: ANOREXIA NERVOSA - DRUG THERAPY

1.4.1.B Imipramine Hydrochloride

1.4.1.B.1 Oral route

Attention deficit hyperactivity disorder, predominantly inattentive type

Depression

Nocturnal enuresis

1.4.1.B.1.a Attention deficit hyperactivity disorder, predominantly inattentive type

1) The dose used ranges from 25 to 100 milligrams/day and tends to be lower than those needed tc Children tend to respond within 24 hours after initiating therapy. The monitoring of serum imipramine levels may be useful. The serum levels associated with reported responses have been 10 to 54 nan imipramine and 10 to 65 nanograms/milliliter of desipramine (Hussey & Wright, 1970)(Linnoila et al, 1985; Winsberg et al, 1980).

1.4.1.B.1.b Depression

1) For the treatment of depression in children the initial starting dose of imipramine is 1.5 milligrams given in 1 to 4 divided doses with dosage increased 1 milligram/kilogram every 3 to 4 days. The dail imipramine should not exceed 5 milligrams/kilogram/day, and children receiving doses of 3.5 milligra or more should be closely monitored (Taketomo et al, 1992).

2) Adolescents should initially receive 30 to 40 milligrams/day. Dosages exceeding 100 mg/day are necessary (Prod Info TOFRANIL(R) tablets, 2005).

1.4.1.B.1.c Nocturnal enuresis

1) Children, aged 6 and over, should initially receive 25 milligrams orally, 1 hour before bedtime. If s response does not occur within 1 week, the dose may be increased by 25 milligrams/day: children u receive a maximum daily dose of 50 milligrams and children over 12 may receive 75 milligrams (Pro 1995b; Taketomo et al, 1992).

2) In early-night bedwetters, it is more effective to give the drug earlier and in divided doses, ie, 25 afternoon and then at bedtime (Prod Info Tofranil(R), 1995b).

3) The daily dose of imipramine should not exceed 2.5 milligrams/kilogram, or 50 milligrams at bedt years of age, or 75 milligrams at bedtime if 12 years of age or older (Prod Info Tofranil(R), 1995b; Ta 1992; Denniston et al, 1994).

4) The optimization of imipramine dose in the treatment of enuresis should be guided by clinical res imipramine/desipramine levels. The use of serum imipramine/desipramine levels may help determin with the drug regimen and outliers. The use of a Bayesian dosing method offers no major advantage method used in combination using serum level data. However, the Bayesian method may be useful possible analytical errors, noncompliance, and non-steady state serum concentrations (Tamayo et a

1.4.1.C Imipramine Pamoate

1.4.1.C.1 Oral route

1.4.1.C.1.a Depression

1) Tofranil-PM(R) should not be used in children because of the increased potential for overdose du capsule potency (75 mg, 100 mg, 125 mg and 150 mg capsule) (Prod Info TOFRANIL-PM(R) capsu

1.4.2 Dosage in Renal Failure

A) Imipramine Hydrochloride

1) No specific dosage adjustment is necessary (Bennett et al, 1994).

B) Imipramine Pamoate

1) No specific dosage adjustment is necessary (Bennett et al, 1994).

1.4.4 Dosage Adjustment During Dialysis

A) Imipramine Hydrochloride

1) HEMODIALYSIS

a) No dosage supplementation is required following hemodialysis or peritoneal dialysis (Bennett et al, 19

2) PERITONEAL DIALYSIS

a) No dosage supplementation is required following hemodialysis or peritoneal dialysis (Bennett et al, 19

B) Imipramine Pamoate

1) HEMODIALYSIS

a) No dosage supplementation is required following hemodialysis or peritoneal dialysis (Bennett et al, 19

2) PERITONEAL DIALYSIS

a) No dosage supplementation is required following hemodialysis or peritoneal dialysis (Bennett et al, 19

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Initial Response

a) Depression, oral: 7 to 21 days (Prod Info Tofranil(R), 1995a); (Greenblatt & Shader, 1975).

2) Peak Response

a) Depression, oral: 4 to 6 weeks (Eisenberg & Asnis, 1986).

2.2 Drug Concentration Levels

A) Therapeutic Drug Concentration

1) Endogenous depression, greater than 200 ng/mL (IMIPRAMINE plus DESIPRAMINE) (Peselow et al, 1983; G 1977).

2) Prepubertal depressive symptoms, 200 to 225 ng/mL (IMIPRAMINE plus DESIPRAMINE), minimum level of 1 (Preskorn et al, 1983).

3) Hyperactivity, 10 to 54 ng/mL (imipramine only) (Linnoila et al, 1979).

4) Enuresis in children, no correlation (Fritz et al, 1994; Manglick & Buchanan, 1992; DeVane et al, 1984).

a) Some studies have shown levels of 80 to 150 ng/mL (IMIPRAMINE plus DESIPRAMINE) to be effective (I 1980a; Fernandez de Gatta et al, 1984).

5) Ventricular premature depolarizations, 74 to 385 ng/mL (IMIPRAMINE plus desipramine) (Giardina et al, 1983)

6) Diabetic neuropathy, less than 100 nmol/L (IMIPRAMINE plus DESIPRAMINE); 400 to 500 nmol/L required in (Sindrup et al, 1990).

B) Time to Peak Concentration

1) Oral: 1 hour (Gram & Christiansen, 1975).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

Extracorporeal Elimination

2.3.1 Absorption

A) Bioavailability

1) Oral, tablet: 94% to 96% (Heck et al, 1979).

a) The bioavailability of IMIPRAMINE from tablet and syrup form is equivalent (Gagnon et al, 1980).

B) Effects of Food

1) None (Abernethy et al, 1984h).

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding

a) 89% (Kristensen, 1983).

1) Patients with severe burns (35% to 85% BSA) exhibit increased binding during the initial convale 20 days) (Martyn et al, 1984).

2) The free fraction is reduced in cancer patients (Schulz & Luttrell, 1982).

3) The free fraction in rheumatoid arthritis patients is slightly lower than in healthy control subjects ((Kristensen, 1985).

2) OTHER DISTRIBUTION SITES

a) Tissue

1) At steady-state, tissue concentrations are greatest in the lung followed by the brain, the adipose (Sallee & Pollock, 1990a).

B) Distribution Kinetics

1) Volume of Distribution
a) 10 to 20 L/kg (Bennett et al, 1994a; Sallee & Pollock, 1990a).

2.3.3 Metabolism
A) Metabolism Sites and Kinetics
1) Liver, extensive (Gram & Christensen, 1975)(Olivier-Martin et al, 1975).
a) First-pass metabolism occurs with extensive metabolism to conjugated and non-conjugated metaboli
et al, 1975).
b) N-demethylation of imipramine is under pharmacogenic control of CYP2C19 (Morinobu et al, 1997).
c) Hydroxylation may become saturated resulting in drug accumulation (Brosen et al, 1986).
B) Metabolites
1) N-desmethyl metabolite (DESIPRAMINE), active (Drayer, 1976).
a) Patients with recurrent episodes of depression have a significantly lower IMIPRAMINE/DESIPRAMIN
those who do not experience recurrences (1.73) (Tollefson et al, 1985).
b) DESIPRAMINE exists in a 0.3 to 15.0 ratio to IMIPRAMINE in plasma (Nagy & Treiber, 1973).
2) 2-hydroxy IMIPRAMINE, active (Buckley, 1975).
a) Reported to depress cardiac contractility in dogs (Buckley, 1975).
3) 2-hydroxydesipramine, active (DeVane & Jusko, 1981).
a) Serum concentration of the hydroxy metabolites may have some relationship to the drug's toxicity (De
DeVane & Jusko, 1981a).

2.3.4 Excretion
A) Kidney
1) Renal Excretion (%)
a) 0.05 to 0.1% (DESIPRAMINE only) (Gram & Christiansen, 1975).
2) IMIPRAMINE metabolites are excreted in urine (Gram et al, 1971; Crammer et al, 1969).

2.3.5 Elimination Half-life
A) Parent Compound
1) ELIMINATION HALF-LIFE
a) 6 to 18 hours (Benetello et al, 1990a; Sutfin et al, 1984).
1) The half-life of IMIPRAMINE in children ranges from 6 to 15 hours (Rancurello, 1985).
2) In elderly patients the serum half-life ranges from 25 to 30 hours (Benetello et al, 1990a; Abernet
3) The terminal half-life of IMIPRAMINE and the active metabolites is 1.5 to 2.0 times longer followi
administration than that observed following oral administration (Sutfin et al, 1984).
B) Metabolites
1) DESIPRAMINE, 12 to 36 hours (Sutfin et al, 1984).
2) 2-hydroxyimipramine, 6 to 18 hours (Sutfin et al, 1984).
3) 2-hydroxydesipramine, 12 to 36 hours (Sutfin et al, 1984).

2.3.6 Extracorporeal Elimination
A) Hemodialysis
1) Dialyzable: No (Prod Info Tofranil(R), 1995a; Asbach & Schuler, 1974; Bailey et al, 1974; Wright & Cooke
B) Peritoneal
1) Dialyzable: No (Prod Info Tofranil(R), 1995a; Asbach & Schuler, 1974; Bailey et al, 1974; Wright & Cooke

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING
1) Imipramine Hydrochloride
a) Oral (Tablet)
Suicidality and Antidepressant Drugs
Antidepressants increased the risk compared to placebo of suicidal thinking and behavior (suicidality) in child
and young adults in short-term studies of major depressive disorder (MDD) and other psychiatric disorders. A
the use of imipramine hydrochloride or any other antidepressant in a child, adolescent, or young adult must b

with the clinical need. Short-term studies did not show an increase in the risk of suicidality with antidepressar placebo in adults beyond age 24; there was a reduction in risk with antidepressants compared to placebo in a older. Depression and certain other psychiatric disorders are themselves associated with increases in the risk Patients of all ages who are started on antidepressant therapy should be monitored appropriately and observ clinical worsening, suicidality, or unusual changes in behavior. Families and caregivers should be advised of observation and communication with the prescriber. Imipramine hydrochloride is not approved for use in pedi Info imipramine hcl oral tablets, 2007).

2) Imipramine Pamoate

a) Oral (Capsule)

Suicidality and Antidepressant Drugs

Antidepressants increased the risk compared to placebo of suicidal thinking and behavior (suicidality) in child and young adults in short-term studies of major depressive disorder (MDD) and other psychiatric disorders. A the use of imipramine pamoate or any other antidepressant in a child, adolescent, or young adult must balanc clinical need. Short-term studies did not show an increase in the risk of suicidality with antidepressants comp adults beyond age 24; there was a reduction in risk with antidepressants compared to placebo in adults aged Depression and certain other psychiatric disorders are themselves associated with increases in the risk of su all ages who are started on antidepressant therapy should be monitored appropriately and observed closely f worsening, suicidality, or unusual changes in behavior. Families and caregivers should be advised of the nee observation and communication with the prescriber. Imipramine pamoate is not approved for use in pediatric TOFRANIL-PM(R) oral capsules, 2007).

3.1 Contraindications

A) Imipramine Hydrochloride

1) coadministration with a MAOI or use within 14 days of discontinuing a MAOI; may cause serious reactions (eg crisis, convulsive seizures, death) (Prod Info imipramine hcl oral tablets, 2007)

2) hypersensitivity to dibenzazepines; risk of cross-sensitivity reactions (Prod Info imipramine hcl oral tablets, 200

3) hypersensitivity to imipramine hydrochloride (Prod Info imipramine hcl oral tablets, 2007)

4) myocardial infarction, during the acute recovery period (Prod Info imipramine hcl oral tablets, 2007)

B) Imipramine Pamoate

1) coadministration with an MAOI or use within 14 days of discontinuing an MAOI; may cause serious reactions (crisis, severe convulsive seizures, death) (Prod Info TOFRANIL-PM(R) oral capsules, 2007)

2) hypersensitivity to dibenzazepines; risk of cross-sensitivity reactions (Prod Info TOFRANIL-PM(R) oral capsule

3) hypersensitivity to imipramine pamoate (Prod Info TOFRANIL-PM(R) oral capsules, 2007)

4) myocardial infarction, during the acute recovery period (Prod Info TOFRANIL-PM(R) oral capsules, 2007)

3.2 Precautions

A) Imipramine Hydrochloride

1) suicidal ideation and behavior or worsening depression, increased risk, particularly in children, adolescents, ar during the first few months of therapy or following changes in dosage (Prod Info imipramine hcl oral tablets, 2007)

2) alcohol, excessive use; increased danger of intentional or unintentional imipramine overdose (Prod Info imipra tablets, 2007)

3) bipolar disorder, in patients at risk; increased risk of precipitation of a mixed/manic episode with only antidepre (Prod Info imipramine hcl oral tablets, 2007)

4) cardiovascular disease, current or history; may cause cardiac conduction defects, arrhythmias, congestive hea myocardial infarction, stoke, and tachycardia (Prod Info imipramine hcl oral tablets, 2007)

5) concurrent use with electroshock therapy; may increase hazards of electroshock therapy (Prod Info imipramine 2007)

6) cyclic-type psychiatric disorders, history; may cause mania or hypomania (Prod Info imipramine hcl oral tablets

7) elderly patients; increased risk of developing cardiac abnormalities (Prod Info imipramine hcl oral tablets, 2007

8) excessive exposure to sunlight; may cause photosensitization (Prod Info imipramine hcl oral tablets, 2007)

9) glaucoma, narrow-angle, history of; due to anticholinergic effects of imipramine hydrochloride (Prod Info imipra tablets, 2007)

10) hepatic function, significantly impaired (Prod Info imipramine hcl oral tablets, 2007)

11) hyperthyroidism or concurrent use of thyroid medications; may increase risk of cardiovascular toxicity (Prod I oral tablets, 2007)

12) intraocular pressure, increased; exacerbation of condition due to cholinergic antagonism (Prod Info imipramir 2007)

13) neutrophil depression, pathological, may occur (Prod Info imipramine hcl oral tablets, 2007)

14) renal function, significantly impaired (Prod Info imipramine hcl oral tablets, 2007)

15) schizophrenia; may activate psychosis (Prod Info imipramine hcl oral tablets, 2007)

16) seizure disorder, history; may lower the convulsive threshold (Prod Info imipramine hcl oral tablets, 2007)

17) surgery, elective (Prod Info imipramine hcl oral tablets, 2007)

18) urinary retention, history of; due to anticholinergic effects of imipramine hydrochloride (Prod Info imipramine h 2007)

B) Imipramine Pamoate

1) suicidal ideation and behavior or worsening depression; increased risk, particularly in children, adolescents, ar during the first few months of therapy or following changes in dosage (Prod Info TOFRANIL-PM(R) oral capsules,

2) alcohol, excessive use; increased danger of intentional or unintentional imipramine overdose (Prod Info TOFR

capsules, 2007)
3) bipolar disorder; increased risk of precipitation of a mixed/manic episode with only antidepressant treatment (F
TOFRANIL-PM(R) oral capsules, 2007)
4) cardiovascular disease, current or history; may increase risk of tachycardia, congestive heart failure, cardiac c
arrhythmias, myocardial infarction (MI), and stroke (Prod Info TOFRANIL-PM(R) oral capsules, 2007)
5) concurrent use with electroshock therapy; may increase hazards of electroshock therapy (Prod Info TOFRANI
capsules, 2007)
6) elderly patients; may increase risk of ECG changes (Prod Info TOFRANIL-PM(R) oral capsules, 2007)
7) glaucoma, history of narrow-angle; exacerbation of condition due to cholinergic antagonism (Prod Info TOFRA
capsules, 2007)
8) hyperthyroidism or concurrent use of thyroid medications; may cause cardiac toxicity (Prod Info TOFRANIL-PM
2007)
9) intraocular pressure, increased; exacerbation of condition due to cholinergic antagonism (Prod Info TOFRANI
capsules, 2007)
10) mania/hypomania; risk of disease activation (Prod Info TOFRANIL-PM(R) oral capsules, 2007)
11) schizophrenia; may activate psychosis (Prod Info TOFRANIL-PM(R) oral capsules, 2007)
12) seizure disorder, history; may lower the convulsive threshold (Prod Info TOFRANIL-PM(R) oral capsules, 200
13) surgery, elective (Prod Info TOFRANIL-PM(R) oral capsules, 2007)
14) urinary retention, history of; exacerbation of condition due to cholinergic antagonism (Prod Info TOFRANIL-P
capsules, 2007)

Vasoconstriction

3.3.1.A Abnormal ECG

1) Summary

a) ECG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include INCF RATE, PROLONGED PR INTERVAL, INTRAVENTRICULAR CONDUCTION DELAYS, INCREASED CC INTERVAL (QTc), and FLATTENED T WAVES (Marshall & Forker, 1982ak).

2) In one comparative study, phenelzine and mianserin were less likely than imipramine or amitriptyline to pr cardiac conduction, in patients without cardiac disease. Prolongation of the PR interval was observed with im amitriptyline but not with phenelzine or mianserin. There was a trend towards prolongation of the QRS compl tricyclics, as well as the QTc interval; no QRS changes were observed with phenelzine or mianserin and ther phenelzine to decrease the QTc interval, whereas mianserin produced no effect on the QTc interval. These d mianserin and phenelzine are less likely than imipramine or amitriptyline to produce heart block in patients wi mianserin appeared to be the least likely of the four agents to induce cardiac conduction abnormalities (McGı

3) Forty-four depressed patients receiving imipramine 3.5 mg/kg/day for 4 weeks demonstrated prolonged P intervals, lowered T-wave amplitude, and increased heart rate compared to a 2 week drug-free period. None developed severe intraventricular conduction abnormalities nor high-grade AV block (Giardina et al, 1979).

4) IMIPRAMINE therapy in the elderly has been associated with increased heart rate and isolated ECG comp (shortening of the QT interval, changes in ST segments, and T waves) (Hayes et al, 1983). Two elderly, depr with preexisting cardiac arrhythmias, had significant increases in PR interval, QRS segment, and QTc interva treatment with oral imipramine 3.5 mg/kg/day. Both patients also had a reduction in atrial and ventricular prer depolarizations during therapy (Bigger et al, 1977b).

3.3.1.B Cardiac dysrhythmia

1) Summary

a) Production and suppression of atrial and ventricular arrhythmias have been reported in patients recei (Marshall & Forker, 1982ak; Raskind et al, 1982; Levin et al, 1985; Williams & Sherter, 1971). Multifocal ventricular contractions occurred in a 62-year-old woman following withdrawal of IMIPRAMINE. The depı preexisting nonspecific intraventricular conduction delay (Regan et al, 1989).

2) ARRHYTHMIAS ADULT

a) A 25-year-old quadriplegic patient receiving oral imipramine 200 mg at bedtime developed a life-threa arrhythmia shortly after achieving therapeutic levels (Levin et al, 1985). This may have occurred because patients frequently have autonomic supersensitivity. Thus the autonomic effects of imipramine may have cardiac arrhythmia.

b) A 37-year-old black male, who was receiving antihypertensive therapy (guanethidine, hydralazine, an experienced cardiac stand still and died following treatment with 25 mg of imipramine TID for 5 days, des discontinuation of all drugs (Williams & Sherter, 1971). In other reports, discontinuation of imipramine us improvement of cardiac arrhythmias although in some cases of AV block, a pacemaker was required (Ra Moorehead & Knox, 1965; Kantor et al, 1975). Arrhythmias, usually supraventricular or VENTRICULAR T have also been reported following acute overdose of imipramine (Brown et al, 1972; Lund-Larsen & Sive

c) The cardiovascular effects associated with imipramine therapy were evaluated in 12 men with stable disease who had become depressed following a myocardial infarction or coronary artery bypass-graft su al, 1982). All other drug regimens were kept constant during the course of the study. The mean maximur was 125 mg/day with a mean plasma level (imipramine plus desmethylimipramine) of 194 ng/mL. During imipramine therapy some patients experienced an antiarrhythmic effect from the imipramine, observed a premature ventricular contractions. Other cardiovascular side effects observed in this study included a m PR interval, QT interval, and heart rate, and orthostatic blood pressure changes.

3) ARRHYTHMIAS - PEDIATRIC

a) The cardiovascular status of 23 pediatric patients (ages 5 to 17 years), who were candidates for imipı

(eg, oppositional behavior, conduct disorders, and depression), were evaluated before and after the initia therapy. Each patient was started on 1.5 mg/kg/day which could be increased to a maximum of 5 mg/kg/ divided doses. The follow-up cardiovascular evaluation was conducted 10 to 14 days after clinical improv condition or steady-state serum concentration of between 150 ng/mL and 250 ng/mL. Resting heart rate PR interval lengthened (average 21.2 msec) in all 23 children (p less than 0.001). One child developed M while on imipramine, but this child had a resting PR interval of 176 msec before the initiation of imipramir on these findings the authors support the recommendation that baseline electrocardiogram should be co patients. In addition, patients with a family history of sudden death, a baseline PR interval greater than th for age, or any alterations in intraventricular conduction are candidates for ambulatory Holter monitor wh imipramine therapy (Fletcher et al, 1993).

3.3.1.C Cardiogenic shock

1) An imipramine-provoked paradoxical pheochromocytoma crisis occurred in a 35-year-old male who prese with severe cardiogenic shock after taking two unknown doses of imipramine for headaches. The hypotensio unresponsive to fluids and anatropes (Ferguson, 1994). Subsequent CT scan revealed a pheochromocytoma confirmed with other diagnostic tests. Previous cases reports of the adverse effects of imipramine in patients pheochromocytoma have resulted in hypertensive crises. It appears that imipramine should be avoided or us patients with known or suspected pheochromocytoma.

3.3.1.D Cardiomyopathy

1) CONGESTIVE CARDIOMYOPATHY was reported in a 50-year-old male after receiving tricyclic antidepre period (amitriptyline/perphenazine for 6 months, then imipramine 150 mg/day for 4 years). The patient experi onset of weakness, shortness of breath, and pedal edema over 2 months prior to admission. Evaluation reve and interstitial edema on chest X-ray and EKG revealed bilateral enlargement. The patient improved somewh furosemide and hydralazine but remained severely disabled (functional class 3) (Howland et al, 1983). A caus relationship was not definitely established in this case.

3.3.1.E Cardiovascular finding

1) Summary

a) Some of the following adverse effects have not been associated with imipramine but have occurred w antidepressants. These include MYOCARDIAL INFARCTION, STROKE, HEART BLOCK, precipitation o HEART FAILURE, ECG CHANGES, ORTHOSTATIC HYPOTENSION, HYPERTENSION, and TACHYC Tofranil(R), 1995). ECG effects reported in patients receiving therapeutic doses of tricyclic antidepressar INCREASED HEART RATE, PROLONGED PR INTERVAL, INTRAVENTRICULAR CONDUCTION DEL INCREASED CORRECTED QT INTERVAL (QTc), and FLATTENED T WAVES (Marshall & Forker, 198 shock, vasoconstriction, vasospasm of the hands and feet (ACROCYANOSIS), and myocarditis have ea in 1 to 2 patients (Appelbaum & Kapoor, 1983; Anderson & Morris, 1988; Ferguson, 1994; Morrow et al,

2) Two authors reported that tricyclic antidepressants when given in therapeutic doses are essentially free of cardiovascular effects in patients without cardiovascular disease and may improve the status of patients with arrhythmias (Glassman & Bigger, 1981; Roose et al, 1987a). The development of second degree atrioventric significantly greater in patients with preexisting bundle-branch block than in patients with normal electrocardio hypotension occurred more frequently in patients with conduction abnormalities (Roose et al, 1987a).

3.3.1.F Dead - sudden death

1) According to one study, the use of higher-dose tricyclic antidepressants (TCAs) was associated with an in SUDDEN CARDIAC DEATH, while lower doses did not increase this risk. In a cohort study including 481,744 cases of sudden cardiac death occurring in a community setting, researchers found that compared to non-us of TCAs was associated with a dose-related increase in the risk of sudden cardiac death. For doses lower tha (mg) (amitriptyline or its equivalent), the rate ratio was 0.97 (95% CI, 0.72 to 1.29), however this increased to 1.04 to 6.12) for doses of 300 mg or more (p=0.03, test for dose-response). In the entire cohort, users of TCA mg or higher (amitriptyline or its equivalent) had a 41% increased rate of sudden cardiac death (rate ratio, 1.4 1.95). However, TCAs taken in doses of less than 100 mg (amitriptyline or its equivalent) were not associated risk of sudden cardiac death in the entire cohort or in any subgroups, including persons with treated cardiova Use of selective serotonin reuptake inhibitors was not associated with an increased risk of sudden cardiac de 0.95; 95% CI, 0.42 to 2.15) (Ray et al, 2004).

2) An 8-year-old boy died of cardiac arrest that was attributed to imipramine toxicity. Although there were no taken more than the prescribed dose, the dose at time of death (6.9 milligrams/kilogram/day (mg/kg/day)) wa excess of the recommended dose of 5 mg/kg/day. One month after his dose had been raised to 100 mg twice (approximately a year after starting treatment), he complained of his heart hurting and of being dizzy. Two mo dextroamphetamine 5 mg/day was added to his regimen and was raised to 10 mg/day one month later. Two initial cardiac episode, he again complained of his heart hurting. One month later, while playing basketball, he arrest. On autopsy (20 hours after death), highly elevated venous and ventricular levels of imipramine and its desipramine, were the only abnormalities found (Varley, 2000).

3.3.1.G Hypertension

1) A 57-year-old female treated with 150 mg/day of imipramine for 12 days developed hypertension (Hessov pressure before therapy was noted to be 140/90 mmHg and 3 days after initiating imipramine for endogenous blood pressure rose to 150/110 mmHg. Nine days after initiating therapy the blood pressure had risen to 175/

no associated changes in the EKG. Twenty-four hour urinary excretion of noradrenaline-adrenaline and vanill
was normal. Dosage reduction failed to lower blood pressure and so the drug was discontinued. After 3 week
pressure was close to or at controlled levels.
2) Imipramine, 75 mg at bedtime, produced a rise in diastolic blood pressure in 18 enuretic boys (mean age
diastolic pressure increased by 8 +/- 6 mmHG and standing by 10 +/- 12 mmHG (Lake et al, 1979).

3.3.1.H Hypotension

1) Summary: ORTHOSTATIC HYPOTENSION has been reported in patients receiving imipramine (Glassma
Koehl & Wenzel, 1971; Glassman et al, 1979). Elderly depressed patients (n=45) may be at an increased risk
ORTHOSTATIC HYPOTENSION if they have preexisting severe heart disease, impaired left ventricular funct
concurrent cardiovascular medications. Another factor, that requires further assessment, was increased forea
Individuals with increased forearm resistance had a greater frequency of imipramine-induced orthostatic hypo
with normal or low forearm resistance. Patients were receiving therapeutic doses of imipramine (Glassman et
2) A 9-year-old white female treated with imipramine 25 mg twice daily for 9 days developed POSTURAL HY
the fifth day of therapy, the child developed decreased appetite, dry mouth, and constipation. During the sixth
therapy, she developed WEAKNESS, and DIZZINESS upon standing, pallor, diaphoresis, vomiting when pro
rapid heart rate. Physical exam revealed a supine pulse rate of 120/min with supine blood pressure of 100/70
pressure was noted to fall to 80/50 mmHg and pulse rate increased to 170/min, and the patient also became
sweated profusely. Upon standing, blood pressure dropped to 60/0 mmHg with pulse increasing to greater th
association with a SYNCOPAL ATTACK. An ECG revealed a FIRST DEGREE AV BLOCK. Discontinuation o
resulted in improvement of the patient's condition over the 7 day hospital course with subsequent normalizati
& Wenzel, 1971).
3) A study of 44 depressed adults receiving therapeutic doses of imipramine (average 245 mg/day in males,
females) demonstrated a significant decrease in blood pressure upon standing; average decrease during imi
was 26.1 mmHg during therapy and 10.9 mmHg prior to therapy. This decrease was independent of age, pla
preexisting heart rate (Glassman et al, 1979).
4) Forty-five elderly patients (mean age 63.6) were initially treated with 25 mg/day imipramine with dose bein
mg/day (Branconnier et al, 1983). Cardiovascular function was assessed 3 times during the course of the stu
day 7 and day 28). On day 7 and day 28 the patient exhibited a significant orthostatic change in diastolic bloo
increase in heart rate compared to pretreatment.
5) The cardiovascular effects of imipramine, doxepin, and placebo were compared in 24 depressed patients
The tricyclic antidepressants had no effects on left ventricular ejection fraction but did cause orthostatic chan
pressure. The imipramine therapy was associated with a reduction in premature ventricular contractions, whi
consistently seen in the placebo and doxepin treated patients. Based on the results of this study it would app
patients with preexisting heart disease, without any severe impairment of myocardial performance, can be tre
imipramine or doxepin without an adverse effect on ventricular rhythm or hemodynamic function (Veith et al,

3.3.1.I Myocarditis

1) A 54-year-old female developed myocarditis and hepatitis after restarting imipramine therapy. The patient
later secondary to the myocarditis. It could not be determined if this rare hypersensitivity reaction was directly
imipramine, its desipramine metabolite, or the combination of imipramine and desipramine (Morrow et al, 198

3.3.1.J Vasoconstriction

1) A 37-year-old female, developed severe and prolonged episodes of vasospasm of the hands within 10 da
discontinuation of her amitriptyline therapy and the initiation of 150 mg/day imipramine. Vasospasm reoccurre
rechallenge (Appelbaum & Kapoor, 1983).
2) ACROCYANOSIS of the hands and feet occurred in an 11-year-old girl following imipramine therapy (25 r
approximately 10 weeks) for nocturnal enuresis (Anderson & Morris, 1988). The patient developed initial sym
after initiation of treatment (painful swelling of metacarpophalangeal joints of the feet). Examination after 10 v
revealed cold, blue and moist hands and feet which blanched on pressure. LIVEDO RETICULARIS was obse
forearms. Withdrawal of imipramine resulted in resolution of symptoms in 3 days.

3.3.2 Dermatologic Effects

3.3.2.A Discoloration of skin

1) HYPERPIGMENTATION was described in 4 women (53 to 75 years old) receiving imipramine 150 to 375
years (Ming et al, 1999). Hyperpigmentation began after 2 to 11 years of use. Coloration was described as sl
women and as dark brown or golden brown in the other 2. The site of the reaction was in the face, chest, arm
woman also had a darkening of her iris. The pigmentation disappeared over 6 to 12 months in 2 of the wome
discontinue imipramine.
2) A 46-year-old male was treated with imipramine 75 to 100 mg three times/day for 9 years and developed
pigmentation of his face, neck, and fingers (Hare, 1970). Characteristically the skin of the nose and ears was
the patient had normal skin folds with no ophthalmological disturbances.
3) A 48-year-old white female developed a slate-gray discoloration in sun-exposed areas, predominately her
both hands, and eyes, after receiving imipramine 150 mg/day for five years (Hashimoto et al, 1991). These di
became lighter after discontinuation of the imipramine therapy and returned to normal within one year.

3.3.3 Endocrine/Metabolic Effects

Acute intermittent porphyria

Anticholinergic adverse reaction

Galactorrhea

Hyperthyroidism

Hypoglycemia

Syndrome of inappropriate antidiuretic hormone secretion

3.3.3.A Acute intermittent porphyria

See Drug Consult reference: DRUGS CONSIDERED UNSAFE- ACUTE PORPHYRIAS

3.3.3.B Anticholinergic adverse reaction

1) IMIPRAMINE HYDROCHLORIDE may produce a slightly higher incidence of anticholinergic side effects t
salt due to higher peak concentrations with this salt form; however, this has not been proven. Any dissimilarit
when changed from one salt form to the other is most likely psychological, and is probably due to changes in
between the two products (ie hydrochloride salt - tablet, pamoate salt - capsule (Prod Info Tofranil PM(R), 19
Tofranil(R), 1990; Pers Comm, 1982a).

3.3.3.C Galactorrhea

1) A 34-year-old female treated with imipramine 75 to 100 mg/day for 6 months developed spontaneous gala
Discontinuation of imipramine resulted in subsiding of the LACTATION which recurred when therapy with imi
resumed. During imipramine therapy, it was noted that the patient had low levels of serum serotonin and urin
The author postulated that the mechanism for the galactorrhea was similar to that seen with reserpine which
of the normal hypothalamic inhibition of pituitary prolactin secretion (Klein, 1964).

3.3.3.D Hyperthyroidism

1) A case of a 9.5-year-old female was treated with 25 mg/day oral imipramine for enuresis and also receive
thyroid therapy; the patient demonstrated increased restlessness, hyperkineticism, nervousness, easy fatigab
and warm skin. Physical exam revealed a resting heart rate of 120 beats/min with deep tendon reflexes noted
without clonus. Lab values revealed a thyroxine level of 9.2 mg/dL and a triiodothyronine uptake of 31.9%. EI
sinus tachycardia with ST-T wave changes and basal metabolic rate was elevated by 33%. Discontinuing imi
continuing the same dose of thyroid resulted in the child becoming euthyroid (Colantonio & Orson, 1974).

3.3.3.E Hypoglycemia

1) A 50-year-old male treated with 200 mg/d of imipramine developed severe hypoglycemia (Shrivastava & E
Six days after starting imipramine therapy the patient complained of fatigue, dizziness, loss of weight, and inc
On laboratory examination, he was found to have a nonfasting serum glucose of 57 mg/dL with all other lab v
normal limits. Imipramine therapy was discontinued and his serum glucose returned to 79 mg/dL and sympto
Following an unintentional rechallenge the man began complaining of weakness and dizziness one week late
serum glucose was 34 mg/dL. Following discontinuation of the imipramine therapy his serum glucose returne
2) Imipramine may increase an individual's sensitivity to insulin-induced hypoglycemia, but does not affect th
regulatory response of ACTH and cortisol (Kathol et al, 1991).

3.3.3.F Syndrome of inappropriate antidiuretic hormone secretion

1) Imipramine was associated with SIADH in a 78-year-old woman during therapy for major depression. The
imipramine 25 to 50 mg orally daily for approximately 3 months prior to admission. HYPONATREMIA was ob
admission and subsided during a 9 day interval without imipramine therapy. The patient subsequently develo
bupropion and upon rechallenge with imipramine (Liskin et al, 1984).
2) A 73-year-old thin and frail white female was admitted to a psychiatric unit for evaluation after deliberate ir
cleaning fluid (Colgate, 1993). She was diagnosed with severe depression and started on paroxetine therapy
the paroxetine was discontinued because the depression was getting worse. A single session of electroconvu
tried and then she was started on imipramine syrup, 25 mg twice daily. The dose was increased to 125 mg pe
divided doses, and diazepam was used in doses up to 10 mg/day to control her agitation. Over the next few v
condition improved, but she did fall and sustained a fractured left femur neck. Her mental condition continued
her mobility deteriorated and she suffered several more falls. Physical examination revealed a profound orthc
blood pressure (40 mmHg) and she had hyponatremia (124 mmol/l) and a low serum osmolality (266 mOsm/
intoxication was ruled out and a diagnosis of inappropriate secretion of antidiuretic hormone was made. The i
was then held. Over the next ten days her serum sodium levels returned to the normal range.

3.3.4 Gastrointestinal Effects

Colitis

Xerostomia

3.3.4.A Colitis

1) ISCHEMIC COLITIS, requiring surgical intervention, has been reported in one patient following the ingesti quantity of imipramine (Patel et al, 1992). The individual was a 38-year-old female with a past medical history hospitalized following an ingestion of unspecified quantity of imipramine. Her serum imipramine level was 1,0 micrograms/milliliter. Over the next few days her abdomen became increasingly distended with rebound tend absence of bowel sounds. Laparotomy revealed a necrotic ascending and transverse colon which was subse and the patient's condition improved.

3.3.4.B Xerostomia

1) XEROSTOMIA is frequently associated with imipramine therapy in usual therapeutic doses (150 mg/day). mouth is often associated with gum shrinkage, inflammation of the oral cavity, stomatitis, cracking of the lips mouth, pseudomembrane formation, hairy tongue with white or black or bald beefy red tongue, ill-fitting dentu and oral moniliasis. Discontinuation of the drug and/or treatment with pilocarpine (5 mg four times/day) usuall increase of salivation (Pollack, 1964; Winer & Bahn, 1967).

2) Imipramine, 75 mg every day, given to 12 volunteers in a placebo controlled study caused a significant re secretion rate (Sheth et al, 1979a).

3) A comparison of 5 different antidepressants on salivary flow reveals that amitriptyline and doxepin had the salivation and desipramine the least (Blackwell et al, 1980). Imipramine and nortriptyline were intermediate a in their effects.

3.3.5 Hematologic Effects

3.3.5.A Hematology finding

1) Summary

a) Some of the following adverse effects have not been associated with imipramine but have occurred w antidepressants. These include BONE MARROW DEPRESSION including AGRANULOCYTOSIS, EOS PURPURA, and THROMBOCYTOPENIA (Prod Info Tofranil(R), 1995). IMIPRAMINE-induced agranuloc about 10 cases have been reported (Gravenor et al, 1986).

2) A 59-year-old white female treated with imipramine 50 mg three times per day for 2 months developed ag which was fatal. The patient died 2 weeks after discontinuing imipramine (Hnatko, 1965).

3) A 55-year-old male treated with 25 mg/day of IMIPRAMINE developed asymptomatic eosinophilia. The pa cell count was noted to be 19,650 which gradually decreased in association with an eosinophil count of 693 (300). All through the course the patient remained asymptomatic and well. Following discontinuation of the dru recovered with the eosinophilia subsiding (Penick & Carrier, 1967).

3.3.6 Hepatic Effects

3.3.6.A Hepatotoxicity

1) Summary

a) Hepatotoxicity induced by imipramine (hepatic necrosis) occurs infrequently. The mechanism by whic reaction occurs in unknown, but may be a hypersensitivity reaction. Elevations in bilirubin, alkaline phosp transaminases, and other liver function tests can occur within one to two weeks of the start of therapy. C include pruritus, jaundice, icterus, rashes (erythematous maculopapular, desquamation, xanthelasma an and splenomegaly. Most cases improve following discontinuation of therapy. However, a few patients co severe that they either died or required a liver transplant (Hynes, 1965; Powell et al, 1968; Grace, 1970; 1982; Morrow et al, 1989; Schaefer et al, 1990).

2) High, single-daily dosing of imipramine may be more hazardous to the liver than divided doses. A 33-year receiving 300 mg (6 mg/kg) of imipramine at bedtime along with thiothixene 10 mg and developed an elevatic (Moskovitz et al, 1982). Prior to the hospitalization for worsening mental status she had been receiving 200 to imipramine in divided doses. On day 26 of the single daily dosage of imipramine therapy, liver function tests following subjective complaints by the patient. The test revealed an elevation in liver enzymes. No baseline li were obtained at the time of hospitalization, but a previous liver function test taken one month after the initiati therapy was normal. Antihepatitis A and B antibodies and HAA tests were negative. The imipramine therapy and the thiothixene therapy was continued. Two weeks following the discontinuation of the imipramine therap returned to normal.

3) A 11-year-old boy developed fulminant HEPATIC FAILURE seven days after being started on imipramine for enuresis (Schaefer et al, 1990). Histologically, the liver showed massive HEPATOCELLULAR NECROSIS proliferation and loss of parenchymal volume. Mild amounts of acute and chronic inflammation were found in Hepatocellular necrosis occurred predominantly in the pericentral areas with focal hemorrhage encircling the damage was so extensive a liver transplant was required.

4) A rare hypersensitivity reaction to imipramine is the development of myocarditis and HEPATITIS (Morrow

3.3.7 Immunologic Effects

3.3.7.A Cross sensitivity reaction

1) Two patients developed a skin rash during therapy with desipramine (Norpramin(R)) and amitriptyline (Ela al, 1982). Discontinuation of these medications in each patient resulted in subsidence of the skin rash. Doxep in the patient receiving desipramine and imipramine was substituted in the patient receiving amitriptyline. On recurrence of the rash did not occur. These data would suggest that substitution of a structurally dissimilar an is a viable alternative in patients developing allergic skin reactions.

3.3.8 Musculoskeletal Effects

Fracture of bone, Nonvertebral

Hip fracture

Myasthenia gravis

3.3.8.A Fracture of bone, Nonvertebral

1) In a prospective, population-based, cohort study (n=7983) with a mean follow-up of 8.4 years, there was a nonvertebral fracture in adult participants older than 55 years of age (mean age of 77.5 years) who were curr tricyclic antidepressant (TCA), including amitriptyline, clomipramine, dosulepine, doxepine, imipramine, mapr nortriptyline, and opipramol, compared to those who were not exposed to antidepressants. Current TCA use with an increased risk of nonvertebral fracture (hazard ratio (HR), 1.6; 95% confidence interval (CI), 1.08 to 2 with no antidepressant use. Current TCA use was also associated with an increased risk of nonvertebral frac CI, 1.02 to 2.5) compared with past antidepressant use (n=1217). Duration of TCA use of greater than 6 mon associated with an increased risk of fractures when compared with no antidepressant use and with past antid Fractures of the hip (most frequent), wrist, humerus, and pelvis were reported (Ziere et al, 2008).

3.3.8.B Hip fracture

1) An increased incidence of hip fracture was reported in elderly patients receiving psychotropic agents. This control evaluation of 1021 patients with hip fractures and 5606 control patients. An increased risk of hip fractu with the use of hypnotic/anxiolytic agents with a long elimination half-life (greater than 24 hours), tricyclic anti antipsychotic agents. Current users were defined as subjects who had received a prescription in the 30 day p admission date for the initial hospitalization. The long half-life hypnotic/anxiolytic agents studied were lorazep chlordiazepoxide, and barbiturates (excluding phenobarbital). The tricyclic antidepressants included amitripty imipramine; antipsychotic agents evaluated were thioridazine, haloperidol, chlorpromazine, and perphenazine contrast, shorter-acting hypnotic/anxiolytic agents (half-life of 24 hours or less) were not associated with an in fracture in these patients. The most frequently used agents in this category were diphenhydramine, hydroxyz hydrate. The increased risk of hip fracture observed in this study was directly related to the doses of the drug confounding by dementia did not alter the results. Additional studies are needed to confirm these results in th populations and to evaluate the effects of other psychotropic drugs that have less pronounced sedative effect 1987).

3.3.8.C Myasthenia gravis

See Drug Consult reference: DRUG-INDUCED MYASTHENIA GRAVIS

3.3.9 Neurologic Effects

Akathisia

Central nervous system finding

Cerebral ischemia

Gilles de la Tourette's syndrome

Impaired psychomotor performance

Myoclonus

Seizure

Suicidal thoughts

Tremor

3.3.9.A Akathisia

1) One patient developed akathisia while receiving imipramine therapy and 4 others developed the same wh desipramine, trazodone, or tranylcypromine. The imipramine patient was a 54-year-old female who was treat and imipramine for depression. After titrating the dose of imipramine to 150 mg/day, the patient complained o feeling in her legs and the inability to remain still. Propranolol 10 mg three times daily was started, and the sy completely within several hours of the first dose. Discontinuation of the propranolol resulted in a recurrence o within 24 hours (Zubenko et al, 1987).

3.3.9.B Central nervous system finding

1) Summary

a) Some of the following adverse effects have not been associated with imipramine but have occurred w antidepressants. These include NUMBNESS, TINGLING, PARESTHESIAS of the extremities, ATAXIA, T EXTRAPYRAMIDAL SYMPTOMS, PERIPHERAL NEUROPATHY, SEIZURES, EEG CHANGES, CONF STATES with HALLUCINATIONS especially in the elderly, DISORIENTATION, DELUSIONS, FORGETF ANXIETY, RESTLESSNESS, AGITATION, INSOMNIA, NIGHTMARES, HYPOMANIA, and exacerbation (Prod Info Tofranil(R), 1995; Davies et al, 1971). PARANOIA, AGGRESSIVE BEHAVIOR (Rampling, 19 Petti, 1979), psychomotor impairment (Clayton et al, 1977a), delirium (Godwin, 1983), myoclonus (Garve 1987), akathisia (Zubenko et al, 1987), and Tourette's syndrome (Parraga & Cochran, 1992) have been use of imipramine; SUICIDAL IDEATION is a potential side effect of imipramine (Prod Info Tofranil(R), 19 1992). LEARNING IMPAIRMENT in a social context is NOT seen with tricyclic antidepressants (Gillis, 19

3.3.9.C Cerebral ischemia

1) A 59-year-old male treated with usual therapeutic doses of imipramine for mild depression developed cere attacks (Brechter, 1968). Two weeks after starting drug therapy PARESTHESIA over the entire left side of his with short attacks of SPEECH DISTURBANCES. The drug was discontinued but PARESIS continued to prog involvement and total stenosis of the medial cerebral artery. Although no definite cause and effect relationshi the author postulated that tricyclic antidepressants may cause recurrent ischemic attacks in persons with par the cerebral arteries.

3.3.9.D Gilles de la Tourette's syndrome

1) Two children experienced tics or Tourette's syndrome that may have been precipitated by imipramine (Pa 1992). Motor (throat clearing, head shaking) and vocal tics (stuttering, echolalia, palilalia, profane utterances) boys two weeks after treatment with imipramine (75 to 100 mg/day) for attention deficit hyperactivity disorder concurrent depression. The tics remained despite discontinuation of the imipramine. Remission of the tics wa through the use of haloperidol and thioridazine.

3.3.9.E Impaired psychomotor performance

1) A placebo-controlled study of healthy male volunteers demonstrated DETERIORATION OF DRIVING SKI received 25 mg imipramine three times a day compared with 10 who received placebo and 10 who were cont 1977a).

3.3.9.F Myoclonus

1) A high incidence of myoclonus was reported during cyclic antidepressant therapy with imipramine, desipra amitriptyline, doxepin, trazodone, nortriptyline, and maprotiline (Garvey & Tollefson, 1987). Ninety-eight patie depression (93) or panic disorder were treated with these agents in initial doses of 50 mg daily of imipramine increasing to a maximum of 300 mg daily after several weeks. Of these patients, 39 (40%) developed myoclo of therapy, with the myoclonus being clinically significant in 9 (9%) and resulting in withdrawal of the antidepr medication change. Myoclonus occurred within one month of initiation of therapy in 81% of the 39 patients, w developing myoclonus within 2 weeks; the mean dose of antidepressant administered at the time of myoclonu daily in imipramine equivalents, which was similar to the mean dose utilized by the patients not developing m daily). Myoclonus was reversible upon withdrawal of the antidepressant but persisted if medication changes v however, spontaneous remission of myoclonus was observed in 9 patients. No predictors for the developmer were observed.

3.3.9.G Seizure

1) Summary

a) Imipramine has been shown to decrease the convulsive threshold (Misurec & Nahunek, 1969) and ha documented to cause seizure disorders including the occurrence of GRAND MAL TONIC-CLONIC SEIZ with or without seizure histories. Three reports have cited cases in pediatric patients (Fromm et al, 1972; Petti & Campbell, 1975b). However, cases of grand mal seizures occurring in younger adults (30 years o reported (Fromm et al, 1972; Kaufmann, 1974). Discontinuation of the tricyclic antidepressant and/or inst anticonvulsant therapy usually results in control of seizures.

2) A 25-year-old female that had been treated with 4 weeks therapy of imipramine (150 mg/day) and cloraze developed a seizure following the abrupt discontinuation of clorazepate therapy (Simons, 1983). Since the se solely contributed to the abrupt discontinuation of the clorazepate therapy, the author feels that all patients re prescriptions for antidepressant and benzodiazepines should avoid the abrupt discontinuation of the benzodi See Drug Consult reference: COMPARATIVE INCIDENCE OF SEIZURES FROM ANTIDEPRESSANTS

3.3.9.H Suicidal thoughts

1) Adult and pediatric patients being treated with antidepressants for major depressive disorder who experie anxiety, agitation, panic attacks, insomnia, irritability, hostility (aggressiveness), impulsivity, akathisia (psycho restlessness), hypomania, or mania may be at risk of suicidal ideation and behavior (SUICIDALITY). This sar to treating patients with other psychiatric and nonpsychiatric disorders. If these symptoms are observed, ther reevaluated and it may be necessary to discontinue medications when symptoms are severe, sudden in onse of the patient's initial symptoms. Patients and their caregivers should be provided with the Medication Guide f this drug (Anon, 2004).

2) A causal role for antidepressants in inducing suicidality has been established in pediatric patients. Anyone use of antidepressants in a child or adolescent must balance this risk with the clinical need. In pooled analyse placebo-controlled trials of nine antidepressants (citalopram, fluoxetine, fluvoxamine, paroxetine, sertraline, b mirtazapine, nefazodone, and venlafaxine extended-release) including over 4400 pediatric patients with majo disorder, obsessive compulsive disorder, or other psychiatric disorders, a greater risk of suicidal behavior or i first few months of therapy was demonstrated in patients receiving antidepressants as compared with placeb respectively). The risk of suicidality was most consistently observed in the trials that included patients with ma disorder, but there were signs of risk emerging from trials in other psychiatric indications, such as obsessive c disorder and social anxiety disorder. No suicides occurred in these trials. The risk of suicidality during longer- beyond several months) in pediatric patients is not known. It is also unknown whether this risk extends to adu 2004).

3.3.9.I Tremor

1) Imipramine-induced TREMOR occurred in a 61-year-old male. Following doses of 75 mg daily for 3 days, developed a marked action tremor of the upper extremities which was smooth and rhythmic (6 to 9 cycles pe interfered with routine activities. The tremor did not worsen when the dose of imipramine was increased to 15 Propranolol (20 mg twice a day) produced attenuation of the tremor within 25 to 48 hours (Kronfol et al, 1983

2) Some patients with panic disorder imipramine therapy may develop a jitteriness syndrome (Yeragani et al condition is characterized by jitteriness, restlessness, trouble sitting still, insomnia, increased energy, increas possible decreased serum iron level. Whether iron supplementation will prevent or treat this syndrome remai

3.3.11 Otic Effects

3.3.11.A Ototoxicity

1) TINNITUS has been reported in 4 patients: a 37-year-old female, a 30-year-old fem old male, all receiving 50 to 150 mg imipramine daily. Tinnitus disappeared when the imipramine dose was re females and the male required a change in therapy (Racy & Ward-Racy, 1980).

2) Five additional reports of tinnitus secondary to imipramine therapy have been published (Tandon et al, 19 had no history of tinnitus or other otologic abnormalities. All patients developed tinnitus during the second or treatment, with doses of 150 to 250 mg daily of imipramine (combined plasma imipramine-desipramine levels 450 ng/mL). The tinnitus subsided spontaneously within 2 to 4 weeks without any specific treatment in all pat imipramine was maintained in 3 patients and increased in 2). Based upon a chart review of 475 patients treat University of Michigan Medical Center, the authors indicate that approximately 1% of patients receiving tricyc develop tinnitus.

3) A 38 year-old depressed female develop ringing in her ears one week after the dose of imipramine was in mg/day (Laird & Lydiard, 1989). She had no history of ear problems and denied using aspirin or other salicyla medication was continued since the tinnitus was only mildly bothersome and no abnormalities could be found physical examination. The dose of imipramine was increased to 150 mg/day during the second week. The tin approximately six weeks and then diminished without any changes in drug therapy.

3.3.12 Psychiatric Effects

Aggressive behavior

Delirium

Psychotic disorder

Sleep disorder

3.3.12.A Aggressive behavior

1) A 26-year-old male treated with a single oral dose of imipramine for cataplexy developed a feeling of aggr increased intensely over the next half hour with the patient struggling to keep control. The patient was noted staggering, and feelings of drunkenness. It was noted that the patient had previously received diazepam and (Rampling, 1976). In addition, increased aggression was reported in 2 depressed boys, ages 12 and 6 years, therapy (Pallmeyer & Petti, 1979).

2) Four cases of rapid onset untoward aggressiveness was associated with the use of tricyclic antidepressar cases the aggressive behavior coincided with the reintroduction of the tricyclic antidepressant. The mechanis paradoxical response of rapid onset and qualitative characteristics of their reaction are consistent with a prob in the reticular formation which is the rational for their usefulness in cataplexy (Rampling, 1978).

3.3.12.B Delirium

1) Summary

a) Risk factors for the development of tricyclic-induced delirium include high tricyclic serum concentratio organic brain disease, and concomitant neuroleptic therapy (Godwin, 1983).

2) A 31-year-old hospitalized female developed delirium during imipramine therapy; the patient had no know (Godwin, 1983). Initially she presented with a hypomanic reaction (characterized by restlessness, hyperactivi lability of mood, and insomnia) that later developed into the delirium reaction (disorientation to time and place speech, periods of blank stares, periods of unresponsiveness, visual distortions, hallucinations) while on stan imipramine therapy. Plasma imipramine concentrations were in the low end of the therapeutic range. Thus, in delirium may occur in some patients as an idiosyncratic reaction unrelated to imipramine serum concentratior

3.3.12.C Psychotic disorder

1) Summary

a) Psychotic reactions following doses of imipramine ranging from 75 to 600 mg/day have been reportec included DISORIENTATION, AGITATION, CONFUSION, RESTLESSNESS, INSOMNIA, tremor, ATAXI HALLUCINATIONS, PARANOIA and other abnormal manifestations. Some data suggests that these effe more frequently in elderly patients and/or those receiving higher doses. Discontinuation of the drug resul and disappearance of the symptoms (Kane & Keeler, 1964; Ananth, 1973; Wilson et al, 1974; Schulterbr Prod Info Tofranil(R), 1995).

2) A high number of geriatric patients on tricyclic antidepressant therapy have developed confusional reactio as restlessness, sleep disturbances, FORGETFULNESS, agitation, disorientation, and DELUSIONS. This rea appear to be dose-related and is possibly due to the central anticholinergic effects of these drugs. These epis reported to develop within the first 2 weeks of drug therapy and are usually self-limiting, lasting from 3 to 20 d reduction of dosage or discontinuation of the drug appears to result in resolution of these confusional reactior (Davies et al, 1971).

3.3.12.D Sleep disorder

1) Imipramine can markedly suppress REM sleep (REM time, REM activity, and number of REM periods) in adults (Shain et al, 1990).

3.3.13 Renal Effects

3.3.13.A Nephrotoxicity

1) A 65-year-old white male was treated with doses of up to 100 mg three times/day of imipramine for 24 day developed RENAL DAMAGE (Sathananthan & Gershon, 1973c). The patient developed symptoms of anorex confusion, disorientation, and tremulousness in association with elevated BUN (80 mg/dL) and creatinine (2.5 Urine output fell to 725 mL/day despite a fluid intake of approximately 2.5 L. Discontinuation of imipramine re improvement of this clinical condition and abnormal laboratory values returning to normal by the third day.

3.3.14 Reproductive Effects

3.3.14.A Sexual dysfunction

1) ERECTILE DYSFUNCTION and EJACULATORY DELAY or loss has been reported in depressed and nor minimum daily dose of 75 mg. Pain on ejaculation (Couper-Smartt & Rodham, 1973; Simpson et al, 1965; Gr Aizenberg et al, 1991) and loss of libido (Jenkins et al, 1976) as well as increased libido has been reported (S 1965).

2) The occurrence of sexual dysfunction associated with antidepressant therapy is frequent. Decreases in se occurs in 8% of males and 16% of females treated with placebo, 80% of males and 57% of females treated w and 50% of males and 27% of females treated with imipramine (Harrison et al, 1985). Sexual dysfunctions re DECREASE IN LIBIDO, excitement, and orgasm and a delay in ejaculation. Similar results have been reporte by the same group of investigators (Harrison et al, 1986).

3) Other investigators feel that long-term treatment with imipramine has no negative effect on sexual functior 1994). Instead they feel that the presence of depressive symptoms is associated with diminished libido or dec pleasure. An evaluation of 90 patients with a major depressive disorder treated with imipramine found no rela imipramine and sexual function in the total group or the females alone. The number of males included in the s inadequate to draw any conclusions regarding population.

4) A 51-year-old male was treated with an initial dose of 75 mg/day which was reduced to oral imipramine 25

weeks and developed erectile IMPOTENCE at the higher dose. Potency rapidly returned upon decreasing the
25 mg/day (Greenberg, 1965).
5) ANORGASMIA has been reported in a woman treated with imipramine therapy and disappeared when de
was substituted for the imipramine (Sovner, 1983).
See Drug Consult reference: DRUG-INDUCED SEXUAL DYSFUNCTION

3.3.15 Respiratory Effects

3.3.15.A Acute respiratory distress syndrome

1) A 15-year-old was admitted to the emergency department following the ingestion of 5 grams (150 mg/kg)
approximately 45 minutes prior to arrival (Flaherty et al, 1986). Within 5 hours of ingestion the patient develop
hypoxemia, increased QS/QT, and decreased lung compliance. At that time a diagnosis of adult respiratory d
(ARDS) was made. Positive end-expiratory pressure (PEEP) resulted in an improvement in lung compliance,
shunting. Whether or not the development of adult respiratory distress syndrome ARDS was a direct result of
overdose or the development of bradycardia, hypoxemia, metabolic acidosis, hypotension or physostigmine t
unknown.

3.3.16 Other

Drug tolerance - finding

Withdrawal sign or symptom

3.3.16.A Drug tolerance - finding

1) Tolerance to the therapeutic effects of IMIPRAMINE therapy has been reported in a small number of patie
Baldessarini, 1985). Usually these patients initially respond to therapy and then weeks to months later they re
continued antidepressant therapy. Remission can usually be regained by increasing the dose of the medicati
medication. The exact mechanism for the development of this tolerance is not known.

3.3.16.B Withdrawal sign or symptom

1) Withdrawal symptoms have been associated with the discontinuation of tricyclic antidepressant therapy a
to 55% of the patients. These symptoms frequently occur within the first 24 to 48 hours after cessation of ther
withdrawal period is characterized by general somatic malaise (muscle aches, coryza, excessive sweating), g
(nausea, vomiting, diarrhea, and abdominal pain), motor restlessness, and/or neuropsychiatric symptoms (dr
irritability, agitation, and recurrence of depressed mood). Restarting imipramine therapy generally improves th
prevent the occurrence of this withdrawal reaction, the imipramine therapy should be withdrawn gradually, wh
(Sathananthan & Gershon, 1973a; Stern & Mendels, 1980; Petti & Law, 1981; Shrivastava & Itil, 1985; Prod I
1995).
2) Children withdrawn from high-dose imipramine therapy over 3 to 10 days may develop a withdrawal syndr
1981). The syndrome is characterized by nausea, vomiting, decreased appetite, tearfulness, headaches, agit
It is thought that this withdrawal syndrome may be the result of a cholinergic rebound following the discontinu
anticholinergic medications. Extending the duration of the tapering period may be helpful in avoiding the occu
syndrome, but there is no clinical evidence to support this theory.
3) A 53-year-old woman, with a 25-year history of unipolar depression but no evidence of bipolar illness, dev
cycling bipolar disorder following abrupt discontinuation of her long-term tricyclic antidepressant therapy (Jon
The bipolar illness presented as hypomania 2 days after stopping drug therapy. The hypomanic period was fo
depression and subsequent fluctuation between mania and depression, each lasting from 2 to 8 weeks.
4) Multifocal premature ventricular contractions (PVCs) occurred in a 62-year-old woman following withdrawa
The depressed women had preexisting nonspecific intraventricular conduction delay (Regan et al, 1989). Imip
daily) was tapered over a 4-day period, and then doxepin was initiated at a dose of 50 mg at bedtime. PVCs a
observed the day following discontinuance of imipramine. Reinitiation of imipramine therapy (100 mg daily) pr
sinus rhythm with only occasional uniform PVCs, and no couplets, multiforms, runs, or pauses. It was felt that
drug resulted in rebound irritability with resultant aberrant rhythms. Tricyclic antidepressants should be withdr
with frequent EKG monitoring, in patients with a preexisting conduction defects. In patients with no suspected
defect, monitoring for signs of ectopy should be undertaken during withdrawal.
5) Withdrawal of imipramine therapy used to treat postpsychotic depression after six months in six schizophr
resulted in DEPRESSIVE RELAPSES (Siris et al, 1989). All six patients had benefit from the initial addition of
their fluphenazine decanoate and benztropine therapy. After six months the dose of imipramine was decreas
weekly intervals without the patient knowledge until it was discontinued. All six patients had experienced recu
depressive-like state and three manifested a coincident exacerbation of psychotic symptoms. While only one
maintained on all three drugs experienced a depressive-like relapse.

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy
1) Australian Drug Evaluation Committee's (ADEC) Category: C (Batagol, 1996)

a) Drugs which, owing to their pharmacological effects, have caused or may be suspected of causing harmfu human fetus or neonate without causing malformations. These effects may be reversible. Accompanying text consulted for further details.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

2) Crosses Placenta: Yes

3) Clinical Management

a) Due to reported teratogenic effects, use of imipramine during pregnancy should be avoided if possible, es first trimester. The dangers of failure to treat major depression, however, are obvious, and in each case these weighed against the potential for teratogenic effects. If pregnancy occurs during treatment, the patient should possible consequences to the fetus.

4) Literature Reports

a) Imipramine has been associated with teratogenic effects, however, a clear causal relationship has not bee the large cohort study (Heinonen et al, 1977), of 19 mother-child pairs exposed to imipramine in the first trime malformations were reported, suggesting an increased risk of teratogenic effects.

b) A review of the Finnish register of congenital malformations for 1964 to 1972 revealed 3 possible cases of effects (2 cleft lips, 1 CNS anomaly) that were related to the use of an imipramine/chloropyramine combinatio Heikkila & Saxen, 1973).

c) Neonatal intoxication and withdrawal symptoms may be observed with maternal use of imipramine. Sympt the neonate include cyanosis, respiratory distress, vasomotor instability, irritability, hypokinesia, convulsions, increased respiratory rate, autonomic dysfunction, hypoactivity, and belly dance movements of the abdomen (Anon, 1983; Shrand, 1982).

d) Several infants have been described who developed transient respiratory and neurological symptoms sho possibly in relation to maternal imipramine. Of 3 infants whose mothers had used imipramine throughout the infants developed postnatal symptoms of irritability, restlessness, inconsolable crying, tachypnea, cyanosis, h fasciculations, and tremors. One infant developed signs of heart failure despite a normal electrocardiogram, a to 180 per minute, and absence of a congenital cardiac malformation. One infant experienced laryngeal spas difficulties (Eggermont et al, 1972).

e) Based on data collected through the Motherisk Program, there appear to be no differences in cognitive fu temperament and general behavior in children exposed to imipramine throughout gestation when compared t et al, 2002). However, among infants who were exposed to either fluoxetine or tricyclic antidepressants thoug those born to mothers with uncontrolled depressive symptoms showed lower cognitive and language achieve born to mothers who were well-controlled (Nulman et al, 2002).

B) Breastfeeding

1) American Academy of Pediatrics Rating: Drugs for which the effect on nursing infants is unknown but may be 2001)

2) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk wh breastfeeding. Weigh the potential benefits of drug treatment against potential risks before prescribing this dr breastfeeding.

3) Clinical Management

a) Imipramine and its metabolite, desipramine, appear in breast milk in low concentrations. The potential for the nursing infant has not been evaluated. When the maternal dose is high, exposure of the infant to the drug minimized by limiting the number of feeds per day (Bennett, 1996).

4) Literature Reports

a) The amount of imipramine and desipramine available to an infant is small. The amount of imipramine mea milk was 4 to 29 ng/mL and desipramine was 17 to 35 ng/mL; a milk:plasma ratio of 1 has been suggested (S 1979).

5) Drug Levels in Breastmilk

a) Parent Drug

1) Milk to Maternal Plasma Ratio

a) 1 (Briggs et al, 1998)

b) Active Metabolites

1) desipramine (Sallee & Pollock, 1990)

3.5.1.A Acecainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).

b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any interac initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.B Acenocoumarol

1) Interaction Effect: increased risk of bleeding

2) Summary: Tricyclic antidepressants (TCAs) may increase the half-life and bioavailability of oral anticoagul 1970c; Williams et al, 1976c). Considerable interindividual differences may be found (Pond et al, 1975c).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: In patients receiving tricyclic antidepressants and oral anticoagulant therapy, the pr ratio or INR (international normalized ratio) should be closely monitored with the addition and withdrawal of th and should be periodically reassessed during concurrent therapy. Achieving a stable drug regimen which pro level of anticoagulation may be difficult in patients on this combination, and frequent adjustments of the antic be required.
7) Probable Mechanism: decreased acenocoumarol metabolism; increased acenocoumarol absorption
8) Literature Reports
a) In a study of healthy volunteers, the concurrent use of nortriptyline or amitriptyline resulted in an incre levels and an increase in the plasma half-life of dicumarol, although the effect was not consistent in all su 1975b). This effect was not observed with warfarin.
b) A single oral dose of bishydroxycoumarin after 8 days of nortriptyline resulted in a significantly prolon decreased volume of distribution of the coumarin anticoagulant in 6 healthy volunteers (Vesell et al, 197(mechanism of action was suggested to be reduced bishydroxycoumarin metabolism and/or altered coum
c) Drug dosing was studied in 16 patients on long-term anticoagulant therapy who used concurrent TCA 1976b). TCAs affected the stability of anticoagulant control leading to frequent changes in the doses of a Inhibition of coumarin metabolism was the postulated mechanism.

3.5.1.C Ajmaline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class Ia antiarrhythmics and tricyclic antidepressants have been shown to prolong the QTc inte recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadm Ia antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is n (Prod Info Elavil(R), 1999g; Prod Info Quinaglute(R), 1999; Marshall & Forker, 1982n).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic agent and a tricyclic anti recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Quinidine is an inhibitor of the cytochrome P450 isoenzyme responsible for the 2-hydroxylation of imi desipramine (Brosen & Gram, 1989). Inhibition of this enzyme system can result in a 35% decrease in im clearance and 85% decrease in desipramine clearance. Demethylation of imipramine by the cytochrome unaffected by this interaction. Until more information is available all patients having quinidine added to dr containing imipramine or desipramine should be monitored for increased antidepressant serum concentr potential toxicity.
b) An increased incidence in sudden death was observed in six out of 53 patients with cardiac disease r amitriptyline, compared to 0 out of 53 in the control group. It was recommended that amitriptyline be avo with underlying cardiac disease except when depression was debilitating and no other drugs were helpfu Coull et al, 1970).
c) In a placebo controlled study, imipramine 3.5 mg/kg was administered daily for seven patients with se and titrated doses to obtain therapeutic plasma concentrations. Two patients displayed premature atrial c and premature ventricular depolarizations before therapy. On patient had 33 premature atrial depolarizat premature ventricular depolarizations (PVD) per hour, which decreased to 0.4 PAC and zero PVC per ho The other patient had 12 PAD and 169 PVD per hour before treatment and 1.8 PAD and 28.1 PVD per h The authors also cautioned that the incidence of cardiotoxicity may increase if tricyclic antidepressants a with Type I antiarrhythmics. It was also recommended that quinidine and procainamide not be used to tre of a tricyclic overdose. The similarities between these agents may exacerbate the cardiotoxicity (Kantor e

3.5.1.D Alprazolam

1) Interaction Effect: increased imipramine plasma concentrations
2) Summary: Imipramine steady state plasma concentrations increased an average of 31% when used conc alprazolam at doses up to 4 mg/day. The clinical significance of this increase is unknown. A decrease in the i should be considered for patients who are being treated with alprazolam and imipramine concurrently and wh increase in side effects such as dry eyes and mouth, constipation, decreased urination, or arrhythmias (Prod (TM) orally disintegrating tablet, 2003).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Concomitant use of alprazolam and imipramine may increase the plasma concentra imipramine. The clinical significance of this increase is unknown. If signs or symptoms of increased imipramir as blurred vision, dry mouth, constipation, urinary retention, or arrhythmias are noticed, a downward dosage imipramine should be considered.

7) Probable Mechanism: unknown

3.5.1.E Amiodarone

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).

b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any intera initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.F Amisulpride

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod 1999), haloperidol (O'Brien et al, 1999), risperidone (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001 (Owens, 2001b), sultopride (Lande et al, 1992), and zotepine (Sweetman, 2003). Even though no formal drug studies have been done, the coadministration of a tricyclic antidepressant and an antipsychotic is not recomm Pamelor(R), 2001; Marshall & Forker, 1982t).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic is n

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included pr corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 m proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricu (Prod Info Orap(R), 1999).

3.5.1.G Amobarbital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive

2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.

7) Probable Mechanism: increased tricyclic antidepressant metabolism

8) Literature Reports

a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were e metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar eff expected with any combination of TCA and barbiturate.

3.5.1.H Amphetamine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sin also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.I Amprenavir

1) Interaction Effect: increased tricyclic serum concentrations and potential toxicity (anticholinergic effects, se cardiac arrhythmias)
2) Summary: Coadministered amprenavir may increase serum concentrations of tricyclic antidepressants, ca risk of arrhythmias or other serious adverse effects. Currently no interaction study has been conducted. Ampr metabolized by cytochrome P450 3A4 enzymes in addition to being a CYP3A4 inhibitor, and tricyclics may pa this pathway for metabolism. Plasma concentrations of the tricyclic should be closely monitored and dose adj accordingly in patients also receiving amprenavir (Prod Info Agenerase(R), 2000).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: If concomitant therapy with amprenavir and a tricyclic antidepressant is unavoidable concentrations of the tricyclic should be closely monitored and dose adjustments made accordingly. Also mon signs and symptoms of tricyclic toxicity (anticholinergic effects, sedation, confusion, cardiac arrhythmias).
7) Probable Mechanism: inhibition of cytochrome P450-mediated tricyclic metabolism

3.5.1.J Anisindione

1) Interaction Effect: increased risk of bleeding
2) Summary: Tricyclic antidepressants (TCAs) may increase the half-life and bioavailability of oral anticoagul 1970k; Williams et al, 1976k). Considerable interindividual differences may be found (Pond et al, 1975k).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: In patients receiving tricyclic antidepressants and oral anticoagulant therapy, the pr ratio or INR (international normalized ratio) should be closely monitored with the addition and withdrawal of th and should be periodically reassessed during concurrent therapy. Achieving a stable drug regimen which pro level of anticoagulation may be difficult in patients on this combination, and frequent adjustments of the antic

be required.
7) Probable Mechanism: decreased anisindione metabolism; increased anisindione absorption
8) Literature Reports
a) In a study of healthy volunteers, the concurrent use of nortriptyline or amitriptyline resulted in an incre levels and an increase in the plasma half-life of dicumarol, although the effect was not consistent in all su 1975j). This effect was not observed with warfarin.
b) A single oral dose of bishydroxycoumarin after 8 days of nortriptyline resulted in a significantly prolon decreased volume of distribution of the coumarin anticoagulant in 6 healthy volunteers (Vesell et al, 197(mechanism of action was suggested to be reduced bishydroxycoumarin metabolism and/or altered coum
c) Drug dosing was studied in 16 patients on long-term anticoagulant therapy who used concurrent TCA 1976j). TCAs affected the stability of anticoagulant control leading to frequent changes in the doses of ar Inhibition of coumarin metabolism was the postulated mechanism.

3.5.1.K Aprindine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class I antiarrhythmics have been shown to prolong the QTc interval at the recommended ther Even though no formal drug interaction studies have been done, the coadministration of Class I antiarrhythmi known to prolong the QTc interval, including tricyclic antidepressants, is not recommended (Prod Info Tambo acetate, 1998; Larochelle et al, 1984; Scagliotti et al, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class I antiarrhythmic and a tricyclic antidepress recommended.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982q).
b) A 68-year-old man suffering from agitated major depression was begun on a dose of desipramine 12 produced a subtherapeutic serum level of 442 nmol/L (therapeutic range = 500 to 1000 nmol/L). An incre mg daily produced excellent clinical response with no side effects. He developed atrial fibrillation and flut mg daily was added to his therapy, and desipramine was discontinued. His arrhythmia was suppressed v propafenone 150 mg twice daily and 300 mg at bedtime. Desipramine 150 mg daily was again begun, at experienced dry mouth, sedation, and shakiness; the desipramine serum level was measured at 2092 nr desipramine was discontinued for five days, the side effects ceased, and desipramine therapy was resur The desipramine serum level was measured at 1130 nmol/L (Katz, 1991).

3.5.1.L Aprobarbital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive
2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa
3) Severity: minor
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.
7) Probable Mechanism: increased tricyclic antidepressant metabolism
8) Literature Reports
a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were e metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar effe expected with any combination of TCA and barbiturate.

3.5.1.M Arbutamine

1) Interaction Effect: unreliable arbutamine test results
2) Summary: Because tricyclic antidepressants may affect heart rate, arbutamine should not be administered receiving a tricyclic antidepressant, since arbutamine test results may be unreliable (Prod Info GenESA(R), 1
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable

6) Clinical Management: Arbutamine should not be administered to a patient receiving tricyclic antidepressar
7) Probable Mechanism: alteration of heart rate by the tricyclic antidepressant

3.5.1.N Arformoterol

1) Interaction Effect: an increased risk of cardiovascular excitation
2) Summary: Concurrent administration of arformoterol with a tricyclic antidepressant (TCA) may lead to pote arformoterol's adrenergic effects on the cardiovascular system. Therefore, extreme caution is advised if arfor administered to patients who are being treated with a TCA (Prod Info BROVANA(TM) inhalation solution, 200 patients closely for adverse cardiovascular effects.
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Extreme caution and close observation for adverse cardiovascular effects are warra arformoterol is administered concurrently with a tricyclic antidepressant (TCA) as the cardiovascular effects o be potentiated by TCAs (Prod Info BROVANA(TM) inhalation solution, 2006).
7) Probable Mechanism: potentiation of cardiovascular effects

3.5.1.O Arsenic Trioxide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Any drug known to have the potential to prolong the QT interval should not be used with arseni pharmacodynamic interactions can occur between arsenic trioxide and potentially arrhythmogenic agents suc antidepressants that prolong the QT interval (Prod Info Trisenox(R), 2000a). Even though no formal drug inte have been done, the coadministration of arsenic trioxide and other drugs known to prolong the QTc interval, i antidepressants, is not recommended (Prod Info Elavil(R), 1999l; Marshall & Forker, 1982ai).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of arsenic trioxide and other drugs that may prolong such as tricyclic antidepressants is not recommended.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) An increased incidence in sudden death was observed in six out of 53 patients with cardiac disease r amitriptyline, compared to zero out of 53 in the control group using a hospital based information system. recommended that amitriptyline not be used in patients with underlying cardiac disease except when dep debilitating and no other drugs were helpful (Moir et al, 1972a; Coull et al, 1970a).
b) QT/QTc prolongation should be expected during treatment with arsenic trioxide and torsade de pointe complete heart block has been reported. Over 460 ECG tracings from 40 patients with refractory or relap with arsenic trioxide were evaluated for QTc prolongation. Sixteen of 40 patients (40%) had at least one QTc interval greater than 500 msec. Prolongation of the QTc was observed between 1 and 5 weeks afte infusion, and then returned towards baseline by the end of 8 weeks after arsenic trioxide infusion. In thes evaluations, women did not experience more pronounced QT prolongation than men, and there was no (Prod Info Trisenox(R), 2000).

3.5.1.P Astemizole

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Tricyclic antidepressants have been shown to prolong the QTc interval at the recommended th Even though no formal drug interaction studies have been done, the coadministration of astemizole and othe prolong the QTc interval, including tricyclic antidepressants, is not recommended (Prod Info Elavil(R), 1999m Hismanal(R), 1996).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of astemizole and agents that prolong the QT interva antidepressants, is not recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) A comprehensive discussion of the cardiovascular effects of tricyclic antidepressants has been prese Forker, 1982aj). Electrocardiogram effects reported in patients receiving therapeutic doses of tricyclic an include increased heart rate, prolonged PR interval, intraventricular conduction delays, increased correct (QTc) and flattened T waves.

3.5.1.Q Atazanavir

1) Interaction Effect: increased plasma concentrations of tricyclic antidepressants (drowsiness, hypotension,
2) Summary: Coadministration of atazanavir and tricyclic antidepressants has not been studied. However, th of atazanavir and tricyclic antidepressants has the potential to produce serious and/or life-threatening advers Reyataz(TM), 2003).
3) Severity: major
4) Onset: unspecified

5) Substantiation: theoretical
6) Clinical Management: If atazanavir and tricyclic antidepressants are used concomitantly, monitor patient f and symptoms of tricyclic antidepressant toxicity (hypotenstion, akathisia, anticholinergic effects, sedation, cc arrhythmias).
7) Probable Mechanism: unknown

3.5.1.R Atomoxetine

1) Interaction Effect: an increase in atomoxetine steady-state plasma concentrations
2) Summary: Atomoxetine is primarily metabolized by the cytochrome P450 2D6 (CYP 2D6) pathway to 4-hy In extensive metabolizers, atomoxetine steady-state plasma concentrations are increased with selective inhib such as imipramine. The exposure is similar to that observed in poor metabolizers. In extensive metabolizers imipramine, the area under the concentration-time curve of atomoxetine is approximately 6- to 8-fold greater, plasma concentration at steady-state is about 3- to 4-fold greater than atomoxetine alone (Prod Info Strattera
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Dosage adjustment of atomoxetine may be necessary when coadministered with im
7) Probable Mechanism: inhibition of cytochrome P450 2D6-mediated metabolism of atomoxetine by imipran

3.5.1.S Azimilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).
b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any intera initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.T Belladonna

1) Interaction Effect: excessive anticholinergic activity (severe dry mouth, constipation, decreased urination, sedation, blurred vision)
2) Summary: The anticholinergic activity of the active alkaloids present in belladonna may predispose the pa anticholinergic activity if taken with tricyclic antidepressants. Belladonna contains L-hyoscyamine, atropine, a with a total alkaloid content of at least 0.3% in the leaves and 0.5% in the roots (Blumenthal et al, 1998). Bec typically available as a homeopathic preparation, the clinical severity of the interaction with tricyclic antidepre Caution is advised.
3) Severity: minor
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Excessive anticholinergic activity may be manifested by dry mouth, constipation, ur tachycardia, decreased sweating, mydriasis, blurred vision, elevated temperature, muscular weakness, and s effects are noted, belladonna should be discontinued immediately. In severe cases, paralytic ileus, confusion agitation, delusions, delirium, and paranoia may be encountered as well as tachycardia, dysrhythmia, and hy severe cases, immediate medical attention should be obtained.
7) Probable Mechanism: additive anticholinergic effect

3.5.1.U Belladonna Alkaloids

1) Interaction Effect: excessive anticholinergic activity (severe dry mouth, constipation, decreased urination, sedation, blurred vision)
2) Summary: The anticholinergic activity of the active alkaloids present in belladonna may predispose the pa anticholinergic activity if taken with tricyclic antidepressants. Belladonna contains L-hyoscyamine, atropine, a with a total alkaloid content of at least 0.3% in the leaves and 0.5% in the roots (Blumenthal et al, 1998). Bec typically available as a homeopathic preparation, the clinical severity of the interaction with tricyclic antidepre Caution is advised.

3) Severity: minor
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Excessive anticholinergic activity may be manifested by dry mouth, constipation, ur tachycardia, decreased sweating, mydriasis, blurred vision, elevated temperature, muscular weakness, and s effects are noted, belladonna should be discontinued immediately. In severe cases, paralytic ileus, confusion agitation, delusions, delirium, and paranoia may be encountered as well as tachycardia, dysrhythmia, and hy severe cases, immediate medical attention should be obtained.
7) Probable Mechanism: additive anticholinergic effect

3.5.1.V Bepridil
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: In US clinical trials, the QT and QTc intervals were commonly prolonged by bepridil in a dose-r (Prod Info Vascor(R), 2000). Tricyclic antidepressants (TCAs) have been shown to prolong the QTc interval a recommended therapeutic dose (Marshall & Forker, 1982w).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of bepridil and other drugs which may prolong the QTc interval, incl antidepressants, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.W Bethanidine
1) Interaction Effect: decreased antihypertensive effectiveness
2) Summary: Antidepressants inhibit the uptake of bethanidine at its site of action in the adrenergic neuron. T may last for several days after discontinuation of the antidepressant (Skinner et al, 1969a; Avery, 1973; Feag
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The combination of bethanidine and imipramine, as well as other tricyclic antidepres should be avoided. An alternative antihypertensive agent should be considered.
7) Probable Mechanism: decreased uptake of bethanidine into adrenergic neurons
8) Literature Reports
a) Adequate control of hypertension was reported in only 2 of 8 adult hypertensive patients who receive debrisoquine concurrently with a tricyclic antidepressant. In 24 control patients given the same drugs wit antidepressants, blood pressure control was achieved in 18. Withdrawal of antidepressant therapy in sev resulted in postural hypotension that necessitated a reduction in dosage of bethanidine or debrisoquine (1969).

3.5.1.X Bretylium
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).
b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any interac initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.Y Bupropion
1) Interaction Effect: increased imipramine plasma level
2) Summary: Bupropion was reported to decrease clearance and increase plasma levels of imipramine and i metabolite desipramine in a 64-year-old woman (Shad & Preskorn, 1997a). Coadministration of bupropion wi metabolized by the cytochrome P450 2D6 isoenzyme, such as imipramine, should be approached with cautic initiated at the lower end of the dose range of imipramine. If bupropion is added to the treatment regimen of a

receiving imipramine, a decrease in the dose of imipramine should be considered (Prod Info Wellbutrin XL(TM Zyban(R), 2000).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: When imipramine is given with bupropion, monitor for signs of imipramine toxicity o imipramine plasma concentrations. Coadministration of imipramine with bupropion should be approached wit should be initiated at the lower end of the dose range of imipramine. If bupropion is added to the treatment re already receiving imipramine, consider decreasing the dose of imipramine.
7) Probable Mechanism: inhibition of cytochrome P450 2D6-mediated imipramine metabolism
8) Literature Reports
a) Bupropion was reported to decrease clearance and increase plasma levels of imipramine and its prim desipramine in a 64-year-old woman. This patient was treated with imipramine for 8 years prior to additio therapy. Estimated imipramine clearance decreased from 1.7 mL/min without bupropion to 0.73 mL/min Additional studies are needed to confirm this observation (Shad & Preskorn, 1997).

3.5.1.Z Butabarbital
1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive
2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa
3) Severity: minor
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.
7) Probable Mechanism: increased tricyclic antidepressant metabolism
8) Literature Reports
a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were ex metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipram half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar effe expected with any combination of TCA and barbiturate.

3.5.1.AA Butalbital
1) Interaction Effect: decreased efficacy of imipramine
2) Summary: A 44-year old female on imipramine therapy experienced a relapse of her depressive disorder a butalbital-containing product for headaches. Her imipramine concentration decreased by approximately 50% attributed to an induction of cytochrome P450 1A2 enzymes caused by butalbital (Garey et al, 1997a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Imipramine serum levels should be measured one week after the addition of butalbi dosage adjustments should be based on the results of the imipramine level and on the patient's response.
7) Probable Mechanism: induction of imipramine metabolism by butalbital
8) Literature Reports
a) A 44-year old woman was admitted to a psychiatric unit for an exacerbation of her depression. At the antidepressant regimen included imipramine 300 mg daily, with an imipramine concentration of 174 ng/m desipramine concentration of 134 ng/mL. These levels were considered within the normal range, and we her past concentrations. Because of recurring headaches, she was prescribed a product containing buta required 8 tablets (butalbital 400 mg) daily to control her headaches. The patient progressed well until tw hospital stay, when she again experienced a relapse of her depressive disorder. Concentrations at this ti imipramine 48 ng/mL and desipramine 122 ng/mL. Butalbital was the most reasonable explanation for th imipramine levels, so it was discontinued and imipramine was increased to 325 mg daily. However, furth documenting a return to normal imipramine concentrations were futile, since the patient restarted the but product from her stockpile at home (Garey et al, 1997).

3.5.1.AB Butalbital
1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive
2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa

3) Severity: minor
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.
7) Probable Mechanism: increased tricyclic antidepressant metabolism
8) Literature Reports
a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were ex metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar effe expected with any combination of TCA and barbiturate.

3.5.1.AC Cannabis

1) Interaction Effect: tachycardia and delirium
2) Summary: Concomitant tetrahydrocannabinol and tricyclic antidepressant therapy has increased the hear delirium beyond that expected with either drug alone (Wilens et al, 1997a; Hillard & Vieweg, 1983a).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Caution is advised if patients use cannabis with a tricyclic antidepressant. Monitor h closely.
7) Probable Mechanism: possibly due to beta-adrenergic effect of cannabis coupled with the anticholinergic antidepressants
8) Literature Reports
a) A 21-year-old female receiving oral nortriptyline 30 milligrams at bedtime for 9 months developed ma tachycardia (160 beats/minute) within 30 minutes of smoking a cannabis cigarette. The patient's heart ra beats/minute before smoking the cannabis. She had used cannabis many times before starting the nortri effects (Hillard & Vieweg, 1983).
b) Four cases of tachycardia, cognitive changes, and delirium have been reported in adolescent males t tricyclic antidepressants who smoked marijuana. One of the four cases was evaluated by a physician, th accounts of the event. The toxic effects were considered by the reporters to have resulted from a drug in they occurred with lower doses of marijuana than are common in other reports of marijuana toxicity (usu mg). In case 1, a 16-year-old male taking nortriptyline 75 mg/day presented with tachycardia (130 beats/ confusion, and short-term memory loss 30 minutes after smoking one marijuana cigarette. Symptoms re spontaneously after 24 hours. In case 2, and 18-year-old male taking desipramine 200 mg/day presente smoking marijuana with symptoms of edginess, severe dry mouth, lightheadedness, confusion, short-ter impairment, and tachycardia (110 beats/minute). Symptoms resolved within 48 hours. Case 3, a 15-year desipramine 150 mg/day and sertraline 50 mg/day, reported mood lability, irritability, and a racing heart a marijuana cigarettes which resolved after 16 hours. Case 4, a 16-year-old male taking desipramine and hallucinations, confusion, mild shortness of breath, and elevated heart rate after smoking marijuana. This than the effect he experienced prior to taking desipramine (Wilens et al, 1997).

3.5.1.AD Carbamazepine

1) Interaction Effect: decreased imipramine effectiveness
2) Summary: In a retrospective study of 36 children suffering from hyperactivity secondary to attention deficit antidepressant levels (imipramine and its metabolite desipramine) were decreased by 50% in children receivi compared to levels obtained with imipramine alone (Brown et al, 1990a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor for clinical efficacy of the imipramine therapy and for any signs of toxicity of Serum levels of both agents should be considered when either agent is added or discontinued, with appropria adjustments made accordingly.
7) Probable Mechanism: increased imipramine metabolism
8) Literature Reports
a) In a retrospective study, of 36 children with attention deficit hyperactivity disorder, the average plasma imipramine was significantly lower in patients treated with carbamazepine concurrently. The average dos was 1.3 mg/kg in patients receiving imipramine alone, compared to an imipramine dose of 1.8 mg/kg in p both imipramine and carbamazepine. The plasma level of imipramine, desipramine, and total tricyclic ant plasma levels were significantly lower in patients treated with carbamazepine concurrently. The dose of i need to be increased if carbamazepine is added to therapy and the dose of imipramine may need to be carbamazepine is stopped (Brown et al, 1990).
b) Combination therapy with carbamazepine decreases steady-state total serum concentrations of imipr

concentrations of desipramine. Thirteen patients were treated with imipramine 2 mg/kg/day for 3 weeks, carbamazepine 400 mg/day was added. The ratios of total concentrations of imipramine to desipramine and two weeks after carbamazepine intake (0.7 +/- 0.41 versus 0.63 +/- 0.36; p greater than 0.05). Free imipramine and desipramine were elevated after the addition of carbamazepine. Despite lowever imipran desipramine total concentrations, the combination treatment with carbamazepine in depressed patients i tolerated. Dosage increase of imipramine does not appear to be necessary in the depressed patients inc (Szymura-Oleksiak et al, 2001).

3.5.1.AE Chloral Hydrate

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Chloral hydrate and tricyclic antidepressants have been shown to prolong the QTc interval at th therapeutic dose (Young et al, 1986; Marshall & Forker, 1982m). Even though no formal drug interaction stud done, the coadministration of drugs known to prolong the QTc interval is not recommended.
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of chloral hydrate and a tricyclic antidepressant is no
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AF Chloroquine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Chloroquine can prolong the QT interval in some patients, which may result in ventricular tachy fibrillation, and torsades de pointes. Because tricyclic antidepressants may also prolong the QT interval and i arrhythmias, the concurrent administration of chloroquine and tricyclic antidepressants is not recommended ((R), 1999; Marshall & Forker, 1982y).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of chloroquine and a tricyclic antidepressant is not re
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AG Chlorotrianisene

1) Interaction Effect: attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypotension, a
2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de estrogens (Somani & Khurana, 1973e), with paradoxical loss of antidepressant effect yet tricyclic toxicity beir simultaneously (Prange, 1972e). The effects of the interaction appear to be estrogen dose-related (Khurana, be of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started o (Krishnan et al, 1984e).
3) Severity: minor
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.
7) Probable Mechanism: unknown
8) Literature Reports

a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I depressed female prisoners were randomly assigned to 4 treatment groups. Ten patients received place imipramine (150 mg daily) and placebo, five patients received imipramine (150 mg daily) and ethinyl estr daily), while five patients received imipramine (150 mg daily) and ethinyl estradiol (25 mcg daily). The ter received placebo did not improve over the six weeks of the study. The ten patients taking estrogen and i demonstrated a significantly greater improvement in symptoms than did the ten patients taking imipramir after two weeks, the five patients who received imipramine and high-dose estrogen had not improved as patients receiving imipramine and low-dose estrogen. The only side effect reported was drowsiness, whi the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period of two wee for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed to the pr estrogen in the high-dose group. In another group, five women received imipramine 150 mg and ethinyl e daily did not improve as much as ten patients receiving only imipramine. Also, the patients on the combi side-effects including lethargy, coarse tremor and systolic hypotension (Prange, 1972d).

b) A case reported demonstrated an interaction in a 32-year-old female taking conjugated estrogens 2.5 imipramine 100 mg (Khurana, 1972d). The patient developed lethargy, tremors, and signs of depersonal years of therapy, the patient increased her estrogen dose to 5 mg and then 7.5 mg daily. The patient bec had constant headaches, and low normal blood pressure. All lab work was normal. Upon discontinuing th side-effects abated. Some investigators have proposed that the side effects resulted from enhanced TCA secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1973d).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begin there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients'

clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973b).

d) The effects of oral contraceptives on clomipramine were studied in 42 women between the ages of 18 three women took clomipramine 25 mg at bedtime while 19 took clomipramine 25 mg at bedtime with ora Over the four-week study, three control patients (two due to side-effects) and five in the experimental gro side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of ser concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980b).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep concurrently. A 24-year-old patient receiving clomipramine 120 mg daily for anorexia nervosa and conjug 1.25 mg daily for amenorrhea developed restless legs and a constant desire to move continuously. Estro discontinued and benztropine 2 mg was administered, resulting in marked reduction and resolution withi Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogen 1.25 mg daily wh amitriptyline 50 mg daily for depression. Within hours of amitriptyline, the patient was confused, restless, inner desire to move continuously. Symptoms disappeared after discontinuing amitriptyline. A third case reported in a 35-year-old patient who received conjugated estrogen 1.25 mg daily and amitriptyline 50 m developed within a few hours after taking the first dose of amitriptyline and resolved within 48 hours follo discontinuation of the antidepressant (Krishnan et al, 1984d).

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept less of ethinyl estradiol) from 27% to 44% (p less than 0.05) as evident by an increase in the area under concentration time curve (Abernethy et al, 1984c).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19 are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer system resulting in an antidepressant effect (Oppenheim, 1983b).

3.5.1.AH Cimetidine

1) Interaction Effect: imipramine toxicity (dry mouth, urinary retention, blurred vision)

2) Summary: Concomitant cimetidine and imipramine therapy has resulted in inhibition of the metabolism of leading to prolonged half-life and elevated serum concentrations (Miller & Macklin, 1983a; Wells et al, 1986a; 1984b) and adverse effects (Miller & Macklin, 1983a; Sutherland et al, 1987; Wells et al, 1986a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Imipramine levels should be considered within the first few days of starting or disco cimetidine. An alternative H2 blocker that does not appear to impair the metabolism of imipramine, such as ra famotidine, might be considered.

7) Probable Mechanism: decreased imipramine metabolism

8) Literature Reports

a) In a case report, a 32-year-old woman concurrently on cimetidine 300 mg four times daily for abdomi exhibited severe anticholinergic side effects and orthostatic hypotension with the addition of imipramine, (Miller & Macklin, 1983). Upon rechallenge, imipramine pharmacokinetics with and without cimetidine we concurrent administration of cimetidine 300 mg four times daily and imipramine 100 mg daily, steady stat life for imipramine was 44 hours and plasma clearance 210 mL/minute. The ratio of imipramine to desipr calculated to be 2.6 (normal ratio 1 to 1.2). Upon discontinuation of cimetidine the elimination half-life of i decreased to 23 hours and the plasma clearance increased to 355 mL/minute. The patient was able to c without complaints of anticholinergic side effects without cimetidine. Cimetidine also was reported to incr bioavailability of oral imipramine doses in six healthy volunteers, in addition to impairing imipramine clea increasing the desipramine area under the curve (Abernethy et al, 1984a).

b) Six healthy young (24 to 25 year-old) volunteers participated in four randomly sequenced clinical trial effects of cimetidine administration on the pharmacokinetics of imipramine. Each clinical trial was separa week. Trial 1: 12.5 mg of imipramine was infused over 30 minutes. Trial 2: 300 mg of cimetidine was adm every six hours, starting 12 hours prior to the imipramine dose (12.5 mg intravenously infused over 30 m continued for 96 hours after the imipramine dose. Trial 3: 50 mg of imipramine was administered orally fo overnight fast, with the fast continued for three hours following administration of the drug. Trial 4: Cimetic administered as described in trial 2 and 50 mg imipramine was administered oral as described in trial 3. half-life for imipramine was significantly increased (15.5 hours to 22.1 hours) during cimetidine therapy ir administration group and increased (15.3 hours to 20.7 hours), but not significantly, in the oral administra Absolute bioavailability for orally administered imipramine nearly doubled (40% to 75%) during cimetidine on these results patients receiving concurrent cimetidine and imipramine therapy should have a 50% to 6 imipramine dose in order to avoid potential imipramine toxicity or should have their plasma imipramine/d monitored closely (Abernethy & Kerzner, 1984b).

c) Concomitant administration of cimetidine and imipramine was reported to result in psychosis (in the p sensorium) in a 38-year-old woman with major depression. Discontinuation of both drugs resulted in reso and depression within 72 hours. However, it is unclear if this patient's psychotic features were induced s combination of these two agents (Miller et al, 1987).

d) The impaired elimination of these tricyclic antidepressants is rather rapid and new steady state serum

would be expected to be achieved in three to five days after initiation of cimetidine therapy. It is suggeste doses be adjusted downward by 50% when cimetidine is given concurrently with further adjustments in c determined by plasma level monitoring (Wells et al, 1986).

e) Using microsomes from 4 human livers, cimetidine was shown to inhibit the demethylation of imipram hydroxylation of desmethylimipramine (Spina & Koike, 1986).

3.5.1.AI Cisapride

1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Cisapride therapy has resulted in serious cardiac arrhythmias, including ventricular tachycardia fibrillation, torsades de pointes, and QT prolongation. Because tricyclic antidepressant agents also may prolo and increase the risk of arrhythmias, the concurrent administration of cisapride with a drug from this class is c (Prod Info Propulsid(R), 2000).

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent use of cisapride and tricyclic antidepressants is contraindicated.

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AJ Citalopram

1) Interaction Effect: an increase in the bioavailability and half-life of desipramine, the major metabolite of im

2) Summary: Imipramine pharmacokinetics were not influenced by citalopram when the two were coadminist Celexa(TM), 2002; Gram et al, 1993a). However, citalopram may increase exposure to desipramine, the majo imipramine. Clinical events have not been reported and, in an isolated report, citalopram was successfully su paroxetine in a patient who had experienced elevated tricyclic antidepressant levels during paroxetine treatm an inhibitor of cytochrome P450 2D6 enzymes, and imipramine, a tertiary amine, is converted to a secondary (desipramine) by N-demethylation. The secondary amine then undergoes hydroxylation, a process which is c oxidative enzymes of the CYP2D6 system (Taylor, 1995).

3) Severity: moderate

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Caution is indicated in the coadministration of tricyclic antidepressants and citalopra monitoring tricyclic antidepressant concentration and/or dose adjustment when there is a change in therapy c citalopram. However, citalopram may be preferred over paroxetine when tricyclic antidepressants are coadmi

7) Probable Mechanism: inhibition of desipramine metabolism, the major metabolite of imipramine

8) Literature Reports

a) Eight healthy male volunteers completed three phases of an interaction study to determine the effects imipramine and citalopram. All subjects were extensive metabolizers of sparteine, indicating normal cyto enzyme activity. Each subject received citalopram 40 mg alone as a single daily dose for 10 days, imipra single oral dose, and a single oral dose of imipramine 100 mg coadministered on day 7 of citalopram the weeks separated each treatment phase. Results showed that the concurrent administration of citalopram resulted in a 50% increase in the desipramine area under the concentration-time curve (AUC) and a simi 2-hydroxy-desipramine AUC. Also, the desipramine half-life was approximately seven hours longer wher citalopram (27 hours vs. 20 hours). The AUC and half-life of imipramine were not affected by citalopram These results showed that citalopram is an inhibitor of cytochrome P450 2D6 hepatic enzymes, since mo antidepressants rely on this system for metabolism (Gram et al, 1993).

b) A case report describes a 45-year-old white female with major depressive disorder and dysthymia. Th several trials of antidepressants from all available drug classes, as well as electroconvulsive therapy. Th medications included pindolol, desipramine, clonazepam, and olanzapine. Paroxetine was initiated and t mg/day occurred over 3 months. The patient developed light-headedness, ataxia, and increased confusi titration. Desipramine serum levels were 1810 ng/mL (therapeutic range 75-300 ng/mL). After decreasing desipramine 200 mg, the serum desipramine level was still 1665 ng/mL. The reduction in side effects we the paroxetine dose was decreased to 30 mg/day and desipramine dose was decreased to 150 mg/day. dosage reduction of both drugs the patient's serum desipramine level was 1153 ng/mL. Paroxetine was d desipramine dose was decreased to 100 mg/day in divided doses. Citalopram was initiated and titrated t the next two months the patient's desipramine level decreased to 195 ng/mL. Depressive symptoms also Desipramine toxicity is presumed to be caused by hepatic cytochrome P450 2D6 (CYP2D6) isoenzyme I paroxetine. The author concludes that the switch to citalopram likely is responsible for diminished desipra levels, although alternative explanations should not be discounted (Ashton, 2000).

3.5.1.AK Clarithromycin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Tricyclic antidepressants (TCAs) and clarithromycin have been shown to prolong the QTc inter recommended therapeutic dose (Prod Info Biaxin(R), 2002; Marshall & Forker, 1982o). Even though no forma studies have been done, the coadministration of tricyclic antidepressants and other drugs known to prolong th such as clarithromycin, is not recommended (Prod Info Elavil(R), 1999h).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of tricyclic antidepressants and agents that prolong t
such as clarithromycin, is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.AL Clonidine

1) Interaction Effect: decreased antihypertensive effectiveness
2) Summary: Concomitant clonidine and tricyclic antidepressant (TCA) therapy may impair the antihypertens
clonidine (Prod Info Catapres(R), 1996). Tricyclic antidepressants increase the release of noradrenaline, pres
re-uptake blockade. Clonidine reduces the release of noradrenaline by stimulating pre-synaptic alpha-2 adrer
whose function is to inhibit noradrenaline release (Briant et al, 1973a; Hicks et al, 1981; Hui, 1983; Glass et a
Mianserin, a tetracyclic antidepressant, was not shown to exhibit the impairment of clonidine's antihypertensi
with tricyclic antidepressants (Elliott et al, 1981; Elliott et al, 1983).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Blood pressure should be monitored for an appropriate clinical response. Higher do
may be required. An alternative class of antihypertensive agents or an alternative class of antidepressants m
7) Probable Mechanism: pharmacological antagonism at central alpha-2 receptors
8) Literature Reports

a) The interaction between clonidine and desipramine was studied in five hypertensive patients. The res
blind placebo controlled study showed that the introduction of the tricyclic antidepressant led to the loss
control in four of the five subjects within two weeks. The rise in the arterial pressure was more prominent
position than in the erect. The average blood pressure increase in the desipramine period compared to t
was 22/15 mm Hg in the lying position and 12/11 mm Hg standing (Briant et al, 1973).

b) Eleven drug-free patients who met the Research Diagnostic Criteria for Major Depressive Disorder er
determine the effects of desipramine on central adrenergic function. Patients were given a clonidine infus
3 weeks of treatment with desipramine. Results showed that the sedative and hypotensive effects of clor
significantly inhibited after three weeks of treatment with desipramine. This interaction was also seen at
not reach clinical significance. The authors concluded that the effects that were observed during the stuc
acute drug effect, rather than to a chronic adaptive change (Glass et al, 1982).

c) One case report describes a 65-year-old man who was experiencing perineal pain following the excis
carcinoma. Pain management of amitriptyline 75 mg nightly and sodium valproate 500 mg three times da
after slow-release morphine only had a limited effect. A clonidine spinal intrathecal injection of 75 microg
when it was felt that the patient had become tolerant to opioid treatment. Within five minutes, the patient
severe pain, which resolved within 30 minutes after diamorphine was given. Two mechanisms for this int
postulated. In the first, the pain could have been the result of a clonidine-cholinergic interaction. In the se
augmentation of serotoninergic transmission may have unmasked an effect of clonidine at central recept
nociception (Hardy & Wells, 1988).

3.5.1.AM Clorgyline

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus
changes)
2) Summary: Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concur
and TCAs has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982e; Spig
Brodribb et al, 1994e; Neuvonen et al, 1993b). Serotonin syndrome is a rare but potentially fatal condition of
hyperstimulation characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Ste
Consequently, coadministration of TCAs and MAOIs is contraindicated in most cases. If TCAs and MAOIs mu
concurrently, avoid large doses, use only oral TCAs, avoid imipramine, clomipramine, desipramine, and trany
monitor patients closely (Schuckit et al, 1971e; White & Simpson, 1984d).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of a tricyclic antidepressant, such as imipramine with an monoam
inhibitor (MAOI), such as clorgyline is contraindicated. If imipramine is replacing treatment with clorgyline, a m
weeks should elapse after clorgyline is discontinued before therapy with imipramine begins (Prod Info imipran
oral tablet, 2003). There is no specific washout period for replacing imipramine treatment with clorgyline. How
advisable to gradually taper the tricyclic antidepressant dosage before starting treatment with the MAOI (Rem
7) Probable Mechanism: altered catecholamine uptake and metabolism
8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T
considered an absolute contraindication in the past and still is listed as such by the manufacturers (Prod
hydrochloride oral tablet, 2003). Reports of excitation, hyperpyrexia, convulsions, and possible death hav
to the combination (Lockett & Milner, 1965b; Brachfeld et al, 1963a; Winston, 1971b; Schuckit et al, 197
1965a; Spiker & Pugh, 1976b). The mechanism may relate to the combined inhibition of catecholamine r
central nervous system and inhibition of catecholamine metabolism (Sjoqvist, 1965b).

b) The development of serotonin syndrome due to administration of a TCA after MAOI therapy has beer
double-blind, crossover study examining the effects of clorgyline and clomipramine for the treatment of o
compulsive disorder, two subjects developed severe reactions characteristic of serotonin syndrome. Dur

patients had received clorgyline therapy, followed by a washout period of approximately four weeks and clomipramine therapy. After taking the first 100 mg dose of clomipramine, one patient developed coarse in both legs, hyperreflexia, diaphoresis, and arrhythmia. Another patient developed a similar reaction afte with upper motor neuron symptoms, myoclonic movements, and cardiac irritability. Both patient's sympto several hours later, and both patients were later treated successfully with clomipramine without adverse 1982d).

c) A 76-year old woman who had been taking clomipramine 50 mg daily for several months was switche 300 mg daily. The patient experienced somnolence, confusion, and fever which then progressed to furth impairment, muscle stiffness, myoclonus, and convulsive attacks. The patient's symptoms were describe diagnostic criteria for serotonin syndrome and were resolved a few days later after discontinuing all antid medications (Spigset et al, 1993e).

d) A 39-year old woman with bipolar disorder developed serotonin syndrome after imipramine was adde The patient was taking moclobemide 300 mg twice daily when imipramine was started at 50 mg daily, fol dosage increases of imipramine to 200 mg and a reduction of moclobemide dosage to 150 mg twice dail the increase in imipramine to 200 mg per day, the patient developed symptoms of serotonin syndrome, i shivering, confusion, fever, and spasms in the extremities. The patient was treated with chlorpromazine a resolved over the next few days without further complications (Brodribb et al, 1994d).

e) Three patients with bipolar disorder developed manic symptoms while undergoing concurrent therapy isocarboxazid and amitriptyline. In all three cases the patients had been given MAOIs and TCAs alone w complications. It was only when the drugs were used in combination that symptoms of mania emerged, s synergistic effect (de la Fuente et al, 1986a).

f) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a pl 34-year old man. After taking several doses, the patients developed symptoms of nausea and profuse sw by pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulatio death (Tackley & Tregaskis, 1987c).

g) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unrespons TCA alone. A few precautions must be followed including: a) avoidance of large doses (no more than 15 or its equivalent, 45 mg phenelzine, or 60 mg isocarboxazid) b) oral administration c) avoidance of clomi imipramine, desipramine, and tranylcypromine in any combination, and d) close monitoring of patients (K Winston, 1971b; Schuckit et al, 1971d; White & Simpson, 1984c; Rom & Benner, 1972a). The combinati in one of two ways. Most frequently, the recommendation is to stop all previous antidepressants (five to t and 14 days for MAOIs); the combination is then simultaneously started (Perry et al, 1991b). Alternativel previously receiving a TCA, small doses of the MAOI may be slowly added (Schoonover, 1983). Some s that the combination of amitriptyline and isocarboxazid is preferred (Perry et al, 1991b). Numerous studie refractory depression or phobic anxiety states have successfully used the combination of MAOIs and TC 1977b; Schuckit et al, 1971d; Ashcroft, 1975b).

3.5.1.AN Conjugated Estrogens

1) Interaction Effect: possible attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypo

2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de estrogens (Somani & Khurana, 1973c), with paradoxical loss of antidepressant effect yet tricyclic toxicity bein simultaneously (Prange, 1972c). The effects of the interaction appear to be estrogen dose-related (Khurana, be of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started o (Krishnan et al, 1984c).

3) Severity: minor

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.

7) Probable Mechanism: possible inhibition of hepatic metabolism of the tricyclic antidepressant

8) Literature Reports

a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I depressed female prisoners were randomly assigned to four treatment groups. Ten patients received pla imipramine (150 mg daily) and placebo, five patients received imipramine (150 mg daily) and ethinyl estr daily), while five patients received imipramine (150 mg daily) and ethinyl estradiol (25 mcg daily). The 10 received placebo did not improve over the six weeks of the study. The 10 patients taking estrogen and in demonstrated a significantly greater improvement in symptoms than did the 10 patients taking imipramin after two weeks, the five patients that received imipramine and high-dose estrogen had not improved as patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsiness, whi the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period of two wee for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed to the pr estrogen in the high-dose group. In another group, five women received imipramine 150 mg and ethinyl e daily did not improve as much as 10 patients receiving only imipramine. Also, the patients on the combin side-effects including lethargy, coarse tremor and systolic hypotension (Prange, 1972b).

b) A 32-year-old female taking conjugated estrogens 2.5 mg and imipramine 100 mg developed lethargy signs of depersonalization. After two years of therapy, the patient increased her estrogen dose to 5 mg a daily. The patient became nauseated, had constant headaches, and low normal blood pressure. All lab v

Upon discontinuing the estrogen, the side effects abated. Some investigators have proposed that the sid from enhanced TCA effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1972b).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begir there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the c matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients' clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973a).

d) The effects of oral contraceptives on clomipramine was studied in 42 women between the ages of 18 three women took clomipramine 25 mg at bedtime while 19 took clomipramine 25 mg at bedtime with ora Over the four-week study, three control patients (two due to side-effects) and five in the experimental gro side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of se concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980a).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep concurrently. A 24-year-old patient receiving clomipramine 120 mg daily for anorexia nervosa and conjug 1.25 mg daily for amenorrhea developed restless legs and a constant desire to move continuously. Estro discontinued and benztropine 2 mg was administered, resulting in marked reduction and resolution withi Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogen 1.25 mg daily wh amitriptyline 50 mg daily for depression. Within hours of amitriptyline, the patient was confused, restless, inner desire to move continuously. Symptoms disappeared after discontinuing amitriptyline. A third case reported in a 35-year-old patient who received conjugated estrogen 1.25 mg daily and amitriptyline 50 m developed within a few hours after taking the first dose of amitriptyline and resolved within 48 hours follo discontinuation of the antidepressant (Krishnan et al, 1984b).

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept less of ethinyl estradiol) from 27% to 44% (p less than 0.05) as evident by an increase in the area under concentration time curve (Abernethy et al, 1984a).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19 are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer system resulting in an antidepressant effect (Oppenheim, 1983a).

3.5.1.AO Darifenacin

1) Interaction Effect: increased imipramine exposure and potentially increased adverse effects

2) Summary: Concomitant use of darifenacin and imipramine may result in substantially increased exposure its active metabolite desipramine. The mean maximum concentration (Cmax) and area under the concentrati (AUC) of imipramine increased 57% and 70%, respectively, when used together with darifenacin 30 mg once state. Note: The recommended dose of darifenacin is 7.5 or 15 mg once daily. The AUC of desipramine, the a of imipramine, increased 3.6-fold. Caution should be used with the coadministration of darifenacin and CYP2 a narrow therapeutic window, such as tricyclic antidepressants, including imipramine (Prod Info Enablex, 200

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Use caution with the coadministration of darifenacin and other CYP2D6 substrates therapeutic window, such as imipramine. Monitor for imipramine toxicity.

7) Probable Mechanism: competitive inhibition of CYP2D6-mediated imipramine metabolism

3.5.1.AP Dexfenfluramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen
coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i
amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE
sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o
antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde
2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i
such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm
of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return
normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle
Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g
four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie
clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami
1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc
therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior
although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru
depression, with one exception, indicated little advantage of drug over placebo and did not appear to be
conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.AQ Dexmethylphenidate

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte
enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sin
also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n
(Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co
not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of
agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects
dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o
Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t
Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru
depression, with one exception, indicated little advantage of drug over placebo and did not appear to be
conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.AR Dextroamphetamine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte
enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sin

also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n
(Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co
not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of
agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects
dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o
Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t
Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen
coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained in
amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE
sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o
antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde
2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in
such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm
of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return
normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle
Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g
four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie
clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami
1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc
therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior
although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru
depression, with one exception, indicated little advantage of drug over placebo and did not appear to be
conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.AS Dicumarol
1) Interaction Effect: increased risk of bleeding
2) Summary: Tricyclic antidepressants (TCAs) may increase the half-life and bioavailability of oral anticoagul
1970e; Williams et al, 1976e). Considerable interindividual differences may be found (Pond et al, 1975e).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: In patients receiving oral anticoagulant therapy, the prothrombin time ratio or INR (i
normalized ratio) should be closely monitored with the addition and withdrawal of treatment with imipramine,
reassessed periodically during concurrent therapy. Adjustments of the dicumarol dose may be necessary in o
the desired level of anticoagulation.
7) Probable Mechanism: decreased dicumarol metabolism; increased dicumarol absorption
8) Literature Reports
a) In a study of healthy volunteers, the concurrent use of nortriptyline or amitriptyline resulted in an incre
levels and an increase in the plasma half-life of dicumarol, although the effect was not consistent in all su
1975d). This effect was not observed with warfarin.
b) A single oral dose of bishydroxycoumarin after eight days of nortriptyline resulted in a significantly pro
and decreased volume of distribution of the coumarin anticoagulant in six healthy volunteers (Vesell et a
mechanism of action was suggested to be reduced bishydroxycoumarin metabolism and/or altered coum
c) Drug dosing was studied in 16 patients on long-term anticoagulant therapy who used concurrent TCA
1976d). TCAs affected the stability of anticoagulant control leading to frequent changes in the doses of a
Inhibition of coumarin metabolism was the postulated mechanism.

3.5.1.AT Dienestrol
1) Interaction Effect: attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypotension, a
2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de
estrogens (Somani & Khurana, 1973g), with paradoxical loss of antidepressant effect yet tricyclic toxicity beir
simultaneously (Prange, 1972g). The effects of the interaction appear to be estrogen dose-related (Khurana,
be of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started o
(Krishnan et al, 1984g).

3) Severity: minor
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.
7) Probable Mechanism: possible estrogen-enhanced hepatic metabolism of the tricyclic
8) Literature Reports

a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I depressed female prisoners were randomly assigned to 4 treatment groups. Ten patients received place imipramine (150 milligrams/day) and placebo, 5 patients received imipramine (150 milligrams/day) and e micrograms/day), while 5 patients received imipramine (150 milligrams/day) and ethinyl estradiol (25 mic 10 patients that received placebo did not improve over the 6 weeks of the study. The 10 patients taking e imipramine demonstrated a significantly greater improvement in symptoms than did the 10 patients takin alone. However, after 2 weeks, the 5 patients that received imipramine and high-dose estrogen had not i as the patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsine affected the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period o required for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed residual estrogen in the high-dose group. In another group, 5 women received imipramine 150 milligrams estradiol 50 micrograms daily did not improve as much as 10 patients receiving only imipramine. Also, th combination had severe side-effects including lethargy, coarse tremor and systolic hypotension (Prange,

b) A case reported by (Khurana, 1972f) demonstrated an interaction in a 32-year-old female taking conj 2.5 milligrams and imipramine 100 milligrams. The patient developed lethargy, tremors, and signs of dep After 2 years of therapy, the patient increased her estrogen dose to 5 milligrams and then 7.5 milligrams became nauseated, had constant headaches, and low normal blood pressure. All lab work was normal. the estrogen, the side-effects abated. Some investigators have proposed that the side effects resulted fr effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1973f).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begin there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients' clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973c).

d) The effect of oral contraceptives on clomipramine was studied in 42 women between the ages of 18 a three women took clomipramine 25 milligrams at bedtime while 19 took clomipramine 25 milligrams at be contraceptives. Over the 4-week study, 3 control patients (2 due to side-effects) and 5 in the experimenta side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of se concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980c).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep concurrently. A 24-year-old patient receiving clomipramine 120 milligrams/day for anorexia nervosa and estrogens 1.25 milligrams/day for amenorrhea developed restless legs and a constant desire to move co Estrogen was discontinued and benztropine 2 milligrams was administered, resulting in marked reductio within 48 hours. Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogens milligrams/day who was prescribed amitriptyline 50 milligrams/day for depression. Within hours of amitrip was confused, restless, and possessed an inner desire to move continuously. Symptoms disappeared af amitriptyline. Positive rechallenge at one week with doxepin 100 milligrams, with resolution following disc doxepin. A third case of akathisia was reported in a 35-year-old patient who received conjugated estroge milligrams/day and amitriptyline 50 milligrams/day. Akathisia developed within a few hours after taking th amitriptyline and resolved within 48 hours following discontinuation of the antidepressant (Krishnan et al,

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept micrograms or less of ethinyl estradiol) from 27 to 44% (p less than 0.05) as evident by an increase in th plasma concentration time curve (Abernethy et al, 1984d).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19 are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer system resulting in an antidepressant effect (Oppenheim, 1983c).

3.5.1.AU Diethylpropion

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sin also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects

dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.AV Diethylstilbestrol
1) Interaction Effect: attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypotension, a
2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de estrogens (Somani & Khurana, 1973k), with paradoxical loss of antidepressant effect yet tricyclic toxicity bein simultaneously (Prange, 1972k). The effects of the interaction appear to be estrogen dose-related (Khurana, be of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started o (Krishnan et al, 1984k).
3) Severity: minor
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.
7) Probable Mechanism: possible estrogen-enhanced hepatic metabolism of the tricyclic
8) Literature Reports
a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I depressed female prisoners were randomly assigned to 4 treatment groups. Ten patients received place imipramine (150 milligrams/day) and placebo, 5 patients received imipramine (150 milligrams/day) and e micrograms/day), while 5 patients received imipramine (150 milligrams/day) and ethinyl estradiol (25 mic 10 patients that received placebo did not improve over the 6 weeks of the study. The 10 patients taking e imipramine demonstrated a significantly greater improvement in symptoms than did the 10 patients takin alone. However, after 2 weeks, the 5 patients that received imipramine and high-dose estrogen had not i as the patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsine affected the patients taking imipramine. This effect was attributed residual estrogen in the high-dose group. In another group, 5 women received imipramine 150 milligrams estradiol 50 micrograms daily did not improve as much as 10 patients receiving only imipramine. Also, th combination had severe side-effects including lethargy, coarse tremor and systolic hypotension (Prange,
b) A case reported by (Khurana, 1972j) demonstrated an interaction in a 32-year-old female taking conju 2.5 milligrams and imipramine 100 milligrams. The patient developed lethargy, tremors, and signs of dep After 2 years of therapy, the patient increased her estrogen dose to 5 milligrams and then 7.5 milligrams became nauseated, had constant headaches, and low normal blood pressure. All lab work was normal. U the estrogen, the side-effects abated. Some investigators have proposed that the side effects resulted fr effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1973j).
c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begin there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the c

matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients' clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973f).

d) The effect of oral contraceptives on clomipramine was studied in 42 women between the ages of 18 a three women took clomipramine 25 milligrams at bedtime while 19 took clomipramine 25 milligrams at be contraceptives. Over the 4-week study, 3 control patients (2 due to side-effects) and 5 in the experimenta side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of ser concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980e).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep concurrently. A 24-year-old patient receiving clomipramine 120 milligrams/day for anorexia nervosa and estrogens 1.25 milligrams/day for amenorrhea developed restless legs and a constant desire to move co Estrogen was discontinued and benztropine 2 milligrams was administered, resulting in marked reductio within 48 hours. Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogens milligrams/day who was prescribed amitriptyline 50 milligrams/day for depression. Within hours of amitrip was confused, restless, and possessed an inner desire to move continuously. Symptoms disappeared af amitriptyline. Positive rechallenge at one week with doxepin 100 milligrams, with resolution following disc doxepin. A third case of akathisia was reported in a 35-year-old patient who received conjugated estroge milligrams/day and amitriptyline 50 milligrams/day. Akathisia developed within a few hours after taking th amitriptyline and resolved within 48 hours following discontinuation of the antidepressant (Krishnan et al,

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept micrograms or less of ethinyl estradiol) from 27 to 44% (p less than 0.05) as evident by an increase in th plasma concentration time curve (Abernethy et al, 1984f).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19 are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer system resulting in an antidepressant effect (Oppenheim, 1983e).

3.5.1.AW Diltiazem

1) Interaction Effect: imipramine toxicity (dry mouth, sedation)

2) Summary: Diltiazem decreased imipramine oral clearance by 35% (statistically significant) compared to pl randomized, crossover study in 12 healthy subjects (Hermann et al, 1992c). Diltiazem increased imipramine l 30% compared to placebo which was also significant; the clinical significance of this is not known.

3) Severity: minor

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Monitor for anticholinergic side effects of imipramine if diltiazem is added to therapy imipramine may be appropriate. Conversely, if diltiazem is discontinued, monitor continued clinical efficacy of adjust dosage accordingly.

7) Probable Mechanism: decreased imipramine clearance

8) Literature Reports

a) Imipramine serum concentrations may be altered if administered concomitantly with diltiazem. Follow imipramine 100 mg/day on day 4 of a 7 day course of diltiazem 90 mg/q8h during a controlled study, the imipramine decreased by 35% resulting in a significant increase (35%) in the peak serum concentration. failed to occur when the drug was given to those receiving placebo. Monitor drug levels for effectiveness when adding or decreasing diltiazem dosages (Hermann et al, 1992b).

3.5.1.AX Disopyramide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Class Ia antiarrhythmics and tricyclic antidepressants have been shown to prolong the QTc inte recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadm Ia antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is n (Prod Info Elavil(R), 1999g; Prod Info Quinaglute(R), 1999; Marshall & Forker, 1982n).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic agent and a tricyclic anti recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) Quinidine is an inhibitor of the cytochrome P450 isoenzyme responsible for the 2-hydroxylation of imi desipramine (Brosen & Gram, 1989). Inhibition of this enzyme system can result in a 35% decrease in im clearance and 85% decrease in desipramine clearance. Demethylation of imipramine by the cytochrome unaffected by this interaction. Until more information is available all patients having quinidine added to dr containing imipramine or desipramine should be monitored for increased antidepressant serum concentr potential toxicity.

b) An increased incidence in sudden death was observed in six out of 53 patients with cardiac disease r

amitriptyline, compared to 0 out of 53 in the control group. It was recommended that amitriptyline be avo with underlying cardiac disease except when depression was debilitating and no other drugs were helpfu Coull et al, 1970).

c) In a placebo controlled study, imipramine 3.5 mg/kg was administered daily for seven patients with se and titrated doses to obtain therapeutic plasma concentrations. Two patients displayed premature atrial and premature ventricular depolarizations before therapy. On patient had 33 premature atrial depolarizat premature ventricular depolarizations (PVD) per hour, which decreased to 0.4 PAC and zero PVC per ho The other patient had 12 PAD and 169 PVD per hour before treatment and 1.8 PAD and 28.1 PVD per h The authors also cautioned that the incidence of cardiotoxicity may increase if tricyclic antidepressants a with Type I antiarrhythmics. It was also recommended that quinidine and procainamide not be used to tre of a tricyclic overdose. The similarities between these agents may exacerbate the cardiotoxicity (Kantor

3.5.1.AY Disulfiram

1) Interaction Effect: increased bioavailability of imipramine

2) Summary: Increased elimination half-life, higher peak plasma levels, and decreased total body clearance when administered during disulfiram therapy have been demonstrated (Ciraulo et al, 1985). The clinical signif finding is unknown.

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor the patient for excessive adverse effects to imipramine.

7) Probable Mechanism: disulfiram-induced inhibition of imipramine hepatic metabolism

8) Literature Reports

a) Two healthy men who had been detoxified for 14 days participated in a study to determine the effect pharmacokinetics of imipramine and desipramine. Doses of imipramine 12.5 mg were administered intra to disulfiram 500 mg daily therapy and after 14 days of therapy with disulfiram. The protocol for desipram same but was performed only in one subject. For imipramine, the area under the concentration-time curv by 32.5% and 26.8% after disulfiram administration in patient 1 and patient 2, respectively. The eliminati also increased by 18.3% and 13.6%, respectively, while the total body imipramine clearance decreased respectively. Desipramine showed a 32.3% increase in the AUC when administered with disulfiram. The also increased by 19.8% and the total body clearance decreased 24.3% (Ciraulo et al, 1985).

3.5.1.AZ Dofetilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).

b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any interac initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.BA Dolasetron

1) Interaction Effect: cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Tricyclic antidepressants (TCAs) and dolasetron have been shown to prolong the QTc interval recommended therapeutic dose (Marshall & Forker, 1982b). Even though no formal drug interaction studies h the coadministration of tricyclic antidepressants and other drugs known to prolong the QTc interval, such as c recommended (Prod Info Elavil(R), 1999a; Prod Info Anzemet(R), 1997).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of dolasetron with other agents that may prolong the as tricyclic antidepressants, is not recommended.

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.BB Droperidol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Droperidol has been shown to prolong the QTc interval at the recommended therapeutic dose. formal drug interaction studies have been done, the coadministration of droperidol and other drugs known to interval, including tricylclic antidepressants is not recommended (Prod Info Inapsine(R), 2002; Marshall & For

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of droperidol and tricyclic antidepressants is not reco

7) Probable Mechanism: additive cardiac effects

3.5.1.BC Duloxetine

1) Interaction Effect: increased tricyclic antidepressant serum concentrations and potential toxicity (anticholir sedation, confusion, cardiac arrhythmias)

2) Summary: The coadministration of duloxetine with a tricyclic antidepressant is likely to increase bioavailab agent, increasing the risk of adverse events. Duloxetine is a moderately potent inhibitor of CYP2D6. When a CYP2D6 substrate desipramine 50 mg and duloxetine 60 mg twice daily were coadministered, the desipramir 3-fold over baseline (Prod Info CYMBALTA(R) delayed-release oral capsules, 2008).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Use caution with the combined use of duloxetine with tricyclic antidepressants (TCA therapy with duloxetine and a TCA is unavoidable, plasma concentrations of the tricyclic should be closely m adjustments made accordingly (Prod Info CYMBALTA(R) delayed-release oral capsules, 2008). Also, monito and symptoms of TCA toxicity (anticholinergic effects, sedation, confusion, and cardiac arrhythmias).

7) Probable Mechanism: duloxetine inhibition of CYP2D6-mediated tricyclic agent metabolism

3.5.1.BD Enflurane

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest) risk of seizure activity

2) Summary: Enflurane may prolong the QT interval in some patients (Owens, 2001). Because tricyclic antid also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of enflurane a antidepressants is not recommended (Marshall & Forker, 1982a). Concomitant administration of amitriptyline anesthesia has been reported to result in seizures in two cases (Sprague & Wolf, 1982a).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: Avoid concurrent use of enflurane and tricyclic antidepressants, particularly in patie of seizure activity or when hyperventilation or high concentrations of enflurane will be required.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Two case reports of patients on amitriptyline therapy who experienced seizure activity while receiving anesthesia have been documented (Sprague & Wolf, 1982). The first patient, a 42-year old female, was 100 mg daily. Anesthesia was induced with fentanyl, enflurane, and nitrous oxide. Approximately three h anesthesia was induced, clonic movements of the patient's right hand and forearm were noted. Enflurane was 1% at the time. Changes in ventilation did not affect the involuntary movements, so enflurane was d replaced with halothane 1%. The movements decreased in frequency and amplitude and subsequently c approximately one minute. The second case report involved a 39-year old male who was taking amitripty Anesthesia was maintained with enflurane 1% to 2%, and intermittent clonic movements started in the ri approximately one hour into the surgery. Enflurane was discontinued and halothane was instituted, whic involuntary movements to disappear in approximately two minutes. No further movements were seen du three hours of anesthesia.

3.5.1.BE Epinephrine

1) Interaction Effect: hypertension, cardiac arrhythmias, and tachycardia

2) Summary: Clinical trials have demonstrated a 2- to 8-fold increase in the effects of intravenous infusions c drugs to volunteers on tricyclic antidepressants. Arrhythmias and other severe adverse effects have also bee 1980; Avery, 1973a; Boakes et al, 1973a; Boakes, 1973; Mitchell et al, 1970; Stone et al, 1964a). Local use (anesthesia) of epinephrine in concentrations of 1:100,000 or less is less likely to precipitate clinically significa changes (Steinberg & Block, 1971).

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: The vasoconstriction and other alpha-adrenergic effects of sympathomimetic drugs enhanced in the presence of tricyclic antidepressants (TCAs). Concomitant use should be avoided. If these d together, careful monitoring and a dose reduction of the sympathomimetic is required. Patients should be inst their doctor or dentist that they are taking a tricyclic antidepressant prior to any surgery or procedure.

7) Probable Mechanism: inhibition of norepinephrine reuptake

8) Literature Reports

a) Four healthy volunteers received intravenous infusions of various sympathomimetic amines (epineph norepinephrine, phenylephrine, and isoproterenol) before and after imipramine (25 mg three times daily f showed an increased pressor response to epinephrine (2- to 4-fold), norepinephrine (4- to 8-fold), and ph 3-fold) after imipramine, but no difference was observed in the response to isoproterenol. Thus, the incre response appeared to occur only for alpha adrenergic effects. All four subjects demonstrated changes in with epinephrine and imipramine consisting of sinus arrhythmia in three subjects and multiple ectopic be rhythm in the fourth subject (Boakes et al, 1973).

b) A review of spontaneous reports of adverse reactions to vasoconstrictors in local anesthetics found th receiving a local anesthetic with norepinephrine (1:25,000) had severe reactions (severe headaches, che subarachnoid hemorrhage). The drug history was incomplete, but at least three had been taking a tricycl at the time (Anon, 1972).

3.5.1.BF Erythromycin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Erythromycin significantly increased the mean QTc interval versus baseline in a retrospective s (Oberg & Bauman, 1995a). Erythromycin has demonstrated QTc prolongation in combination with other drug QT interval (Prod Info PCE(R), 1997). Tricyclic antidepressants have been shown to prolong the QTc interval recommended therapeutic dose (Marshall & Forker, 1982g). Caution is advised with coadministration of drug prolong the QTc interval.

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Caution is advised if erythromycin and tricyclic antidepressants are used concomita interval at baseline and periodically during treatment.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) Erythromycin did not significantly affect the metabolism of tricyclic antidepressants in a study of 8 pat were maintained on desipramine (n equal to 5), imipramine (n equal to 1), doxepin (n equal to 1), or doxe All patients received erythromycin stearate 250 mg four times daily for six days while maintaining their us regimen. No change in the antidepressant or active metabolite concentrations was seen during coadmini erythromycin (Amsterdam & Maislin, 1991).

b) Tricyclic antidepressants have been shown to prolong the QTc interval at the recommended therapeu & Forker, 1982f).

c) Erythromycin significantly increased the QTc interval compared with baseline in a retrospective study The erythromycin dose was 500 milligrams or 1 gram four times daily, with a mean of 15 doses received to 9) who received 60 mg/kg/day or more all developed increases in QT interval of 15% or greater. For a mean QTc interval increased from 432 milliseconds (msec) at baseline to 483 msec (p less than 0.01). In delayed repolarization at baseline (n equal to 9), the QTc interval increased from 473 msec to 525 msec In patients with heart disease (n equal to 30), all experienced an increase in QTc interval (mean of 15%) increase of 8% in patients without heart disease (p less than 0.05). In 5 patients (10%), the QTc interval prolonged. One patient developed torsades de pointes attributed to erythromycin. Of 16 patients receivin concomitantly, 8 developed QT prolongation of 15% or greater (Oberg & Bauman, 1995).

3.5.1.BG Esterified Estrogens

1) Interaction Effect: possible attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypo

2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de estrogens (Somani & Khurana, 1973c), with paradoxical loss of antidepressant effect yet tricyclic toxicity bein simultaneously (Prange, 1972c). The effects of the interaction appear to be estrogen dose-related (Khurana, be of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started o (Krishnan et al, 1984c).

3) Severity: minor

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.

7) Probable Mechanism: possible inhibition of hepatic metabolism of the tricyclic antidepressant

8) Literature Reports

a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I depressed female prisoners were randomly assigned to four treatment groups. Ten patients received pla imipramine (150 mg daily) and placebo, five patients received imipramine (150 mg daily) and ethinyl estr daily), while five patients received imipramine (150 mg daily) and ethinyl estradiol (25 mcg daily). The 10 received placebo did not improve over the six weeks of the study. The 10 patients taking estrogen and in demonstrated a significantly greater improvement in symptoms than did the 10 patients taking imipramin after two weeks, the five patients that received imipramine and high-dose estrogen had not improved as patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsiness, whi the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period of two wee

for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed to the pr
estrogen in the high-dose group. In another group, five women received imipramine 150 mg and ethinyl e
daily did not improve as much as 10 patients receiving only imipramine. Also, the patients on the combin
side-effects including lethargy, coarse tremor and systolic hypotension (Prange, 1972b).

b) A 32-year-old female taking conjugated estrogens 2.5 mg and imipramine 100 mg developed lethargy
signs of depersonalization. After two years of therapy, the patient increased her estrogen dose to 5 mg a
daily. The patient became nauseated, had constant headaches, and low normal blood pressure. All lab v
Upon discontinuing the estrogen, the side effects abated. Some investigators have proposed that the sid
from enhanced TCA effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani &
Khurana, 1972b).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begir
there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the c
matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients'
clomipramine. It was proposed that there was no significant difference in side-effects between the groups
groups were matched after patients had dropped out of the study. Had the patients been matched prior t
different conclusions may have been drawn (Beaumont, 1973a).

d) The effects of oral contraceptives on clomipramine was studied in 42 women between the ages of 18
three women took clomipramine 25 mg at bedtime while 19 took clomipramine 25 mg at bedtime with ora
Over the four-week study, three control patients (two due to side-effects) and five in the experimental gro
side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of ser
concentrations. No difference in serum concentrations was noted between the groups. However, this res
due to the low dose of clomipramine given (Luscombe & John, 1980a).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep
concurrently. A 24-year-old patient receiving clomipramine 120 mg daily for anorexia nervosa and conjug
1.25 mg daily for amenorrhea developed restless legs and a constant desire to move continuously. Estro
discontinued and benztropine 2 mg was administered, resulting in marked reduction and resolution withi
Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogen 1.25 mg daily wh
amitriptyline 50 mg daily for depression. Within hours of amitriptyline, the patient was confused, restless,
inner desire to move continuously. Symptoms disappeared after discontinuing amitriptyline. A third case
reported in a 35-year-old patient who received conjugated estrogen 1.25 mg daily and amitriptyline 50 m
developed within a few hours after taking the first dose of amitriptyline and resolved within 48 hours follo
discontinuation of the antidepressant (Krishnan et al, 1984b).

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept
less of ethinyl estradiol) from 27% to 44% (p less than 0.05) as evident by an increase in the area under
concentration time curve (Abernethy et al, 1984a).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19
are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result
and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer
system resulting in an antidepressant effect (Oppenheim, 1983a).

3.5.1.BH Estradiol

1) Interaction Effect: possible attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypo

2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de
estrogens (Somani & Khurana, 1973c), with paradoxical loss of antidepressant effect yet tricyclic toxicity bein
simultaneously (Prange, 1972c). The effects of the interaction appear to be estrogen dose-related (Khurana,
be of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started o
(Krishnan et al, 1984c).

3) Severity: minor

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down
estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d
may be required.

7) Probable Mechanism: possible inhibition of hepatic metabolism of the tricyclic antidepressant

8) Literature Reports

a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I
depressed female prisoners were randomly assigned to four treatment groups. Ten patients received pla
imipramine (150 mg daily) and placebo, five patients received imipramine (150 mg daily) and ethinyl estr
daily), while five patients received imipramine (150 mg daily) and ethinyl estradiol (25 mcg daily). The 10
received placebo did not improve over the six weeks of the study. The 10 patients taking estrogen and in
demonstrated a significantly greater improvement in symptoms than did the 10 patients taking imipramin
after two weeks, the five patients that received imipramine and high-dose estrogen had not improved as
patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsiness, whi
the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period of two wee
for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed to the pr
estrogen in the high-dose group. In another group, five women received imipramine 150 mg and ethinyl e
daily did not improve as much as 10 patients receiving only imipramine. Also, the patients on the combin
side-effects including lethargy, coarse tremor and systolic hypotension (Prange, 1972b).

b) A 32-year-old female taking conjugated estrogens 2.5 mg and imipramine 100 mg developed lethargy signs of depersonalization. After two years of therapy, the patient increased her estrogen dose to 5 mg a daily. The patient became nauseated, had constant headaches, and low normal blood pressure. All lab v Upon discontinuing the estrogen, the side effects abated. Some investigators have proposed that the sid from enhanced TCA effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1972b).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begin there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the c matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients' clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973a).

d) The effects of oral contraceptives on clomipramine was studied in 42 women between the ages of 18 three women took clomipramine 25 mg at bedtime while 19 took clomipramine 25 mg at bedtime with ora Over the four-week study, three control patients (two due to side-effects) and five in the experimental gro side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of se concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980a).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep concurrently. The only side-effect reported was drowsiness, whi the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period of two we for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed to the pr estrogen in the high-dose group. In another group, five women received imipramine 150 mg and ethinyl daily did not improve as much as 10 patients receiving only imipramine. Also, the patients on the combin side-effects including lethargy, coarse tremor and systolic hypotension (Prange, 1972b).

b) A 32-year-old female taking conjugated estrogens 2.5 mg and imipramine 100 mg developed lethargy signs of depersonalization. After two years of therapy, the patient increased her estrogen dose to 5 mg a daily. The patient became nauseated, had constant headaches, and low normal blood pressure. All lab v Upon discontinuing the estrogen, the side effects abated. Some investigators have proposed that the sid from enhanced TCA effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1972b).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begin there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients' clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973a).

d) The effects of oral contraceptives on clomipramine was studied in 42 women between the ages of 18 three women took clomipramine 25 mg at bedtime while 19 took clomipramine 25 mg at bedtime with ora Over the four-week study, three control patients (two due to side-effects) and five in the experimental gro side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of se concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980a).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep concurrently. A 24-year-old patient receiving clomipramine 120 mg daily for anorexia nervosa and conjug 1.25 mg daily for amenorrhea developed restless legs and a constant desire to move continuously. Estro discontinued and benztropine 2 mg was administered, resulting in marked reduction and resolution withi Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogen 1.25 mg daily wh amitriptyline 50 mg daily for depression. Within hours of amitriptyline, the patient was confused, restless, inner desire to move continuously. Symptoms disappeared after discontinuing amitriptyline. A third case reported in a 35-year-old patient who received conjugated estrogen 1.25 mg daily and amitriptyline 50 m developed within a few hours after taking the first dose of amitriptyline and resolved within 48 hours follo discontinuation of the antidepressant (Krishnan et al, 1984b).

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept less of ethinyl estradiol) from 27% to 44% (p less than 0.05) as evident by an increase in the area under concentration time curve (Abernethy et al, 1984a).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19 are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer system resulting in an antidepressant effect (Oppenheim, 1983a).

3.5.1.BL Eterobarb

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive

2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.

7) Probable Mechanism: increased tricyclic antidepressant metabolism

8) Literature Reports

a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were e metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipram half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar eff expected with any combination of TCA and barbiturate.

3.5.1.BM Ethinyl Estradiol

1) Interaction Effect: possible attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypo

2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or d estrogens (Somani & Khurana, 1973i), with paradoxical loss of antidepressant effect yet tricyclic toxicity being simultaneously (Prange, 1972i). The effects of the interaction appear to be estrogen dose-related (Khurana, 1 of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started on e (Krishnan et al, 1984i).

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.

7) Probable Mechanism: possible inhibition of hepatic metabolism of the tricyclic antidepressant

8) Literature Reports

a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I depressed female prisoners were randomly assigned to 4 treatment groups. Ten patients received place imipramine (150 milligrams/day) and placebo, 5 patients received imipramine (150 milligrams/day) and e micrograms/day), while 5 patients received imipramine (150 milligrams/day) and ethinyl estradiol (25 mic 10 patients that received placebo did not improve over the 6 weeks of the study. The 10 patients taking e imipramine demonstrated a significantly greater improvement in symptoms than did the 10 patients takin

alone. However, after 2 weeks, the 5 patients that received imipramine and high-dose estrogen had not i
as the patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsine
affected the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period o
required for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed
residual estrogen in the high-dose group. In another group, 5 women received imipramine 150 milligram
estradiol 50 micrograms daily did not improve as much as 10 patients receiving only imipramine. Also, th
combination had severe side-effects including lethargy, coarse tremor and systolic hypotension (Prange,
b) A case report demonstrated an interaction in a 32-year-old female taking conjugated estrogens 2.5 m
imipramine 100 milligrams (Khurana, 1972h). The patient developed lethargy, tremors, and signs of depe
After 2 years of therapy, the patient increased her estrogen dose to 5 milligrams and then 7.5 milligrams
became nauseated, had constant headaches, and low normal blood pressure. All lab work was normal. U
the estrogen, the side-effects abated. Some investigators have proposed that the side effects resulted fr
effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1973h).
c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begir
there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the
matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients'
clomipramine. It was proposed that there was no significant difference in side-effects between the groups
groups were matched after patients had dropped out of the study. Had the patients been matched prior t
different conclusions may have been drawn (Beaumont, 1973e).
d) The effects of oral contraceptives on clomipramine was studied in 42 women between the ages of 18
three women took clomipramine 25 milligrams at bedtime while 19 took clomipramine 25 milligrams at be
contraceptives. Over the 4-week study, 3 control patients (2 due to side-effects) and 5 in the experimenta
side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of se
concentrations. No difference in serum concentrations was noted between the groups. However, this res
due to the low dose of clomipramine given (Luscombe & John, 1980d).
e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep
concurrently. A 24-year-old patient receiving clomipramine 120 milligrams/day for anorexia nervosa and
estrogens 1.25 milligrams/day for amenorrhea developed restless legs and a constant desire to move co
Estrogen was discontinued and benztropine 2 milligrams was administered, resulting in marked reductio
within 48 hours. Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogens
milligrams/day who was prescribed amitriptyline 50 milligrams/day for depression. Within hours of amitrip
was confused, restless, and possessed an inner desire to move continuously. Symptoms disappeared af
amitriptyline. Positive rechallenge at one week with doxepin 100 milligrams, with resolution following disc
doxepin. A third case of akathisia was reported in a 35-year-old patient who received conjugated estroge
milligrams/day and amitriptyline 50 milligrams/day. Akathisia developed within a few hours after taking th
amitriptyline and resolved within 48 hours following discontinuation of the antidepressant (Krishnan et al,
f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept
micrograms or less of ethinyl estradiol) from 27 to 44% (p less than 0.05) as evident by an increase in th
plasma concentration time curve (Abernethy et al, 1984e).
g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19
are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result
and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer
system resulting in an antidepressant effect (Oppenheim, 1983d).

3.5.1.BN Etilefrine

1) Interaction Effect: hypertension, cardiac arrhythmias, and tachycardia
2) Summary: Clinical trials have demonstrated a 2- to 8-fold increase in the effects of intravenous infusions o
drugs to volunteers on tricyclic antidepressants. Arrhythmias and other severe adverse effects have also bee
1980; Avery, 1973a; Boakes et al, 1973a; Boakes, 1973; Mitchell et al, 1970; Stone et al, 1964a). Local use (
anesthesia) of epinephrine in concentrations of 1:100,000 or less is less likely to precipitate clinically significa
changes (Steinberg & Block, 1971).
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: The vasoconstriction and other alpha-adrenergic effects of sympathomimetic drugs
enhanced in the presence of tricyclic antidepressants (TCAs). Concomitant use should be avoided. If these d
together, careful monitoring and a dose reduction of the sympathomimetic is required. Patients should be inst
their doctor or dentist that they are taking a tricyclic antidepressant prior to any surgery or procedure.
7) Probable Mechanism: inhibition of norepinephrine reuptake
8) Literature Reports
a) Four healthy volunteers received intravenous infusions of various sympathomimetic amines (epineph
norepinephrine, phenylephrine, and isoproterenol) before and after imipramine (25 mg three times daily f
showed an increased pressor response to epinephrine (2- to 4-fold), norepinephrine (4- to 8-fold), and ph
3-fold) after imipramine, but no difference was observed in the response to isoproterenol. Thus, the incre
response appeared to occur only for alpha adrenergic effects. All four subjects demonstrated changes in
with epinephrine and imipramine consisting of sinus arrhythmia in three subjects and multiple ectopic be
rhythm in the fourth subject (Boakes et al, 1973).
b) A review of spontaneous reports of adverse reactions to vasoconstrictors in local anesthetics found th

receiving a local anesthetic with norepinephrine (1:25,000) had severe reactions (severe headaches, che subarachnoid hemorrhage). The drug history was incomplete, but at least three had been taking a tricycl at the time (Anon, 1972).

3.5.1.BO Fenfluramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transi clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.BP Fenfluramine

1) Interaction Effect: an increased risk of imipramine toxicity (sedation)

2) Summary: When fenfluramine was added to imipramine therapy, the blood concentration of imipramine pl was dramatically increased in a 55-year old female. The increased blood levels caused the patient to fall asle (Fogelson, 1997a).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: If fenfluramine is used in combination with imipramine, the patient should be monitc sedation, hypertension and dysrhythmias.

7) Probable Mechanism: inhibition of imipramine metabolism

8) Literature Reports

a) A 55-year old female patient was maintained on imipramine 350 mg daily for several years, with imipr desipramine blood levels ranging from 218 mcg/L to 145 mcg/L. After four weeks of treatment with fenflu three times daily, the patient fell asleep while driving. The imipramine plus desipramine level was 704 mc may have inhibited the cytochrome p450 isoenzyme responsible for metabolizing imipramine (Fogelson,

b) A study was conducted in 15 patients with DSM-III major depression who failed to respond to treatme desipramine given for at least four weeks. Fenfluramine 40 mg to 120 mg daily for two weeks was then a transient or sustained clinical improvement. However, fenfluramine more than doubled steady-state plas desipramine (Price et al, 1990a).

3.5.1.BQ Flecainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class I antiarrhythmics have been shown to prolong the QTc interval at the recommended ther Even though no formal drug interaction studies have been done, the coadministration of Class I antiarrhythmi known to prolong the QTc interval, including tricyclic antidepressants, is not recommended (Prod Info Tambo acetate, 1998; Larochelle et al, 1984; Scagliotti et al, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class I antiarrhythmic and a tricyclic antidepress recommended.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982q).
b) A 68-year-old man suffering from agitated major depression was begun on a dose of desipramine 12 produced a subtherapeutic serum level of 442 nmol/L (therapeutic range = 500 to 1000 nmol/L). An incre mg daily produced excellent clinical response with no side effects. He developed atrial fibrillation and flut mg daily was added to his therapy, and desipramine was discontinued. His arrhythmia was suppressed v propafenone 150 mg twice daily and 300 mg at bedtime. Desipramine 150 mg daily was again begun, at experienced dry mouth, sedation, and shakiness; the desipramine serum level was measured at 2092 nr desipramine was discontinued for five days, the side effects ceased, and desipramine therapy was resur The desipramine serum level was measured at 1130 nmol/L (Katz, 1991).

3.5.1.BR Fluconazole

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Case reports have described QT prolongation and torsades de points associated with fluconaz al, 1999). Several tricyclic antidepressants (TCAs) have been shown to prolong the QTc interval at the recom therapeutic dose (Marshall & Forker, 1982x). Even though no formal drug interaction studies have been done coadministration of drugs known to prolong the QTc interval is not recommended.
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of fluconazole and a tricyclic antidepressant is not re
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.BS Fluoxetine

1) Interaction Effect: tricyclic antidepressant toxicity (dry mouth, urinary retention, sedation) and an increase cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Tricyclic antidepressants (TCAs) and fluoxetine have been shown to prolong the QTc interval a recommended therapeutic dose (Prod Info Prozac(R), 2001; Marshall & Forker, 1982h). Even though no form studies have been done which demonstrate QT prolongation, the coadministration of tricyclic antidepressants known to prolong the QTc interval, such as fluoxetine, is not recommended (Prod Info Elavil(R), 1999d). In ac use of fluoxetine and TCAs such as desipramine, nortriptyline, and imipramine has resulted in significant incr concentrations (Preskorn et al, 1994a; Preskorn et al, 1994a; Aranow et al, 1989a; Downs et al, 1989a; Gooc & Cole, 1988a).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of fluoxetine and a tricyclic antidepressant is not rec
7) Probable Mechanism: decreased tricyclic antidepressant metabolism; additive effects on QT prolongation
8) Literature Reports
a) Fluoxetine increased the level of tricyclic antidepressants (nortriptyline, imipramine, desipramine) in 4 addition of fluoxetine, the ratio of antidepressant level to dose increased by 109% to 486% in the patient developed clinical symptoms (anticholinergic effects, constipation, urinary hesitancy, sedation, unstable the increased levels (Aranow et al, 1989).
b) Fluoxetine statistically and clinically significantly increased desipramine concentrations in 18 healthy fluoxetine (20 mg daily) was added to desipramine (50 mg daily), the mean maximum concentration of d increased by 278% and the area under the concentration-time curve increased by 342%. Desipramine tr concentrations continued to be 198% above baseline three weeks after fluoxetine was discontinued. The compared pharmacokinetics of desipramine when combined with sertraline. The impact of sertraline was in small and short-term increases in desipramine plasma concentrations (Preskorn et al, 1994).
c) A 75-year-old female experienced symptomatic increases in her desipramine serum concentrations w was added. Desipramine serum levels ranged from 109 to 150 ng/mL with oral doses of 300 mg at bedti fluoxetine therapy. Following the addition of oral fluoxetine 20 mg daily to the regimen, the desipramine s increased to 212 ng/mL within five days. The fluoxetine dose was increased to 40 mg/day three days late desipramine serum level was 419 ng/mL after four days. A worsening of depression and severe fatigue c increases in desipramine serum levels. Withdrawal of fluoxetine and reduction in the desipramine dose t

reduced the desipramine serum level to 231 ng/mL within two weeks (Bell & Cole, 1988).
d) A 33-year-old depressed male developed adverse effects of dry mouth, tinnitus, and difficulties with a memory while receiving fluoxetine 40 mg daily and desipramine 150 mg daily for five weeks; fluoxetine w and the blood levels of desipramine decreased from 938 to 48 ng/mL with resolution of clinical symptoms 1989).
e) A 39-year-old female experienced symptomatic increases in her desipramine levels with concomitant Prior to fluoxetine therapy, the patient's measured levels of desipramine had ranged from 148 to 160 ng/ of 300 mg daily. Five weeks after the addition of fluoxetine 20 mg daily, she reported anticholinergic sym and confusion with a desipramine level of 527 ng/mL. The desipramine dose was lowered to 200 mg/day later, the level was 244 ng/mL; the patient reported decreased energy, impaired short-term memory, and speech, as well as an episode of nausea, dizziness, and syncope. The desipramine dose was reduced to adverse effects resolved in six days. Eight days later, the desipramine level was 122 ng/mL (Downs et al
f) Concomitant administration of fluoxetine and desipramine was reported to result in an increased desip new onset of delirium in a 69-year-old male within 10 days of the addition of fluoxetine to the patient's reg al, 1990).

3.5.1.BT Fluvoxamine

1) Interaction Effect: imipramine toxicity (dry mouth, urinary retention, sedation)
2) Summary: Addition of fluvoxamine to imipramine or desipramine therapy can result in significantly increas antidepressant plasma levels and signs of tricyclic toxicity (Spina et al, 1992a; Spina et al, 1993aa; Spina et a Fluvoxamine significantly increases imipramine half-life and reduces clearance (Spina et al, 1993a). The add fluvoxamine to imipramine or desipramine therapy may result in greatly increased tricyclic antidepressant pla tricyclic toxicity (Spina et al, 1992a; Spina et al, 1993aa). A bidirectional effect is suggested, in which fluvoxa imipramine concentrations (by interfering with N-demethylation), and imipramine increases fluvoxamine level 1993a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients for signs of imipramine and fluvoxamine toxicity; lower doses of on may be required with concomitant therapy.
7) Probable Mechanism: decreased imipramine metabolism
8) Literature Reports
a) The pharmacokinetics of combined imipramine and fluvoxamine were studied in healthy volunteers (S After a 7-day course of fluvoxamine, imipramine half-life was significantly increased (from 23 to 41 hours decreased (from 1.02 to 0.28 L/h/kg).
b) The addition of fluvoxamine to imipramine or desipramine in four patients was reported to result in gre tricyclic antidepressant plasma levels (Spina et al, 1992). Three of four patients showed signs of tricyclic of fluvoxamine 100 mg daily for 10 days on plasma concentrations of imipramine was studied in seven d on maintenance therapy (Spina et al, 1993a). Imipramine plasma levels were three to four times higher d coadministration. One patient complained of anticholinergic effects, along with tremor and confusion. The this drug interaction was inhibition of demethylation of imipramine. A pharmacokinetic study in healthy vo demonstrated a significantly increased imipramine half-life and reduced clearance (Spina et al, 1993).
c) Metabolism of tricyclic antidepressants coadministered with fluvoxamine was studied in eight depress patients received imipramine) (Hartter et al, 1993). Fluvoxamine was found to interfere with N-demethyla The combination of fluvoxamine and imipramine led to increased plasma levels of imipramine and decrea concentrations of the N-demethylated imipramine metabolite desimipramine. In addition, TCA-fluvoxamin apparently raised plasma levels of fluvoxamine.

3.5.1.BU Formoterol

1) Interaction Effect: an increased risk of cardiovascular excitation
2) Summary: Concurrent administration of formoterol with a tricyclic antidepressant (TCA) may lead to poten formoterol's adrenergic effects on the cardiovascular system. Therefore, extreme caution is advised if formote to patients who are being treated with a TCA (Prod Info FORADIL(R) AEROLIZER(R) inhalation powder, 200 patients closely for adverse cardiovascular effects.
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Extreme caution and close observation for adverse cardiovascular effects are warra formoterol is administered concurrently with a tricyclic antidepressant (TCA) as the cardiovascular effects of f potentiated by TCAs (Prod Info FORADIL(R) AEROLIZER(R) inhalation powder, 2006).
7) Probable Mechanism: potentiation of cardiovascular effects

3.5.1.BV Fosamprenavir

1) Interaction Effect: increased tricyclic agent serum concentrations and potential toxicity (anticholinergic effe confusion, cardiac arrhythmias)
2) Summary: Coadministration of fosamprenavir with a tricyclic antidepressant may provoke increased serum the tricyclic antidepressant, causing a potential risk of arrhythmias or other serious adverse effects. Fosampr of amprenavir, an inhibitor of the CYP3A4 isoenzyme in addition to being a CYP3A4 substrate. Tricyclic agen

depend on the CYP3A4 pathway for metabolism. Plasma concentrations of the tricyclic agent should be close patients also receiving fosamprenavir (Prod Info LEXIVA(R) oral solution, oral tablets, 2009).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: If concomitant therapy with fosamprenavir and a tricyclic antidepressant is unavoida concentrations of the tricyclic agent should be closely monitored. Also monitor patients for signs and symptor toxicity (anticholinergic effects, sedation, confusion, cardiac arrhythmias) (Prod Info LEXIVA(R) oral solution,
7) Probable Mechanism: inhibition of CYP3A4-mediated tricyclic agent metabolism

3.5.1.BW Foscarnet
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Foscarnet can prolong the QT interval in some patients, which may result in ventricular tachyca fibrillation, and torsades de pointes. Because tricyclic antidepressants may also prolong the QT interval and i arrhythmias, the concurrent administration of foscarnet and tricyclic antidepressants is not recommended (Pr (R), 1998; Marshall & Forker, 1982u).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of foscarnet and tricyclic antidepressants is not recor
7) Probable Mechanism: additive cardiac effects

3.5.1.BX Fosphenytoin
1) Interaction Effect: an increased risk of phenytoin toxicity (ataxia, hyperreflexia, nystagmus, tremor)
2) Summary: Fosphenytoin is a prodrug of phenytoin and the same interactions that occur with phenytoin are occur with fosphenytoin (Prod Info Cerebyx(R), 1999). A few case reports have indicated that imipramine inhi metabolism resulting in increased serum phenytoin concentration (Petti & Campbell, 1975; Perucca & Richer antidepressants (TCAs) may lower the seizure threshold in epileptic patients stabilized on anticonvulsants. Tl because phenytoin is an enzyme inducer, the metabolism of antidepressants may be increased resulting in re levels.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Consider monitoring phenytoin serum levels if a tricyclic antidepressant is added to patient begins to exhibit signs of toxicity (tremor, nystagmus, ataxia, hyperreflexia); lower doses of phenytoin If phenytoin is added to tricyclic antidepressant therapy, monitor for clinical efficacy of the tricyclic agent.
7) Probable Mechanism: inhibition of phenytoin metabolism

3.5.1.BY Gatifloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Gatifloxacin may prolong the QT interval in some patients, which may result in ventricular tachy fibrillation, and torsades de pointes. Although pharmacokinetic studies between gatifloxacin and other drugs v QT interval have not been performed, an additive effect cannot be excluded. Therefore, the concurrent admir gatifloxacin and a tricyclic antidepressant is not recommended (Prod Info Tequin(TM), 1999).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of gatifloxacin and a tricyclic antidepressant is not re
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.BZ Gemifloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although pharmacokinetic studies between gemifloxacin and drugs that prolong the QT interva antidepressants, have not been performed, gemifloxacin should be used cautiously when given concurrently antidepressants (Prod Info Factive(R), 2003).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of two drugs that prolong the QT interval, such as ge tricyclic antidepressants, is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.CA Grepafloxacin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Healthy volunteers who received grepafloxacin during a Phase I study experienced prolongatio interval. On an outpatient basis, grepafloxacin is contraindicated with other drugs that are known to also prolo interval or cause torsades de pointes, including tricyclic antidepressants. When appropriate cardiac monitorin such as in the hospitalized patient, these two agents should be coadministered with caution (Prod Info Raxar

3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: The concurrent use of grepafloxacin and tricyclic antidepressants is contraindicated appropriate cardiac monitoring can be assured, such as in the hospitalized patient.
7) Probable Mechanism: additive cardiac effects

3.5.1.CB Guanadrel
1) Interaction Effect: decreased antihypertensive effectiveness
2) Summary: Tricyclic antidepressants inhibit the uptake of guanethidine and possibly guanadrel into the adr resulting in an inhibition of its antihypertensive effect (Mitchell et al, 1967; Ober & Wang, 1973). When a patie concomitant tricyclic antidepressant and guanadrel therapy, caution should be exercised when the tricyclic ar discontinued, since an exaggerated effect of guanadrel may be seen (Prod Info Hylorel(R), 1995).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Blood pressure should be monitored for an appropriate clinical response; higher do may be required. An alternative class of antihypertensive agents such as angiotensin-converting enzyme inhi considered.
7) Probable Mechanism: decreased uptake of guanadrel into adrenergic neurons

3.5.1.CC Guanethidine
1) Interaction Effect: decreased antihypertensive effectiveness
2) Summary: Tricyclic antidepressants inhibit the uptake of guanethidine, and possibly guanadrel, into the ac resulting in an inhibition of the antihypertensive effect (Gulati et al, 1966; Mitchell et al, 1967a; Ober & Wang, al, 1964).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Blood pressure should be monitored for an appropriate clinical response; higher do guanethidine may be required. An alternative class of antihypertensive agents, such as angiotensin-convertir might be considered.
7) Probable Mechanism: decrease uptake of guanethidine into adrenergic neurons

3.5.1.CD Guanfacine
1) Interaction Effect: decreased antihypertensive effectiveness
2) Summary: Concomitant clonidine and tricyclic antidepressant (TCA) therapy may impair the antihypertens clonidine. Since the mechanism of action of guanfacine is similar to clonidine, patients stabilized on guanfaci monitored for a hypertensive response when TCA (i.e. desipramine or imipramine) therapy is started (Briant e 1983b). A case has been reported of a patient maintained on guanfacine who developed an increase in blooc imipramine was added to therapy. When imipramine was discontinued, her blood pressure returned to baseli Feely, 1991a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Blood pressure should be monitored for an appropriate clinical response; higher do may be required. An alternative class of antihypertensive agents, such as an angiotensin-converting enzyme considered.
7) Probable Mechanism: unknown
8) Literature Reports
a) A case of a hypertensive female who was maintained on guanfacine 2 mg daily with mean blood pres mm Hg was reported (Buckley & Feely, 1991). After amitriptyline 75 mg daily was begun, her mean bloo 150/100 mm Hg; upon discontinuation of the amitriptyline, the blood pressure returned to 136/91 mm Hg was given imipramine 50 mg daily and experienced similar changes in loss of blood pressure control; up of imipramine, the blood pressure again returned to 137/90 mm Hg.
b) Concomitant clonidine and tricyclic antidepressant therapy may impair the antihypertensive effects of the mechanism of action of guanfacine is similar to clonidine, patients stabilized on guanfacine should be hypertensive response when desipramine therapy is started (Briant et al, 1973b; Hui, 1983a).

3.5.1.CE Halofantrine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Halofantrine can prolong the QT interval in some patients, which may result in ventricular tachy fibrillation, and torsades de pointes. Because tricyclic antidepressants may also prolong the QT interval and i arrhythmias, the concurrent administration of halofantrine and tricyclic antidepressants is not recommended ((R), 1998; Marshall & Forker, 1982aa).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable

6) Clinical Management: The concurrent administration of halofantrine and a tricyclic antidepressant is not re
7) Probable Mechanism: additive cardiac effects

3.5.1.CF Haloperidol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod I 1999), haloperidol (O'Brien et al, 1999), risperidone (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001 (Owens, 2001b), sultopride (Lande et al, 1992), and zotepine (Sweetman, 2003). Even though no formal drug studies have been done, the coadministration of a tricyclic antidepressant and an antipsychotic is not recomm Pamelor(R), 2001; Marshall & Forker, 1982t).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic is n
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included pr corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 m proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricu (Prod Info Orap(R), 1999).

3.5.1.CG Halothane

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Halothane may prolong the QT interval in some patients (Owens, 2001a). Because tricyclic ant also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of halothane a antidepressants is not recommended (Marshall & Forker, 1982p).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Because of the potential for additive QT interval prolongation, the concurrent admin halothane and tricyclic antidepressants is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.CH Heptabarbital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive
2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa
3) Severity: minor
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.
7) Probable Mechanism: increased tricyclic antidepressant metabolism
8) Literature Reports
a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were ex metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipram half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar effe expected with any combination of TCA and barbiturate.

3.5.1.CI Hexobarbital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive
2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa
3) Severity: minor
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con

be of value in determining appropriate dosage.
7) Probable Mechanism: increased tricyclic antidepressant metabolism
8) Literature Reports
a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were ex metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipram half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar effe expected with any combination of TCA and barbiturate.

3.5.1.CJ Hydroquinidine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class Ia antiarrhythmics and tricyclic antidepressants have been shown to prolong the QTc inte recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadm Ia antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is n (Prod Info Elavil(R), 1999g; Prod Info Quinaglute(R), 1999; Marshall & Forker, 1982n).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic agent and a tricyclic anti recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Quinidine is an inhibitor of the cytochrome P450 isoenzyme responsible for the 2-hydroxylation of imi desipramine (Brosen & Gram, 1989). Inhibition of this enzyme system can result in a 35% decrease in im clearance and 85% decrease in desipramine clearance. Demethylation of imipramine by the cytochrome unaffected by this interaction. Until more information is available all patients having quinidine added to di containing imipramine or desipramine should be monitored for increased antidepressant serum concentr potential toxicity.
b) An increased incidence in sudden death was observed in six out of 53 patients with cardiac disease r amitriptyline, compared to 0 out of 53 in the control group. It was recommended that amitriptyline be avo with underlying cardiac disease except when depression was debilitating and no other drugs were helpfu Coull et al, 1970).
c) In a placebo controlled study, imipramine 3.5 mg/kg was administered daily for seven patients with se and titrated doses to obtain therapeutic plasma concentrations. Two patients displayed premature atrial c and premature ventricular depolarizations before therapy. On patient had 33 premature atrial depolarizat premature ventricular depolarizations (PVD) per hour, which decreased to 0.4 PAC and zero PVC per ho The other patient had 12 PAD and 169 PVD per hour before treatment and 1.8 PAD and 28.1 PVD per h The authors also cautioned that the incidence of cardiotoxicity may increase if tricyclic antidepressants a with Type I antiarrhythmics. It was also recommended that quinidine and procainamide not be used to tre of a tricyclic overdose. The similarities between these agents may exacerbate the cardiotoxicity (Kantor e

3.5.1.CK Ibutilide
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).
b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any interac initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.CL Iobenguane I 131

1) Interaction Effect: false-negative results of scintigraphy
2) Summary: Imipramine, which selectively blocks the active transport of catecholamines into storage vesicle myocardial uptake of iobenguane I-131 and increases the rate of loss of iobenguane I-131 from the liver, thus scintigraphy (Sisson et al, 1987).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Imipramine should be discontinued prior to any procedure using iobenguane I-131.
7) Probable Mechanism: reduction of iobenguane I-131 uptake

3.5.1.CM Iproniazid

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus changes)
2) Summary: Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concu and TCAs has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982o; Spig Brodribb et al, 1994m; Neuvonen et al, 1993g). Serotonin syndrome is a rare but potentially fatal condition of hyperstimulation characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Ste TCAs and MAOIs must be used concurrently, avoid large doses, use only oral TCAs, avoid imipramine, clom desipramine, and tranylcypromine, and monitor patients closely (Schuckit et al, 1971n; White & Simpson, 198
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concomitant use of a tricyclic antidepressant (TCA) and a monoamine oxidase inhi should be done only with close monitoring and where the clinical benefit outweighs the potential risk. Other a therapy should first be considered. Consider using a 14 day washout period between treatment with both me clinically necessary, avoid large doses and use agents other than imipramine, clomipramine, desipramine, ar
7) Probable Mechanism: altered catecholamine uptake and metabolism
8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T considered an absolute contraindication in the past. Reports of excitation, hyperpyrexia, convulsions, an have been attributed to the combination (Lockett & Milner, 1965g; Winston, 1971g; Schuckit et al, 1971m 1976g). The mechanism may relate to the combined inhibition of catecholamine reuptake into the centra and inhibition of catecholamine metabolism (Sjoqvist, 1965g).

b) Administration of a TCA after MAOI therapy may result in the development of serotonin syndrome. In crossover study examining the effects of clorgyline and clomipramine for the treatment of obsessive-com two subjects developed severe reactions characteristic of serotonin syndrome. During the study, patients clorgyline therapy, followed by a washout period of approximately four weeks and subsequent clomipram taking the first 100 mg dose of clomipramine, one patient developed coarse myoclonic jerking in both leg diaphoresis, and arrhythmia. Another patient developed a similar reaction after the first dose, with upper symptoms, myoclonic movements, and cardiac irritability. Both patient's symptoms resolved several hou patients were later treated successfully with clomipramine without adverse effects (Insel et al, 1982n).

c) A drug interaction occurred in a 76-year old woman who had been taking clomipramine 50 mg daily fo prior to switching to moclobemide 300 mg daily. The patient experienced somnolescence, confusion, an progressed to further mental impairment, muscle stiffness, myoclonus, and convulsive attacks. The patie were described as fulfilling the diagnostic criteria for serotonin syndrome and were resolved a few days l discontinuing all antidepressant medications (Spigset et al, 1993o).

d) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a p 34-year old man. After taking several doses, the patients developed symptoms of nausea and profuse sw by pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulatio death (Tackley & Tregaskis, 1987h).

e) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unrespons TCA alone. The combination may be utilized in one of two ways. Most frequently, the recommendation is previous antidepressants (five to ten days for TCAs and 14 days for MAOIs); the combination is then sim started (Perry et al, 1991g). Alternatively, in a patient previously receiving a TCA, small doses of the MA added (Schoonover, 1983). Numerous studies in patients with refractory depression or phobic anxiety st successfully used the combination of MAOIs and TCAs (Ponto et al, 1977g; Schuckit et al, 1971m; Ashc

3.5.1.CN Isocarboxazid

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus changes)
2) Summary: The concurrent administration of isocarboxazid and imipramine is contraindicated (Prod Info M Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concurrent use of MA has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982g; Spigset et al, 1 al, 1994g; Neuvonen et al, 1993c). Serotonin syndrome is a rare but potentially fatal condition of serotonergic characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Sternbach, 1991d). MAOIs must be used concurrently, avoid large doses, use only oral TCAs, avoid imipramine, clomipramine, d tranylcypromine, and monitor patients closely (Schuckit et al, 1971g; White & Simpson, 1984f).
3) Severity: contraindicated

4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent use of imipramine and isocarboxazid is contraindicated. In patients to isocarboxazid therapy from a dibenzazepine-related entity, allow at least a one-week medication-free inter initiate isocarboxazid at one-half of the normal dose for at least the first week of therapy. Also allow one week between the discontinuation of isocarboxazid and the administration of another MAO inhibitor or dibenzazepi
7) Probable Mechanism: altered catecholamine uptake and metabolism
8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOI) with tricyclic antidepressants (TC considered an absolute contraindication in the past and still is listed as such by the manufacturers. Repo hyperpyrexia, convulsions, and possible death have been attributed to the combination (Lockett & Milner et al, 1963b; Winston, 1971c; Schuckit et al, 1971f; Sargent, 1965b; Spiker & Pugh, 1976c). The mechar the combined inhibition of catecholamine reuptake into the central nervous system and inhibition of catec metabolism (Sjoqvist, 1965c).

b) The development of serotonin syndrome was reported due to administration of a TCA after MAOI the blind, crossover study examining the effects of clorgyline and clomipramine for the treatment of obsessiv disorder, two subjects developed severe reactions characteristic of serotonin syndrome. During the study received clorgyline therapy, followed by a washout period of approximately four weeks and subsequent c therapy. After taking the first 100 mg dose of clomipramine, one patient developed coarse myoclonic jerk hyperreflexia, diaphoresis, and arrhythmia. Another patient developed a similar reaction after the first do motor neuron symptoms, myoclonic movements, and cardiac irritability. Both patient's symptoms resolve later, and both patients were later treated successfully with clomipramine without adverse effects (Insel e

c) A drug interaction was reported when a 76-year old woman who had been taking clomipramine 50 mg months was switched to moclobemide 300 mg daily. The patient experienced somnolescence, confusion then progressed to further mental impairment, muscle stiffness, myoclonus, and convulsive attacks. The symptoms were described as fulfilling the diagnostic criteria for serotonin syndrome and were resolved a after discontinuing all antidepressant medications (Spigset et al, 1993g).

d) A 39-year old woman with bipolar disorder developed serotonin syndrome after imipramine was adde The patient was taking moclobemide 300 mg twice daily when imipramine was started at 50 mg daily, fol dosage increases of imipramine to 200 mg and a reduction of moclobemide dosage to 150 mg twice dail the increase in imipramine to 200 mg per day, the patient developed symptoms of serotonin syndrome, i shivering, confusion, fever, and spasms in the extremities. The patient was treated with chlorpromazine a resolved over the next few days without further complications (Brodribb et al, 1994f).

e) Three patients with bipolar disorder developed manic symptoms while undergoing concurrent therapy isocarboxazid and amitriptyline. In all three cases the patients had been given MAOIs and TCAs alone w complications. It was only when the drugs were used in combination that symptoms of mania emerged, s synergistic effect (de la Fuente et al, 1986b).

f) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a pl 34-year old man. After taking several doses, the patients developed symptoms of nausea and profuse sw by pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulatio death (Tackley & Tregaskis, 1987d).

g) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unresponsi TCA alone. A few precautions must be followed including: a) avoidance of large doses (no more than 15 or its equivalent, 45 mg phenelzine, or 60 mg isocarboxazid) b) oral administration c) avoidance of clomi imipramine, desipramine, and tranylcypromine in any combination, and d) close monitoring of patients (K Winston, 1971c; Schuckit et al, 1971f; White & Simpson, 1984e; Rom & Benner, 1972b). The combinatio in one of two ways. Most frequently, the recommendation is to stop all previous antidepressants (five to t and 14 days for MAOIs); the combination is then simultaneously started (Perry et al, 1991c). Alternatively previously receiving a TCA, small doses of the MAOI may be slowly added (Schoonover, 1983). Some s that the combination of amitriptyline and isocarboxazid is preferred (Perry et al, 1991c). Numerous studie refractory depression or phobic anxiety states have successfully used the combination of MAOIs and TC 1977c; Schuckit et al, 1971f; Ashcroft, 1975c).

3.5.1.CO Isoflurane

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Isoflurane may prolong the QT interval in some patients (Owens, 2001c). Because tricyclic anti also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of isoflurane a antidepressants is not recommended (Marshall & Forker, 1982v).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Because of the potential for additive QT interval prolongation, the concurrent admin isoflurane and a tricyclic antidepressants is not recommended.
7) Probable Mechanism: additive effect on QT prolongation

3.5.1.CP Isradipine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Isradipine can prolong the QT interval in some patients, which may result in ventricular tachyca

fibrillation, and torsades de pointes. Because tricyclic antidepressants may also prolong the QT interval and i arrhythmias, the concurrent administration of isradipine with a tricyclic antidepressant is not recommended (F (R), 2000; Marshall & Forker, 1982z).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of isradipine and a tricyclic antidepressant is not rec
7) Probable Mechanism: additive cardiac effects

3.5.1.CQ Ketoconazole
1) Interaction Effect: decreased clearance and prolonged half-life of imipramine
2) Summary: In a controlled study of six healthy volunteers, coadministration of ketoconazole with a single d resulted in an increase in imipramine area under the concentration-time curve (AUC) and imipramine half-life decrease in imipramine clearance. The changes were minor, however, and deemed to be likely clinically insig considering the wide therapeutic range of imipramine (Spina et al, 1997a).
3) Severity: minor
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, downward dosage adju imipramine may be necessary.
7) Probable Mechanism: inhibition of imipramine hepatic metabolism
8) Literature Reports
a) A controlled study evaluated oral ketoconazole and the pharmacokinetic effects on oral imipramine a 12 healthy male volunteers. The subjects were divided into two groups and received either a single dose mg or desipramine 100 mg, both alone and after 10 days of a 14-day regimen of oral ketoconazole 200 r Coadministration of ketoconazole resulted in significantly increased imipramine area under the concentra (AUC) values (from 3795 +/- 918 nmol h/L to 4567 +/- 1076 nmol h/L) and significantly decreased imipra clearance (from 1.16 +/- 0.21 L/hr/kg to 0.96 +/- 0.20 L/hr/kg). Imipramine half-life was also significantly i coadministration with ketoconazole, from 16.7 +/- 3.3 hours to 19.2 +/- 5.4 hours. The changes in imipra pharmacokinetics were deemed to be minor considering the therapeutic range of the drug. During coadm ketoconazole with desipramine, no significant pharmacokinetic changes were observed. The authors cor ketoconazole inhibits the N-demethylation of imipramine by cytochrome P450 3A4, without affecting the imipramine and desipramine, which is thought to be mediated through the cytochrome P450 2D6 pathwa 1997).

3.5.1.CR Labetalol
1) Interaction Effect: imipramine toxicity (dry mouth, urinary retention, sedation)
2) Summary: Labetalol decreased imipramine clearance by 38% (statistically significant) compared to placeb crossover study in 12 healthy subjects (Hermann et al, 1992). Labetalol increased imipramine area under the time curve (AUC) by 53% compared to placebo, which was also significant. The clinical significance of the ph interaction is undetermined.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor for anticholinergic side effects of imipramine if labetalol is added to therapy imipramine may be appropriate. Conversely, if labetalol is discontinued, monitor continued clinical efficacy of adjust dosage accordingly.
7) Probable Mechanism: decreased imipramine metabolism, increased imipramine AUC

3.5.1.CS Levomethadyl
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Any drug known to have the potential to prolong the QT interval should not be used with levom pharmacodynamic interactions can occur between levomethadyl and potentially arrhythmogenic agents such prolong the QT interval (Prod Info Orlaam(R), 2001).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Levomethadyl is contraindicated in patients being treated with imipramine as it may prolongation and interact with levomethadyl.
7) Probable Mechanism: unknown

3.5.1.CT Lidoflazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Tricyclic antidepressants (TCAs) and lidoflazine have been shown to prolong the QTc interval a recommended therapeutic dose (Hanley & Hampton, 1983; Marshall & Forker, 1982r). Even though no forma studies have been done, the coadministration of tricyclic antidepressants and other drugs known to prolong tl such as lidoflazine, is not recommended (Prod Info Elavil(R), 1999i).
3) Severity: major

4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of lidoflazine and tricyclic antidepressants is not reco
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.CU Linezolid

1) Interaction Effect: increased risk of serotonin syndrome (hyperthermia, hyperreflexia, myoclonus, mental s
2) Summary: Concomitant use of linezolid and a tricyclic antidepressant, such as imipramine, is contraindica of monitoring for serotonin syndrome. If symptoms occur, consider discontinuation of either one or both of the is a reversible, nonselective inhibitor of monoamine oxidase and may therefore interact with tricyclic antidepr Spontaneous reports of serotonin syndrome associated with the co-administration of linezolid and serotonerg been reported (Prod Info ZYVOX(R) IV injection, oral tablets, oral suspension, 2008).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of linezolid and tricyclic antidepressants, such as imipramine, is cor unless patient is closely observed for signs and/or symptoms of serotonin syndrome. If concomitant use is cli monitor for signs and symptoms of serotonin syndrome, such as neuromuscular abnormalities (including hyp muscle rigidity, clonus, peripheral hypertonicity, and shivering), autonomic hyperactivity (including tachycardi diaphoresis, the presence of bowel sounds, and diarrhea), and mental status changes (including agitation an Serotonin syndrome can be life-threatening. If serotonin syndrome develops, discontinue the offending agent supportive care and other therapy as necessary (Boyer & Shannon, 2005; Prod Info ZYVOX(R) IV injection, o suspension, 2008).
7) Probable Mechanism: linezolid inhibition of monoamine oxidase resulting in an increased concentration of

3.5.1.CV Lisdexamfetamine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transi clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramin 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.CW Lorcainide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class I antiarrhythmics have been shown to prolong the QTc interval at the recommended ther
Even though no formal drug interaction studies have been done, the coadministration of Class I antiarrhythmi
known to prolong the QTc interval, including tricyclic antidepressants, is not recommended (Prod Info Tambo
acetate, 1998; Larochelle et al, 1984; Scagliotti et al, 1982).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class I antiarrhythmic and a tricyclic antidepress
recommended.
7) Probable Mechanism: additive effects on QT prolongation
8) Literature Reports
a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre
prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat
(Marshall & Forker, 1982q).
b) A 68-year-old man suffering from agitated major depression was begun on a dose of desipramine 12
produced a subtherapeutic serum level of 442 nmol/L (therapeutic range = 500 to 1000 nmol/L). An incre
mg daily produced excellent clinical response with no side effects. He developed atrial fibrillation and flut
mg daily was added to his therapy, and desipramine was discontinued. His arrhythmia was suppressed v
propafenone 150 mg twice daily and 300 mg at bedtime. Desipramine 150 mg daily was again begun, at
experienced dry mouth, sedation, and shakiness; the desipramine serum level was measured at 2092 nr
desipramine was discontinued for five days, the side effects ceased, and desipramine therapy was resur
The desipramine serum level was measured at 1130 nmol/L (Katz, 1991).

3.5.1.CX Lumefantrine

1) Interaction Effect: an increased risk of QT interval prolongation
2) Summary: Lumefantrine is a CYP2D6 inhibitor and may cause QT interval prolongation. Concomitant use
artemether/lumefantrine and a CYP2D6 substrate (eg, amitriptyline, clomipramine, flecainide, and imipramine
elevated drug levels of the CYP2D6 substrate. As some CYP2D6 substrates can also prolong the QT interva
for additive QT prolongation. Therefore, artemether/lumefantrine should not be coadministered with CYP2D6
possess cardiac effects (Prod Info COARTEM(R) oral tablets, 2009).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Artemether/lumefantrine should not be administered concomitantly with CYP2D6 su
amitriptyline, clomipramine, flecainide, and imipramine, due to the potential additive effect on QT interval prol
Info COARTEM(R) oral tablets, 2009).
7) Probable Mechanism: additive effects on QT interval prolongation

3.5.1.CY Mazindol

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte
enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim
also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n
(Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co
not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of
agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects
dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o
Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t
Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen
coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained in
amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE
sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o
antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde
2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in
such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm

of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.CZ Mephentermine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sin also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.DA Mephobarbital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive

2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant dc required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.

7) Probable Mechanism: increased tricyclic antidepressant metabolism

8) Literature Reports

a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were e metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar eff expected with any combination of TCA and barbiturate.

3.5.1.DB Mesoridazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Although citing no data, the manufacturer of mesoridazine states that concomitant use with oth prolong the QT interval is contraindicated (Prod Info Serentil(R), 2001). Tricyclic antidepressants (TCAs) at th can cause QT prolongation (Marshall & Forker, 1982e).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Concurrent administration of a tricyclic antidepressant and mesoridazine is contrain

7) Probable Mechanism: additive effect on QT interval

3.5.1.DC Mestranol

1) Interaction Effect: possible attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypo

2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de estrogens (Somani & Khurana, 1973i), with paradoxical loss of antidepressant effect yet tricyclic toxicity being simultaneously (Prange, 1972i). The effects of the interaction appear to be estrogen dose-related (Khurana, 1 of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started on e (Krishnan et al, 1984i).

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.

7) Probable Mechanism: possible inhibition of hepatic metabolism of the tricyclic antidepressant

8) Literature Reports

a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I depressed female prisoners were randomly assigned to 4 treatment groups. Ten patients received place imipramine (150 milligrams/day) and placebo, 5 patients received imipramine (150 milligrams/day) and e micrograms/day), while 5 patients received imipramine (150 milligrams/day) and ethinyl estradiol (25 mic 10 patients that received placebo did not improve over the 6 weeks of the study. The 10 patients taking e imipramine demonstrated a significantly greater improvement in symptoms than did the 10 patients takin alone. However, after 2 weeks, the 5 patients that received imipramine and high-dose estrogen had not i as the patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsine affected the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period o required for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed residual estrogen in the high-dose group. In another group, 5 women received imipramine 150 milligrams estradiol 50 micrograms daily did not improve as much as 10 patients receiving only imipramine. Also, th combination had severe side-effects including lethargy, coarse tremor and systolic hypotension (Prange,

b) A case report demonstrated an interaction in a 32-year-old female taking conjugated estrogens 2.5 m imipramine 100 milligrams (Khurana, 1972h). The patient developed lethargy, tremors, and signs of depe After 2 years of therapy, the patient increased her estrogen dose to 5 milligrams and then 7.5 milligrams became nauseated, had constant headaches, and low normal blood pressure. All lab work was normal. U the estrogen, the side-effects abated. Some investigators have proposed that the side effects resulted fr effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1973h).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begin there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients' clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973e).

d) The effects of oral contraceptives on clomipramine was studied in 42 women between the ages of 18 three women took clomipramine 25 milligrams at bedtime while 19 took clomipramine 25 milligrams at be contraceptives. Over the 4-week study, 3 control patients (2 due to side-effects) and 5 in the experimenta side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of se concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980d).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep

concurrently. A 24-year-old patient receiving clomipramine 120 milligrams/day for anorexia nervosa and estrogens 1.25 milligrams/day for amenorrhea developed restless legs and a constant desire to move co Estrogen was discontinued and benztropine 2 milligrams was administered, resulting in marked reductio within 48 hours. Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogens milligrams/day who was prescribed amitriptyline 50 milligrams/day for depression. Within hours of amitrip was confused, restless, and possessed an inner desire to move continuously. Symptoms disappeared af amitriptyline. Positive rechallenge at one week with doxepin 100 milligrams, with resolution following disc doxepin. A third case of akathisia was reported in a 35-year-old patient who received conjugated estroge milligrams/day and amitriptyline 50 milligrams/day. Akathisia developed within a few hours after taking th amitriptyline and resolved within 48 hours following discontinuation of the antidepressant (Krishnan et al,

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept micrograms or less of ethinyl estradiol) from 27 to 44% (p less than 0.05) as evident by an increase in th plasma concentration time curve (Abernethy et al, 1984e).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19 are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer system resulting in an antidepressant effect (Oppenheim, 1983d).

3.5.1.DD Methamphetamine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained in amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramin 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.DE Methohexital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive

2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable
6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.
7) Probable Mechanism: increased tricyclic antidepressant metabolism
8) Literature Reports
a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were e metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar effe expected with any combination of TCA and barbiturate.

3.5.1.DF Methoxamine

1) Interaction Effect: hypertension, cardiac arrhythmias, and tachycardia
2) Summary: Clinical trials have demonstrated a 2- to 8-fold increase in the effects of intravenous infusions d drugs to volunteers on tricyclic antidepressants. Arrhythmias and other severe adverse effects have also bee 1980; Avery, 1973a; Boakes et al, 1973a; Boakes, 1973; Mitchell et al, 1970; Stone et al, 1964a). Local use (anesthesia) of epinephrine in concentrations of 1:100,000 or less is less likely to precipitate clinically significa changes (Steinberg & Block, 1971).
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: The vasoconstriction and other alpha-adrenergic effects of sympathomimetic drugs enhanced in the presence of tricyclic antidepressants (TCAs). Concomitant use should be avoided. If these d together, careful monitoring and a dose reduction of the sympathomimetic is required. Patients should be inst their doctor or dentist that they are taking a tricyclic antidepressant prior to any surgery or procedure.
7) Probable Mechanism: inhibition of norepinephrine reuptake
8) Literature Reports
a) Four healthy volunteers received intravenous infusions of various sympathomimetic amines (epineph norepinephrine, phenylephrine, and isoproterenol) before and after imipramine (25 mg three times daily f showed an increased pressor response to epinephrine (2- to 4-fold), norepinephrine (4- to 8-fold), and ph 3-fold) after imipramine, but no difference was observed in the response to isoproterenol. Thus, the incre response appeared to occur only for alpha adrenergic effects. All four subjects demonstrated changes in with epinephrine and imipramine consisting of sinus arrhythmia in three subjects and multiple ectopic be rhythm in the fourth subject (Boakes et al, 1973).
b) A review of spontaneous reports of adverse reactions to vasoconstrictors in local anesthetics found th receiving a local anesthetic with norepinephrine (1:25,000) had severe reactions (severe headaches, che subarachnoid hemorrhage). The drug history was incomplete, but at least three had been taking a tricycl at the time (Anon, 1972).

3.5.1.DG Methylphenidate

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained in amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o

antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transi clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.DH Mibefradil

1) Interaction Effect: an increased risk of imipramine toxicity (drowsiness, hypotension, akathisia)

2) Summary: Imipramine is metabolized by cytochrome P450 2D6 and has a high first-pass effect. When mib inhibitor of CYP450 2D6) and imipramine were coadministered, the area under the concentration-time curve (imipramine was increased seven- to eight-fold (Prod Info Posicor(R), 1997).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor patients for excessive imipramine adverse effects (drowsiness, hypotensior dosage adjustment of imipramine may be necessary.

7) Probable Mechanism: inhibition of imipramine metabolism

3.5.1.DI Midodrine

1) Interaction Effect: hypertension, cardiac arrhythmias, and tachycardia

2) Summary: Clinical trials have demonstrated a 2- to 8-fold increase in the effects of intravenous infusions c drugs to volunteers on tricyclic antidepressants. Arrhythmias and other severe adverse effects have also bee 1980; Avery, 1973a; Boakes et al, 1973a; Boakes, 1973; Mitchell et al, 1970; Stone et al, 1964a). Local use (anesthesia) of epinephrine in concentrations of 1:100,000 or less is less likely to precipitate clinically significa changes (Steinberg & Block, 1971).

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: The vasoconstriction and other alpha-adrenergic effects of sympathomimetic drugs enhanced in the presence of tricyclic antidepressants (TCAs). Concomitant use should be avoided. If these d together, careful monitoring and a dose reduction of the sympathomimetic is required. Patients should be inst their doctor or dentist that they are taking a tricyclic antidepressant prior to any surgery or procedure.

7) Probable Mechanism: inhibition of norepinephrine reuptake

8) Literature Reports

a) Four healthy volunteers received intravenous infusions of various sympathomimetic amines (epineph norepinephrine, phenylephrine, and isoproterenol) before and after imipramine (25 mg three times daily f showed an increased pressor response to epinephrine (2- to 4-fold), norepinephrine (4- to 8-fold), and ph 3-fold) after imipramine, but no difference was observed in the response to isoproterenol. Thus, the incre response appeared to occur only for alpha adrenergic effects. All four subjects demonstrated changes in with epinephrine and imipramine consisting of sinus arrhythmia in three subjects and multiple ectopic be rhythm in the fourth subject (Boakes et al, 1973).

b) A review of spontaneous reports of adverse reactions to vasoconstrictors in local anesthetics found th receiving a local anesthetic with norepinephrine (1:25,000) had severe reactions (severe headaches, che subarachnoid hemorrhage). The drug history was incomplete, but at least three had been taking a tricycl at the time (Anon, 1972).

3.5.1.DJ Moclobemide

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus changes)

2) Summary: Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concur and TCAs has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982c; Spig Brodribb et al, 1994c; Neuvonen et al, 1993a). Serotonin syndrome is a rare but potentially fatal condition of s hyperstimulation characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Ste Subsequently, the concomitant use of TCAs and MAOIs is contraindicated in most cases. If TCAs and MAOIs concurrently, avoid large doses, use only oral TCAs, avoid imipramine, clomipramine, desipramine, and trany monitor patients closely (Schuckit et al, 1971c; White & Simpson, 1984b).

3) Severity: contraindicated

4) Onset: delayed
5) Substantiation: established
6) Clinical Management: Concomitant use of moclobemide and imipramine is contraindicated. If imipramine i
treatment with moclobemide, a minimum of 2 weeks should elapse after moclobemide is discontinued and im
is begun (Prod Info imipramine hydrochloride oral tablet, 2003). However, the manufacturer of moclobemide
short washout period of 2 days after discontinuation of moclobemide and before imipramine is initiated (Prod
2001). There is no specific washout period for replacing imipramine treatment with moclobemide. However, it
gradually taper the tricyclic antidepressant dosage before starting treatment with an MAOI (Remick, 2002).
7) Probable Mechanism: altered catecholamine uptake and metabolism
8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T
considered an absolute contraindication in the past and still is listed as such by the manufacturers. Repo
hyperpyrexia, convulsions, and possible death have been attributed to the combination (Prod Info imipra
oral tablet, 2003; Lockett & Milner, 1965a; Brachfeld et al, 1963; Winston, 1971a; Schuckit et al, 1971b; S
Spiker & Pugh, 1976a). The mechanism may relate to the combined inhibition of catecholamine reuptake
nervous system and inhibition of catecholamine metabolism (Sjoqvist, 1965a).

b) A clinical study designed to detect an interaction between moclobemide and a tricyclic antidepressan
resulted in severe adverse effects, and the study was terminated. Information about interactions with mo
other tricyclic antidepressants is limited (Prod Info Manerix(R), 2001).

c) A 39-year old woman with bipolar disorder developed serotonin syndrome after imipramine was adde
The patient was taking moclobemide 300 mg twice daily when imipramine was started at 50 mg daily, fol
dosage increases of imipramine to 200 mg and a reduction of moclobemide dosage to 150 mg twice dail
the increase in imipramine to 200 mg per day, the patient developed symptoms of serotonin syndrome, i
shivering, confusion, fever, and spasms in the extremities. The patient was treated with chlorpromazine a
resolved over the next few days without further complications (Brodribb et al, 1994b).

d) A drug interaction occurred in which a 76-year old woman who had been taking clomipramine 50 mg
months prior to switching to moclobemide 300 mg daily.The patient experienced somnolence, confusion,
then progressed to further mental impairment, muscle stiffness, myoclonus, and convulsive attacks. The
symptoms were described as fulfilling the diagnostic criteria for serotonin syndrome and were resolved a
after discontinuing all antidepressant medications (Spigset et al, 1993c).

e) A clinical study designed to detect an interaction between moclobemide and a tricyclic antidepressan
resulted in severe adverse effects, and the study was terminated. Information about interactions with mo
other tricyclic antidepressants is limited (Prod Info Manerix(R), 2001).

f) Administration of a TCA after MAOI therapy may result in the development of serotonin syndrome. In
crossover study examining the effects of clorgyline and clomipramine for the treatment of obsessive-com
two subjects developed severe reactions characteristic of serotonin syndrome. During the study, patients
clorgyline therapy, followed by a washout period of approximately four weeks and subsequent clomipram
taking the first 100 mg dose of clomipramine, one patient developed coarse myoclonic jerking in both leg
diaphoresis, and arrhythmia. Another patient developed a similar reaction after the first dose, with upper
symptoms, myoclonic movements, and cardiac irritability. Both patient's symptoms resolved several hou
patients were later treated successfully with clomipramine without adverse effects (Insel et al, 1982b).

g) Three patients with bipolar disorder developed manic symptoms while undergoing concurrent therapy
isocarboxazid and amitriptyline. In all three cases the patients had been given MAOIs and TCAs alone w
complications. It was only when the drugs were used in combination that symptoms of mania emerged, s
synergistic effect (de la Fuente et al, 1986).

h) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a p
34-year old man. After taking several doses, the patients developed symptoms of nausea and profuse sv
by pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulatic
death (Tackley & Tregaskis, 1987b).

i) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unrespons
TCA alone. A few precautions must be followed including: a) avoidance of large doses (no more than 15
or its equivalent, 45 mg phenelzine, or 60 mg isocarboxazid) b) oral administration c) avoidance of clomi
imipramine, desipramine, and tranylcypromine in any combination, and d) close monitoring of patients (K
Winston, 1971a; Schuckit et al, 1971b; White & Simpson, 1984a; Rom & Benner, 1972). The combinatio
in one of two ways. Most frequently, the recommendation is to stop all previous antidepressants (five to t
and 14 days for MAOIs); the combination is then simultaneously started (Perry et al, 1991a). Alternatively
previously receiving a TCA, small doses of the MAOI may be slowly added (Schoonover, 1983). Some s
that the combination of amitriptyline and isocarboxazid is preferred (Perry et al, 1991a). Numerous studie
refractory depression or phobic anxiety states have successfully used the combination of MAOIs and TC
1977a; Schuckit et al, 1971b; Ashcroft, 1975a).

3.5.1.DK Moxifloxacin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Moxifloxacin has been shown to prolong the QT interval in some patients and should be avoide
receiving agents that also prolong the QT interval, such as tricyclic antidepressants. Although pharmacokinet
moxifloxacin and other drugs which prolong the QT interval have not been performed, an additive effect cann
Therefore, moxifloxacin should be used with caution when given concurrently with a tricyclic antidepressant (
(TM), 2000).

3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Moxifloxacin should be used with caution when given concurrently with a tricyclic ar
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.DL Nefopam

1) Interaction Effect: an increased risk of seizures
2) Summary: Nefopam inhibits the neuronal uptake of norepinephrine and serotonin and increases the risk o especially in patients with a history of a convulsive disorder. Tricyclic antidepressants also lower the seizure t Therefore, the manufacturer of nefopam advises caution in patients on concurrent tricyclic antidepressant the Woods, 1995).
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Because of the increased risk of seizures, extreme caution should be exercised in p nefopam and a tricyclic antidepressant. An alternative analgesic may be considered.
7) Probable Mechanism: additive lowering of seizure threshold

3.5.1.DM Nialamide

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus changes)
2) Summary: Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concur and TCAs has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982k; Spig Brodribb et al, 1994j; Neuvonen et al, 1993e). Serotonin syndrome is a rare but potentially fatal condition of s hyperstimulation characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Ste TCAs and MAOIs must be used concurrently, avoid large doses, use only oral TCAs, avoid imipramine, clom desipramine, and tranylcypromine, and monitor patients closely (Schuckit et al, 1971j; White & Simpson, 198
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concomitant use of a tricyclic antidepressant (TCA) and a monoamine oxidase inhi should be done only with close monitoring and where the clinical benefit outweighs the potential risk. Other a therapy should first be considered. If deemed clinically necessary, avoid large doses and use agents other th clomipramine, desipramine, and tranylcypromine.
7) Probable Mechanism: altered catecholamine uptake and metabolism
8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T considered an absolute contraindication in the past. Reports of excitation, hyperpyrexia, convulsions, and have been attributed to the combination (Lockett & Milner, 1965e; Winston, 1971e; Schuckit et al, 1971i; 1976e). The mechanism may relate to the combined inhibition of catecholamine reuptake into the centra and inhibition of catecholamine metabolism (Sjoqvist, 1965e).

b) In a double-blind, crossover study examining the effects of clorgyline and clomipramine for the treatm compulsive disorder, two subjects developed severe reactions characteristic of serotonin syndrome. Dur patients had received clorgyline therapy, followed by a washout period of approximately four weeks and clomipramine therapy. After taking the first 100 mg dose of clomipramine, one patient developed coarse in both legs, hyperreflexia, diaphoresis, and arrhythmia. Another patient developed a similar reaction afte with upper motor neuron symptoms, myoclonic movements, and cardiac irritability. Both patient's sympto several hours later, and both patients were later treated successfully with clomipramine without adverse 1982j).

c) A drug interaction occurred in a 76-year old woman who had been taking clomipramine 50 mg daily fo prior to switching to moclobemide 300 mg daily. The patient experienced somnolescence, confusion, and progressed to further mental impairment, muscle stiffness, myoclonus, and convulsive attacks. The patie were described as fulfilling the diagnostic criteria for serotonin syndrome and were resolved a few days l discontinuing all antidepressant medications (Spigset et al, 1993k).

d) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a p 34-year old man. After taking several doses, the patients developed symptoms of nausea and profuse sw by pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulatio death (Tackley & Tregaskis, 1987f).

e) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unresponsi TCA alone. The combination may be utilized in one of two ways. Most frequently, the recommendation is previous antidepressants (five to ten days for TCAs and 14 days for MAOIs); the combination is then sim started (Perry et al, 1991e). Alternatively, in a patient previously receiving a TCA, small doses of the MA added (Schoonover, 1983). Numerous studies in patients with refractory depression or phobic anxiety st successfully used the combination of MAOIs and TCAs (Ponto et al, 1977e; Schuckit et al, 1971i; Ashcro

3.5.1.DN Norepinephrine

1) Interaction Effect: hypertension, cardiac arrhythmias, and tachycardia

2) Summary: Clinical trials have demonstrated a 2- to 8-fold increase in the effects of intravenous infusions o drugs to volunteers on tricyclic antidepressants. Arrhythmias and other severe adverse effects have also bee 1980; Avery, 1973a; Boakes et al, 1973a; Boakes, 1973; Mitchell et al, 1970; Stone et al, 1964a). Local use (anesthesia) of epinephrine in concentrations of 1:100,000 or less is less likely to precipitate clinically significa changes (Steinberg & Block, 1971).
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: The vasoconstriction and other alpha-adrenergic effects of sympathomimetic drugs enhanced in the presence of tricyclic antidepressants (TCAs). Concomitant use should be avoided. If these d together, careful monitoring and a dose reduction of the sympathomimetic is required. Patients should be inst their doctor or dentist that they are taking a tricyclic antidepressant prior to any surgery or procedure.
7) Probable Mechanism: inhibition of norepinephrine reuptake
8) Literature Reports
a) Four healthy volunteers received intravenous infusions of various sympathomimetic amines (epineph norepinephrine, phenylephrine, and isoproterenol) before and after imipramine (25 mg three times daily f showed an increased pressor response to epinephrine (2- to 4-fold), norepinephrine (4- to 8-fold), and ph 3-fold) after imipramine, but no difference was observed in the response to isoproterenol. Thus, the incre response appeared to occur only for alpha adrenergic effects. All four subjects demonstrated changes in with epinephrine and imipramine consisting of sinus arrhythmia in three subjects and multiple ectopic be rhythm in the fourth subject (Boakes et al, 1973).
b) A review of spontaneous reports of adverse reactions to vasoconstrictors in local anesthetics found th receiving a local anesthetic with norepinephrine (1:25,000) had severe reactions (severe headaches, che subarachnoid hemorrhage). The drug history was incomplete, but at least three had been taking a tricycl at the time (Anon, 1972).

3.5.1.DO Octreotide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Tricyclic antidepressants (TCAs) and octreotide have been shown to prolong the QTc interval a recommended therapeutic dose (Prod Info Sandostatin(R), 1999; Marshall & Forker, 1982). Even though no f interaction studies have been done, the coadministration of tricyclic antidepressants and other drugs known t interval, such as octreotide, is not recommended (Prod Info Elavil(R), 1999).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of octreotide and tricyclic antidepressants is not reco
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.DP Oxilofrine

1) Interaction Effect: hypertension, cardiac arrhythmias, and tachycardia
2) Summary: Clinical trials have demonstrated a 2- to 8-fold increase in the effects of intravenous infusions o drugs to volunteers on tricyclic antidepressants. Arrhythmias and other severe adverse effects have also bee 1980; Avery, 1973a; Boakes et al, 1973a; Boakes, 1973; Mitchell et al, 1970; Stone et al, 1964a). Local use (anesthesia) of epinephrine in concentrations of 1:100,000 or less is less likely to precipitate clinically significa changes (Steinberg & Block, 1971).
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: The vasoconstriction and other alpha-adrenergic effects of sympathomimetic drugs enhanced in the presence of tricyclic antidepressants (TCAs). Concomitant use should be avoided. If these d together, careful monitoring and a dose reduction of the sympathomimetic is required. Patients should be inst their doctor or dentist that they are taking a tricyclic antidepressant prior to any surgery or procedure.
7) Probable Mechanism: inhibition of norepinephrine reuptake
8) Literature Reports
a) Four healthy volunteers received intravenous infusions of various sympathomimetic amines (epineph norepinephrine, phenylephrine, and isoproterenol) before and after imipramine (25 mg three times daily f showed an increased pressor response to epinephrine (2- to 4-fold), norepinephrine (4- to 8-fold), and ph 3-fold) after imipramine, but no difference was observed in the response to isoproterenol. Thus, the incre response appeared to occur only for alpha adrenergic effects. All four subjects demonstrated changes in with epinephrine and imipramine consisting of sinus arrhythmia in three subjects and multiple ectopic be rhythm in the fourth subject (Boakes et al, 1973).
b) A review of spontaneous reports of adverse reactions to vasoconstrictors in local anesthetics found th receiving a local anesthetic with norepinephrine (1:25,000) had severe reactions (severe headaches, che subarachnoid hemorrhage). The drug history was incomplete, but at least three had been taking a tricycl at the time (Anon, 1972).

3.5.1.DQ Pargyline

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus

changes)
2) Summary: Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concu
and TCAs has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982a; Spig
Brodribb et al, 1994; Neuvonen et al, 1993). Serotonin syndrome is a rare but potentially fatal condition of se
hyperstimulation characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Ste
TCAs and MAOIs must be used concurrently, avoid large doses, use only oral TCAs, avoid imipramine, clom
desipramine, and tranylcypromine, and monitor patients closely (Schuckit et al, 1971a; White & Simpson, 198
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concomitant use of a tricyclic antidepressant (TCA) and a monoamine oxidase inhi
should be done only with close monitoring and where the clinical benefit outweighs the potential risk. Other a
therapy should first be considered. If deemed clinically necessary, avoid large doses and use agents other th
clomipramine, desipramine, and tranylcypromine.
7) Probable Mechanism: altered catecholamine uptake and metabolism
8) Literature Reports
a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T
considered an absolute contraindication in the past. Reports of excitation, hyperpyrexia, convulsions, an
have been attributed to the combination (Lockett & Milner, 1965; Winston, 1971; Schuckit et al, 1971; Sp
1976). The mechanism may relate to the combined inhibition of catecholamine reuptake into the central
and inhibition of catecholamine metabolism (Sjoqvist, 1965).
b) Administration of a TCA after MAOI therapy may result in the development of serotonin syndrome. In
crossover study examining the effects of clorgyline and clomipramine for the treatment of obsessive-com
two subjects developed severe reactions characteristic of serotonin syndrome. During the study, patients
clorgyline therapy, followed by a washout period of approximately four weeks and subsequent clomipram
taking the first 100 mg dose of clomipramine, one patient developed coarse myoclonic jerking in both leg
diaphoresis, and arrhythmia. Another patient developed a similar reaction after the first dose, with upper
symptoms, myoclonic movements, and cardiac irritability. Both patient's symptoms resolved several hou
patients were later treated successfully with clomipramine without adverse effects (Insel et al, 1982).
c) A drug interaction occurred in a 76-year old woman who had been taking clomipramine 50 mg daily fo
prior to switching to moclobemide 300 mg daily. The patient experienced somnolescence, confusion, an
progressed to further mental impairment, muscle stiffness, myoclonus, and convulsive attacks. The patie
were described as fulfilling the diagnostic criteria for serotonin syndrome and were resolved a few days l
discontinuing all antidepressant medications (Spigset et al, 1993).
d) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a p
34-year old man. After taking several doses, the patients developed symptoms of nausea and profuse sv
by pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulatio
death (Tackley & Tregaskis, 1987).
e) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unrespons
TCA alone. The combination may be utilized in one of two ways. Most frequently, the recommendation is
previous antidepressants (five to ten days for TCAs and 14 days for MAOIs); the combination is then sim
started (Perry et al, 1991). Alternatively, in a patient previously receiving a TCA, small doses of the MAO
added (Schoonover, 1983). Numerous studies in patients with refractory depression or phobic anxiety st
successfully used the combination of MAOIs and TCAs (Ponto et al, 1977; Schuckit et al, 1971; Ashcroft

3.5.1.DR Paroxetine
1) Interaction Effect: imipramine toxicity (dry mouth, sedation, urinary retention)
2) Summary: Paroxetine coadministered with desipramine or imipramine produced higher serum concentrati
antidepressant (TCA) in some patients (Prod Info Paxil CR(TM), 2003; Hartter et al, 1994; Brosen et al, 1993
effect on TCAs may resemble that of fluoxetine (another selective serotonin reuptake inhibitor), which is knov
metabolism (Aranow et al, 1989b; Vaughan, 1988; Goodnick, 1989b). With coadministration, monitor patients
toxicity. Imipramine doses may need to be reduced.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Coadministration of paroxetine with other drugs that are metabolized by cytochrom
(CYP2D6) should be approached with caution. When paroxetine is coadministered with imipramine, monitor
and symptoms of imipramine toxicity (dry mouth, sedation, urinary retention, blurred vision). Imipramine dose
reduced.
7) Probable Mechanism: decreased cytochrome P450 2D6-mediated imipramine metabolism
8) Literature Reports
a) The effect of paroxetine on desipramine metabolism was studied in nine extensive metabolizers (EM)
metabolizers (PM) of desipramine. Subjects took a single oral dose of desipramine before starting paroxe
dose after 11 days of paroxetine use. After the addition of paroxetine, EMs experienced a 5-fold decreas
desipramine, indicating that paroxetine inhibits oxidation reactions catalyzed by CYP2D6. PMs had a slig
clearance of desipramine with paroxetine. With concurrent administration of desipramine and paroxetine
two drugs may result in a need for dosage adjustments, especially in extensive metabolizers of desipram
1993).

3.5.1.DS Pemoline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sin also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramin 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.DT Pentamidine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Tricyclic antidepressants (TCAs) and pentamidine have been shown to prolong the QTc interva recommended therapeutic dose (Lindsay et al, 1990; Marshall & Forker, 1982i). Even though no formal drug have been done, the coadministration of tricyclic antidepressants and other drugs known to prolong the QTc pentamidine, is not recommended (Prod Info Elavil(R), 1999e).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of pentamidine and tricyclic antidepressants is not re

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.DU Pentobarbital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive

2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.

7) Probable Mechanism: increased tricyclic antidepressant metabolism

8) Literature Reports

a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were ex metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar effe expected with any combination of TCA and barbiturate.

3.5.1.DV Phendimetrazine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sin also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained in amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramin 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.DW Phenelzine

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus changes)

2) Summary: Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concur and TCAs has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982r; Spig Brodribb et al, 1994q; Neuvonen et al, 1993i). Serotonin syndrome is a rare but potentially fatal condition of s hyperstimulation characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Ste Consequently, coadministration of TCAs and MAOIs is contraindicated in most cases (Prod Info imipramine h tablet, 2003). If TCAs and MAOIs must be used concurrently, avoid large doses, use only oral TCAs, avoid in clomipramine, desipramine, and tranylcypromine, and monitor patients closely (Schuckit et al, 1971t; White &

3) Severity: contraindicated

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Concomitant use of imipramine with an monoamine oxidase inhibitor (MAOI) is con imipramine is replacing treatment with phenelzine, a minimum of 2 weeks should elapse after phenelzine is d therapy with imipramine begins (Prod Info imipramine hydrochloride oral tablet, 2003). The manufacturer of p

recommends that at least 10 days should elapse before imipramine therapy is replaced by phenelzine (Prod
Tablets, USP, 2005).

7) Probable Mechanism: altered catecholamine uptake and metabolism

8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T considered an absolute contraindication in the past and still is listed as such by the manufacturers (Prod hydrochloride oral tablet, 2003). Reports of excitation, hyperpyrexia, convulsions, and possible death hav to the combination (Lockett & Milner, 1965j; Brachfeld et al, 1963f; Winston, 1971j; Schuckit et al, 1971s Spiker & Pugh, 1976j). The mechanism may relate to the combined inhibition of catecholamine reuptake nervous system and inhibition of catecholamine metabolism (Sjoqvist, 1965j).

b) Administration of a TCA after MAOI therapy may result in the development of serotonin syndrome. In crossover study examining the effects of clorgyline and clomipramine for the treatment of obsessive-com two subjects developed severe reactions characteristic of serotonin syndrome. During the study, patients clorgyline therapy, followed by a washout period of approximately four weeks and subsequent clomipram taking the first 100 mg dose of clomipramine, one patient developed coarse myoclonic jerking in both leg diaphoresis, and arrhythmia. Another patient developed a similar reaction after the first dose, with upper symptoms, myoclonic movements, and cardiac irritability. Both patient's symptoms resolved several hou patients were later treated successfully with clomipramine without adverse effects (Insel et al, 1982q).

c) A drug interaction was reported in a 76-year old woman who had been taking clomipramine 50 mg da months was switched to moclobemide 300 mg daily. The patient experienced somnolence, confusion, ar progressed to further mental impairment, muscle stiffness, myoclonus, and convulsive attacks. The patie were described as fulfilling the diagnostic criteria for serotonin syndrome and were resolved a few days l discontinuing all antidepressant medications (Spigset et al, 1993r).

d) A 39-year old woman with bipolar disorder developed serotonin syndrome after imipramine was adde The patient was taking moclobemide 300 mg twice daily when imipramine was started at 50 mg daily, fol dosage increases of imipramine to 200 mg and a reduction of moclobemide dosage to 150 mg twice dail the increase in imipramine to 200 mg per day, the patient developed symptoms of serotonin syndrome, i shivering, confusion, fever, and spasms in the extremities. The patient was treated with chlorpromazine a resolved over the next few days without further complications (Brodribb et al, 1994p).

e) Three patients with bipolar disorder developed manic symptoms while undergoing concurrent therapy isocarboxazid and amitriptyline. In all three cases the patients had been given MAOIs and TCAs alone w complications. It was only when the drugs were used in combination that symptoms of mania emerged, s synergistic effect (de la Fuente et al, 1986e).

f) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a pl 34-year old man. After taking several doses, the patient developed symptoms of nausea and profuse sw pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulation a (Tackley & Tregaskis, 1987i).

g) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unrespons TCA alone. A few precautions must be followed including: a) avoidance of large doses (no more than 15 or its equivalent, 45 mg phenelzine, or 60 mg isocarboxazid) b) oral administration c) avoidance of clomi imipramine, desipramine, and tranylcypromine in any combination, and d) close monitoring of patients (K Winston, 1971j; Schuckit et al, 1971s; White & Simpson, 1984n; Rom & Benner, 1972e). The combinatio in one of two ways. Most frequently, the recommendation is to stop all previous antidepressants (five to t and 14 days for MAOIs); the combination is then simultaneously started (Perry et al, 1991i). Alternatively previously receiving a TCA, small doses of the MAOI may be slowly added (Schoonover, 1983). Some s that the combination of amitriptyline and isocarboxazid is preferred (Perry et al, 1991i). Numerous studie refractory depression or phobic anxiety states have successfully used the combination of MAOIs and TC 1977j; Schuckit et al, 1971s; Ashcroft, 1975i).

3.5.1.DX Phenindione

1) Interaction Effect: increased risk of bleeding

2) Summary: Tricyclic antidepressants (TCAs) may increase the half-life and bioavailability of oral anticoagul 1970g; Williams et al, 1976g). Considerable interindividual differences may be found (Pond et al, 1975g).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: In patients receiving tricyclic antidepressants and oral anticoagulant therapy, the pr ratio or INR (international normalized ratio) should be closely monitored with the addition and withdrawal of th and should be periodically reassessed during concurrent therapy. Achieving a stable dosage regimen which p desired level of anticoagulation may be difficult in patients on this combination, and frequent adjustments of t dose may be required.

7) Probable Mechanism: decreased phenindione metabolism; increased phenindione absorption

8) Literature Reports

a) In a study of healthy volunteers, the concurrent use of nortriptyline or amitriptyline resulted in an incre levels and an increase in the plasma half-life of dicumarol, although the effect was not consistent in all su 1975f). This effect was not observed with warfarin.

b) A single oral dose of bishydroxycoumarin after 8 days of nortriptyline resulted in a significantly prolon decreased volume of distribution of the coumarin anticoagulant in 6 healthy volunteers (Vesell et al, 197(

mechanism of action was suggested to be reduced bishydroxycoumarin metabolism and/or altered coum
c) Drug dosing was studied in 16 patients on long-term anticoagulant therapy who used concurrent TCA
1976f). TCAs affected the stability of anticoagulant control leading to frequent changes in the doses of a
Inhibition of coumarin metabolism was the postulated mechanism.

3.5.1.DY Phenmetrazine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte
enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim
also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n
(Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co
not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of
agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects
dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o
Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t
Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen
coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i
amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE
sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o
antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde
2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i
such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm
of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return
normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle
Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g
four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transi
clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramin
1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc
therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressio
although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru
depression, with one exception, indicated little advantage of drug over placebo and did not appear to be
conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.DZ Phenobarbital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive

2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me
TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence
(Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s
reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do
required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con
be of value in determining appropriate dosage.

7) Probable Mechanism: increased tricyclic antidepressant metabolism

8) Literature Reports

a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa
treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were e
metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp
epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s
area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipram
half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h
and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar eff

expected with any combination of TCA and barbiturate.

3.5.1.EA Phenprocoumon

1) Interaction Effect: increased risk of bleeding

2) Summary: Tricyclic antidepressants (TCAs) may increase the half-life and bioavailability of oral anticoagul 1970i; Williams et al, 1976i). Considerable interindividual differences may be found (Pond et al, 1975i).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: In patients receiving tricyclic antidepressants and oral anticoagulant therapy, the pr ratio or INR (international normalized ratio) should be closely monitored with the addition and withdrawal of th and should be periodically reassessed during concurrent therapy. Achieving a stable drug regimen which pro level of anticoagulation may be difficult in patients on this combination, and frequent adjustments of the antic be required.

7) Probable Mechanism: decreased phenprocoumon metabolism; increased phenprocoumon absorption

8) Literature Reports

a) In a study of healthy volunteers, the concurrent use of nortriptyline or amitriptyline resulted in an incre levels and an increase in the plasma half-life of dicumarol, although the effect was not consistent in all su 1975h). This effect was not observed with warfarin.

b) A single oral dose of bishydroxycoumarin after 8 days of nortriptyline resulted in a significantly prolon decreased volume of distribution of the coumarin anticoagulant in 6 healthy volunteers (Vesell et al, 197(mechanism of action was suggested to be reduced bishydroxycoumarin metabolism and/or altered coum

c) Drug dosing was studied in 16 patients on long-term anticoagulant therapy who used concurrent TCA 1976h). TCAs affected the stability of anticoagulant control leading to frequent changes in the doses of a Inhibition of coumarin metabolism was the postulated mechanism.

3.5.1.EB Phentermine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained in amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transie clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desipramin 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.EC Phenylephrine

1) Interaction Effect: hypertension, cardiac arrhythmias, and tachycardia

2) Summary: Clinical trials have demonstrated a 2- to 8-fold increase in the effects of intravenous infusions c drugs to volunteers on tricyclic antidepressants. Arrhythmias and other severe adverse effects have also bee 1980; Avery, 1973a; Boakes et al, 1973a; Boakes, 1973; Mitchell et al, 1970; Stone et al, 1964a). Local use (anesthesia) of epinephrine in concentrations of 1:100,000 or less is less likely to precipitate clinically significa changes (Steinberg & Block, 1971).

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: The vasoconstriction and other alpha-adrenergic effects of sympathomimetic drugs enhanced in the presence of tricyclic antidepressants (TCAs). Concomitant use should be avoided. If these d together, careful monitoring and a dose reduction of the sympathomimetic is required. Patients should be inst their doctor or dentist that they are taking a tricyclic antidepressant prior to any surgery or procedure.

7) Probable Mechanism: inhibition of norepinephrine reuptake

8) Literature Reports

a) Four healthy volunteers received intravenous infusions of various sympathomimetic amines (epineph norepinephrine, phenylephrine, and isoproterenol) before and after imipramine (25 mg three times daily f showed an increased pressor response to epinephrine (2- to 4-fold), norepinephrine (4- to 8-fold), and ph 3-fold) after imipramine, but no difference was observed in the response to isoproterenol. Thus, the incre response appeared to occur only for alpha adrenergic effects. All four subjects demonstrated changes in with epinephrine and imipramine consisting of sinus arrhythmia in three subjects and multiple ectopic be rhythm in the fourth subject (Boakes et al, 1973).

b) A review of spontaneous reports of adverse reactions to vasoconstrictors in local anesthetics found th receiving a local anesthetic with norepinephrine (1:25,000) had severe reactions (severe headaches, che subarachnoid hemorrhage). The drug history was incomplete, but at least three had been taking a tricycl at the time (Anon, 1972).

3.5.1.ED Phenytoin

1) Interaction Effect: an increased risk of phenytoin toxicity (ataxia, hyperreflexia, nystagmus, tremors)

2) Summary: A few case reports have indicated that imipramine inhibits phenytoin metabolism resulting in in phenytoin concentration (Petti & Campbell, 1975a; Perucca & Richens, 1977a). Tricyclic antidepressants (TC seizure threshold in epileptic patients stabilized on anticonvulsants. Theoretically, because phenytoin is an en metabolism of antidepressants may be increased resulting in reduced TCA serum levels.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Consider phenytoin serum levels if a tricyclic antidepressant is added to therapy or begins to exhibit signs of toxicity; lower doses of phenytoin may be required. If phenytoin is added to tricyclic therapy, monitor for clinical efficacy of the tricyclic agent.

7) Probable Mechanism: inhibition of phenytoin metabolism

3.5.1.EE Pimozide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Although citing no data, the manufacturer of pimozide states that concomitant use with other dr the QT interval is contraindicated (Prod Info Orap(R), 1999a). Tricyclic antidepressants (TCAs) at therapeutic QT prolongation (Prod Info Norpramin(R), 2000; Marshall & Forker, 1982ad).

3) Severity: contraindicated

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Because of the potential to prolong the QT interval, concurrent administration of a tr antidepressant and pimozide is contraindicated.

7) Probable Mechanism: additive effects on QT interval

8) Literature Reports

a) Electrocardiogram (ECG) changes seen during clinical trials of pimozide in Tourette's syndrome and s patients include prolongation of the QT interval, flattening, notching, and inversion of the T wave, and the waves. Sudden, unexpected deaths have occurred at doses greater than 20 milligrams/day (Prod Info O 1999).

3.5.1.EF Pirmenol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Class Ia antiarrhythmics and tricyclic antidepressants have been shown to prolong the QTc inte recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadm Ia antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is n (Prod Info Elavil(R), 1999g; Prod Info Quinaglute(R), 1999; Marshall & Forker, 1982n).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic agent and a tricyclic anti
recommended.
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Quinidine is an inhibitor of the cytochrome P450 isoenzyme responsible for the 2-hydroxylation of imi
desipramine (Brosen & Gram, 1989). Inhibition of this enzyme system can result in a 35% decrease in im
clearance and 85% decrease in desipramine clearance. Demethylation of imipramine by the cytochrome
unaffected by this interaction. Until more information is available all patients having quinidine added to di
containing imipramine or desipramine should be monitored for increased antidepressant serum concentr
potential toxicity.
b) An increased incidence in sudden death was observed in six out of 53 patients with cardiac disease r
amitriptyline, compared to 0 out of 53 in the control group. It was recommended that amitriptyline be avo
with underlying cardiac disease except when depression was debilitating and no other drugs were helpfu
Coull et al, 1970).
c) In a placebo controlled study, imipramine 3.5 mg/kg was administered daily for seven patients with se
and titrated doses to obtain therapeutic plasma concentrations. Two patients displayed premature atrial c
and premature ventricular depolarizations before therapy. On patient had 33 premature atrial depolarizat
premature ventricular depolarizations (PVD) per hour, which decreased to 0.4 PAC and zero PVC per ho
The other patient had 12 PAD and 169 PVD per hour before treatment and 1.8 PAD and 28.1 PVD per h
The authors also cautioned that the incidence of cardiotoxicity may increase if tricyclic antidepressants a
with Type I antiarrhythmics. It was also recommended that quinidine and procainamide not be used to tre
of a tricyclic overdose. The similarities between these agents may exacerbate the cardiotoxicity (Kantor e

3.5.1.EG Prajmaline

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Class Ia antiarrhythmics and tricyclic antidepressants have been shown to prolong the QTc inte
recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadm
Ia antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is n
(Prod Info Elavil(R), 1999g; Prod Info Quinaglute(R), 1999; Marshall & Forker, 1982n).
3) Severity: major
4) Onset: unspecified

5) Substantiation: probable
6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant do
required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con
be of value in determining appropriate dosage.
7) Probable Mechanism: increased tricyclic antidepressant metabolism

8) Literature Reports

a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were ex metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar effe expected with any combination of TCA and barbiturate.

3.5.1.EI Procainamide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Class Ia antiarrhythmics and tricyclic antidepressants have been shown to prolong the QTc inte recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadm Ia antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is n (Prod Info Elavil(R), 1999g; Prod Info Quinaglute(R), 1999; Marshall & Forker, 1982n).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic agent and a tricyclic anti recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) Quinidine is an inhibitor of the cytochrome P450 isoenzyme responsible for the 2-hydroxylation of imi desipramine (Brosen & Gram, 1989). Inhibition of this enzyme system can result in a 35% decrease in im clearance and 85% decrease in desipramine clearance. Demethylation of imipramine by the cytochrome unaffected by this interaction. Until more information is available all patients having quinidine added to dr containing imipramine or desipramine should be monitored for increased antidepressant serum concentr potential toxicity.

b) An increased incidence in sudden death was observed in six out of 53 patients with cardiac disease r amitriptyline, compared to 0 out of 53 in the control group. It was recommended that amitriptyline be avo with underlying cardiac disease except when depression was debilitating and no other drugs were helpfu Coull et al, 1970).

c) In a placebo controlled study, imipramine 3.5 mg/kg was administered daily for seven patients with se and titrated doses to obtain therapeutic plasma concentrations. Two patients displayed premature atrial c and premature ventricular depolarizations before therapy. On patient had 33 premature atrial depolarizat premature ventricular depolarizations (PVD) per hour, which decreased to 0.4 PAC and zero PVC per ho The other patient had 12 PAD and 169 PVD per hour before treatment and 1.8 PAD and 28.1 PVD per h The authors also cautioned that the incidence of cardiotoxicity may increase if tricyclic antidepressants a with Type I antiarrhythmics. It was also recommended that quinidine and procainamide not be used to tre of a tricyclic overdose. The similarities between these agents may exacerbate the cardiotoxicity (Kantor e

3.5.1.EJ Procarbazine

1) Interaction Effect: neurotoxicity, seizures

2) Summary: Concomitant tricyclic antidepressant and more potent MAOI use has resulted in hyperpyrexia, c death. Procarbazine has relatively weak MAOI actions, so while the potential for drug interactions between tri antidepressants and procarbazine exists, clinical data are lacking at this time (Schuckit et al, 1971r; White & S Concurrent use is not recommended (Prod Info Matulane(R), 1997).

3) Severity: major

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Concomitant use is not recommended and should probably be initiated only under c supervision, and then only if other antidepressant class agents have proven unsuccessful. With more potent I recommendations for concurrent use of TCAs have included avoiding large doses of the TCA, using only oral avoiding imipramine, clomipramine, and desipramine. Procarbazine therapy should not begin until seven day discontinuation of tricyclic antidepressants and 14 days following the discontinuation of other MAO inhibitors.

7) Probable Mechanism: altered catecholamine uptake and metabolism

8) Literature Reports

a) Procarbazine is primarily used as an antineoplastic agent, but was originally investigated as a monoa inhibitor (Gilman et al, 1985a). Animal studies have indicated that procarbazine is a monoamine oxidase (DeVita et al, 1965) but appears to be a relatively weak MAOI in man (Gilman et al, 1985a). Hypertensiv still result from concomitant administration of tricyclic antidepressants, sympathomimetics, and tyramine (Gilman et al, 1985a; Ponto et al, 1977i).

b) Concomitant administration of monoamine oxidase (MAO) inhibitors with tricyclic antidepressants has an absolute contraindication in the past and still is listed as such by the manufacturers. Reports of excita convulsions, and possible death have been attributed to the combination (Lockett & Milner, 1965i; Brach Winston, 1971i; Schuckit et al, 1971q; Sargent, 1965e; Spiker & Pugh, 1976i). Careful examination of su unusual circumstances in most cases such as parenteral administration of a tricyclic. The mechanism ma

combined inhibition of catecholamine reuptake into the central nervous system and inhibition of catechol (Sjoqvist, 1965i).

c) Procarbazine therapy should not begin until 7 days following discontinuation of tricyclic antidepressar following the discontinuation of other MAO inhibitors (AMA Department of Drugs, 1992; Gilman et al, 198

3.5.1.EK Prochlorperazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Q and T wave distortions have been observed in patients taking phenothiazines (Prod Info Cor Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, are available. Tricyclic antidepressants (TCAs) at therapeutic doses can cause QT prolongation (Marshall & F Case reports have described increased plasma levels and adverse effects when phenothiazines and tricyclic were taken together, likely due to inhibition of their metabolism (Ghaemi & Kirkwood, 1998; Geller et al, 1985 Loga et al, 1981).

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Concurrent administration of a phenothiazine and a tricyclic antidepressant is not re

7) Probable Mechanism: additive effect on QT interval

3.5.1.EL Propafenone

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Class I antiarrhythmics have been shown to prolong the QTc interval at the recommended ther Even though no formal drug interaction studies have been done, the coadministration of Class I antiarrhythmi known to prolong the QTc interval, including tricyclic antidepressants, is not recommended (Prod Info Tambo acetate, 1998; Larochelle et al, 1984; Scagliotti et al, 1982).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a Class I antiarrhythmic and a tricyclic antidepress recommended.

7) Probable Mechanism: additive effects on QT prolongation

8) Literature Reports

a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include increa prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982q).

b) A 68-year-old man suffering from agitated major depression was begun on a dose of desipramine 12 produced a subtherapeutic serum level of 442 nmol/L (therapeutic range = 500 to 1000 nmol/L). An increa mg daily produced excellent clinical response with no side effects. He developed atrial fibrillation and flut mg daily was added to his therapy, and desipramine was discontinued. His arrhythmia was suppressed v propafenone 150 mg twice daily and 300 mg at bedtime. Desipramine 150 mg daily was again begun, at experienced dry mouth, sedation, and shakiness; the desipramine serum level was measured at 2092 nr desipramine was discontinued for five days, the side effects ceased, and desipramine therapy was resur The desipramine serum level was measured at 1130 nmol/L (Katz, 1991).

3.5.1.EM Propranolol

1) Interaction Effect: increased imipramine concentrations

2) Summary: One report of 2 cases of children receiving imipramine and propranolol was suggestive of inter metabolism of imipramine with this combination (Gillette & Tannery, 1994). In one case, imipramine levels ros when the propranolol dose was increased following admission to the hospital. No toxicity was noted. The pos compliance prior to admission might have played a role was not considered by the authors, and no rechalleng The other case involved several changes in dose of both drugs. Prospective study is needed to determine the interaction.

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for an enhanced effect of imipramine. A dosage adjustment may be require

7) Probable Mechanism: decreased imipramine metabolism

3.5.1.EN Propylhexedrine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported enhanced amphetamine effects from the release of norepinephrine (Beaumont, 1973d; Raisfeld, 1972). A sim also occur with all drugs that have amphetamine-like effects. Acute elevations in blood pressure have been n (Flemenbaum, 1971a). Some amphetamine-like drugs may inhibit the metabolism of TCAs, although most co not been studied. When amphetamine analogs are being used to treat obesity, it should be noted that TCAs f moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo therapy with some TCAs (Merigian & Browning, 1993). Caution is advised when concurrent administration of agents and TCAs is warranted. The patient should be closely monitored for increased cardiovascular effects

dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho could lead to hypertension, increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) o Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral t Flemenbaum, 1972). Use caution if such therapy is warranted. Monitor the patient closely for hypertension ar
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen coadministration of d-amphetamine with TCAs such as desipramine or protriptyline results in sustained i amphetamine concentration in the brain (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Info DEXE sustained-release oral capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c antidepressants, such as imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transde 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i such that the hypotensive effects induced by TCAs may lead to blood pressures as high as 170/120 mm of combined therapy. Discontinuation of the methylphenidate usually results in the blood pressure return normotensive levels; reinstitution of the methylphenidate resulted in further blood pressure elevation (Fle Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g four weeks, were given fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transi clinical improvement. However, fenfluramine more than doubled steady-state plasma levels of desiprami 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc therapy (Garrettson et al, 1969). However, a systemic review of stimulants in the treatment of depressior although uncontrolled studies were generally positive, the ten placebo-controlled studies of stimulant dru depression, with one exception, indicated little advantage of drug over placebo and did not appear to be conventional antidepressants in primary depression (Satel & Nelson, 1989).

3.5.1.EO Quetiapine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod 1999), haloperidol (O'Brien et al, 1999), risperidone (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001 (Owens, 2001b), sultopride (Lande et al, 1992), and zotepine (Sweetman, 2003). Even though no formal drug studies have been done, the coadministration of a tricyclic antidepressant and an antipsychotic is not recomm Pamelor(R), 2001; Marshall & Forker, 1982t).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic is n
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included pr corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 m proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricu (Prod Info Orap(R), 1999).

3.5.1.EP Quinestrol

1) Interaction Effect: attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypotension, a
2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de estrogens (Somani & Khurana, 1973m), with paradoxical loss of antidepressant effect yet tricyclic toxicity bei simultaneously (Prange, 1972m). The effects of the interaction appear to be estrogen dose-related (Khurana, be of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started o (Krishnan et al, 1984m).
3) Severity: minor
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.
7) Probable Mechanism: possible estrogen-enhanced hepatic metabolism of the tricyclic
8) Literature Reports
a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I depressed female prisoners were randomly assigned to 4 treatment groups. Ten patients received place

imipramine (150 milligrams/day) and placebo, 5 patients received imipramine (150 milligrams/day) and e micrograms/day), while 5 patients received imipramine (150 milligrams/day) and ethinyl estradiol (25 mic 10 patients that received placebo did not improve over the 6 weeks of the study. The 10 patients taking e imipramine demonstrated a significantly greater improvement in symptoms than did the 10 patients takin alone. However, after 2 weeks, the 5 patients that received imipramine and high-dose estrogen had not i as the patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsine affected the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period o required for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed residual estrogen in the high-dose group. In another group, 5 women received imipramine 150 milligrams estradiol 50 micrograms daily did not improve as much as 10 patients receiving only imipramine. Also, th combination had severe side-effects including lethargy, coarse tremor and systolic hypotension (Prange,

b) A case reported by (Khurana, 1972l) demonstrated an interaction in a 32-year-old female taking conju 2.5 milligrams and imipramine 100 milligrams. The patient developed lethargy, tremors, and signs of dep After 2 years of therapy, the patient increased her estrogen dose to 5 milligrams and then 7.5 milligrams became nauseated, had constant headaches, and low normal blood pressure. All lab work was normal. U the estrogen, the side-effects abated. Some investigators have proposed that the side effects resulted fr effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1973l).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begir there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients' clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973g).

d) The effect of oral contraceptives on clomipramine was studied in 42 women between the ages of 18 a three women took clomipramine 25 milligrams at bedtime while 19 took clomipramine 25 milligrams at be contraceptives. Over the 4-week study, 3 control patients (2 due to side-effects) and 5 in the experimenta side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of se concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980f).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep concurrently. A 24-year-old patient receiving clomipramine 120 milligrams/day for anorexia nervosa and estrogens 1.25milligrams/day for amenorrhea developed restless legs and a constant desire to move co Estrogen was discontinued and benztropine 2 milligrams was administered, resulting in marked reductio within 48 hours. Akathisia and disorientation developed in a 55-year-old patient on conjugated estrogens milligrams/day who was prescribed amitriptyline 50 milligrams/day for depression. Within hours of amitrip was confused, restless, and possessed an inner desire to move continuously. Symptoms disappeared a amitriptyline. Positive rechallenge at one week with doxepin 100 milligrams, with resolution following disc doxepin. A third case of akathisia was reported in a 35-year-old patient who received conjugated estroge milligrams/day and amitriptyline 50 milligrams/day. Akathisia developed within a few hours after taking th amitriptyline and resolved within 48 hours following discontinuation of the antidepressant (Krishnan et al,

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept micrograms or less of ethinyl estradiol) from 27 to 44% (p less than 0.05) as evident by an increase in th plasma concentration time curve (Abernethy et al, 1984g).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19 are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer system resulting in an antidepressant effect (Oppenheim, 1983f).

3.5.1.EQ Quinidine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Class Ia antiarrhythmics and tricyclic antidepressants have been shown to prolong the QTc inte recommended therapeutic dose. Even though no formal drug interaction studies have been done, the coadm Ia antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is n (Prod Info Elavil(R), 1999g; Prod Info Quinaglute(R), 1999; Marshall & Forker, 1982n).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of a Class IA antiarrhythmic agent and a tricyclic anti recommended.

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) Quinidine is an inhibitor of the cytochrome P450 isoenzyme responsible for the 2-hydroxylation of imi desipramine (Brosen & Gram, 1989). Inhibition of this enzyme system can result in a 35% decrease in im clearance and 85% decrease in desipramine clearance. Demethylation of imipramine by the cytochrome unaffected by this interaction. Until more information is available all patients having quinidine added to d containing imipramine or desipramine should be monitored for increased antidepressant serum concentr potential toxicity.

b) An increased incidence in sudden death was observed in six out of 53 patients with cardiac disease r

amitriptyline, compared to 0 out of 53 in the control group. It was recommended that amitriptyline be avo with underlying cardiac disease except when depression was debilitating and no other drugs were helpfu Coull et al, 1970).

c) In a placebo controlled study, imipramine 3.5 mg/kg was administered daily for seven patients with se and titrated doses to obtain therapeutic plasma concentrations. Two patients displayed premature atrial and premature ventricular depolarizations before therapy. On patient had 33 premature atrial depolarizat premature ventricular depolarizations (PVD) per hour, which decreased to 0.4 PAC and zero PVC per ho The other patient had 12 PAD and 169 PVD per hour before treatment and 1.8 PAD and 28.1 PVD per h The authors also cautioned that the incidence of cardiotoxicity may increase if tricyclic antidepressants a with Type I antiarrhythmics. It was also recommended that quinidine and procainamide not be used to tre of a tricyclic overdose. The similarities between these agents may exacerbate the cardiotoxicity (Kantor e

3.5.1.ER Quinidine

1) Interaction Effect: imipramine toxicity (dry mouth, sedation) and an increased risk of cardiotoxicity (QT pro torsades de pointes, cardiac arrest)

2) Summary: Two studies have demonstrated that concomitant use of quinidine and imipramine or desipram increased serum concentrations of these antidepressants (Brosen & Gram, 1989b; Steiner et al, 1987). Due t cardiac effects, the incidence of cardiotoxicity (increased PR interval, QRS complex, and QTc interval) may a tricyclic antidepressants are administered with Type I antiarrhythmics (Kantor et al, 1978b; Bigger et al, 1977

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: The concurrent use of imipramine and quinidine is not recommended. Monitor for in antidepressant side effects with concurrent therapy; lower doses of the tricyclic agent may be required in som monitor the patient for signs and symptoms of additive cardiac effects, including any changes in the EKG.

7) Probable Mechanism: decreased imipramine metabolism, additive cardiac effects

8) Literature Reports

a) Quinidine is an inhibitor of the cytochrome P450 isoenzyme responsible for the 2-hydroxylation of imi desipramine. Inhibition of this enzyme system can result in a 35% decrease in imipramine clearance and desipramine clearance. Demethylation of imipramine by the cytochrome P450 system is unaffected by th more information is available all patients having quinidine added to a drug regimen containing imipramin should be monitored for increased antidepressant serum concentrations and potential toxicity (Brosen &

b) One study reported the cardiac effects of imipramine in two patients with depression and cardiac arrh week single-blind protocol of imipramine 3.5 mg/kg daily. The PR interval, QRS complex, and QTc interv significantly in both cases, producing EKG changes similar to those of Type I antiarrhythmics (quinidine, disopyramide). Each patient showed a decrease in both atrial and ventricular premature depolarizations The first patient decreased from 33.4 atrial and 30.1 ventricular premature depolarizations per hour to 0. ventricular premature depolarizations per hour. A second patient had 12.3 atrial and 169 ventricular pren depolarizations per hour prior to drug treatment which decreased to 1.8 atrial and 28.1 ventricular prema depolarizations per hour during imipramine therapy. The investigators concluded that the doses of antiar should be adjusted downward when used concurrently with tricyclic antidepressants due to an increased cardiotoxicity (Bigger et al, 1977).

c) A placebo controlled study administered imipramine 3.5 mg/kg daily to seven patients with severe de titrated doses to obtain therapeutic plasma concentrations. Two patients displayed premature atrial depo premature ventricular depolarizations before therapy. On patient had 33 premature atrial depolarizations premature ventricular depolarizations (PVD) per hour, which decreased to 0.4 PAC and zero PVC per ho The other patient had 12 PAD and 169 PVD per hour before treatment and 1.8 PAD and 28.1 PVD per h The authors also cautioned that the incidence of cardiotoxicity may increase if tricyclic antidepressants a with Type I antiarrhythmics. It was also recommended that quinidine and procainamide not be used to tre of a tricyclic overdose. The similarities between these agents may exacerbate the cardiotoxicity (Kantor e

3.5.1.ES Rasagiline

1) Interaction Effect: severe CNS toxicity

2) Summary: Concomitant use of rasagiline and tricyclic antidepressants should be avoided. Concurrent adm overlapping therapy with tricyclic antidepressants and non-selective MAOIs has been reported to cause serio fatal, reactions; the mechanisms of these reactions are not fully understood. Signs and symptoms include sev (behavioral and mental status changes, diaphoresis, muscular rigidity, hypertension, and syncope) associate hyperpyrexia and death. Data from clinical studies, where rasagiline-treated patients (n=115) were concomita tricyclic antidepressants, are insufficient to rule out an interaction. At least 14 days should elapse after discon before initiating therapy with a tricyclic antidepressant (Prod Info AZILECT(R) oral tablets, 2006).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Concurrent use of rasagiline and a tricyclic antidepressant is not recommended. Wa after discontinuing rasagiline before initiating therapy with a tricyclic antidepressant (Prod Info AZILECT(R) o

7) Probable Mechanism: unknown

3.5.1.ET Risperidone

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod I 1999), haloperidol (O'Brien et al, 1999), risperidone (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001 (Owens, 2001b), sultopride (Lande et al, 1992), and zotepine (Sweetman, 2003). Even though no formal drug studies have been done, the coadministration of a tricyclic antidepressant and an antipsychotic is not recomm Pamelor(R), 2001; Marshall & Forker, 1982t).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic is n
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included pr corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 m proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricu (Prod Info Orap(R), 1999).

3.5.1.EU Ritonavir
1) Interaction Effect: increased imipramine serum concentrations and potential toxicity (anticholinergic effects confusion, cardiac arrhythmias)
2) Summary: Coadministered ritonavir may increase serum concentrations of imipramine, resulting in imipra Info Norvir(R), 1999). Therapeutic concentration monitoring is recommended for tricyclic antidepressants whe with ritonavir (Prod Info Invirase(R), 2003).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients for signs and symptoms of tricyclic antidepressant toxicity (anticho sedation, confusion, cardiac arrhythmias). Reduce doses of imipramine as required.
7) Probable Mechanism: decreased imipramine metabolism

3.5.1.EV Ropivacaine
1) Interaction Effect: increased plasma levels of ropivacaine
2) Summary: Ropivacaine is metabolized in the liver by the cytochrome P4501A enzyme system to 3-hydrox major metabolite. Drugs which are metabolized by P4501A2 via competitive inhibition, such as imipramine, w interact with the metabolism of ropivacaine. This would result in decreased renal clearance and increased pla concentrations of ropivacaine (Prod Info Naropin(TM), 1996).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Care must be taken to monitor the patient for signs of local anesthetic toxicity with t coadministration of ropivacaine and other drugs which are known to be metabolized by cytochrome P4501A2 inhibition, such as imipramine.
7) Probable Mechanism: inhibition of ropivacaine metabolism

3.5.1.EW S-Adenosylmethionine
1) Interaction Effect: an increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, ment
2) Summary: A single case has been reported of serotonin syndrome likely resulting from the combination of adenosylmethionine (SAMe) and clomipramine (Iruela et al, 1993a). SAMe was shown to hasten the onset of response of imipramine in a clinical trial involving 40 patients, without serotonergic side effects (Berlanga et a is initiated with SAMe and a tricyclic antidepressant, the patient should be monitored closely for early signs of syndrome. Serotonin syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness changes in mental status, hyperreflexia, diaphoresis, shivering, and tremor. If the syndrome is not recognized treated, death can result (Sternbach, 1991).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: S-adenosylmethionine (SAMe) used concomitantly with imipramine was found to de symptoms sooner than imipramine alone (Berlanga et al, 1992). One case has been reported of serotonin sy resulting from concomitant use of SAMe and clomipramine (Iruela et al, 1993). If SAMe and a tricyclic antidep together, use low doses of each and titrate upward slowly, while monitoring closely for early signs of serotoni as increasing anxiety, confusion, and disorientation.
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation
8) Literature Reports
a) A 71 year-old female was hospitalized with anxiety, agitation, confusion, and symptoms of serotonin s been taking S-adenosylmethionine 100 milligrams (mg) intramuscularly daily and clomipramine 25 mg da which was then increased to 75 mg/day. Within 48-72 hours of the increased clomipramine dosage, she progressively anxious, agitated, and confused. On admission she was verbally unresponsive and stupor

130 beats/minute, respiratory rate 30 breaths/minute, temperature 40.5 degrees Celsius, diarrhea, myoc tremors, rigidity, hyperreflexia, shivering, diaphoresis, and dehydration. Temperature increased to 43 de during her hospital stay, with no documented infection. White blood cell count (WBC) was 13,040 mm3, dehydrogenase was 662 units/liter (U/L), creatine phosphokinase was 8920 U/L, serum potassium 2.7 m (mEq/L), creatinine 1.1 mg/100 milliliter (mL) (laboratory reference values were not provided). A cranial c tomography (CT) scan was normal. The patient was not taking neuroleptics. Serum benzodiazepine and antidepressant levels were normal. Symptoms resolved gradually with 4 days of hydration and supportiv interaction was proposed to be a result of synergistic activity of S-adenosylmethionine and clomipramine 1993).

3.5.1.EX Salmeterol

1) Interaction Effect: an increased risk of cardiovascular excitation

2) Summary: Salmeterol should be administered with extreme caution to patients who are being treated with antidepressant, or within two weeks of the discontinuation of a tricyclic antidepressant (Prod Info SEREVENT inhalation powder, 2006). Clinically significant changes in systolic and diastolic blood pressure, pulse rate, ar electrocardiograms have been seen with the use of salmeterol, and these changes may be exacerbated by th antidepressant.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Close observation for adverse cardiovascular effects is warranted when these ager administered concurrently or if salmeterol is given within two weeks of discontinuation of a tricyclic antidepres

7) Probable Mechanism: potentiation of vascular effects

3.5.1.EY Secobarbital

1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive

2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa

3) Severity: minor

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant dc required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.

7) Probable Mechanism: increased tricyclic antidepressant metabolism

8) Literature Reports

a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were e metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar eff expected with any combination of TCA and barbiturate.

3.5.1.EZ Selegiline

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus changes)

2) Summary: Coadministration of imipramine and selegiline is contraindicated (Prod Info imipramine hydroch 2003; Prod Info EMSAM(R) transdermal patch, 2006). Concomitant tricyclic antidepressants (TCAs) and MA in hyperpyrexia, convulsions, and death. Concurrent use of MAOIs and TCAs has also been reported to resu termed serotonin syndrome (Insel et al, 1982i; Spigset et al, 1993j; Brodribb et al, 1994i; Neuvonen et al, 199 syndrome is a rare but potentially fatal condition of serotonergic hyperstimulation characterized by hypertensi myoclonus, and changes in mental status (Sternbach, 1991e). A minimum of 14 days should elapse after dis selegiline before initiating therapy with imipramine. A time period of 4 to 5 half-lives, approximately 1 week, s discontinuing imipramine prior to initiating therapy with selegiline (Prod Info EMSAM(R) transdermal patch, 2

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Concomitant use of imipramine with selegiline is contraindicated. A minimum of 14 elapse after discontinuing selegiline before initiating therapy with imipramine. A time period of 4 to 5 half-lives week, should elapse after discontinuing imipramine prior to initiating therapy with selegiline.

7) Probable Mechanism: altered catecholamine uptake and metabolism

8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T considered an absolute contraindication in the past and still is listed as such by the manufacturers. Repo

hyperpyrexia, convulsions, and possible death have been attributed to the combination (Prod Info imipra oral tablet, 2003; Lockett & Milner, 1965d; Brachfeld et al, 1963c; Winston, 1971d; Schuckit et al, 1971h; Spiker & Pugh, 1976d). The mechanism may relate to the combined inhibition of catecholamine reuptake nervous system and inhibition of catecholamine metabolism (Sjoqvist, 1965d).

b) Coadministration of selegiline with TCAs such as protriptyline or amitriptyline has resulted in severe C hyperpyrexia and death. Combination of selegiline with various other tricyclic antidepressants has cause effects, including hypertension, syncope, and muscular rigidity (Prod Info selegiline hydrochloride oral tal

c) Administration of a TCA after MAOI therapy may result in the development of serotonin syndrome. In crossover study examining the effects of clorgyline and clomipramine for the treatment of obsessive-com two subjects developed severe reactions characteristic of serotonin syndrome. During the study, patients clorgyline therapy, followed by a washout period of approximately four weeks and subsequent clomipram taking the first 100 mg dose of clomipramine, one patient developed coarse myoclonic jerking in both leg diaphoresis, and arrhythmia. Another patient developed a similar reaction after the first dose, with upper symptoms, myoclonic movements, and cardiac irritability. Both patient's symptoms resolved several hou patients were later treated successfully with clomipramine without adverse effects (Insel et al, 1982h).

d) A drug interaction occurred in a 76-year old woman who had been taking clomipramine 50 mg daily f prior to switching to moclobemide 300 mg daily. The patient experienced somnolence, confusion, and fe progressed to further mental impairment, muscle stiffness, myoclonus, and convulsive attacks. The patie were described as fulfilling the diagnostic criteria for serotonin syndrome and were resolved a few days l discontinuing all antidepressant medications (Spigset et al, 1993i).

e) A 39-year old woman with bipolar disorder developed serotonin syndrome after imipramine was adde The patient was taking moclobemide 300 mg twice daily when imipramine was started at 50 mg daily, fol dosage increases of imipramine to 200 mg and a reduction of moclobemide dosage to 150 mg twice dail the increase in imipramine to 200 mg per day, the patient developed symptoms of serotonin syndrome, i shivering, confusion, fever, and spasms in the extremities. The patient was treated with chlorpromazine a resolved over the next few days without further complications (Brodribb et al, 1994h).

f) Three patients with bipolar disorder developed manic symptoms while undergoing concurrent therapy and amitriptyline. In all three cases the patients had been given MAOIs and TCAs alone without complica when the drugs were used in combination that symptoms of mania emerged, suggesting a synergistic ef et al, 1986c).

g) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a p 34-year old man. After taking several doses, the patient developed symptoms of nausea and profuse sw pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulation a (Tackley & Tregaskis, 1987e).

h) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unrespons TCA alone. A few precautions must be followed including: a) avoidance of large doses (no more than 15 or its equivalent, 45 mg phenelzine, or 60 mg isocarboxazid) b) oral administration c) avoidance of clomi imipramine, desipramine, and tranylcypromine in any combination, and d) close monitoring of patients (K Winston, 1971d; Schuckit et al, 1971h; White & Simpson, 1984g; Rom & Benner, 1972c). The combinati in one of two ways. Most frequently, the recommendation is to stop all previous antidepressants (five to t and 14 days for MAOIs); the combination is then simultaneously started (Perry et al, 1991d). Alternativel previously receiving a TCA, small doses of the MAOI may be slowly added (Schoonover, 1983). Some s that the combination of amitriptyline and isocarboxazid is preferred (Perry et al, 1991d). Numerous studie refractory depression or phobic anxiety states have successfully used the combination of MAOIs and TC 1977d; Schuckit et al, 1971h; Ashcroft, 1975d).

3.5.1.FA Sematilide

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).

b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any interac initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.FB Sertindole

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod I 1999), haloperidol (O'Brien et al, 1999), risperidone (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001 (Owens, 2001b), sultopride (Lande et al, 1992), and zotepine (Sweetman, 2003). Even though no formal drug studies have been done, the coadministration of a tricyclic antidepressant and an antipsychotic is not recomm Pamelor(R), 2001; Marshall & Forker, 1982t).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic is n

7) Probable Mechanism: additive cardiac effects

8) Literature Reports

a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included pr corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 m proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricu (Prod Info Orap(R), 1999).

3.5.1.FC Sertraline

1) Interaction Effect: modest elevations in imipramine serum levels or possible serotonin syndrome (hyperter hyperthermia, myoclonus, mental status changes)

2) Summary: There is limited evidence suggesting that sertraline may inhibit tricyclic antidepressant (TCA) m resulting in higher TCA serum concentrations. Sertraline inhibits cytochrome P450 2D6 enzyme activity and r plasma concentrations of coadministered drugs that are metabolized by this pathway, including the tricyclic a (Preskorn et al, 1994c; Lydiard et al, 1993; Prod Info Zoloft(R), 1999). Effects of the interaction may have littl impact, however. Increases in TCA serum levels associated with sertraline coadministration were modest cor found when fluoxetine (another selective serotonin reuptake inhibitor) was combined with desipramine (von M Monitor patients on imipramine-sertraline therapy for TCA toxicity (dry mouth, urinary retention, CNS depress doses may need to be reduced.

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: The combined use of tricyclic antidepressants (TCAs) and selective serotonin reupt (SSRIs) may result in the inhibition of the TCA metabolism. A few cases of serotonin syndrome have also be concurrent TCA and SSRI therapy. Caution should be observed when drugs in these two classes are used to

7) Probable Mechanism: inhibition of imipramine metabolism

8) Literature Reports

a) Desipramine pharmacokinetics was studied in 18 healthy male volunteers. Study subjects received o (50 mg daily) for 7 days followed by desipramine with sertraline (50 mg daily) for 21 days. When sertralin desipramine therapy, the mean maximum concentration of desipramine increased by 34% and the area concentration-time curve increased by 26%. Trough concentrations of desipramine were close to baselin sertraline was discontinued. The changes in desipramine concentrations were modest and the interactio clinically significant (Preskorn et al, 1994b).

3.5.1.FD Sotalol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.

7) Probable Mechanism: additive QT prolongation

8) Literature Reports

a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).

b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any interac initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.FE Sparfloxacin

1) Interaction Effect: prolongation of the QTc interval and/or torsades de pointes

2) Summary: Torsades de pointes has been reported in patients receiving sparfloxacin concomitantly with di amiodarone. The use of sparfloxacin is contraindicated with drugs which produce an increase in the QTc inte torsades de pointes, including tricyclic antidepressants. Sparfloxacin is also contraindicated in persons with k prolongation (Prod Info Zagam(R), 1998a).

3) Severity: contraindicated

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Sparfloxacin is contraindicated in individuals with known QTc prolongation or in pat concurrently with drugs that are known to increase the QTc interval and/or cause torsades de pointes.

7) Probable Mechanism: additive effects on QTc prolongation

8) Literature Reports

a) In clinical trials involving 1489 patients with a baseline QTc measurement, the mean prolongation of t sparfloxacin steady-state was 10 msec (2.5%). Of these subjects, 0.7% had a QTc interval greater than steady-state. However, no arrhythmic effects were seen in any of the patients. The magnitude of the QT increase with repeated administration of sparfloxacin, and the QTc interval returns to baseline within 48 discontinuation of sparfloxacin (Prod Info Zagam(R), 1998).

b) A case of sparfloxacin-induced torsades de pointes is described (Dupont et al, 1996). A 47-year old v for suppurative otitis media and mastoiditis was treated with sparfloxacin due to an allergy to betalactam six of treatment she felt dizzy and lost consciousness. This was attributed to torsades de pointes on the was followed by cardiac arrest which required cardiopulmonary resuscitation. Her pre-treatment electroc QT and QTc intervals of 0.34 and 0.46 seconds, respectively. An electrocardiogram post-arrest revealed intervals of 0.35 and 0.60 seconds, respectively. A 24-hour continuous electrocardiography confirmed nu of torsades de pointes occurring after episodes of sino-auricular block. Sparfloxacin was discontinued ar returned to baseline within a week. Upon further testing, it was determined that the patient suffered from long QT syndrome. Due to the onset of symptoms with administration of sparfloxacin and the relief of sy discontinuation of the drug, it is highly probable that sparfloxacin contributed to the torsades de pointes.

3.5.1.FF Spiramycin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Tricyclic antidepressants (TCAs) and spiramycin have been shown to prolong the QTc interval recommended therapeutic dose (Stramba-Badiale et al, 1997; Marshall & Forker, 1982c). Even though no for interaction studies have been done, the coadministration of tricyclic antidepressants and other drugs known t interval, such as spiramycin, is not recommended (Prod Info Elavil(R), 1999b).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: The concurrent administration of spiramycin and tricyclic antidepressants is not rec

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.FG St John's Wort

1) Interaction Effect: an increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, ment

2) Summary: Theoretically, since St. John's Wort is thought to inhibit serotonin reuptake and may have mild oxidase inhibitory activity (Singer et al, 1999; Thiede & Walper, 1994), serotonin syndrome could result when taken along with a tricyclic antidepressant. This theoretical risk of serotonin syndrome is also based on case serotonin syndrome resulting from concomitant use of selective serotonin reuptake inhibitors with tricyclic ant (Alderman & Lee, 1996), as well as concomitant use of monoamine oxidase inhibitors with tricyclic antidepres al, 1994a; Spigset et al, 1993b; Tackley & Tregaskis, 1987a). Coadministration of amitriptyline and St. John's the area under the concentration-time curve of amitriptyline and its metabolite nortriptyline (Roots et al, 2000) antidepressants are similarly affected by St. John's Wort, the risk of serotonin syndrome may be reduced, yet the tricyclic antidepressant may also be reduced. To maintain maximal effectiveness of the tricyclic antidepre avoid any potential risk of serotonin syndrome, avoid concomitant use of St. John's Wort and tricyclic antidep

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Avoid concomitant use of St. John's Wort with tricyclic antidepressants.

7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation

3.5.1.FH Sulfamethoxazole

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Tricyclic antidepressants (TCAs) and cotrimoxazole have been shown to prolong the QTc inter recommended therapeutic dose (Lopez et al, 1987; Marshall & Forker, 1982s). Even though no formal drug in have been done, the coadministration of tricyclic antidepressants and other drugs known to prolong the QTc cotrimoxazole, is not recommended (Prod Info Elavil(R), 1999j).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable
6) Clinical Management: The concurrent administration of cotrimoxazole and tricyclic antidepressants is not r
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.FI Sultopride
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod I 1999), haloperidol (O'Brien et al, 1999), risperidone (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001 (Owens, 2001b), sultopride (Lande et al, 1992), and zotepine (Sweetman, 2003). Even though no formal drug studies have been done, the coadministration of a tricyclic antidepressant and an antipsychotic is not recomm Pamelor(R), 2001; Marshall & Forker, 1982t).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic is n
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included pro corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 m proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricu (Prod Info Orap(R), 1999).

3.5.1.FJ Tapentadol
1) Interaction Effect: increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, mental s
2) Summary: Concurrent use of tapentadol and a tricyclic antidepressant may result in serotonin syndrome, v threatening. Symptoms of serotonin syndrome may include restlessness, hallucinations, loss of coordination, rapid changes in blood pressure, increased body temperature, overreactive reflexes, nausea, vomiting, and d tapentadol immediate release oral tablets, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Coadministration of tapentadol and a tricyclic antidepressant may result in a life-thr called serotonin syndrome. If these agents are used together, monitor the patient closely for symptoms of ser (restlessness, hyperthermia, hyperreflexia, incoordination), especially during treatment initiation and dose inc tapentadol immediate release oral tablets, 2008).
7) Probable Mechanism: additive serotonergic effect

3.5.1.FK Tedisamil
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Cases of QTc prolongation and/or torsades de pointes have been reported with all Class III ant agents, including acecainide (Chow et al, 1984), amiodarone (Faggiano et al, 1996), azimilide (Corey et al, 1 (Gilman et al, 1985), ibutilide (Rodriguez et al, 2001), sematilide (Singh, 1996), dofetilide (Allen et al, 2002), a & Runge, 2001). Even though no formal drug interaction studies have been done, the coadministration of Cla antiarrhythmics and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is not r (Yamreudeewong et al, 2003a; Prod Info Corvert(R), 2000).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a Class III antiarrhythmic and a tricyclic antidepres recommended.
7) Probable Mechanism: additive QT prolongation
8) Literature Reports
a) EKG effects reported in patients receiving therapeutic doses of tricyclic antidepressants include incre prolonged PR interval, intraventricular conduction delays, increased corrected QT interval (QTc) and flat (Marshall & Forker, 1982ab).
b) Concurrent use of Class III antiarrhythmic agents, and other drugs that can prolong the QT interval, s antidepressants, is not recommended. Dofetilide should be stopped for at least 2 days before any interac initiated. If concurrent use cannot be avoided, cautious dosing and telemetric monitoring is advised (Yam 2003).

3.5.1.FL Telithromycin
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Telithromycin may prolong the QT interval in some patients (Owens, 2001d). Because tricyclic may also prolong the QT interval and increase the risk of arrhythmias, the concurrent administration of telithr tricyclic antidepressants is not recommended (Marshall & Forker, 1982af).
3) Severity: major
4) Onset: unspecified

5) Substantiation: theoretical
6) Clinical Management: Because of the potential for additive QT interval prolongation, the concurrent admin telithromycin and a tricyclic antidepressants is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.FM Terfenadine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Tricyclic antidepressants (TCAs) have been shown to prolong the QTc interval at the recomme dose (Marshall & Forker, 1982ae). Even though no formal drug interaction studies have been done, the coad terfenadine and other drugs known to prolong the QTc interval, including tricyclic antidepressants, is contrain Elavil(R), 1999k; Anon, 1997).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of terfenadine with any drug that prolongs the QT int tricyclic antidepressants, is contraindicated.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.FN Thiopental
1) Interaction Effect: possible decreased tricyclic antidepressant serum concentrations and possible additive
2) Summary: Concomitant barbiturate and tricyclic antidepressant (TCA) therapy may result in increased me TCA. There have been scattered reports of individuals with decreased serum levels of TCAs in the presence (Moody et al, 1977; Silverman & Braithwaite, 1972; Burrows & Davies, 1971). In addition, TCAs can worsen s reducing the seizure threshold (Brodie, 1992). These drugs also have additive CNS and respiratory depressa
3) Severity: minor
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor for efficacy of antidepressant effect. Increases in tricyclic antidepressant dc required. Additionally, monitor for toxicity when either drug is added to or withdrawn from therapy. Serum con be of value in determining appropriate dosage.
7) Probable Mechanism: increased tricyclic antidepressant metabolism
8) Literature Reports
a) The pharmacokinetics of a single oral dose of desipramine (100 mg) were studied in eight epileptic pa treated with phenobarbital and in eight drug-free healthy controls (Spina et al, 1996). All subjects were e metabolizers with respect to the genetically determined CYP2D6-related metabolic polymorphism. Comp epileptic patients exhibited lower peak plasma desipramine concentrations (74 nmol/L vs. 107 nmol/L), s area under the concentration-time curve values (1943 nmol/L/h vs. 3234 nmol/L/h), and shorter desipran half-lives (15.1 h vs. 20.6 h). All barbiturates are believed to have similar effects leading to induction of h and the 2D6 isozyme is believed to be important in the metabolism of most or all TCAs. Thus, similar eff expected with any combination of TCA and barbiturate.

3.5.1.FO Thioridazine
1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Although citing no data, the manufacturer of thioridazine states that concomitant use with other prolong the QT interval is contraindicated (Prod Info Mellaril(R), 2001). Tricyclic antidepressants (TCAs) at th can cause QT prolongation (Marshall & Forker, 1982k).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concurrent administration of a tricyclic antidepressant and thioridazine is contraindi
7) Probable Mechanism: additive effect on QT interval

3.5.1.FP Tibolone
1) Interaction Effect: attenuation of antidepressant effectiveness; tricyclic toxicity (drowsiness, hypotension, a
2) Summary: In isolated cases, the pharmacologic effects of tricyclic antidepressants may be increased or de estrogens (Somani & Khurana, 1973a), with paradoxical loss of antidepressant effect yet tricyclic toxicity beir simultaneously (Prange, 1972a). The effects of the interaction appear to be estrogen dose-related (Khurana, be of clinical importance primarily in patients previously stabilized on tricyclic therapy who are being started o (Krishnan et al, 1984a).
3) Severity: minor
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If signs or symptoms of altered tricyclic response are noted, dose adjustment down estrogen or tricyclic component may be successful in restoring effectiveness or resolving toxicity. However, d may be required.
7) Probable Mechanism: possible estrogen-enhanced hepatic metabolism of the tricyclic
8) Literature Reports
a) Some studies evaluated the qualitative effects of concomitant administration of estrogen and TCAs. I

depressed female prisoners were randomly assigned to 4 treatment groups. Ten patients received place imipramine (150 milligrams/day) and placebo, 5 patients received imipramine (150 milligrams/day) and e micrograms/day), while 5 patients received imipramine (150 milligrams/day) and ethinyl estradiol (25 mic 10 patients that received placebo did not improve over the 6 weeks of the study. The 10 patients taking e imipramine demonstrated a significantly greater improvement in symptoms than did the 10 patients takin alone. However, after 2 weeks, the 5 patients that received imipramine and high-dose estrogen had not i as the patients receiving imipramine and low-dose estrogen. The only side-effect reported was drowsine affected the patients taking imipramine. Following the discontinuation of ethinyl estradiol, a time period o required for the high-dose estrogen group to do as well as the low-dose group. This effect was attributed residual estrogen in the high-dose group. In another group, 5 women received imipramine 150 milligrams estradiol 50 micrograms daily did not improve as much as 10 patients receiving only imipramine. Also, th combination had severe side-effects including lethargy, coarse tremor and systolic hypotension (Prange,

b) A case reported by (Khurana, 1972) demonstrated an interaction in a 32-year-old female taking conju 2.5 milligrams and imipramine 100 milligrams. The patient developed lethargy, tremors, and signs of dep After 2 years of therapy, the patient increased her estrogen dose to 5 milligrams and then 7.5 milligrams became nauseated, had constant headaches, and low normal blood pressure. All lab work was normal. U the estrogen, the side-effects abated. Some investigators have proposed that the side effects resulted fr effects secondary to estrogen inhibition of hepatic microsomal enzymes (Somani & Khurana, 1973).

c) In a study women received clomipramine and oral contraceptives or clomipramine alone. At the begin there were 30 women taking the combination, but 12 subsequently dropped out. The 18 patients on the matched with 18 patients taking clomipramine alone. No significant difference was noted in the patients' clomipramine. It was proposed that there was no significant difference in side-effects between the groups groups were matched after patients had dropped out of the study. Had the patients been matched prior t different conclusions may have been drawn (Beaumont, 1973).

d) The effect of oral contraceptives on clomipramine was studied in 42 women between the ages of 18 a three women took clomipramine 25 milligrams at bedtime while 19 took clomipramine 25 milligrams at be contraceptives. Over the 4-week study, 3 control patients (2 due to side-effects) and 5 in the experimenta side-effects) dropped out. Venous blood samples were drawn at weekly intervals for measurement of se concentrations. No difference in serum concentrations was noted between the groups. However, this res due to the low dose of clomipramine given (Luscombe & John, 1980).

e) The onset of akathisia was reported in 3 patients receiving conjugated estrogens and tricyclic antidep concurrently. A 24-year-old patient receiving clomipramine 120 milligrams/day for anorexia nervosa and estrogens 1.25 milligrams/day for amenorrhea developed restless legs and a constant desire to move co Estrogen was discontinued and benztropine 2 milligrams was administered, resulting in marked reductio within 48 hours. LI Akathisia and disorientation developed in a 55-year-old patient on conjugated estroge milligrams/day who was prescribed amitriptyline 50 milligrams/day for depression. Within hours of amitrip was confused, restless, and possessed an inner desire to move continuously. Symptoms disappeared a amitriptyline. Positive rechallenge at one week with doxepin 100 milligrams, with resolution following disc doxepin. A third case of akathisia was reported in a 35-year-old patient who received conjugated estroge milligrams/day and amitriptyline 50 milligrams/day. Akathisia developed within a few hours after taking th amitriptyline and resolved within 48 hours following discontinuation of the antidepressant (Krishnan et al,

f) The absolute bioavailability of imipramine increased in women who received low-dose oral contracept micrograms or less of ethinyl estradiol) from 27 to 44% (p less than 0.05) as evident by an increase in th plasma concentration time curve (Abernethy et al, 1984).

g) Estrogens may inhibit the oxidation of TCAs by affecting hepatic microsomal enzymes (John et al, 19 are metabolized via oxidation and conjugation pathways. Inhibition of the oxidation of TCAs could result and toxicity due to decreased clearance. Estrogens are suspected of possessing other effects on the cer system resulting in an antidepressant effect (Oppenheim, 1983).

3.5.1.FQ Toloxatone

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus changes)

2) Summary: Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concu and TCAs has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982p; Spig Brodribb et al, 1994o; Neuvonen et al, 1993h). Serotonin syndrome is a rare but potentially fatal condition of hyperstimulation characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Ste TCAs and MAOIs must be used concurrently, avoid large doses, use only oral TCAs, avoid imipramine, clom desipramine, and tranylcypromine, and monitor patients closely (Schuckit et al, 1971p; White & Simpson, 198

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Concomitant use of a tricyclic antidepressant (TCA) and a monoamine oxidase inhi should be done only with close monitoring and where the clinical benefit outweighs the potential risk. Other a therapy should first be considered. If deemed clinically necessary, avoid large doses and use agents other th clomipramine, desipramine, and tranylcypromine.

7) Probable Mechanism: altered catecholamine uptake and metabolism

8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T

considered an absolute contraindication in the past. Reports of excitation, hyperpyrexia, convulsions, an have been attributed to the combination (Lockett & Milner, 1965h; Winston, 1971h; Schuckit et al, 1971o 1976h). The mechanism may relate to the combined inhibition of catecholamine reuptake into the centra and inhibition of catecholamine metabolism (Sjoqvist, 1965h).

b) There is minimal risk of a clinically significant pharmacokinetic interaction between amitriptyline and t MAOI-A (Vandel et al, 1993). Seventeen inpatients being treated for major depressive illness were admi amitriptyline 125 mg once daily for two weeks, and the following two weeks they received amitriptyline 12 toloxatone 600 mg daily. With combined therapy there was a small, nonsignificant increase in amitriptylir The availability and urinary excretion of amitriptyline and its metabolites were not significantly affected.

c) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unrespons TCA alone. The combination may be utilized in one of two ways. Most frequently, the recommendation is previous antidepressants (five to ten days for TCAs and 14 days for MAOIs); the combination is then sim started (Perry et al, 1991h). Alternatively, in a patient previously receiving a TCA, small doses of the MA added (Schoonover, 1983). Numerous studies in patients with refractory depression or phobic anxiety st successfully used the combination of MAOIs and TCAs (Ponto et al, 1977h; Schuckit et al, 1971o; Ashcr

d) Serotonin syndrome has been reported with the use of moclobemide, a reversible inhibitor of monoar a TCA. A 39-year old woman with bipolar disorder developed serotonin syndrome after imipramine was a moclobemide. The patient was taking moclobemide 300 mg twice daily when imipramine was started at 5 followed by two dosage increases of imipramine to 200 mg and a reduction of moclobemide dosage to 1 Five days after the increase in imipramine to 200 mg per day, the patient developed symptoms of seroto including sweating, shivering, confusion, fever, and spasms in the extremities. The patient was treated w and symptoms resolved over the next few days without further complications (Brodribb et al, 1994n).

3.5.1.FR Tramadol

1) Interaction Effect: an increased risk of seizures

2) Summary: Seizures have been reported in patients using tramadol. Some medications, including tricyclic a (TCAs), are known to reduce the seizure threshold. The risk of seizures may be enhanced when imipramine a therapy are combined (Prod Info Ultram(R), 1998).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: Caution should be used if tramadol is to be administered to patients receiving conc therapy. If possible, avoid this combination, especially in patients with underlying conditions that might predis

7) Probable Mechanism: unknown

3.5.1.FS Tranylcypromine

1) Interaction Effect: neurotoxicity, seizures, or serotonin syndrome (hypertension, hyperthermia, myoclonus changes)

2) Summary: Concomitant TCA and MAOI use has resulted in hyperpyrexia, convulsions, and death. Concu and TCAs has also been reported to result in a condition termed serotonin syndrome (Insel et al, 1982m; Spi Brodribb et al, 1994l; Neuvonen et al, 1993f). Serotonin syndrome is a rare but potentially fatal condition of se hyperstimulation characterized by hypertension, hyperthermia, myoclonus, and changes in mental status (Ste Consequently, coadministration of TCAs and MAOIs is contraindicated in most cases. If TCAs and MAOIs mu concurrently, avoid large doses, use only oral TCAs, avoid imipramine, clomipramine, desipramine, and trany monitor patients closely (Schuckit et al, 1971l; White & Simpson, 1984j).

3) Severity: contraindicated

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Concomitant use of imipramine with a monoamine oxidase inhibitor (MAOI), such a is contraindicated. If imipramine is replacing treatment with tranylcypromine, a minimum of 14 days should el tranylcypromine is discontinued before therapy with imipramine begins (Prod Info imipramine hydrochloride o The manufacturer of tranylcypromine recommends that at least 7 days should elapse before tranylcypromine replaced by imipramine. Similarly, if imipramine therapy is substituted by tranylcypromine, there should be a period. Tranylcypromine should then be given using half the normal starting dosage for, minimally, the first w (Prod Info Parnate(R), 2001).

7) Probable Mechanism: altered catecholamine uptake and metabolism

8) Literature Reports

a) Concomitant administration of monoamine oxidase inhibitors (MAOIs) with tricyclic antidepressants (T considered an absolute contraindication in the past and still is listed as such by the manufacturers (Prod hydrochloride oral tablet, 2003). Reports of excitation, hyperpyrexia, convulsions, and possible death hav to the combination (Lockett & Milner, 1965f; Brachfeld et al, 1963d; Winston, 1971f; Schuckit et al, 1971k Spiker & Pugh, 1976f). The mechanism may relate to the combined inhibition of catecholamine reuptake nervous system and inhibition of catecholamine metabolism (Sjoqvist, 1965f).

b) Administration of a TCA after MAOI therapy may result in the development of serotonin syndrome. In crossover study examining the effects of clorgyline and clomipramine for the treatment of obsessive-com two subjects developed severe reactions characteristic of serotonin syndrome. During the study, patients clorgyline therapy, followed by a washout period of approximately four weeks and subsequent clomipram taking the first 100 mg dose of clomipramine, one patient developed coarse myoclonic jerking in both leg

diaphoresis, and arrhythmia. Another patient developed a similar reaction after the first dose, with upper symptoms, myoclonic movements, and cardiac irritability. Both patient's symptoms resolved several hou patients were later treated successfully with clomipramine without adverse effects (Insel et al, 1982l).

c) A drug interaction occurred in a 76-year old woman who had been taking clomipramine 50 mg daily fo prior to switching to moclobemide 300 mg daily. The patient experienced somnolence, confusion, and fe progressed to further mental impairment, muscle stiffness, myoclonus, and convulsive attacks. The patie were described as fulfilling the diagnostic criteria for serotonin syndrome and were resolved a few days l discontinuing all antidepressant medications (Spigset et al, 1993m).

d) A 39-year old woman with bipolar disorder developed serotonin syndrome after imipramine was adde The patient was taking moclobemide 300 mg twice daily when imipramine was started at 50 mg daily, fol dosage increases of imipramine to 200 mg and a reduction of moclobemide dosage to 150 mg twice dail the increase in imipramine to 200 mg per day, the patient developed symptoms of serotonin syndrome, i shivering, confusion, fever, and spasms in the extremities. The patient was treated with chlorpromazine a resolved over the next few days without further complications (Brodribb et al, 1994k).

e) Three patients with bipolar disorder developed manic symptoms while undergoing concurrent therapy isocarboxazid and amitriptyline. In all three cases the patients had been given MAOIs and TCAs alone w complications. It was only when the drugs were used in combination that symptoms of mania emerged, s synergistic effect (de la Fuente et al, 1986d).

f) In one case, clomipramine 10 mg twice daily was added to a stable regimen of tranylcypromine in a pl 34-year old man. After taking several doses, the patient developed symptoms of nausea and profuse sw pyrexia, dyspnea, and agitation. The hyperpyrexical state led to disseminated intravascular coagulation a (Tackley & Tregaskis, 1987g).

g) There is evidence that MAOIs and TCAs can be given concomitantly in patients previously unrespons TCA alone. A few precautions must be followed including: a) avoidance of large doses (no more than 15 or its equivalent, 45 mg phenelzine, or 60 mg isocarboxazid) b) oral administration c) avoidance of clomi imipramine, desipramine, and tranylcypromine in any combination, and d) close monitoring of patients (K Winston, 1971f; Schuckit et al, 1971k; White & Simpson, 1984i; Rom & Benner, 1972d). The combinatio one of two ways. Most frequently, the recommendation is to stop all previous antidepressants (five to ten and 14 days for MAOIs); the combination is then simultaneously started (Perry et al, 1991f). Alternatively previously receiving a TCA, small doses of the MAOI may be slowly added (Schoonover, 1983). Some s that the combination of amitriptyline and isocarboxazid is preferred (Perry et al, 1991f). Numerous studie refractory depression or phobic anxiety states have successfully used the combination of MAOIs and TC 1977f; Schuckit et al, 1971k; Ashcroft, 1975f).

3.5.1.FT Trifluoperazine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Q and T wave distortions have been observed in patients taking phenothiazines (Prod Info Cor Prod Info Stelazine(R), 2002; Prod Info Thorazine(R), 2002). Other phenothiazines may have similar effects, are available. Tricyclic antidepressants (TCAs) at therapeutic doses can cause QT prolongation (Marshall & F Case reports have described increased plasma levels and adverse effects when phenothiazines and tricyclic were taken together, likely due to inhibition of their metabolism (Ghaemi & Kirkwood, 1998; Geller et al, 1985 Loga et al, 1981).

3) Severity: major

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Concurrent administration of a phenothiazine and a tricyclic antidepressant is not re

7) Probable Mechanism: additive effect on QT interval

3.5.1.FU Trimethoprim

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Tricyclic antidepressants (TCAs) and cotrimoxazole have been shown to prolong the QTc inter recommended therapeutic dose (Lopez et al, 1987; Marshall & Forker, 1982s). Even though no formal drug in have been done, the coadministration of tricyclic antidepressants and other drugs known to prolong the QTc cotrimoxazole, is not recommended (Prod Info Elavil(R), 1999j).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: The concurrent administration of cotrimoxazole and tricyclic antidepressants is not r

7) Probable Mechanism: additive effects on QT prolongation

3.5.1.FV Vasopressin

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Tricyclic antidepressants and vasopressin have been shown to prolong the QTc interval at the therapeutic dose (Prod Info Vivactil(R), 1999; McCue et al, 1989; Munger & Effron, 1988; Mauro et al, 1988; I 1982j; Goldstein & Claghorn, 1980; Buckhardt et al, 1978; Pinder et al, 1977; Thorstrand, 1976; Singh, 1972) formal drug interaction studies have been done, the coadministration of drugs known to prolong the QTc inter recommended.

3) Severity: major

4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of drugs that prolong the QT interval, such as tricycli and vasopressin, is not recommended.
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.FW Venlafaxine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest) effects of both drugs
2) Summary: Tricyclic antidepressants (TCAs) and venlafaxine have been shown to prolong the QTc interval recommended therapeutic dose (Prod Info Effexor(R) XR, 2003; Marshall & Forker, 1982d). Even though no interaction studies have been done, the coadministration of tricyclic antidepressants and other drugs known t interval, such as venlafaxine, is not recommended (Prod Info Elavil(R), 1999c). In addition, venlafaxine and tr antidepressants (TCAs) may competitively inhibit each other's metabolism which may increase side effects o 2000; Prod Info Effexor(R) XR, 2003; Ellingrod & Perry, 1994). Venlafaxine increased the AUC, Cmax, and C desipramine by approximately 35%. The AUCs of 2-OH-desipramine increased by 2.5 and 4.5 fold when adm venlafaxine 37.5 mg and 75 mg every 12 hours, respectively. The pharmacokinetics of imipramine and the 2- were not affected (Prod Info venlafaxine extended release oral tablets, 2008).
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive effects on the QT interval, the concurrent administra venlafaxine and tricyclic antidepressants is not recommended.
7) Probable Mechanism: decreased TCA and venlafaxine metabolism; additive effects on QT prolongation
8) Literature Reports
a) When administered with imipramine, the pharmacokinetics of imipramine and the 2-hydroxy metaboli affected. Venlafaxine increased the area under the concentration-time curve (AUC), maximum concentra minimum concentration (Cmin) of desipramine by approximately 35%. The 2-OH-desipramine AUCs incr (venlafaxine 37.5 mg every 12 hours) and by 4.5-fold (venlafaxine 75 mg every 12 hours). The clinical si finding is unknown (Prod Info venlafaxine extended release oral tablets, 2008).

3.5.1.FX Verapamil

1) Interaction Effect: imipramine toxicity (dry mouth, sedation, urinary retention)
2) Summary: Verapamil decreased imipramine clearance by 25% (statistically significant) compared with pla controlled, single-dose study in 12 healthy volunteers (Hermann et al, 1992a). Imipramine bioavailability was by verapamil (15% greater than with placebo). The clinical significance of this interaction and whether it occu tricyclic antidepressants has yet to be determined.
3) Severity: minor
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Monitor for anticholinergic side effects of imipramine if verapamil is added to therap imipramine may be appropriate. Conversely, if verapamil is discontinued, monitor continued clinical efficacy c adjust dosage accordingly.
7) Probable Mechanism: decreased imipramine clearance

3.5.1.FY Warfarin

1) Interaction Effect: an increased risk of bleeding
2) Summary: Tricyclic antidepressants (TCAs) may increase the half-life and bioavailability of oral anticoagul 1970a; Williams et al, 1976a). Considerable interindividual differences may be found (Pond et al, 1975a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: In patients receiving imipramine and warfarin, closely monitor prothrombin time ratio warfarin doses accordingly.
7) Probable Mechanism: decreased warfarin metabolism; increased warfarin absorption
8) Literature Reports
a) In a study of healthy volunteers, the concurrent use of nortriptyline or amitriptyline resulted in an incre levels and an increase in the plasma half-life of dicumarol, although the effect was not consistent in all su 1975). This effect was not observed with warfarin.
b) A single oral dose of bishydroxycoumarin after eight days of nortriptyline resulted in a significantly pro and decreased volume of distribution of the coumarin anticoagulant in six healthy volunteers (Vesell et a mechanism of action was suggested to be reduced bishydroxycoumarin metabolism and/or altered coum
c) Drug dosing was studied in 16 patients on long-term anticoagulant therapy who used concurrent TCA 1976). TCAs affected the stability of anticoagulant control leading to frequent changes in the doses of an Inhibition of coumarin metabolism was the postulated mechanism.

3.5.1.FZ Ziprasidone

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)

2) Summary: Ziprasidone use is associated with dose-related prolongation of the QTc interval. Even though interaction studies have been done, it is recommended that concurrent use with other agents that may prolon avoided (Prod Info GEODON(R) oral capsules, IM injection, 2007; Marshall & Forker, 1982ah).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Due to the potential for additive QTc interval prolongation, avoid the concurrent adr ziprasidone and agents that can prolong the QTc interval (Prod Info GEODON(R) oral capsules, IM injection,
7) Probable Mechanism: additive cardiac effects

3.5.1.GA Zolmitriptan

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Tricyclic antidepressants (TCAs) and zolmitriptan have been shown to prolong the QTc interva recommended therapeutic dose (Prod Info Zomig(R), 2001; Marshall & Forker, 1982l). Even though no forma studies have been done, the coadministration of tricyclic antidepressants and other drugs known to prolong tl such as zolmitriptan, is not recommended (Prod Info Elavil(R), 1999f).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of zolmitriptan and tricyclic antidepressants is not rec
7) Probable Mechanism: additive effects on QT prolongation

3.5.1.GB Zotepine

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Several antipsychotic agents have demonstrated QT prolongation including amisulpride (Prod 1999), haloperidol (O'Brien et al, 1999), risperidone (Duenas-Laita et al, 1999), sertindole (Agelink et al, 2001 (Owens, 2001b), sultopride (Lande et al, 1992), and zotepine (Sweetman, 2003). Even though no formal drug studies have been done, the coadministration of a tricyclic antidepressant and an antipsychotic is not recomm Pamelor(R), 2001; Marshall & Forker, 1982t).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concurrent administration of a tricyclic antidepressant and an antipsychotic is n
7) Probable Mechanism: additive cardiac effects
8) Literature Reports
a) Electrocardiographic changes that have occurred during clinical trials with pimozide have included pr corrected QT interval, flattening, notching, and inversion of the T wave and the appearance of U waves. studies, sudden, unexpected deaths have occurred while patients were receiving pimozide doses of 1 m proposed mechanism for these deaths is prolongation of the QT interval predisposing patients to ventricu (Prod Info Orap(R), 1999).

3.5.2 Drug-Food Combinations

3.5.2.A Ethanol

1) Interaction Effect: enhanced drowsiness; impairment of motor skills
2) Summary: Ethanol in combination with antidepressants may alter behavior, with the predominant effect be impairment in psychomotor performance. Almost all studies to date have evaluated the effects of the combina skills, driving behavior and psychomotor skills (Landauer et al, 1969; Patman et al, 1969; Milner & Landauer, al, 1975; Seppala, 1977). There are no studies evaluating respiratory response with the combination.
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Encourage abstention from alcohol during at least the first few weeks of tricyclic ad allow patient accommodation to potential CNS depressant effects of the tricyclic.
7) Probable Mechanism: additive CNS depressant activity; impaired hepatic metabolism of the tricyclic antide
8) Literature Reports
a) The studies available indicate that the interaction between amitriptyline (and other antidepressants) ir ethanol is unpredictable. They indicate that antidepressants may enhance, prevent, or not affect the CNS actions of ethanol. The most significant effect reported is enhanced CNS depression. However, there are tricyclic antidepressants may actually antagonize the sedative effects of ethanol (Milner & Landauer, 197
b) The propensity for interaction may be related to the inherent CNS depressant action of the tricyclic ar listed in one series in descending order as amitriptyline, doxepin, imipramine, nortriptyline, desipramine, (Marco & Randels, 1981).
c) Imipramine and amitriptyline are the best documented examples of disruptions of metabolism. Cleara was 3-fold higher in alcoholics compared with healthy volunteers (Ciraulo et al, 1988).
d) Individual case reports have documented "blackouts" following modest amounts of alcohol in combina amitriptyline or imipramine (Hudson, 1981), and reversible extrapyramidal effects (parkinsonian effects, a amoxapine (Shen, 1984).

3.5.4 Drug-Tobacco Combinations

3.5.4.A Tobacco

1) Interaction Effect: decreased imipramine concentrations
2) Summary: The administration of oral imipramine 3.5 mg/kg to tobacco smokers (15 cigarettes daily) result lower mean plasma levels of combined imipramine and desmethylimipramine (160 ng/mL) when compared to ng/mL) (Perel et al, 1975). Tobacco smoking may alter the response to antidepressants (Linnoila et al, 1981;
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Patients who smoke may require larger doses of imipramine than non-smokers. Mo receiving imipramine for antidepressant efficacy.
7) Probable Mechanism: increased hepatic metabolism

3.5.5 Intravenous Admixtures

3.5.5.1 Drugs

Doxapram

Haloperidol

3.5.5.1.A Doxapram

1) Compatible
a) Doxapram (400 mg/20 mL with imipramine 12.5 mg/1 mL physically compatible and no loss of dc imipramine stability not described) (Trissel, 1990)
b) Imipramine (12.5 mg/1 mL with doxapram 400 mg/20 mL physically compatible in syringe with nc decomposition in 24 hours; temperature not specified) (Trissel, 1990a)

3.5.5.1.B Haloperidol

1) Conflicting Data
a) Incompatible
1) Haloperidol in a 1:1 or 1:2 mixture with imipramine, compatibility is questionable because the no visual changes in 1 hour, was slightly cloudy and viscous in 2 hours, was clear and very visc room temperature, but no haloperidol decomposition was observed in a 4 hour study period; dru not specified (Pers Comm, 1990)
b) Compatible
1) Haloperidol in a 1:1 or 1:2 mixture with imipramine, compatibility is questionable because the no visual changes in 1 hour, was slightly cloudy and viscous in 2 hours, was clear and very visc room temperature, but no haloperidol decomposition was observed in a 4 hour study period; dru not specified (Pers Comm, 1990)

4.0 Clinical Applications

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters

A) Imipramine Hydrochloride
1) Therapeutic
a) Laboratory Parameters

1) MHPG Urinary Concentration
a) Patients with urinary levels of 3-methoxy-4-hydroxy-phenyl glycol (MHPG) less than 1950 mcg/d antidepressant (TCA) therapy, respond to imipramine, and other TCAs, more predictably than patier urinary levels greater than 1950 mcg/day (Rosenbaum et al, 1980); (Beckmann & Goodwin, 1975)(M
b) Newer data (Maas et al, 1982) confirm some of the earlier data and hypotheses while failing to c fact that a low cerebrospinal fluid (CSF) 5-HIAA (5-hydroxyindoleacetic acid) or low urinary MHPG v pretreatment period is associated with a favorable response to amitriptyline therapy was not confirm study showed no significant relationships between pre-treatment urinary MHPG, CSF MHPG, 5-HIA (homovanillic acid) values and subsequent amitriptyline efficacy.
c) Low urinary NE and MHPG values are associated with a greater incidence of response to amitrip imipramine therapy in bipolar affective disorder patients, but not in unipolar patients (Maas et al, 198
2) Dexamethasone Suppression Test (DST)
a) The DST has been reported to be a useful tool in predicting whether or not a patient would respo antidepressant therapy (Brown et al, 1979, Brown et al, 1980). Eighty percent of patients with a posi responded to therapy versus a 37% response rate in patients with a negative DST (Brown et al, 197 of DST results as an indicator of tricyclic antidepressant therapy efficacy in the treatment of depress confirmed in one study (Peselow et al, 1983a).
b) Depressed patients with abnormal DST may respond better to imipramine or desipramine therap or clomipramine therapy (Brown et al, 1980). The result of this study must be considered with cautio investigator made a single evaluation of efficacy after 2 weeks of therapy. These results were not re imipramine and amitriptyline therapy (Greden et al, 1981). Therefore, DST results may not be a usef selection of a particular antidepressant.
3) Platelet Monoamine Oxidase Activity
a) Measurements of platelet MAO activity with serotonin reveals that unmedicated depressed patier significantly higher degree of activity compared to controls. This degree of activity decreases progre imipramine therapy and falls within normal limits at the time the patient is classified as recovered (Q Whether platelet MAO activity is useful as a monitoring parameter remains to be determined.
4) Platelet Binding
a) Imipramine has been shown to have specific high-affinity binding sites on human platelet membr McChesney, 1985). These binding sites appear to be similar to those found in the human brain. Rec indicates that platelet membrane binding may be decreased in some depressed patients (Lewis & M Pecknold et al, 1987; De Leo et al, 1991); (Ambrusini et al, 1992). The exact value of this finding is s however, it may be of value in predicting which depressed patients are more likely to respond to ant therapy.
b) The ability of the platelet to bind imipramine decreases with age. Whether this decrease in platel related to decreases in the density or number of receptors or an alteration in membrane microenviro Even though the decrease in platelet binding is significant, whether the changes effects the efficacy unknown (Marazziti et al, 1987).
c) Significant reductions in platelet imipramine binding have been observed in depressed patients. I diagnosed with panic disorders or panic disorders concurrent with depression and patients with a pr depression have normal platelet imipramine binding compared to controls. The reason for this differ but may indicate that the 2 syndromes differ neurochemically (Pecknold et al, 1987).
5) Serum Concentrations
a) Indications for determination of serum imipramine concentration (Hollister, 1982):
1) Utilization of adequate doses without experience clinical effect;
2) Side effects uncertainly related to imipramine therapy;
3) Monitoring high dose imipramine therapy;
4) Assess the influence of intercurrent illness on imipramine serum concentrations;
5) Evaluating a patient suspected of intentional or unintentional overdose of imipramine.

b) Physical Findings
1) Depression
a) Clinical improvement of the signs and symptoms of depression.
2) Enuresis
a) Decreased frequency of nocturnal wetting episodes.
3) Attention Deficit Hyperactivity Disorder (ADHD)
a) Improvement in mental and behavioral symptoms, including inappropriate inattention, impulsivity cognitive performance.

2) Toxic
a) Laboratory Parameters
1) Obtain WBC and differential cells in patients with fever, sore throat, or other signs of infection (Prod I oral tablets, 2007).

b) Physical Findings
1) Obtain baseline ECG in patients with cardiac disease, elderly, or if initiating larger-than-usual doses. during therapy if clinically warranted (Prod Info imipramine hcl oral tablets, 2007).
a) Depression
1) Monitor patients receiving antidepressants for worsening of depression, suicidality, or unusu behavior, especially at the initiation of therapy or when the dose increases or decreases. Such include at least weekly face-to-face contact with patients or their family members or caregivers

weeks of treatment, then visits every other week for the next 4 weeks, then at 12 weeks, and th indicated beyond 12 weeks. Families and caregivers should be advised of the need for close ob observation) of patients and communication with the prescriber (Anon, 2004).

2) Patients who experience symptoms of anxiety, agitation, panic attacks, insomnia, irritability, impulsivity, akathisia, hypomania, or mania may be at an increased risk for worsening depressi these symptoms are observed, therapy should be reevaluated and it may be necessary to disco medications when symptoms are severe, sudden in onset, or were not part of the patient's initia 2004).

b) Attention Deficit Hyperactivity Disorder (ADHD)

1) The American Academy of Pediatrics (AAP) does not recommend the routine use of electroc (ECGS) or routine subspecialty cardiology evaluations (which were previously recommended by Heart Association (AHA) scientific statement to detect cardiac conditions that might place the ch sudden cardiac death) before initiating stimulant therapy to treat attention-deficit/hyperactivity d most children. The APA cited specific reasons for changing the recommendation including: lack establishing a relationship between stimulant drugs used to treat ADHD and sudden cardiac de frequency of sudden unexpected deaths among patients taking stimulant drugs is not higher tha general population of children, and lack of cost-effective analysis to support ECG screening or s by pediatric cardiologist (Perrin et al, 2008).

2) Based on the American Academy of Pediatrics (AAP) and the American Heart Association (A statements, the following cardiac monitoring recommendations have been established to assist evaluation of children treated with stimulant drugs, including imipramine, for ADHD (Perrin et al, 2008):

- Conduct a thorough examination prior to initiating imipramine therapy for a diagnosis of A attention should be given to symptoms indicative of a cardiac condition, including palpitatio or syncope.
- Obtain a complete family and patient history for conditions associated with SCD, and dete of any other prescription or over-the-counter medications.
- Conduct a complete physical evaluation of the patient for hypertension, cardiac murmurs, associated with Marfan syndrome, and signs of irregular cardiac rhythms. Prolongation of C tachycardia, and rarely sudden death have all been reported with imipramine use.
- Perform further evaluation if family history, patient history or physical exam is suggestive during initial visit or at follow up visits, and if indicated, consult pediatric cardiologist .
- Continue to assess the patient for cardiac symptoms and any changes in family history at
- Blood pressure and heart rate should be evaluated at baseline, at dose increases, during within 1 to 3 months, and at follow up visits every 6 to 12 months.

B) Imipramine Pamoate

1) Therapeutic

a) Laboratory Parameters

1) Dexamethasone Suppression Test (DST)

a) The DST has been reported to be a useful tool in predicting whether or not a patient would respo antidepressant therapy (Brown et al, 1979, Brown et al, 1980). Eighty percent of patients with a posi responded to therapy versus a 37% response rate in patients with a negative DST (Brown et al, 197 of DST results as an indicator of tricyclic antidepressant therapy efficacy in the treatment of depress confirmed in one study (Peselow et al, 1983a).

b) Depressed patients with abnormal DST may respond better to imipramine or desipramine therap or clomipramine therapy (Brown et al, 1980). The result of this study must be considered with cautio investigator made a single evaluation of efficacy after 2 weeks of therapy. These results were not re imipramine and amitriptyline therapy (Greden et al, 1981). Therefore, DST results may not be a usef selection of a particular antidepressant.

2) Platelet Monoamine Oxidase Activity

a) Measurements of platelet MAO activity with serotonin reveals that unmedicated depressed patie significantly higher degree of activity compared to controls. This degree of activity decreases progre imipramine therapy and falls within normal limits at the time the patient is classified as recovered (Q Whether platelet MAO activity is useful as a monitoring parameter remains to be determined.

3) Serum Concentrations

a) Indications for determination of serum imipramine concentration (Hollister, 1982):

1) Utilization of adequate doses without experience clinical effect;
2) Side effects uncertainly related to imipramine therapy;
3) Monitoring high-dose imipramine therapy;
4) Assess the influence of intercurrent illness on imipramine serum concentrations;
5) Evaluating a patient suspected of intentional or unintentional overdose of imipramine.

4) Platelet Binding

a) Imipramine has been shown to have specific high-affinity binding sites on human platelet membr McChesney, 1985). These binding sites appear to be similar to those found in the human brain. Rec indicates that platelet membrane binding may be decreased in some depressed patients (Lewis & M Pecknold et al, 1987; De Leo et al, 1991); (Ambrusini et al, 1992). The exact value of this finding is s however, it may be of value in predicting which depressed patients are more likely to respond to ant therapy.

b) The ability of the platelet to bind imipramine decreases with age. Whether this decrease in platel related to decreases in the density or number of receptors or an alteration in membrane microenviro Even though the decrease in platelet binding is significant, whether the changes effects the efficacy unknown (Marazziti et al, 1987).

c) Significant reductions in platelet imipramine binding have been observed in depressed patients. I diagnosed with panic disorders or panic disorders concurrent with depression and patients with a pr depression have normal platelet imipramine binding compared to controls. The reason for this differ but may indicate that the 2 syndromes differ neurochemically (Pecknold et al, 1987).

b) Physical Findings

1) Depression

a) Clinical improvement of the signs and symptoms of depression.

2) Attention Deficit Hyperactivity Disorder (ADHD)

a) Improvement in mental and behavioral symptoms, including inappropriate inattention, impulsivity cognitive performance.

2) Toxic

a) Laboratory Parameters

1) Obtain WBC and differential cells in patients with fever, sore throat, or other signs of infection (Prod I (R) oral capsules, 2007).

b) Physical Findings

1) Obtain baseline ECG in patients with cardiac disease, elderly, or if initiating larger-than-usual doses. during therapy if clinically warranted (Prod Info TOFRANIL-PM(R) oral capsules, 2007).

2) Monitor patients receiving antidepressants for worsening of depression, suicidality, or unusual chang especially at the initiation of therapy or when the dose increases or decreases. Such monitoring should i weekly face-to-face contact with patients or their family members or caregivers during the initial 4 weeks visits every other week for the next 4 weeks, then at 12 weeks, and then as clinically indicated beyond 1 and caregivers should be advised of the need for close observation (ie, daily observation) of patients and with the prescriber (Anon, 2004).

3) Patients who experience symptoms of anxiety, agitation, panic attacks, insomnia, irritability, hostility, akathisia, hypomania, or mania may be at an increased risk for worsening depression or suicidality. If the observed, therapy should be reevaluated and it may be necessary to discontinue medications when sym sudden in onset, or were not part of the patient's initial symptoms (Anon, 2004).

a) Attention Deficit Hyperactivity Disorder (ADHD)

1) The American Academy of Pediatrics (AAP) does not recommend the routine use of electroc (ECGS) or routine subspecialty cardiology evaluations (which were previously recommended by Heart Association (AHA) scientific statement to detect cardiac conditions that might place the ch sudden cardiac death) before initiating stimulant therapy to treat attention-deficit/hyperactivity d most children. The APA cited specific reasons for changing the recommendation including: lack establishing a relationship between stimulant drugs used to treat ADHD and sudden cardiac de frequency of sudden unexpected deaths among patients taking stimulant drugs is not higher tha general population of children, and lack of cost-effective analysis to support ECG screening or s by pediatric cardiologist (Perrin et al, 2008).

2) Based on the American Academy of Pediatrics (AAP) and the American Heart Association (statements, the following cardiac monitoring recommendations have been established to assist evaluation of children treated with stimulant drugs, including imipramine pamoate, for ADHD (P Vetter et al, 2008):

- Conduct a thorough examination prior to initiating imipramine pamoate therapy for a diagn Special attention should be given to symptoms indicative of a cardiac condition, including p syncope, or syncope.
- Obtain a complete family and patient history for conditions associated with SCD, and dete of any other prescription or over-the-counter medications.
- Conduct a complete physical evaluation of the patient for hypertension, cardiac murmurs, associated with Marfan syndrome, and signs of irregular cardiac rhythms. Prolongation of C tachycardia, and rarely sudden death have all been reported with imipramine pamoate use
- Perform further evaluation if family history, patient history or physical exam is suggestive during initial visit or at follow up visits, and if indicated, consult pediatric cardiologist .
- Continue to assess the patient for cardiac symptoms and any changes in family history at
- Blood pressure and heart rate should be evaluated at baseline, at dose increases, during within 1 to 3 months, and at follow up visits every 6 to 12 months.

4.2 Patient Instructions

A) Imipramine (By mouth)

Imipramine

Treats depression. May also be used to treat bedwetting in children. This medicine is a tricyclic antidepressant.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to imipramine or to related medicines such a (Elavil®), carbamazepine (Tegretol®), maprotiline (Ludiomil®), or nortriptyline (Aventyl®). You should not use this

have had a recent heart attack or have taken an MAO inhibitor such as isocarboxazid (Marplan®), phenelzine (Na
(Eldepryl®), or tranylcypromine (Parnate®) in the past 14 days.

How to Use This Medicine:
Capsule, Tablet

Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed
order to find out what works best for you. Do not use more medicine or use it more often than your doctor tell
You may take this medicine with or without food.
Do not crush or chew the capsules. You may open the capsules and mix the medicine beads with soft food (p
applesauce). Swallow the mixture without chewing.
If you are taking this drug for depression, it may take 2 to 3 weeks before you start to feel better.
This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your d
pharmacist if you have any questions. Ask your pharmacist for the Medication Guide if you do not have one.
ask you to sign some forms to show that you understand this information.

If a Dose is Missed:

If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next d
then to use the medicine and skip the missed dose. Do not use extra medicine to make up for a missed dose
If you take one dose a day at bedtime, you should not use the missed dose the next morning. Wait until your
bedtime dose.

How to Store and Dispose of This Medicine:

Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after
your treatment. You will also need to throw away old medicine after the expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a
products.

Make sure your doctor knows if you are using atropine, benztropine (Cogentin®), cimetidine (Tagamet®), gua
(Ismelin®), methylphenidate (Ritalin®), scopolamine, medicine for high blood pressure (such as clonidine or
certain medicine for heart rhythm problems (such as quinidine, flecainide, propafenone, Quinaglute®, Tambo
Rythmol®), medicine to treat seizures (such as phenobarbital, phenytoin, or Dilantin®), a phenothiazine med
chlorpromazine, perphenazine, prochlorperazine, promethazine, thioridazine, Compazine®, Mellaril®, Phene
Thorazine®, or Trilafon®), or other medicines to treat depression (such as fluoxetine, paroxetine, sertraline, P
Zoloft®).
Tell your doctor if you are using any medicines that make you sleepy. These include sleeping pills, cold and a
narcotic pain relievers, and sedatives.
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:

Make sure your doctor knows if you are pregnant, planning to become pregnant, or breastfeeding. Tell your d
glaucoma, trouble urinating, mental problems, stomach problems, seizures, heart disease, liver disease, kidn
thyroid disease.
For some children, teenagers, and young adults, this medicine can increase thoughts of suicide. Tell your do
doctor right away if you or your child start to feel more depressed and have thoughts about hurting yourselves
unusual thoughts or behaviors that trouble you or your child, especially if they are new or are getting worse q
the doctor knows if you or your child have trouble sleeping, get upset easily, have a big increase in energy, o
reckless. Also tell the doctor if you or your child have sudden or strong feelings, such as feeling nervous, ang
violent, or scared. Let the doctor know if you, your child, or anyone in your family has bipolar disorder (manic-
tried to commit suicide.
Do not give this medicine to a child unless directed to do so by the child's doctor.
This medicine may raise or lower your blood sugar, or it may cover up symptoms of very low blood sugar (hyp
Make sure any doctor or dentist who treats you knows that you are using this medicine. You may need to sto
medicine several days before having surgery or medical tests.
Do not stop using this medicine suddenly without asking your doctor. You may need to slowly decrease your
stopping it completely.
This medicine may make your skin more sensitive to sunlight. Use a sunscreen when you are outdoors. Avoi
tanning beds.
This medicine may cause dizziness and vision changes. Avoid driving, using machines, or doing anything els
dangerous if you are not alert or able to see well.
Your doctor will need to check your progress at regular visits while you are using this medicine. Be sure to ke
appointments.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:

Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, d

trouble breathing.
Anxiety, restlessness, nervousness, or mood or mental changes.
Change in how much or how often you urinate, or problems with urination.
Changes in behavior, or thoughts of hurting yourself or others.
Chest pain, shortness of breath, cold sweats, and bluish-colored skin.
Fast, pounding, or irregular heartbeat.
Lightheadedness or fainting when getting up suddenly from a lying or sitting position.
Numbness or tingling in the hands and feet.
Numbness or weakness in your arm or leg, or on one side of your body.
Seizures or tremors.
Sudden or severe headache, problems with vision, speech, balance, or walking.
Swelling in your hands, ankles, or feet.
Trouble sleeping.
Twitching or muscle movements you cannot control.
Unexplained fever or sore throat.
Unusual bleeding or bruising.
Unusual tiredness or weakness.
Yellowing of your skin or the whites of your eyes.

If you notice these less serious side effects, talk with your doctor:
Breast swelling or discharge.
Changes in vision.
Changes in weight.
Dizziness or drowsiness.
Dry mouth.
Nausea, vomiting, diarrhea, constipation, or upset stomach.
Problems having sex.
Ringing in the ears.
Skin rash or itching.
Swelling of the breast or testicles in men.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Depression is a complicated disorder and consequently this disease's treatment regimens are diverse. The two mc diagnostic syndromes among affective disorders are major depression and bipolar disorders. The tricyclic antidepress the monoamine oxidase inhibitors (MAOIs) are considered the most effective agents for treating major depression. Fo disorders, lithium is considered the standard of therapy over TCAs, MAOIs and other agents such as carbamazepine

B) Imipramine and amitriptyline, along with the selective sorotonin reuptake inhibitors (SSRI) antidepressants, are cor standard of therapy for endogenous or typical depression. In addition, imipramine may be employed for treating agora has also been used adjunctively for pediatric enuresis, adult urinary incontinence associated with neurogenic bladder, incontinence, and geriatric spontaneous unstable detrusor contractions. Some studies indicate that chronic pain and d neuropathies may also be alleviated with imipramine. Although TCAs reportedly lower seizure threshold, imipramine h demonstrated to reduce the frequency of absence and myoclonic seizures. When an epileptic patient is refractory to o antidepressants and a TCA is deemed necessary for treatment, imipramine should be considered.

C) Imipramine and amitriptyline still have a place in therapy as the standards for the treatment of major depression al antidepressants. Newer classes of antidepressants are not more effective than imipramine for typical depression, but alternatives for treating patients intolerant of TCAs or exhibiting atypical depression. Being versatile, imipramine may b therapy of other disorders besides depression and should be included on hospital formularies. Institutions that commo depression should consider a diverse formulary with agents from each antidepressant class.

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) DEPRESSION

a) The antidepressant mechanism of action of imipramine has not been completely determined but appears interaction with biogenic amines. Imipramine, like other tricyclic antidepressants, blocks the re-uptake of nore hydroxy-tryptamine at nerve terminals preventing their degradation and increasing their availability. This resu turnover of these amines in selective neurons but the relation of this effect to anti-depressant activity has not demonstrated (Gilman et al, 1990). Effects on the D1 dopamine receptor may also be important in the mediat antidepressant activity (Gambarana et al, 1995).

2) ENURESIS

a) Why imipramine works in the treatment of enuresis is not well understood. It beneficial effects do not appe changes in sleep architecture, anticholinergic properties, antiadrenergic properties, or effects on thyroid relea induced urinary urgency. In patients with nocturnal polyuria, imipramine had a vasopressin-independent antic attributed primarily to increased tubular reabsorption of urea and to a lesser extent to decreased sodium and excretion (Hunsballe et al, 1997). The drug improves functional bladder capacity during chronic administratio 1992; Prod Info Tofranil(R), 1995a).

B) REVIEW ARTICLES

1) A Consensus Statement on Panic Disorder is available from the International Consensus Group on Depressio
(Ballenger et al, 1998). Also an excellent review is available on the treatment of panic disorder (Bennett et al, 199
2) Drug-interactions of antidepressants are reviewed in German language (Zapotoczky & Simhandl, 1995).

4.5 Therapeutic Uses

Imipramine

Imipramine Hydrochloride

Imipramine Pamoate

4.5.A Imipramine

Anorexia nervosa

Cataplexy - Narcolepsy

Ophthalmoplegic migraine

Severe major depression with psychotic features

4.5.A.1 Anorexia nervosa
See Drug Consult reference: ANOREXIA NERVOSA - DRUG THERAPY

4.5.A.2 Cataplexy - Narcolepsy
See Drug Consult reference: NARCOLEPSY AND CATAPLEXY - DRUG THERAPY

4.5.A.3 Ophthalmoplegic migraine
See Drug Consult reference: THERAPY OF HEADACHE IN CHILDREN

4.5.A.4 Severe major depression with psychotic features
See Drug Consult reference: PSYCHOTIC DEPRESSION - DRUG THERAPY

4.5.B Imipramine Hydrochloride

Agoraphobia

Anorexia nervosa

Attention deficit hyperactivity disorder, predominantly inattentive type

Binging

Bulimia nervosa

Cardiac dysrhythmia

Depression

Diabetic neuropathy

Disorder of ejaculation

Drug dependence

Gardner-Diamond syndrome

Globus hystericus

Mood swings

Nocturnal enuresis

Obsessive-compulsive disorder

Pain

Panic disorder

Posttraumatic stress disorder

Schizophrenia; Adjunct

Separation anxiety disorder of childhood

Sexual disorder

Sleep disorder

Social phobia

Trichotillomania

Urinary incontinence

4.5.B.1 Agoraphobia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective in the treatment of agoraphobia (Deltito et al, 1991)
Efficacy appears to be dose-related and usually requires doses of 150 milligrams or greater per day

c) Adult:

1) Imipramine and placebo were equally effective in the treatment of agoraphobia in a double-blind clinic drug therapy with brief psychological treatment (Cohen et al, 1984a). The drugs were started 2 weeks pr of the psychological therapy. At week 6 the mean dose of IMIPRAMINE was 124 milligrams and at week mg/day. During week 2 to week 12 each treatment group received 6 fortnightly sessions of therapist-aide addition each patient was given a leaflet describing the nature of agoraphobia and ways to cope with it. A requested to complete systematic self-exposure homework and record these activities in a diary. Drug th gradually withdrawn over weeks 26 to 28 of therapy. At the 2-year follow-up only 40 subjects were availa had dropped out of the study (2 refused follow-up, 1 died, 1 moved out of the country, and 1 was untrace of the patients remained improved with regards to their phobias. There was no significant difference betv patients treated with imipramine or placebo therapy. Nor was there a superior effect of therapist-aided ex therapist-aided relaxation.

2) The plasma IMIPRAMINE levels, but not DESIPRAMINE, correlated with the improvement in agoraph (Mavissakalian et al, 1984), which may indicate that the antiphobic effects of IMIPRAMINE therapy are m post-synaptic serotonergic neurotransmitter system and not the noradrenergic system.

3) IMIPRAMINE therapy plus programmed in vivo exposure practice was superior to IMIPRAMINE thera (Mavissakalian & Michelson, 1986; Mavissakalian et al, 1983).

4.5.B.2 Anorexia nervosa

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III

Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Has resulted in some improvement in patients with anorexia nervosa

c) Adult:
1) Imipramine treatment resulted in some improvement in 7 patients with anorexia nervosa treated seria antidepressants (tricyclics, MAOIs, and triazolopyridines) including imipramine. Three of the patients rec imipramine; the treatment trials ranged from 6 to 14 weeks. Four of the patients had some improvement symptoms, 2 experienced some weight gain, and 3 of 3 who had bulimic symptoms reported improveme anorexic symptoms (3 to 6 weeks) was slower than the improvement observed in depression and anxiet following tricyclic therapy (Hudson et al, 1985). Significant weight gain generally began after 2 to 3 montl with IMIPRAMINE tended to tolerate the drug poorly and appeared to have an extraordinary sensitivity to anticholinergic side effects when compared to patients treated with trazodone or MAOIs (Hudson et al, 1 extraordinary sensitivity to the drug's side effects may be associated with their low body weight.

4.5.B.3 Attention deficit hyperactivity disorder, predominantly inattentive type

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive
Recommendation: Pediatric, Class III
Strength of Evidence: Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Stimulants (eg, amphetamine, methylphenidate) are the drugs of choice in the treatment of attention defi

c) Pediatric:
1) Imipramine therapy should be considered an alternative or adjunctive agent when these agents fail o unable to tolerate them (Hilton et al, 1991; Rancurello, 1985a). The dose used ranges from 25 to 100 mi tends to be lower than those needed to treat depression. Children tend to respond within 24 hours after i The monitoring of serum imipramine and desipramine levels may be useful. The serum levels associate responses have been 10 to 54 ng/ml of imipramine and 10 to 65 ng/ml of desipramine (Linnoila et al, 197
2) A 6-year-old retarded child with Fragile X syndrome and attention deficit disorder responded to IMIPR (Hilton et al, 1991). IMIPRAMINE improved the boy's insomnia, enuresis, and attention deficit disorder, w therapy with METHYLPHENIDATE had caused a deterioration in behavior.
3) A 12-year-old boy with a history of severe attention deficit disorder and stimulant-induced Tourette's s responded well to IMIPRAMINE therapy (50 milligrams/d). During the course of IMIPRAMINE therapy th disorder substantially improved and the Tourette's symptomatology was not affected (Dillon et al, 1985).
4) Ten hyperactive children were treated with IMIPRAMINE 75 to 150 milligrams/day and no response w of the patients (Winsberg et al, 1980).
5) Fifty-two children, 3 to 14 years of age, were enrolled in an open clinical study to evaluate the efficac in the treatment of CHILDHOOD HYPERACTIVITY (Huessy & Wright, 1970). Thirty-five of the 52 childre marked improvement in behavior. The average daily dose of IMIPRAMINE was 50 mg (25 to 125 mg). S (11/17) of the children failing to respond to IMIPRAMINE therapy subsequently responded to METHYLPI therapy.

4.5.B.4 Binging

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
May be beneficial for weight loss when added to diet counseling and psychological support in obese bing

c) Adult:
1) A short course of low dose imipramine added to diet counseling and psychological support helped ob to lose weight and maintain their weight loss. In a double-blind study, binge eaters (as defined by DSM-I body mass index of greater than 27.5-kilograms (kg)/square meter randomly received imipramine 25 mil daily (n=15) or placebo (n=16) for 8 weeks. Diet counseling and psychological support were provided du phase and continued for 6 months thereafter. Imipramine- treated patients experienced a weight loss of placebo group remained stable (p=0.0002). The occurrence of depression was low for both groups; how on the Hamilton Depression scale declined in the imipramine group (p less than 0.001) but not in the pla eating episodes declined from 7.1 episodes/week to 2.8 episodes for the imipramine group (p less than episodes to 5.4 episodes in the placebo group (p not significant). After the active treatment phase, imipra continued their weight loss by a mean of 1.9 kg (p less than 0.001) while placebo- treated patients regai significant) (Laederach-Hofmann et al, 1999).

4.5.B.5 Bulimia nervosa

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Approximately 75% of patients show at least a moderate response (reduction of binge eating by 50% antidepressant therapy
Monoamine oxidase inhibitors also appear effective in bulimia, and may be superior to tricyclic antid et al, 1983)

c) Adult:

1) Twenty bulimic subjects were followed for a period of up to 2 years to assess the long term efficacy o therapy (Pope et al, 1985). At the end of the follow-up period, 95% had at least partial improvement and experienced a complete remission. Over the course of the study period 85% had either maintained or im quality of their initial response. The one patient that failed to respond discontinued her medication and pr her original frequency of binge eating.

2) A retrospective study of 22 patients with bulimia treated with antidepressants (AMITRIPTYLINE, IMIP DESIPRAMINE, DOXEPIN, TRAZODONE, TRANYLCYPROMINE, or PHENELZINE) showed a decreas bingeing and/or an improvement in depression (Brotman et al, 1984). During a 3-month follow-up period relapsed despite continuation of their antidepressant therapy, while others continued to benefit from drug

4.5.B.6 Cardiac dysrhythmia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Some patients with ventricular tachycardia or premature ventricular contractions may benefit from imipra

c) Adult:

1) IMIPRAMINE was included in a double-blinded crossover pilot study to evaluate the efficacy of ventri complex (VPC) suppression after acute myocardial infarction as a means to improve survival (Anon, 198 was assigned to ENCAINIDE, FLECAINIDE, IMIPRAMINE, MORICIZINE, or placebo. The dose of the m adjusted to achieve 70% or greater reduction of VPC and greater than 90% reduction in unsustained ver tachycardia. If the patient failed to achieve an adequate response or was unable to tolerate the drug, the discontinued and they were crossed over to a different antiarrhythmic class (class 1C to class 1A or clas ENCAINIDE (79%) and FLECAINIDE (83%) were superior to IMIPRAMINE (52%), MORICIZINE (66%), as first line-drugs. In patients failing IMIPRAMINE or MORICIZINE therapy, ENCAINIDE was 68% and F effective. It would appear that IMIPRAMINE is not the drug of choice for the prevention of VPC following myocardial infarction. In addition, changes in therapy secondary to the development or worsening of con failure occurred in 26% of the treatment groups compared to 18% in the placebo group (Greene et al, 19

2) IMIPRAMINE in doses of 50 to 400 milligrams/day (mean = 210 +/- 103 mg/day) and NORTRIPTYLIN to 150 mg/day (mean = 100 +/- 29 mg/day) were effective in the reduction of PVCs (Giardina et al, 1985a percent of the patients had a greater than 80% suppression of their PVCs. Neither drug significantly cha ejection fraction or peak systolic pressure end-systolic volume ratio. Both drugs produced a reduction in blood pressure.

3) Twenty-two patients with 30 or more ventricular premature complexes (PVCs) per hour were treated IMIPRAMINE 1 milligrams/kilogram/day (in two divided doses), increasing by 1 mg/kg/day every other da suppressed by at least 80% (or until adverse effects were observed or a daily dose of 5 mg/kg/day was a Eighteen patients (82%) exhibited antiarrhythmic effects from IMIPRAMINE therapy. All patients treated psychological depression. The elimination half-life was approximately 8 hours, however, duration of actio much longer and antiarrhythmic effects were observed over at least a 12 hour period, which suggests tha IMIPRAMINE may contribute to the duration of antiarrhythmic efficacy (Giardina & Bigger, 1982).

4) In patients with premature ventricular contractions, IMIPRAMINE was noted to suppress arrhythmias 90% in 10 of 11 patients. IMIPRAMINE shortens action potential duration and decreases conduction velo velocity and therefore is classified as a class 1 antiarrhythmic drug. Since the half-life of IMIPRAMINE is to 18 hours) it may be dosed on a twice daily regimen. Antiarrhythmic doses appear to be similar to antic (3.5 mg/kg/day). The antiarrhythmic activity of IMIPRAMINE is partially attributed to its metabolites, desm and 2-hydroxyimipramine. Due to complications, IMIPRAMINE should not be used in patients with pre-ex defects (Thase & Perel, 1982).

4.5.B.7 Depression

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class IIb

Strength of Evidence: Adult, Category B; Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Indicated for the relief of symptoms of depression (Prod Info TOFRANIL(R) tablets, 2005)
Endogenous depression may be more likely to respond to imipramine therapy than other depressive
TOFRANIL(R) tablets, 2005)

c) Adult:
1) Various depressive illnesses have responded to treatment with IMIPRAMINE in daily doses of 75 to 2
(Prod Info Tofranil(R), 1995b; Kocsis et al, 1989; Kocsis et al, 1988; Battistini et al, 1980a; Eilenberg, 19
1979a); (Lindberg et al, 1979)(Amin et al, 1978). Patients suffering from endogenous depression (Fabre
endogenous depression (Lindberg et al, 1979), depression of myotonic dystrophy (Brumback & Carlson,
depression (Finnerty et al, 1978a) alcoholic patients with primary depression (McGrath et al, 1996), and
patients with depressive disorders (Nunes et al, 1998) may benefit from IMIPRAMINE therapy. However
of IMIPRAMINE and a neuroleptic are effective in the treatment of delusional depression (Kaskey et al, 1
2) High dose tricyclic antidepressant therapy (IMIPRAMINE 150 to 200 milligrams/d, DESMETHYLIMIPI
500 mg/d) was effective in only a small portion of elderly patients with delusional depression. The dropou
to side effects was 58% and the overall success rate was only 25% (Brown et al, 1984).

d) Pediatric:
1) IMIPRAMINE is efficacious in the treatment of depression in children (Rancurello, 1985a; Petti & Con
general overview of the treatment of childhood behavioral and emotional disorders has been published (
1985a).
2) IMIPRAMINE therapy in adolescents with major depressive illness was less effective than in adults in
of 35 patients (Strober et al, 1990). Twenty-four females and 11 male depressed patients between 13 an
with a Hamilton Rating Scale for Depression scores of 16 or greater were enrolled in the study. Followinç
period, patients received IMIPRAMINE 5 milligrams/kilogram/day (up to a maximum of 300 mg) for 6 wee
adolescents completed the trial. The average daily dose was 222 mg/day. Overall efficacy was low, with
with delusional subtypes responding more poorly than the nondelusional patients. Eight of the 24 nondel
displayed delayed onset of response, followed by sustained improvement. Only one delusional patient d
clinical improvement. Steady state plasma levels did not vary between responders and nonresponders. T
study suggest that imipramine may be less efficacious in the treatment of major depression in adolescen
as has previously been suggested for other tricyclic antidepressants, and raises questions about age diff
neurotransmitter and neuroregulatory system responses to specific antidepressant agents.
3) Twenty-one children (ages 5.8 to 10.25 years) with various types of depression were treated with IMI
67% of the children showing some improvement (Conners & Petti, 1983). The dose of IMIPRAMINE was
at bedtime and slowly increased over a period of 7 to 14 days to a maximum dosage of 5 milligrams/kilog
mg/day (one older child was treated with 225 mg/d (4.9 mg/kg/day). Seven (33%) of the children experie
worsening or no significant change in any of the areas monitored. In fact, 2 children showed a significant
and hostility during the IMIPRAMINE therapy.
4) Imipramine was efficacious in the treatment of 20 prepubertal children hospitalized for major depressi
III) with imipramine (Preskorn et al, 1982). IMIPRAMINE therapy consisted of 75 milligrams/day, adminis
for the first 3 weeks and increased to a maximum of 5 milligrams/kilogram if no response. Serum IMIPRA
DESIPRAMINE levels were drawn during each phase of the study. During phase I, none of the 15 childre
tricyclic antidepressant (TCA) plasma concentration outside the 125 to 225 ng/mL range showed a remis
improvement in their condition. Eighty percent of those children with serum levels between 125 to 225 ng
a remission. During phase II, 12 of the 16 children achieved steady-state total TCA plasma concentration
ng/mL and 11 (92%) of them had experienced a remission by the end of the treatment period. Based on
be concluded that IMIPRAMINE is effective in the treatment of depression in prepubertal children and its
concentration-dependent.

4.5.B.8 Diabetic neuropathy

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Effective for diabetic neuropathy in selected patients

c) Adult:
1) In most patients, an imipramine plasma drug concentration of 400 to 500 nmol/L was sufficient to ach
in the treatment of diabetic neuropathy (Sindrup et al, 1990a). All patients were diabetic and had one or
(pain, paresthesia, dysesthesia, and hypesthesia) and signs (reduction of sensibility, strength, or tendon
peripheral neuropathy. One patient demonstrated no significant improvement even with IMIPRAMINE plu
levels below 400 nmol/L. In the other eleven patients doses of 125 to 350 milligrams/day were required t
levels to about 400 mmol/L. One patient required a blood level of 730 mmol/L to achieve maximal relief.
2) A double-blind, cross-over comparison of IMIPRAMINE with placebo was conducted in nine patients
peripheral diabetic neuropathy (Sindrup et al, 1989). The dose of IMIPRAMINE was adjusted to achieve
IMIPRAMINE plus DESIPRAMINE level of 300 to 750 nmol (125 to 225 milligrams/day) during the first w

treatment period was three weeks and no washout phase was used between treatment periods. Efficacy
the end of each treatment period based on symptoms and measurement of peripheral and autonomic ne
IMIPRAMINE provided significant beneficial symptomatic improvement in all patients, but not beneficial c
peripheral or autonomic nerve function.
3) IMIPRAMINE in doses of 50 milligrams (mg) daily for one week, then 100 mg daily for 4 weeks, was e
producing improvement in 7 of 12 patients with severe diabetic neuropathy of the lower extremities in a c
over study (Kvinesdal et al, 1984). IMIPRAMINE had beneficial effects on pain, paresthesia, dysesthesia
nocturnal aggravation.

4.5.B.9 Disorder of ejaculation

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

In case reports, imipramine has been effective in treating ejaculatory disorders

c) Adult:

1) IMIPRAMINE 25 milligrams three times/day corrected RETROGRADE EJACULATION of 18 months
duration in 2 adult diabetics. One patient had normal gonadotropin levels; the other had low plasma testo
testosterone therapy did not correct retrograde ejaculation (Brooks et al, 1980).
2) A 29-year-old male with ASPERMIA of 4 years duration secondary to lymphadenectomy noted ejacul
volume and consistency 1 day after beginning IMIPRAMINE 50 milligrams daily for depression. Motile sp
seen on microscopic examination and sperm count was 115,600,000/mm(3). Aspermia returned within 2
discontinuing IMIPRAMINE therapy. These results recurred on 3 separate occasions (Kelly & Needle, 19

4.5.B.10 Drug dependence

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Has little effect in the treatment of drug addiction
Does improve mood in drug-addicted patients with depressive disorders

c) Adult:

1) Treatment of depressed METHADONE-MAINTENANCE OPIATE ADDICTS with IMIPRAMINE or a p
similar subjective results in one study (Kleber et al, 1983). At the end of 8 weeks of therapy both groups
reduction in depressive symptoms. However, a 12-week, double-blind trial that excluded initial placebo r
pre-randomization period found significantly improved depression rating scores after treatment with imipr
compared to placebo (n=42) (p less than 0.001). Imipramine doses were titrated based on response to a
of 268 milligrams daily (Nunes et al, 1998).
2) Imipramine had little effect in the treatment of COCAINE DEPENDENCE and METHAMPHETAMINE
patients (151 cocaine dependent and 32 methamphetamine dependent) seen at the Haight-Ashbury Fre
et al, 1994). Patients were randomly assigned to treatment with imipramine 10 or 150 milligrams/day for
this double-blind study. In addition, all subjects were given intensive drug abuse counseling during the co
treatment. Efficacy was based on negative urine samples, self reporting of abstinence, craving, and Bec
inventory. The longest retention in the program occurred with the group receiving the higher imipramine
retention 34 days vs 17 days). No differences in craving or depressive symptoms were observed and the
scores in both groups decreased after the start of therapy. Positive urine analyses were less in the high
group (5% vs 14%) at 14 days, but were no different at 28 or 90 days. Based on these results it appears
of limited value in the treatment of cocaine or methamphetamine dependent patients who do not have a
disorder.

4.5.B.11 Gardner-Diamond syndrome

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective only for short-term therapy of autoerythrocyte sensitization

c) Adult:

1) A 20-year-old female with autoerythrocyte sensitization and depression was treated with IMIPRAMIN
1983). One week later the bleeding resolved and after 2 weeks the depression began to resolve. In 3 to

symptoms had resolved. Six weeks later, while still receiving therapeutic doses of IMIPRAMINE, the dep
recurred and 10 days later bleeding restarted. Compared to previous episodes the severity of depressior
less severe. The bleeding resolved in 10 days and the depressive symptoms were gone within 6 weeks.
subsequent relapse in therapy the IMIPRAMINE was discontinued and AMITRIPTYLINE therapy (300 m
Since the start of AMITRIPTYLINE therapy the patient has been free of depression and bleeding for 10 r

4.5.B.12 Globus hystericus

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Efficacy demonstrated in case reports only

c) Adult:

1) Globus hystericus syndrome is a condition in which the individual develops a fear that he/she is interr
and unable to breathe. If the condition is left untreated the patient may become profoundly disabled or m
threatening weight loss. Case reports of three patients have shown that psychoactive drugs may be effe
this condition. IMIPRAMINE therapy was effective in the treatment of one case, PHENELZINE in anothe
TRANYLCYPROMINE in the other case (Brown et al, 1986). Two additional cases of successful imipram
globus hystericus syndrome were reported (Kaplan, 1987; Rosenthal, 1987).

4.5.B.13 Mood swings

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Possibly effective for PATHOLOGICAL CRYING/LAUGHING

c) Adult:

1) Heightened tendency for crying or laughing in frequency and inappropriate circumstances (pathologic
laughing) and emotional lability unrelated to depression can occur in individuals with brain damage (eg, s
Small doses of IMIPRAMINE (30 to 60 milligrams) may partially or completely control the emotionalism v
(Allman, 1992).

4.5.B.14 Nocturnal enuresis

FDA Labeled Indication

a) Overview

FDA Approval: Adult, no; Pediatric, yes (6 years and older)
Efficacy: Pediatric, Effective
Recommendation: Pediatric, Class IIa
Strength of Evidence: Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated as temporary adjunctive therapy for the reduction of enuresis in children 6 years and older
TOFRANIL(R) tablets, 2005)

c) Pediatric:

1) Numerous double-blind, crossover, placebo-controlled studies have demonstrated IMIPRAMINE's eff
adjunct treatment of enuresis in pediatric patients. Most studies report the use of doses ranging from 10
administered at bedtime although doses as high as 100 mg have been utilized. The application of pharm
Bayesian methods) may improve the individualization of IMIPRAMINE dosing in the treatment of enuresi
1994a; Tamayo et al, 1992; Fernandez de Gatta et al, 1989). Most studies report only minor side effects
mouth, constipation, irritability, anorexia, and sleep disturbances (Prod Info Tofranil(R), 1995b; Fernande
1990; Fournier et al, 1987; Wagner et al, 1982; Jorgenson et al, 1980; Rapoport et al, 1980b; Lake et al,
et al, 1974; Maxwell & Seldrup, 1971; Alderton, 1970).

2) Follow-up of 29 young adults, 10 years after IMIPRAMINE therapy for enuresis, suggests that no psy
results from this therapy; these patients showed no psychological decompensation, inhibition of learning
to drug abuse (Bindelglas & Dee, 1978).

4.5.B.15 Obsessive-compulsive disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Questionable efficacy in the treatment of obsessive-compulsive disorder

c) Adult:

1) Imipramine was ineffective in treating obsessive- compulsive disorder (OCD) in a double-blind, placel study that evaluated the efficacy of IMIPRAMINE in the treatment of depression and obsessive-compulsi patients (Foa et al, 1987). Nineteen (10 women and 9 men) were treated with IMIPRAMINE and 18 (9 w were treated with a placebo. Each placebo patient received 10 tablets per day. The IMIPRAMINE group increased by 25 mg every other day until clinical response, side effects, or a maximum daily dose of 250 daily IMIPRAMINE dose was 233 mg (150 to 250 mg). At the end of 6 weeks the IMIPRAMINE was effec symptoms associated with depression, but had little to no effect on their obsessive-compulsive symptom

2) Four patients with obsessive-compulsive bowel obsessions were treated with IMIPRAMINE (3) or DO patients were free of their bowel obsession within 30 days (10, 14, 14, 30) of starting drug therapy (Jenik

4.5.B.16 Pain

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Pain has occasionally resolved with imipramine therapy

c) Adult:

1) Patients with chest pain, but normal coronary angiograms, may respond to imipramine therapy (Cann The dose of medications used in the study were imipramine 50 milligrams at night and placebo in the mo 0.1 milligrams twice daily, and placebo twice daily. The incidence of chest pain was decreased by 52 +/- with 1 +/- 86% with placebo and 39 +/- 51% with clonidine therapy (data is presented as means +/- SD). associated with imipramine use was statistically significant (p=0.03). A follow-up evaluation of these pati average of 21 months, indicated that none of the patients had been seen in an emergency room or had b because of chest pain. Seventeen patients have had the imipramine therapy discontinued and 16 asked imipramine therapy because of recurrent chest pain symptoms (Cannon, 1994b). The mechanism of this unknown, but may be a result of a visceral analgesic effect and not dependent on cardiac, esophageal, c characteristics or gender. Another possible mechanism for this effect may be an increased pain threshol reduction in psychological depression (Hare, 1994).

2) A survey of Italian oncology centers revealed that 43% of their patients were given antidepressants. T frequently utilized drugs were AMITRIPTYLINE, CLOMIPRAMINE, IMIPRAMINE, and TRAZODONE. Mo that the antidepressants were useful in controlling pain and were most efficacious in depressed patients 1987).

3) A case report of a 26-year-old graduate student being treated with IMIPRAMINE for suicidal thoughts esteem noted an improvement in her chronic pelvic pain (induced by endometriosis four years earlier) wl IMIPRAMINE therapy (Beresin, 1986).

4.5.B.17 Panic disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Similar in efficacy to alprazolam

c) Adult:

1) GENERAL INFORMATION

a) The clinical response to IMIPRAMINE in the treatment of panic disorder is independent of the pre depression or dysphoria (Deltito et al, 1991). Patients with high baseline depression scores have ter poorest outcomes (Rosenberg et al, 1991aa; Rosenberg et al, 1991c; Zitrin, 1983; Nurnberg & Cocc Maintenance with half-dose IMIPRAMINE therapy may be useful in providing patients with a protecti relapses (Mavissakalian & Perel, 1992a; Mavissakalian & Perel, 1992b). The use of IMIPRAMINE in panic disorder may not be as safe as other anxiolytics in patients with cardiovascular disease (Roth

2) Combination imipramine and cognitive-behavioral therapy (CBT) was of limited value initially but prov during maintenance therapy in patients with panic disorder. Patients with panic disorder randomly receiv (n=77), imipramine alone (n=83), placebo alone (n=24), CBT with imipramine (n=65), or CBT alone (n=6 acute treatment phase. Thereafter, responders entered a 6-month maintenance phase. Patient response following the 12- week acute treatment phase, the 6-month maintenance phase, and 6-months after ther discontinuation; assessment tools included the Panic Disorder Severity Scale (PDSS) and the Clinical G Scale (CGI). Initial imipramine doses were 10 milligrams (mg)/day slowly increased over 5 weeks to 200 increased to 300 mg if symptoms continued. Following acute treatment, responses for the PDSS were 4

alone, 45.8% for imipramine alone, 21.7% for placebo alone, 60.3% for CBT with imipramine, and 57.1% placebo. Both CBT alone and imipramine alone were significantly better than placebo (p=0.03 and p=0.0 however, combination therapy provided no greater response rate over each treatment alone (p not signif during the acute phase, none of the therapies were significantly better than the others. Following mainter responses on the PDSS were 39.5% for CBT alone, 37.8% for imipramine alone, 13% for placebo alone, with imipramine, and 46.8% for CBT plus placebo. Responses on both the PDSS and the CGI were sign imipramine versus placebo (p=0.02 for both) and CBT versus placebo (p=0.02, p=0.01, respectively). Us combination therapy was significantly better than either CBT alone (p=0.04) and better than imipramine a the CGI, combination therapy was only significantly better than imipramine alone (p=0.03) and not better not significant). Following treatment discontinuation after the 6-month maintenance phase, the only statis was the PDSS scores in the CBT group compared to the placebo group (p=0.05) (Barlow et al, 2000).

3) Maintenance treatment with imipramine had a significant protective effect against relapse in patients and agoraphobia. Patients who had shown an initial good and stable response to imipramine therapy ov randomly received same-dose imipramine continuation (n=29) or placebo discontinuation (n=27). Patient initial imipramine at a target dose of 2.25 milligrams/kilogram or discontinued their imipramine by decrea 25% each week (substituted with placebo). During this study, no patient received behavioral or cognitive a crisis-type intervention was needed. During the study, if relapse was confirmed the patient exited the s defined as a worsening of their condition (measured as a 33% decline in the End- State Function scale s accompanied by insistent requests for therapeutic action. After 12 months, the study population consiste the imipramine group and 10 patients in the placebo group. This resulted in a 92.5% lower hazard rate o imipramine as compared to placebo (Mavissakalian & Perel, 1999).

4) In a double-blind study, an 8-month therapy period for panic disorder with either alprazolam or imipra (Rickels & Schweizer, 1998). Patients received alprazolam (n=37), imipramine (n=34), or placebo (n=35) period of short-term treatment, a 6-month maintenance period, and then a 15-month follow-up period. Pa alprazolam began at 1 milligram (mg) daily and were titrated up to 10 mg. Those receiving imipramine be were increased to 250 mg. Alprazolam patients had notable reductions in panic attacks during the first 2 while imipramine patients showed improvement over placebo patients after 3 to 4 weeks. Drop-out rates were 11% in the alprazolam group, 41% in the imipramine group, and 57% in the placebo group (p less t alprazolam versus the other groups). In the remaining patients it was noted that tolerance developed to a during the maintenance phase. After the 6-month maintenance phase, doses were titrated off over 3 wee 62% of the alprazolam and 26% of the imipramine groups were panic-free (p less than 0.01). During the patients could be treated with non-study medications. Regardless of medication, patients who completed treatment were more likely to be panic-free than those who had dropped out, even if they received non-s (85% versus 55%, p less than 0.01). Remission rates were higher in younger patients, those with a histo or intense panic attacks, those with a lower initial phobia score, and those with an initial lower score of in self-confidence, and passivity (Minnesota Multiphasic Personality Inventory Dependency Scale).

5) A comparison of cognitive therapy, applied relaxation, and imipramine found that at 3 months cognitiv superior to both applied relaxation and imipramine therapy (Clark et al, 1994). At 6 months the cognitive imipramine treatment produced similar results and were better than applied relaxation. However, betwee months of therapy, several of the imipramine patients relapsed while the patients treated with cognitive th to do better than with imipramine and relaxation therapy.

4.5.B.18 Posttraumatic stress disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Resulted in improvement in positive symptoms of post-traumatic stress disorder

c) Adult:

1) Imipramine treatment resulted in improvement in positive symptoms of post-traumatic stress disorder patients (Burstein, 1984). Therapy was initiated at a low dose and increased over the following 7 days to tolerable dose (mean 260 milligrams/day; range 50 to 350 mg/d). After 2 to 3 weeks of therapy, there wa decrease in the severity of forced recollection, sleep and dream disturbances, and a cessation or reducti Most avoidance items, eg, staying away from reminders of the event, trying not to talk about the event, a remove it from their memory, did not decrease significantly in severity. Based on these results it would a IMIPRAMINE, in combination with psychotherapy, may be an effective treatment for patients.

2) Treatment of 3 patients with acute post-traumatic stress disorder (PTSD) with either DOXEPIN or IMI in an improvement in PTSD symptoms (Blake, 1986). Whether or not tricyclic antidepressant therapy is s equivalent, or inferior to psychotherapy or other means of treatment remains to be determined.

4.5.B.19 Schizophrenia; Adjunct

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class III

Strength of Evidence: Adult, Category B; Pediatric, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
May be effective as adjunct therapy in depressed schizophrenic patients
Ineffective for schizophrenia itself

c) Adult:
1) Schizophrenic or schizoaffective patients with POSTPSYCHOTIC DEPRESSION may benefit from th IMIPRAMINE to their neuroleptic therapy. Favorable results were observed in 27 patients previously trea FLUPHENAZINE DECANOATE and BENZTROPINE after the addition of IMIPRAMINE to their drug regi beneficial effects continued in those patients with postpsychotic depression that initially responded to the IMIPRAMINE to their regimen and were monitored for an additional six months on the triple drug regimer patients that did not complete the six-month observation period were discontinued for administrative reas a relapse in either psychosis or depression (Siris et al, 1992). A one-year follow-up study documented th maintaining imipramine therapy in the treatment of postpsychotic depression (Siris et al, 1994).
2) A preliminary study indicates that imipramine may be an effective adjunctive agent in the acute treatn abusing dysphoric schizophrenic or schizoaffective patients (Siris et al, 1993). The importance of these r proven.

d) Pediatric:
1) A pilot study in 10 autistic and schizophrenic children age 2 to 6 years found IMIPRAMINE therapy to (Campbell et al, 1971). The drug did decrease affective blunting, anergy, and withdrawal and stimulated in several children, but increased psychotic speech, behavioral disorganization, and excitation in other cl

4.5.B.20 Separation anxiety disorder of childhood

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive
Recommendation: Pediatric, Class III
Strength of Evidence: Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Routine use of tricyclic antidepressants is not recommended for separation anxiety in children
Behavioral therapy may be just as effective as imipramine

c) Pediatric:
1) The combination of imipramine and nonpharmacologic therapies (eg, parent management training, be and family therapy) may improve subjective comfort, reduce anxiety and somatic symptoms in 70% of th experiencing separation-anxiety disorder (Rancurello, 1985a). This disorder is associated with a high rat recovery, therefore the routine use of tricyclic antidepressants is not recommended (Rancurello, 1985a).
2) Both IMIPRAMINE and placebo therapy were equally effective for separation anxiety. A small, double placebo-controlled study was conducted with 21 children with separation anxiety disorder (Klein et al, 19 children were first given a month of vigorous behavioral treatment, then randomly assigned to IMIPRAMI therapy for six weeks. Both treatments were approximately 50% effective.

4.5.B.21 Sexual disorder

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Effective in case reports only

c) Adult:
1) IMIPRAMINE may be useful, alone or in combination with LITHIUM, in the treatment of men with PAF NONPARAPHILIC SEXUAL ADDICTIONS (Kafka, 1991). Two patients with sexual disorders improved f IMIPRAMINE therapy. Whether IMIPRAMINE and other antidepressants are useful in the treatment of al paraphilias or nonparaphilic sexual addictions or just specific types remains to be determined.

4.5.B.22 Sleep disorder

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Used successfully in the treatment of NIGHT TERRORS, SOMNABULISM, NARCOLEPSY, and CATAP

c) Adult:
1) IMIPRAMINE therapy (50 to 100 milligrams at bedtime) resulted in a dramatic reduction in frequency

night terrors in 2 patients unresponsive to DIAZEPAM therapy (Cooper, 1987).
2) IMIPRAMINE therapy resulted in a significant reduction (242 +/- 156 to 142.8 +/- 120.1) in the total nu episodes in 41.9% of the patients tested (Rubin et al, 1986). Based on these results it appears that IMIPI may be an alternative form of therapy for some nonoverweight patients with negative ear, nose and throa and for some patients who had not responded to weight reduction or ENT surgery.
3) A 62-year-old female had suppression of night terrors with IMIPRAMINE 50 milligrams at bedtime; 75 completely suppressed night terrors but caused daytime drowsiness (Beitman & Carlin, 1979).

4.5.B.23 Social phobia

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
No studies currently support the use of imipramine for social phobia

c) Adult:
1) Imipramine was not useful in the treatment of social phobia in an 8-week, open-trial of 15 patients (Si 1998). Imipramine was started at 50 milligrams (mg) for 3 nights and increased at weekly intervals to a m 300 mg by the fourth week. Only 9 patients were able to complete the study as the others dropped out di effects. Only 2 patients responded to imipramine therapy as determined by the Liebowitz Social Anxiety Liebowitz Social Phobia Disorders Scale-Overall Severity. They were also unable to continue further ther developed urinary hesitancy and the other became hypomanic.

4.5.B.24 Trichotillomania

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive
Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Used successfully in a case of trichotillomania and depression in a pediatric patient (Weller et al, 1989).

4.5.B.25 Urinary incontinence

a) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Used alone or in combination with other anticholinergic medications, can improve urinary continence
May not be better than bladder training in some patients
May help to achieve continence in children with myelodysplasia alone or in combination with oxybut

c) Adult:
1) Imipramine was useful for genuine stress continence. In a prospective study, women with genuine str received imipramine 25 milligrams 3 times daily for 3 months. A urodynamic assessment was done with test to determine the amount of urine leakage. A cure was defined as a pad weight that resulted in 0 gra After 3 months, 35% of women were cured, 25% showed an improved pad weight result of 50% or bette therapy. The women that were cured or improved had a higher urethral closure pressure than those that 0.001). The authors note that a high pre-treatment urethral closure pressure may serve as a predictor fo success (Lin et al, 1999).
2) IMIPRAMINE 75 milligrams orally daily for four weeks was reported effective in the treatment of fema INCONTINENCE in 21 of 30 women (71%). The drug was reported to extend the functional urethral leng independent of stress factors in women who are continent after therapy. These data support that a short result in urinary incontinence and lengthening of the urethra by IMIPRAMINE treatment or vesicopexy wi dysfunction (Gilja et al, 1984).
3) Bladder drill is more effective than drug therapy in the treatment of incontinence due to idiopathic det women. Fifty women with urinary incontinence due to DETRUSOR INSTABILITY were randomly assigne patient bladder drill training or out-patient drug therapy (FLAVOXATE HYDROCHLORIDE 200 mg three IMIPRAMINE 25 milligrams three times/day) for 4 weeks (Jarvis, 1981). At the completion of the study 8 patients treated with bladder drill were continent and 76% were symptom free. Fifty-six percent (14/25) o with medication were continent and 48% were symptom-free. Side effects occurred in 56% of the patient therapy and 5 patients discontinued drug therapy on their own secondary to side effects.
4) Six of 10 elderly patients (x=80 year old, 63 to 88 years) with urinary incontinence associated with sp unstable detrusor contractions were successfully treated with IMIPRAMINE. The dose of IMIPRAMINE w

mg at bedtime and increased every third day by 25 mg, until the patient was continent, experienced side reached 150 mg/day. At the completion of the study 60% of the patients were continent. No correlation b plasma concentrations of desmethylimipramine and clinical or urodynamic effects could be found (Castle

d) Pediatric:

1) Children and adolescents with myelodysplasia and incontinence (i.e. wet between their clean intermit times performed 3 to 5 times daily) benefited from imipramine therapy. Children (n=19, 4- to 12-years-old imipramine 10 milligrams (mg) daily increased to a maximum of 20 mg twice daily. Combination therapy was used in 10 patients. Eight of the children had also failed therapy with oxybutynin, flavoxate, or ephed imipramine, 15 children developed at least partial continence (dry 50% to 80% of the time) with 9 achievi continence (dry at least 80% of the time). The authors suggest low-dose imipramine alone or in combina oxybutynin for children with myelodysplasia to help achieve continence (Hurley et al, 2000).

4.5.C Imipramine Pamoate

Agoraphobia

Anorexia nervosa

Bulimia nervosa

Cardiac dysrhythmia

Depression

Diabetic neuropathy

Gardner-Diamond syndrome

Globus hystericus

Obsessive-compulsive disorder

Pain

Panic disorder

Posttraumatic stress disorder

Separation anxiety disorder of childhood

Sexual disorder

Sleep disorder

Trichotillomania

4.5.C.1 Agoraphobia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective in the treatment of agoraphobia (Deltito et al, 1991)
Efficacy appears to be dose-related and usually requires doses of 150 milligrams or greater per day

c) Adult:

1) Imipramine and placebo were equally effective in the treatment of agoraphobia in a double-blind clinic drug therapy with brief psychological treatment (Cohen et al, 1984a). The drugs were started 2 weeks pr

of the psychological therapy. At week 6 the mean dose of IMIPRAMINE was 124 milligrams and at week
mg/day. During week 2 to week 12 each treatment group received 6 fortnightly sessions of therapist-aide
addition each patient was given a leaflet describing the nature of agoraphobia and ways to cope with it. A
requested to complete systematic self-exposure homework and record these activities in a diary. Drug th
gradually withdrawn over weeks 26 to 28 of therapy. At the 2-year follow-up only 40 subjects were availa
had dropped out of the study (2 refused follow-up, 1 died, 1 moved out of the country, and 1 was untrace
of the patients remained improved with regards to their phobias. There was no significant difference betv
patients treated with imipramine or placebo therapy. Nor was there a superior effect of therapist-aided ex
therapist-aided relaxation.
2) The plasma IMIPRAMINE levels, but not DESIPRAMINE, correlated with the improvement in agoraph
(Mavissakalian et al, 1984), which may indicate that the antiphobic effects of IMIPRAMINE therapy are m
post-synaptic serotonergic neurotransmitter system and not the noradrenergic system.
3) IMIPRAMINE therapy plus programmed in vivo exposure practice was superior to IMIPRAMINE thera
(Mavissakalian & Michelson, 1986; Mavissakalian et al, 1983).

4.5.C.2 Anorexia nervosa

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Has resulted in some improvement in patients with anorexia nervosa

c) Adult:

1) Imipramine treatment resulted in some improvement in 7 patients with anorexia nervosa treated seria
antidepressants (tricyclics, MAOIs, and triazolopyridines) including imipramine. Three of the patients rec
imipramine; the treatment trials ranged from 6 to 14 weeks. Four of the patients had some improvement
symptoms, 2 experienced some weight gain, and 3 of 3 who had bulimic symptoms reported improveme
anorexic symptoms (3 to 6 weeks) was slower than the improvement observed in depression and anxiety
following tricyclic therapy (Hudson et al, 1985). Significant weight gain generally began after 2 to 3 montl
with IMIPRAMINE tended to tolerate the drug poorly and appeared to have an extraordinary sensitivity to
anticholinergic side effects when compared to patients treated with trazodone or MAOIs (Hudson et al, 1
extraordinary sensitivity to the drug's side effects may be associated with their low body weight.

4.5.C.3 Bulimia nervosa

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Approximately 75% of patients show at least a moderate response (reduction of binge eating by 50%
antidepressant therapy
Monoamine oxidase inhibitors also appear effective in bulimia, and may be superior to tricyclic antid
et al, 1983)

c) Adult:

1) Twenty bulimic subjects were followed for a period of up to 2 years to assess the long term efficacy o
therapy (Pope et al, 1985). At the end of the follow-up period, 95% had at least partial improvement and
experienced a complete remission. Over the course of the study period 85% had either maintained or im
quality of their initial response. The one patient that failed to respond discontinued her medication and pr
her original frequency of binge eating.
2) A retrospective study of 22 patients with bulimia treated with antidepressants (AMITRIPTYLINE, IMIP
DESIPRAMINE, DOXEPIN, TRAZODONE, TRANYLCYPROMINE, or PHENELZINE) showed a decreas
bingeing and/or an improvement in depression (Brotman et al, 1984). During a 3-month follow-up period
relapsed despite continuation of their antidepressant therapy, while others continued to benefit from drug

4.5.C.4 Cardiac dysrhythmia

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Some patients with ventricular tachycardia or premature ventricular contractions may benefit from imipra

c) Adult:

1) IMIPRAMINE was included in a double-blinded crossover pilot study to evaluate the efficacy of ventri complex (VPC) suppression after acute myocardial infarction as a means to improve survival (Anon, 198 was assigned to ENCAINIDE, FLECAINIDE, IMIPRAMINE, MORICIZINE, or placebo. The dose of the m adjusted to achieve 70% or greater reduction of VPC and greater than 90% reduction in unsustained ver tachycardia. If the patient failed to achieve an adequate response or was unable to tolerate the drug, the discontinued and they were crossed over to a different antiarrhythmic class (class 1C to class 1A or clas ENCAINIDE (79%) and FLECAINIDE (83%) were superior to IMIPRAMINE (52%), MORICIZINE (66%), as first line-drugs. In patients failing IMIPRAMINE or MORICIZINE therapy, ENCAINIDE was 68% and F effective. It would appear that IMIPRAMINE is not the drug of choice for the prevention of VPC following myocardial infarction. In addition, changes in therapy secondary to the development or worsening of con failure occurred in 26% of the treatment groups compared to 18% in the placebo group (Greene et al, 19

2) IMIPRAMINE in doses of 50 to 400 milligrams/day (mean = 210 +/- 103 mg/day) and NORTRIPTYLIN to 150 mg/day (mean = 100 +/- 29 mg/day) were effective in the reduction of PVCs (Giardina et al, 1985a percent of the patients had a greater than 80% suppression of their PVCs. Neither drug significantly cha ejection fraction or peak systolic pressure end-systolic volume ratio. Both drugs produced a reduction in blood pressure.

3) Twenty-two patients with 30 or more ventricular premature complexes (PVCs) per hour were treated IMIPRAMINE 1 milligrams/kilogram/day (in two divided doses), increasing by 1 mg/kg/day every other da suppressed by at least 80% (or until adverse effects were observed or a daily dose of 5 mg/kg/day was a Eighteen patients (82%) exhibited antiarrhythmic effects from IMIPRAMINE therapy. All patients treated psychological depression. The elimination half-life was approximately 8 hours, however, duration of actio much longer and antiarrhythmic effects were observed over at least a 12 hour period, which suggests tha IMIPRAMINE may contribute to the duration of antiarrhythmic efficacy (Giardina & Bigger, 1982).

4) In patients with premature ventricular contractions, IMIPRAMINE was noted to suppress arrhythmias 90% in 10 of 11 patients. IMIPRAMINE shortens action potential duration and decreases conduction velo velocity and therefore is classified as a class 1 antiarrhythmic drug. Since the half-life of IMIPRAMINE is to 18 hours) it may be dosed on a twice daily regimen. Antiarrhythmic doses appear to be similar to antic (3.5 mg/kg/day). The antiarrhythmic activity of IMIPRAMINE is partially attributed to its metabolites, desm and 2-hydroxyimipramine. Due to complications, IMIPRAMINE should not be used in patients with pre-ex defects (Thase & Perel, 1982).

4.5.C.5 Depression

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective; Pediatric, Evidence is inconclusive
Recommendation: Adult, Class IIb; Pediatric, Class IIb
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Indicated for the relief of symptoms of depression (Prod Info TOFRANIL-PM(R) capsules, 2005)
Endogenous depression may be more likely to respond to imipramine therapy than other depressive TOFRANIL-PM(R) capsules, 2005)

c) Adult:

1) Intramuscular S-adenosyl-L-methionine 1,4-butanedisulphonate (SAMe) was found to be as efficacio imipramine (IMI) for the treatment of depression. In a randomized, double-blind, comparative trial, patien of major depressive episode according to DSM-IV criteria received SAMe 400 milligrams (mg) by intramu once daily (n=146) or oral IMI 150 mg per day in 3 divided doses. Blinding was maintained by a double d IMI dose was titrated over the first week to reach the full dose by day 8. Both treatments were given for 4 preestablished criteria (final score on the Hamilton Depression Rating Scale (HAMD), difference betwee HAMD scores, percentage of responders defined as those with a Clinical Global Impression (CGI) endpo less, and percentage of responders defined as those with a drop of at least 50% from baseline in HAMD treatments were equivalent. By the CGI criterion, 68% of patients in the SAMe group and 66% in the IMI responders; by the HAMD criterion, 59% of the SAME group and 50% of the IMI were responders. Drug reactions occurred in significantly fewer subjects of the SAMe group than of the IMI group: 9.5% vs 33% relevant differences were observed in laboratory measures, vital signs, or ECG parameters (Pancheri et

2) Various depressive illnesses have responded to treatment with IMIPRAMINE in daily doses of 75 to 2 (Prod Info Tofranil(R), 1995b; Kocsis et al, 1989; Kocsis et al, 1988; Battistini et al, 1980a; Eilenberg, 19 1979a); (Lindberg et al, 1979)(Amin et al, 1978). Patients suffering from endogenous depression (Fabre endogenous depression (Lindberg et al, 1979), depression of myotonic dystrophy (Brumback & Carlson, depression (Finnerty et al, 1978a) alcoholic patients with primary depression (McGrath et al, 1996), and patients with depressive disorders (Nunes et al, 1998) may benefit from IMIPRAMINE therapy. However, of IMIPRAMINE and a neuroleptic are effective in the treatment of delusional depression (Kaskey et al, 1

3) High dose tricyclic antidepressant therapy (IMIPRAMINE 150 to 200 milligrams/d, DESMETHYLIMIPI 500 mg/d) was effective in only a small portion of elderly patients with delusional depression. The dropou to side effects was 58% and the overall success rate was only 25% (Brown et al, 1984).

d) Pediatric:

1) IMIPRAMINE is efficacious in the treatment of depression in children (Rancurello, 1985a; Petti & Con

general overview of the treatment of childhood behavioral and emotional disorders has been published (
1985a).
2) Twenty-one children (ages 5.8 to 10.25 years) with various types of depression were treated with IMI
67% of the children showing some improvement (Conners & Petti, 1983).
3) Imipramine was efficacious in the treatment of 20 prepubertal children hospitalized for major depressi
III) with imipramine (Preskorn et al, 1982). IMIPRAMINE therapy consisted of 75 milligrams/day, adminis
for the first 3 weeks and increased to a maximum of 5 milligrams/kilogram if no response. Serum IMIPRA
DESIPRAMINE levels were drawn during each phase of the study. During phase I, none of the 15 childre
tricyclic antidepressant (TCA) plasma concentration outside the 125 to 225 ng/mL range showed a remis
improvement in their condition. Eighty percent of those children with serum levels between 125 to 225 ng
a remission. During phase II, 12 of the 16 children achieved steady-state total TCA plasma concentratior
ng/mL and 11 (92%) of them had experienced a remission by the end of the treatment period. Based on
be concluded that IMIPRAMINE is effective in the treatment of depression in prepubertal children and its
concentration-dependent.

4.5.C.6 Diabetic neuropathy

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective for diabetic neuropathy in selected patients

c) Adult:

1) In most patients, an imipramine plasma drug concentration of 400 to 500 nmol/L was sufficient to ach
in the treatment of diabetic neuropathy (Sindrup et al, 1990a). All patients were diabetic and had one or
(pain, paresthesia, dysesthesia, and hypesthesia) and signs (reduction of sensibility, strength, or tendon
peripheral neuropathy. One patient demonstrated no significant improvement even with IMIPRAMINE plu
levels below 400 nmol/L. In the other eleven patients doses of 125 to 350 milligrams/day were required t
levels to about 400 mmol/L. One patient required a blood level of 730 mmol/L to achieve maximal relief.
2) A double-blind, cross-over comparison of IMIPRAMINE with placebo was conducted in nine patients
peripheral diabetic neuropathy (Sindrup et al, 1989). The dose of IMIPRAMINE was adjusted to achieve
IMIPRAMINE plus DESIPRAMINE level of 300 to 750 nmol (125 to 225 milligrams/day) during the first w
treatment period was three weeks and no washout phase was used between treatment periods. Efficacy
the end of each treatment period based on symptoms and measurement of peripheral and autonomic ne
IMIPRAMINE provided significant beneficial symptomatic improvement in all patients, but not beneficial c
peripheral or autonomic nerve function.
3) IMIPRAMINE in doses of 50 milligrams (mg) daily for one week, then 100 mg daily for 4 weeks, was e
producing improvement in 7 of 12 patients with severe diabetic neuropathy of the lower extremities in a c
over study (Kvinesdal et al, 1984). IMIPRAMINE had beneficial effects on pain, paresthesia, dysesthesia
nocturnal aggravation.

4.5.C.7 Gardner-Diamond syndrome

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective only for short-term therapy of autoerythrocyte sensitization

c) Adult:

1) A 20-year-old female with autoerythrocyte sensitization and depression was treated with IMIPRAMINE
1983). One week later the bleeding resolved and after 2 weeks the depression began to resolve. In 3 to
symptoms had resolved. Six weeks later, while still receiving therapeutic doses of IMIPRAMINE, the dep
recurred and 10 days later bleeding restarted. Compared to previous episodes the severity of depressior
less severe. The bleeding resolved in 10 days and the depressive symptoms were gone within 6 weeks.
subsequent relapse in therapy the IMIPRAMINE was discontinued and AMITRIPTYLINE therapy (300 m
Since the start of AMITRIPTYLINE therapy the patient has been free of depression and bleeding for 10 r

4.5.C.8 Globus hystericus

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Efficacy demonstrated in case reports only

c) Adult:

1) Globus hystericus syndrome is a condition in which the individual develops a fear that he/she is interr and unable to breathe. If the condition is left untreated the patient may become profoundly disabled or m threatening weight loss. Case reports of three patients have shown that psychoactive drugs may be effec this condition. IMIPRAMINE therapy was effective in the treatment of one case, PHENELZINE in anothe TRANYLCYPROMINE in the other case (Brown et al, 1986). Two additional cases of successful imipram globus hystericus syndrome were reported (Kaplan, 1987; Rosenthal, 1987).

4.5.C.9 Obsessive-compulsive disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Questionable efficacy in the treatment of obsessive-compulsive disorder

c) Adult:

1) Imipramine was ineffective in treating obsessive- compulsive disorder (OCD) in a double-blind, placel study that evaluated the efficacy of IMIPRAMINE in the treatment of depression and obsessive-compulsi patients (Foa et al, 1987). Nineteen (10 women and 9 men) were treated with IMIPRAMINE and 18 (9 w were treated with a placebo. Each placebo patient received 10 tablets per day. The IMIPRAMINE group increased by 25 mg every other day until clinical response, side effects, or a maximum daily dose of 250 daily IMIPRAMINE dose was 233 mg (150 to 250 mg). At the end of 6 weeks the IMIPRAMINE was effec symptoms associated with depression, but had little to no effect on their obsessive-compulsive symptom

2) Four patients with obsessive-compulsive bowel obsessions were treated with IMIPRAMINE (3) or DO patients were free of their bowel obsession within 30 days (10, 14, 14, 30) of starting drug therapy (Jenik

4.5.C.10 Pain

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Pain has occasionally resolved with imipramine therapy

c) Adult:

1) Patients with chest pain, but normal coronary angiograms, may respond to imipramine therapy (Cann The dose of medications used in the study were imipramine 50 milligrams at night and placebo in the mo 0.1 milligrams twice daily, and placebo twice daily. The incidence of chest pain was decreased by 52 +/- with 1 +/- 86% with placebo and 39 +/- 51% with clonidine therapy (data is presented as means +/- SD). associated with imipramine use was statistically significant (p=0.03). A follow-up evaluation of these pati average of 21 months, indicated that none of the patients had been seen in an emergency room or had b because of chest pain. Seventeen patients have had the imipramine therapy discontinued and 16 asked imipramine therapy because of recurrent chest pain symptoms (Cannon, 1994b). The mechanism of this unknown, but may be a result of a visceral analgesic effect and not dependent on cardiac, esophageal, c characteristics or gender. Another possible mechanism for this effect may be an increased pain threshol reduction in psychological depression (Hare, 1994).

2) A survey of Italian oncology centers revealed that 43% of their patients were given antidepressants. T frequently utilized drugs were AMITRIPTYLINE, CLOMIPRAMINE, IMIPRAMINE, and TRAZODONE. Mo that the antidepressants were useful in controlling pain and were most efficacious in depressed patients 1987).

3) A case report of a 26-year-old graduate student being treated with IMIPRAMINE for suicidal thoughts esteem noted an improvement in her chronic pelvic pain (induced by endometriosis four years earlier) wh IMIPRAMINE therapy (Beresin, 1986).

4.5.C.11 Panic disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Similar in efficacy to alprazolam

c) Adult:

1) GENERAL INFORMATION

a) The clinical response to IMIPRAMINE in the treatment of panic disorder is independent of the pre depression or dysphoria (Deltito et al, 1991). Patients with high baseline depression scores have ter poorest outcomes (Rosenberg et al, 1991aa; Rosenberg et al, 1991c; Zitrin, 1983; Nurnberg & Cocc use of IMIPRAMINE in the treatment of panic disorder may not be as safe as other anxiolytics in pat cardiovascular disease (Roth et al, 1992a).

2) Combination imipramine and cognitive-behavioral therapy (CBT) was of limited value initially but prov during maintenance therapy in patients with panic disorder. Patients with panic disorder randomly receiv (n=77), imipramine alone (n=83), placebo alone (n=24), CBT with imipramine (n=65), or CBT alone (n=6 acute treatment phase. Thereafter, responders entered a 6-month maintenance phase. Patient response following the 12- week acute treatment phase, the 6-month maintenance phase, and 6-months after ther discontinuation; assessment tools included the Panic Disorder Severity Scale (PDSS) and the Clinical G Scale (CGI). Initial imipramine doses were 10 milligrams (mg)/day slowly increased over 5 weeks to 200 increased to 300 mg if symptoms continued. Following acute treatment, responses for the PDSS were 48 alone, 45.8% for imipramine alone, 21.7% for placebo alone, 60.3% for CBT with imipramine, and 57.1% placebo. Both CBT alone and imipramine alone were significantly better than placebo (p=0.03 and p=0.0 however, combination therapy provided no greater response rate over each treatment alone (p not signif during the acute phase, none of the therapies were significantly better than the others. Following mainter responses on the PDSS were 39.5% for CBT alone, 37.8% for imipramine alone, 13% for placebo alone, with imipramine, and 46.8% for CBT plus placebo. Responses on both the PDSS and the CGI were sign imipramine versus placebo (p=0.02 for both) and CBT versus placebo (p=0.02, p=0.01, respectively). Us combination therapy was significantly better than either CBT alone (p=0.04) and better than imipramine a the CGI, combination therapy was only significantly better than imipramine alone (p=0.03) and not better not significant). Following treatment discontinuation after the 6-month maintenance phase, the only statis was the PDSS scores in the CBT group compared to the placebo group (p=0.05) (Barlow et al, 2000).

3) Maintenance treatment with imipramine had a significant protective effect against relapse in patients and agoraphobia. Patients who had shown an initial good and stable response to imipramine therapy ov randomly received same-dose imipramine continuation (n=29) or placebo discontinuation (n=27). Patient initial imipramine at a target dose of 2.25 milligrams/kilogram or discontinued their imipramine by decrea 25% each week (substituted with placebo). During this study, no patient received behavioral or cognitive a crisis-type intervention was needed. During the study, if relapse was confirmed the patient exited the s defined as a worsening of their condition (measured as a 33% decline in the End- State Function scale s accompanied by insistent requests for therapeutic action. After 12 months, the study population consiste the imipramine group and 10 patients in the placebo group. This resulted in a 92.5% lower hazard rate o imipramine as compared to placebo (Mavissakalian & Perel, 1999).

4) In a double-blind study, an 8-month therapy period for panic disorder with either alprazolam or imipra (Rickels & Schweizer, 1998). Patients received alprazolam (n=37), imipramine (n=34), or placebo (n=35) period of short-term treatment, a 6-month maintenance period, and then a 15-month follow-up period. Pa alprazolam began at 1 milligram (mg) daily and were titrated up to 10 mg. Those receiving imipramine be were increased to 250 mg. Alprazolam patients had notable reductions in panic attacks during the first 2 while imipramine patients showed improvement over placebo patients after 3 to 4 weeks. Drop-out rates were 11% in the alprazolam group, 41% in the imipramine group, and 57% in the placebo group (p less t alprazolam versus the other groups). In the remaining patients it was noted that tolerance developed to a during the maintenance phase. After the 6-month maintenance phase, doses were titrated off over 3 wee 62% of the alprazolam and 26% of the imipramine groups were panic-free (p less than 0.01). During the patients could be treated with non-study medications. Regardless of medication, patients who completed treatment were more likely to be panic-free than those who had dropped out, even if they received non-s (85% versus 55%, p less than 0.01). Remission rates were higher in younger patients, those with a histo or intense panic attacks, those with a lower initial phobia score, and those with an initial lower score of in self-confidence, and passivity (Minnesota Multiphasic Personality Inventory Dependency Scale).

5) A comparison of cognitive therapy, applied relaxation, and imipramine found that at 3 months cognitiv superior to both applied relaxation and imipramine therapy (Clark et al, 1994). At 6 months the cognitive imipramine treatment produced similar results and were better than applied relaxation. However, betwee months of therapy, several of the imipramine patients relapsed while the patients treated with cognitive th to do better than with imipramine and relaxation therapy.

4.5.C.12 Posttraumatic stress disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Resulted in improvement in positive symptoms of post-traumatic stress disorder

c) Adult:

1) Imipramine treatment resulted in improvement in positive symptoms of post-traumatic stress disorder

patients (Burstein, 1984). Therapy was initiated at a low dose and increased over the following 7 days to tolerable dose (mean 260 milligrams/day; range 50 to 350 mg/d). After 2 to 3 weeks of therapy, there wa decrease in the severity of forced recollection, sleep and dream disturbances, and a cessation or reducti Most avoidance items, eg, staying away from reminders of the event, trying not to talk about the event, a remove it from their memory, did not decrease significantly in severity. Based on these results it would a IMIPRAMINE, in combination with psychotherapy, may be an effective treatment for patients.

2) Treatment of 3 patients with acute post-traumatic stress disorder (PTSD) with either DOXEPIN or IMI in an improvement in PTSD symptoms (Blake, 1986). Whether or not tricyclic antidepressant therapy is s equivalent, or inferior to psychotherapy or other means of treatment remains to be determined.

4.5.C.13 Separation anxiety disorder of childhood

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive
Recommendation: Pediatric, Class III
Strength of Evidence: Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Routine use of tricyclic antidepressants is not recommended for separation anxiety in children
Behavioral therapy may be just as effective as imipramine

c) Pediatric:

1) The combination of imipramine and nonpharmacologic therapies (eg, parent management training, be and family therapy) may improve subjective comfort, reduce anxiety and somatic symptoms in 70% of th experiencing separation-anxiety disorder (Rancurello, 1985a). This disorder is associated with a high rat recovery, therefore the routine use of tricyclic antidepressants is not recommended (Rancurello, 1985a).

2) Both IMIPRAMINE and placebo therapy were equally effective for separation anxiety. A small, double placebo-controlled study was conducted with 21 children with separation anxiety disorder (Klein et al, 19 children were first given a month of vigorous behavioral treatment, then randomly assigned to IMIPRAMI therapy for six weeks. Both treatments were approximately 50% effective.

4.5.C.14 Sexual disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective in case reports only

c) Adult:

1) IMIPRAMINE may be useful, alone or in combination with LITHIUM, in the treatment of men with PAR NONPARAPHILIC SEXUAL ADDICTIONS (Kafka, 1991). Two patients with sexual disorders improved f IMIPRAMINE therapy. Whether IMIPRAMINE and other antidepressants are useful in the treatment of al paraphilias or nonparaphilic sexual addictions or just specific types remains to be determined.

4.5.C.15 Sleep disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Used successfully in the treatment of NIGHT TERRORS, SOMNABULISM, NARCOLEPSY, and CATAP

c) Adult:

1) IMIPRAMINE therapy (50 to 100 milligrams at bedtime) resulted in a dramatic reduction in frequency night terrors in 2 patients unresponsive to DIAZEPAM therapy (Cooper, 1987).

2) IMIPRAMINE therapy resulted in a significant reduction (242 +/- 156 to 142.8 +/- 120.1) in the total nu episodes in 41.9% of the patients tested (Rubin et al, 1986). Based on these results it appears that IMIP may be an alternative form of therapy for some nonoverweight patients with negative ear, nose and throa and for some patients who had not responded to weight reduction or ENT surgery.

3) A 62-year-old female had suppression of night terrors with IMIPRAMINE 50 milligrams at bedtime; 75 completely suppressed night terrors but caused daytime drowsiness (Beitman & Carlin, 1979).

4.5.C.16 Trichotillomania

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive

Recommendation: Pediatric, Class IIb
Strength of Evidence: Pediatric, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Used successfully in a case of trichotillomania and depression in a pediatric patient (Weller et al, 1989).

4.6 Comparative Efficacy / Evaluation With Other Therapies

Adinazolam

Tryptophan

Venlafaxine

Viloxazine

Zimeldine

4.6.A Adinazolam

4.6.A.1 Depression

a) SUMMARY: In several small controlled studies, adinazolam has been as effective as imipramine in depres including patients with melancholic depression.

b) Several controlled studies have reported the similar efficacy of adinazolam and imipramine in the treatme depressive disorder in outpatients (Amsterdam et al, 1986; Feighner, 1986). Equivalent efficacy has also bee patients with more severe melancholic depression (Amsterdam et al, 1986). However, all studies have emplo numbers of patients, lending themselves to a type II error. Larger studies of adequate duration, incorporating needed to adequately compare these two agents. In addition, compliance is always a problem in outpatient s involving depressed patients. Either a well-controlled inpatient study or the use of serum drug levels in future required.

c) Adinazolam and imipramine had similar efficacy in the treatment of major depressive disorder, with or with symptoms, in a double-blind study involving 43 outpatients (Amsterdam et al, 1986). Following a 1-week, sing period, patients were randomized to receive either adinazolam 10 milligrams (mg) three times daily initially, ir mg by day 14 of treatment if needed, or imipramine 25 mg three times day initially, increasing up to 225 mg b of therapy, if required. Hamilton Depression Rating (HDR) scores and clinical global impression scale scores similar efficacy of both agents; there was trend toward lower HDR scores in the imipramine group at week 12 improvement in the adinazolam group by week 1. Further analysis revealed the comparable efficacy of the 2 with the more severe, melancholic, subtype of depression. Anticholinergic adverse effects of dry mouth, cons blurred vision occurred more frequently in the imipramine group, as did lightheadedness, agitation and nervo sedation or drowsiness was more prevalent in adinazolam patients. Mood swings into hypomania and worser were more frequent in the adinazolam group, with total episodes during study being 4 versus 1 and 3 versus Other adverse effects occurred to a similar degree in each group.

4.6.B Alprazolam

Anxiety

Depression

Panic disorder

4.6.B.1 Anxiety

a) A six-week, double-blind, parallel study was conducted in 60 patients with generalized anxiety disorder to efficacy of alprazolam and imipramine (Hoehn-Saric et al, 1988). After a three-week washout period, patients divided and randomly assigned to alprazolam 0.5 milligram or imipramine 25 milligrams three times daily for s the first week the dose of the medication could be increased by one capsule daily up to a maximum of 12 cap the end of the study the average dose was for the alprazolam-treated group was 2.2 mg/day (0.5 to 6 mg/day imipramine group 91 mg/day (25 to 200 mg/day). During the first two weeks, alprazolam was superior to imip weeks both drugs were effective based on psychic and somatic parameters, but imipramine predominantly af symptoms (eg, negative anticipatory thinking and dysphoria) as alprazolam was superior in attenuating soma

b) Alprazolam and imipramine might be useful in the treatment of school refusal (school phobia); however, fu need to be conducted to document their usefulness (Bernstein et al, 1991).

4.6.B.2 Depression

a) Alprazolam was as effective as imipramine in the treatment of primary depression (Fabre & McLendon, 19 effective doses of alprazolam in the study were 2.6 milligrams daily in divided doses, as compared with 128.4 for imipramine. The onset of action with alprazolam was more rapid than that observed with imipramine; antic were more evident with alprazolam during the first week of therapy. A similar incidence of side effects occurre medication, with the main side effects being drowsiness, insomnia, nervousness, constipation and lightheade alprazolam was reported to have less anticholinergic side effects (confusion, tachycardia, palpitations, dry mo

retention). Imipramine was reported to cause fewer headaches than alprazolam. However, a detailed descrip in these patients was not provided in this study. In addition, specific data regarding the onset of effects of eac also not provided satisfactorily. More importantly, the patient population ("primary" depression) is unclear in t difficult to evaluate which types of depression were being treated.

b) Alprazolam was compared with imipramine in a 6-week, double-blind study on 723 outpatients (Feighner, were selected with moderate to severe symptoms of a unipolar major depressive disorder of at least one mor Patients were given imipramine 25 milligrams two or three times daily or alprazolam 0.5 milligram two to thre initially, followed by increases in doses at one-week intervals to a maximum of 4.5 mg alprazolam and 225 m Both drugs were more effective than placebo in alleviating depression, with alprazolam being at least as effec imipramine. Alprazolam was reported more effective in relieving somatic symptoms and the data suggested a effect in some evaluated parameters, but the significance of this is questionable. Toxicity, primarily anticholin was reported in patients receiving imipramine; drowsiness was the main side effect reported with alprazolam. suggests benefits of alprazolam in the treatment of unipolar depression as defined by the Feighner Diagnosti primary depression (similar to the DMS-III Criteria for major depression). However, this study was performed basis, and even the best blinding techniques are useless if patients are taking other medications. The author other psychotropic medications were not to be used except for "emergencies". Evaluation of drug response ir difficult at best, especially on an outpatient basis with several investigators doing the evaluation. Alprazolam antidepressant effects.

c) Alprazolam, imipramine, and a placebo were compared in a 6-week, double-blind study of 175 patients wi depressive disorder (DSM-III) (Rickels et al, 1982a). Patients were randomly assigned to alprazolam (N=58), or placebo (N=57) therapy. Dosage increases were allowed during the course of treatment and the mean dos and imipramine during the last 2 weeks of treatment were 3 milligrams/day and 150 milligrams/day, respectiv indicate that alprazolam was more effective than imipramine and placebo therapy. However it should be note placebo response rate was observed at 2 weeks (53% compared to 75% for alprazolam and 64% for imipram placebo response rate may be attributed to the fact that a high percentage of the patient were of the anxious depression subtypes. (Note: The data supplied in the figure comparing clinical improvement over time on the drug therapy is for 171 different patients, which is interesting since only 153 patients completed at least 4 we No information is supplied regarding the study dropouts other than the fact that the dropout rates were not sig between the 3 treatment groups.) Imipramine therapy was associated with a higher incidence of drowsiness a alprazolam or placebo therapy.

d) The efficacy of alprazolam and imipramine were evaluated in the inpatient treatment of depressive illness 1984). Patients were randomly assigned to either alprazolam or imipramine therapy. Dosage was individualiz response. Patients receiving alprazolam therapy improved over the first 10 days of therapy and then reached whereas the patients treated with imipramine continued to improve in vegetative and cognitive symptomology examination of the HAM-D scale indicated that the initial improvements seen with alprazolam is predominantl vegetative features of the illness.

e) Both drugs administered once daily were efficacious in the treatment of outpatients with major depressive (Mendels & Schless, 1986). Fifty percent of the alprazolam treatment group had a greater than 50% improve D scores, compared to the 38% success rate observed in the imipramine treatment group and 18% in the pla groups.

f) Patients who can be classified as DSM-III - major depressive episode but fail to satisfy more restrictive crit depression disorder appear to respond better to alprazolam therapy than imipramine therapy. Patients satisfy criteria for primary depression also appear to tolerate and respond better to alprazolam therapy initially. How appeared to be more efficacious during long term therapy. In addition, patients with biologic depression (eg, r positive DST, and shortened REM latency) tended to respond better to imipramine therapy (Overall et al, 198

g) An 8-week, double-blind, controlled study compared the efficacy of alprazolam (58 patients), diazepam (5 imipramine (63 patients), and placebo (61 patients) in 241 outpatients with a DSM-III diagnosis of major depr was a washout period with all patients receiving placebo. Week 2 through 7, the patients received their assig and during week 8 the dose of the medication was reduced by half for 3 days and discontinued for the remair end of the study the mean daily doses were 143 milligrams imipramine, 3.1 milligrams alprazolam, 24 milligra 6.8 capsules of placebo. Attrition rates were significant, 23% by week 4 of treatment and 39% by week 6. By the study, 41% of the imipramine group had withdrawn, 23% of the alprazolam group, 44% of the diazepam g the placebo group. The main reason given for attrition was side effects with the active compounds and ineffe placebo. Alprazolam and imipramine were both significantly better than placebo in treating depression, but di effective. The clinical effects of imipramine and alprazolam were equivalent, and overall the frequency of side similar. Imipramine produced less drowsiness and more anticholinergic effects than both alprazolam and diaz al, 1987a).

4.6.B.3 Panic disorder

a) Summary: Alprazolam and imipramine appear to be equally efficacious in the treatment of panic disorder i The onset of action is faster with alprazolam, but by the end of four weeks their effectiveness is similar (Ricke 1998)(Taylor et al, 1990; Rosenberg et al, 1991; Rosenberg et al, 1991a; Anon, 1992; Roth et al, 1992; Schw Pollack et al, 1994). The decision to use imipramine over alprazolam should be based on patient-related cha concurrent depression, anxiety disorders, cardiovascular disease), potential drug interactions, and side effect

b) In a double-blind study, an 8-month therapy period for panic disorder with either alprazolam or imipramine (Rickels & Schweizer, 1998). Patients received alprazolam (n=37), imipramine (n=34), or placebo (n=35) duri period of short-term treatment, a 6- month maintenance period, and then a 15-month follow-up period. Patien alprazolam began at 1 milligram (mg) daily and were titrated up to 10 mg. Those receiving imipramine began

were increased to 250 mg. Alprazolam patients had notable reductions in panic attacks during the first 2 wee
imipramine patients showed improvement over placebo patients after 3 to 4 weeks. Drop-out rates during this
the alprazolam group, 41% in the imipramine group, and 57% in the placebo group (p less than 0.001 for alpr
other groups). In the remaining patients it was noted that tolerance developed to adverse effects during the m
After the 6-month maintenance phase, doses were titrated off over 3 weeks. At this point, 62% of the alprazo
the imipramine groups were panic-free (p less than 0.01). During the follow-up period, patients could be treat
medications. Regardless of medication, patients who completed 8 months of treatment were more likely to be
those who had dropped out, even if they received non-study medications (85% versus 55%, p less than 0.01)
were higher in younger patients, those with a history of more frequent or intense panic attacks, those with a l
score, and those with an initial lower score of inadequacy, low self-confidence, and passivity (Minnesota Mult
Inventory Dependency Scale).

c) Seventy-nine patients were enrolled in a placebo controlled, double-blind trial comparing the efficacy and
effects of imipramine, alprazolam, and placebo in patients with panic disorders (Taylor et al, 1990). Doses ra
alprazolam 1 to 8 milligrams/day and imipramine 30 to 270 milligrams/day. In terms of global improvement, th
with alprazolam or imipramine experienced significantly greater improvement than the placebo patients. Alpra
rapid onset of effect, but after four weeks of therapy no significant differences in efficacy were apparent betw
and imipramine treated patients. Imipramine did have a number of significant effects on the cardiovascular sy
the heart rate was significantly increased at resting and standing, and the systolic and diastolic blood pressur

d) Cerebrospinal fluid levels of homovanillic acid, 5-hydroxyindoleacetic acid, 3-methoxy-4-hydroxyphenylgly
somatostatin and beta-endorphin were measured in 12 patients with panic disorders who had been treated w
imipramine for seven months. Seven patients treated with alprazolam (mean dose 4.7 mg, range 2 to 6 mg) a
therapy. Four of the five imipramine-treated patients (mean dose 135 mg, range 100 to 150 mg) benefited. C
levels of the monoamine metabolites and neuropeptides remained unchanged during therapy in both treatme
were similar to levels measured in a control group, suggesting the antipanic activities of alprazolam and imipr
involve the monoamine or neuropeptide systems as was previously believed (Lepola et al, 1989).

e) A double-blind, placebo-controlled trial comparing the effects of imipramine and alprazolam in patients wit
revealed both agents were significantly more effective than placebo, however the patients treated with alpraz
fear than the patients in the imipramine and placebo groups after eight weeks of therapy (Taylor et al, 1990).

f) The Cross-National Collaborative Panic Study compared alprazolam, imipramine, and placebo in the treat
disorder (Anon, 1992). The study used in this evaluation was a double-blind, placebo-controlled, multicenter s
1168 patients with a diagnosis of panic disorder based on DSM-III criteria. Prior to the start of drug treatment
drugs were discontinued during a one- to two-week washout period. Patients were then randomly assigned to
alprazolam 1 milligram, imipramine 25 milligrams, or placebo (1 tablet). The initial starting dose was increase
alprazolam, 150 mg imipramine, and 6 placebo tablets by day 19. Subsequently the dosage could be adjuste
response. Formal psychotherapy and behavioral treatment sessions were to be avoided during the eight wee
Efficacy was assessed by using global improvement scores, a panic attach scale, phobia scale, frequency of
anxiety, 14-item Hamilton Rating Scale for Anxiety, 21-item Hamilton Rating scale for Depression, and Hopki
self-rating scale. The treatment-cohort (anyone completing three weeks of therapy) consisted of 1010 patient
completed the entire eight-week study. Reasons for dropping-out were side effects (alprazolam 3.4%, imipra
placebo 3.1%), lack of efficacy (alprazolam 3.1%, imipramine 2.6%, and placebo 12.8%), treatment refusal (1
reasons (alprazolam 7%, imipramine 7.7%, and placebo 11.8%); percentage are expressed as the number o
divided by number of patients enrolled in that treatment group. Onset of therapeutic benefits was noted by we
alprazolam and week 4 with imipramine. By week 8 there was no difference between the alprazolam and imip
and both groups were statistically superior to placebo.

g) Alprazolam was more effective than imipramine and placebo on anticipatory anxiety and phobic symptom
Scandinavian multicenter study in 41 patients with panic disorder (Andersch et al, 1991). Alprazolam had a m
action than imipramine on all symptoms. Patients receiving alprazolam had more drowsiness and those recei
had more anticholinergic effects.

h) In a study of 123 Scandinavian patients with panic disorder, alprazolam had an early effect on variables re
attacks, such as severity of spontaneous attacks and avoidance, whereas imipramine showed a more delaye
measures (Mellergard et al, 1991).

i) Patients with mild-to-moderate depression and panic disorder will respond equally to either alprazolam (av
milligrams/day) or imipramine (avg dose = 159 milligrams/day) therapy. Both drugs are more effective than pl
treatment of patients with mild-to-moderate depression and panic disorder (Keller et al, 1993).

4.6.C Amineptine

4.6.C.1 Depression

a) A controlled, double-blind study compared the efficacy and safety of amineptine (100 to 200 milligrams (m
imipramine (50 to 100 mg/day) for two months in 33 patients who fulfilled the Diagnostic and Statistical Manu
(DSM-III) criteria for major depressive disorders. Amineptine produced steady improvement of the symptoms
during treatment, according to the Hamilton (p = 0.001) and Montgomery and Asberg (p = 0.002) Depression
Clinical Global Impression Scale (p = 0.002). Imipramine produced a significant improvement in the overall sc
less than 0.001). No statistical differences were found between the two drugs; depressive symptoms improve
of treatment for both amineptine and imipramine. The incidence of anticholinergic adverse effects with amine
lower than with imipramine (Mendis et al, 1989).

4.6.D Amisulpride

4.6.D.1 Dysthymia

a) A double-blind, parallel group study compared the efficacy of amisulpride 50 milligrams (mg) daily versus mg daily and placebo in the treatment of dysthymia. No significant difference was found between the two dru whereas amisulpride showed a tendency to generate fewer adverse effects (Lecrubier et al, 1992).

b) A double-blind study, six months in duration, compared the therapeutic effects of amisulpride (50 milligran imipramine (200 mg daily) and placebo (Boyer & Lecrubier, 1996). The active drugs differed significantly from according to the Clinical Global Impression scale (CGI), Montgomery and Asberg Depressive Rating Scale (M Scale for the Assessment of Negative Symptoms (SANS) global score. Difference in efficacy between the act minimal.

4.6.E Amitriptyline

4.6.E.1 Depression

a) Of 11 studies in which amitriptyline and imipramine were directly compared, 5 reported amitriptyline super imipramine superior and 4 reported no difference between the 2 drugs in efficacy (Hutchinson & Smedberg, 1 1966; Snow & Rickels, 1964; Sandifer et al, 1965; Richmond & Roberts, 1964; Hordern, 1963; Burt, 1962).

b) In another study, imipramine (mean 157 milligrams/day) was compared with amitriptyline (mean 186 millig post-psychotic depressed patients who were also receiving one of several neuroleptics (mean chlorpromazin 795 milligrams/day). Thirteen of 14 patients on imipramine improved, while 8 of 11 on amitriptyline improved

4.6.F Amoxapine

4.6.F.1 Depression

a) SUMMARY: Clinical studies have demonstrated that amoxapine is at least as effective as imipramine in th depression (Sathananthan et al, 1973b; Gelenberg et al, 1984; Wilson et al, 1977; Fabre, 1977; Holden et al, Okerson, 1979; Bagadia et al, 1979; Takahashi et al, 1979; Dominguez et al, 1981; Rickels et al, 1981). Side are comparable in type, frequency, and intensity to imipramine (Dugas & Weber, 1982; Kinney & Evans, 198

b) Maprotiline (mean, 165 mg daily) and amoxapine (mean, 230 mg daily) showed similar efficacy in the trea moderate-to-severe depression in a 4-week, double-blind study involving 76 outpatients. Amoxapine is report rapid onset of action than maprotiline as evidenced by a greater improvement at days 4 and 7 (Fabre, 1985).

c) Equivalent doses of amoxapine and imipramine were equally effective in depressed outpatients during 5- blind clinical trials (Rickels et al, 1981; Gelenberg et al, 1984). Amoxapine produced improvement in a 6-wee study involving 90 depressed outpatients more rapidly than did imipramine; however, the dose of amoxapine milligrams/day) was double that of imipramine (105 milligrams/day) (Kiev & Okerson, 1979).

d) Imipramine and amoxapine were comparable in the treatment of depression in inpatients in a controlled st mean doses of 165 milligrams daily was reported comparable with imipramine 175 milligrams daily in manage depressive illness; however, the imipramine-treated patients had slightly more cardiovascular side effects. An patients reportedly had slightly more neurological toxicity (Ahlfors, 1981).

e) Amoxapine and imipramine were comparable in 90 adult outpatients with mixed depressive illnesses in a controlled, double-blind study. Patients received amoxapine 145 to 265 milligrams daily (mean 235 mg) or im milligrams daily (mean 122.5 mg). Amoxapine and imipramine were both significantly superior to placebo as the Hamilton Rating Scale for depression, Zung Self- Rating Scale, and Clinical Global Impression Scale sco there were no significant differences between the 2 drugs (Fabre, 1977).

4.6.F.2 Efficacy

a) Continuous Performance Test (CPT), a visual vigilance test, of amoxapine and imipramine show several d performance and brain function (Buchsbaum et al, 1988). Amoxapine enhanced N120 amplitude in midline pa parietal cortex. Both amoxapine and imipramine enhanced the P200 area, with amoxapine's greatest effect b midline parietal locations. The clinical importance of these differences in brain activity remains to be determin

4.6.G Binedaline

4.6.G.1 Depression

a) Binedaline, a bicyclic antidepressant, was evaluated against imipramine therapy in the treatment of 50 hos endogenously depressed patients (Faltus & Geerling, 1984). Patients were either treated with 150 mg/d of im mg/d of binedaline in 3 equally divided doses. There was no psychiatric, clinical or statistical differences betw treatment groups. Binedaline efficacy was slightly higher than imipramine utilizing the clinical global impressio Frequency of side effects was less in the binedaline treatment group.

4.6.H Brofaromine

4.6.H.1 Depression

a) Brofaromine is a selective and reversible monoamine oxidase inhibitor (MAOI). In addition, the drug may b inhibitor. A comparison of brofaromine with imipramine was made in 216 outpatients with depression. Patient assigned to brofaromine and imipramine therapy in a 2:1 ratio. Both medications were started at a daily dose milligrams. The average dose of medication at the end of eight weeks was brofaromine 93.1 mg/day and imip mg/day. This phase of the study lasted eight weeks. Baseline HAMD scores were 29.4 in the brofaromine gro imipramine group. At the end of the study period the HAMD scores were 9.34 and 12.31 (p=0.01), respective

of adverse reactions was 27.8% in the brofaromine group (eg, headache, sleep disturbances, palpitation, nau the imipramine group (eg, dryness of mouth accommodation disturbances, impaired vision, and sweating). Du phases of the study only those patients receiving brofaromine were followed for up to 52 weeks. The lower H continued to be maintained, with the exception of a slight increase between weeks 28 to 36, and the drug wa (Moller & Volz, 1992).

4.6.I Bromocriptine

4.6.I.1 Depression

a) No significant differences were observed in 33 outpatients with endogenous depression treated with eithe imipramine. Sixteen patients received bromocriptine 10 to 60 milligrams (mg)/day (mean, 34 mg/day) and sev received imipramine 75 to 250 mg/day (mean, 143 mg/day) for a period of 6 weeks. Based on the Hamilton ra total score of the bromocriptine-treated patients decreased from 19.9 to 7.8 and the imipramine-treated patie 20.1 to 6.1. Side effects associated with bromocriptine included nausea, dizziness and headache and those s imipramine included dryness of mouth, dizziness, and sweating. Although bromocriptine has an antidepressa on anxiety, agitation, and insomnia are less pronounced than that of imipramine (Waehrens & Gerlach, 1981)

b) Bromocriptine (15 milligrams (mg) daily) was as effective as imipramine (75 mg/day daily) in a 10-week, d in patients with endogenous depression. However, only 9 patients were evaluated and more studies are nece definite effects of the drug (Bouras & Bridges, 1982).

4.6.J Bupropion

4.6.J.1 Depression

a) A meta-analysis of published studies between 1980 and 1990 comparing imipramine and bupropion in the major depression indicates that both medications are equally effective (Workman & Short, 1993).

b) Bupropion and imipramine were equally efficacious in a double-blind, 5-week, multicenter trial in 63 elderl patients (Branconnier et al, 1983a). Patients were given either bupropion 150 milligrams/day (18 patients), bu 450 milligrams/day (18 patients), imipramine 150 milligrams/day or less (18 patients), or placebo (9 patients). treatment efficacy utilized depression and anxiety scales. All 3 drug treatment groups were more effective tha 7 to 35.

4.6.J.2 Adverse Effects

a) Bupropion may be safer than imipramine in treating depressed patients with congestive heart failure (Roo The cardiovascular effects of imipramine and bupropion were compared in 10 depressed patients with conge Neither drug had an effect on left ventricular ejection fraction or left ventricular function. Hypotension, severe discontinuation, was a problem in 50% of the imipramine patients but did not occur with bupropion.

4.6.K Buspirone

Depression

Panic disorder

4.6.K.1 Depression

a) Imipramine was more effective than placebo (p less than 0.01) while buspirone trended towards being mo placebo (p less than 0.1) for the treatment of major depression in elderly outpatients. The 8-week, randomize placebo-controlled study involved 177 patients aged 65 years and over. Beginning dosages were imipramine twice daily or buspirone 10 mg twice daily, increased to imipramine 25 mg three times daily and buspirone 10 daily after one week. If tolerated after the second week, imipramine was increased to 100 mg/day and buspir in divided doses. A daily maximum dose of 150 mg of imipramine and 60 mg of buspirone could be reached b response, with the mean optimal dose of 89 mg/day for imipramine and 38 mg/day for buspirone. Following 8 treatment, moderate to marked global improvement occurred in 61% of buspirone patients, 70% of imipramin 42% of placebo patients (Schweizer et al, 1998).

4.6.K.2 Panic disorder

a) A placebo-controlled, double-blind study of outpatients with panic disorder or agoraphobia with panic attac any significant differences in total biweekly numbers of panic attacks, decreases in number of attacks, and ev psychopathology and of global improvement over an eight-week period between patients treated with buspirc placebo. All groups improved. The inconclusive results may have been due to a number of factors, including sizes, the episodic nature of the illness, a possible therapeutic effect of the diagnosis for the subjects (many c diagnosed for the first time during the study), and the limited study duration (Pohl et al, 1989). Somewhat bet seen for both active treatments in a study using higher doses (Robinson et al, 1988).

4.6.L Butylscopolamine

4.6.L.1 Nocturnal enuresis

a) Imipramine was significantly superior to butylscopolamine, which was no better than placebo in 14 childre enuresis (Korczyn & Kish, 1979). Imipramine 10 or 20 milligrams was compared to butylscopolamine 10 or 2(investigators concluded that antimuscarinic activity is not sufficient to inhibit detrusor contraction and that ora is not absorbed to any significant extent.

4.6.M Chlordiazepoxide

4.6.M.1 Depression

a) Imipramine was more effective and better tolerated at assessments made at 4 weeks, 6 weeks, and 8 wee with primary depression who completed a double-blind comparison of imipramine, chlordiazepoxide, and plac 1986). At the end of 2 weeks of therapy the therapeutic advantages associated with imipramine therapy were apparent. By weeks 6 and 8, the imipramine- treated group had a marked superior therapeutic advantage in i symptoms of depression, anxiety, anger-hostility, interpersonal sensitivity, and global improvement. Chlordiaz an advantage in patients with sleep difficulties, but these patients did significantly worse on anger-hostility an sensitivity.

4.6.N Chlorprothixene

4.6.N.1 Depression

a) Imipramine 75 to 225 milligrams/day and chlorprothixene 45 to 135 milligrams/day had comparable efficac double-blind, randomized, crossover study involving 32 patients with depressive disorders. The investigators both drugs were equally efficacious and safe, although the side effect profiles varied (Lodge-Patch et al, 196

4.6.O Citalopram

4.6.O.1 Depression

a) Unpublished studies involving small numbers of patients suggest the comparable efficacy of imipramine a depression, although imipramine has tended to be more effective in improving sleep disturbances (Milne & G well-controlled comparisons of these agents are needed.

4.6.P Clomipramine

Depression

Obsessive-compulsive disorder

4.6.P.1 Depression

a) Clomipramine was as effective as imipramine in treating depression in 24 patients during a 44-day, rando blind study (McClure et al, 1973). The patients were diagnosed with psychotic depression independently by 2 imipramine or oral clomipramine was administered 3 times daily in 50 milligrams doses. Throughout the study assessments using the Hamilton Depression Rating Scale and the Beck Depression Inventory demonstrated reduction in depression from baseline for both drugs; however, a significant difference in antidepressant effec could not be seen. Minor and transient anticholinergic adverse effects were noted in all patients and included mouth, increased sweating, hand tremor, and dizziness. Three patients dropped out of the study, but none of adverse effects.

4.6.P.2 Obsessive-compulsive disorder

a) SUMMARY: Clomipramine is superior to imipramine in the treatment of obsessive-compulsive disorder.

b) Oral clomipramine was slightly superior to oral imipramine in improving symptoms of obsessive-compulsiv (Volavka et al, 1985). A 12-week, double-blind study of 23 patients according to DSM-III with secondary depr was conducted to compare the 2 drugs. Both drugs were started at 50 milligrams/day; this was gradually incr mg/day as tolerated. Seven patients did not complete the study: 4 because of adverse effects (2 from each g of unsatisfactory therapeutic response with imipramine, and 1 for no apparent reason. Both drugs produced i depressive symptoms; however, only clomipramine demonstrated improvement in obsessive symptoms wher baseline. Typical anticholinergic adverse effects were experienced by both treatment groups with no significa between the two. It is difficult to accurately evaluate the clinical response in this study because of the small n and the methods used for statistical analysis.

c) Both oral clomipramine and oral imipramine were effective in improving symptoms in obsessive-compulsiv who met DSM-III criteria (Mavissakalian et al, 1985). The study was a 12-week, double-blind trial that compar clomipramine and imipramine in treating obsessive-compulsive disorders. Both drugs were begun at 25 to 50 this was increased to 300 mg/day as tolerated. At the end of the trial, the mean daily dose of both drugs was clomipramine-treated patients and 2 of 5 imipramine-treated patients were classified as responders. For both improvement in depression was evident at 4 weeks, while maximal improvement in obsessive-compulsive sy seen until 8 weeks. The responders also had higher pretreatment depression scores than did nonresponders corresponded with the results of another study (Marks et al, 1980). Because of the small sample size, differe

efficacy between clomipramine and imipramine could not be determined.
d) The relationship between the antiobsessional and antidepressant effects of tricyclic drugs was studied in p
compulsive disorder. Study 1 consisted of a controlled 12-week trial with clomipramine (n=7) and placebo (n=
analyzed the pooled data from 15 uniformly selected patients who were treated with either clomipramine or in

antiobsessional effects. Clomipramine, and probably imipramine, possess specific antiobsessive effects that
partially independent of the antidepressant effects (Mavissakalian et al, 1985).

4.6.Q Clonazepam

4.6.Q.1 Panic disorder
a) Preliminary results from an ongoing double blind study comparing imipramine and clonazepam in the treat
disorders in twelve patients have been reported (Svebak et al, 1990). Six patients received imipramine and si
clonazepam, and all were treated for a total of six months. Clonazepam treated patients required an average
(range 1 to 3 mg/day) to achieve relief of symptoms; imipramine patients required 62.5 mg/day) (range 25 to
During the final four months of the study no patients required more than 2 mg/day of clonazepam or 50 mg/da
Over the course of the first two weeks of treatment a substantial drop in the incidence of panic attacks occurr
Mean scores in global improvement were significantly improved in both groups, as were patients assessed sc
physician assessed scores. These early results demonstrate the efficacy of both imipramine and clonazepam
panic disorders.

4.6.R Delorazepam

4.6.R.1 Anxiety
a) Delorazepam 3 to 6 milligrams (mg) was compared to imipramine 50 to 100 mg/day and paroxetine 20 mg
weeks in 81 patients with generalized anxiety disorders according to DSM-IV criteria. Delorazepam produced
improvement in anxiety ratings during the first two weeks of treatment, but both paroxetine and imipramine w
by the fourth week of treatment. At study end, reduction of at least 50% in the Hamilton Rating Scale for Anxi
reported in 55% of the delorazepam patients, compared with 68% and 72% for paroxetine and imipramine, re
Delorazepam affects predominantly somatic symptoms, whereas paroxetine and imipramine affect psychic sy
al, 1997a).

4.6.S Desipramine

4.6.S.1 Depression
a) Desipramine has been evaluated in comparison with imipramine with most open or double-blind trials indi
drugs are equally effective with similar time of onset and side effects and that no significant differences or ad
apparent with either drug (Rose & Westhead, 1964; Waldron & Bates, 1965; Lafave et al, 1965; St Jean et al
& Maxwell, 1967; Rose & Westhead, 1967). However, other limited data indicates that imipramine may be su
being more active (Edwards, 1965; Heller et al, 1971) or, conversely, that desipramine has the advantage of
and earlier clinical response (Agin et al, 1965).

4.6.T Desmopressin

4.6.T.1 Nocturnal enuresis
a) Patients treated with oral imipramine followed by intranasal desmopressin therapy (n=28) experienced ad
compared to those who received desmopressin followed by imipramine (n=29) in an open label, cross-over st
with nocturnal enuresis (Vertucci et al, 1997). Following a 2 week observation period, patients were randomiz
either desmopressin 30 micrograms per day (mcg/day) (3 puffs per nostril) for 3 weeks followed by oral imipra
milligrams per kilogram (mg/kg) for 3 weeks followed by 2 more weeks of follow up, or imipramine therapy firs
desmopressin. Both patient groups experienced significant reductions in the number of wet nights in the first
compared to the first observation period (p value not specified). Irrespective of which agent was administered
desmopressin therapy significantly increased the number of dry nights per week compared to imipramine (p l
Overall, desmopressin was associated with 20% wet nights while imipramine was associated with 37% wet n
up, patient who received desmopressin last had fewer weekly wet nights than those who received imipramine
suggest the results of this study indicate desmopressin is long acting and is safe for long-term treatment of n
Both agents were well tolerated with few adverse events reported. One imipramine patient experienced pallo
and cold extremities. One desmopressin patient reported inflammation of nasal mucosal.

4.6.U Diazepam

4.6.U.1 Depression
a) An 8-week, double-blind, controlled study compared the efficacy of alprazolam (58 patients), diazepam (5
imipramine (63 patients), and placebo (61 patients) in 241 outpatients with a DSM-III diagnosis of major depr
was a washout period with all patients receiving placebo. Week 2 through 7, the patients received their assig
and during week 8 the dose of the medication was reduced by half for 3 days and discontinued for the remair
end of the study the mean daily doses were 143 mg imipramine, 3.1 mg alprazolam, 24 mg diazepam, and 6.
placebo. Attrition rates were significant, 23% by week 4 of treatment and 39% by week 6. By the completion

of the imipramine group had withdrawn, 23% of the alprazolam group, 44% of the diazepam group, and 40%
group. The main reason given for attrition was side effects with the active compounds and ineffectiveness wit

The clinical effects of imipramine and alprazolam were equivalent, and overall the frequency of side effects w
Imipramine produced less drowsiness and more anticholinergic effects than both alprazolam and diazepam (
1987).

4.6.V Dibenzepin

4.6.V.1 Depression

a) Dibenzepin and imipramine are both well tolerated and equally effective in the treatment of depression. In
comparative trial, depressed patients (n=22) were administered either dibenzepin (160 milligrams (mg) three
imipramine (50 mg three times daily) for 4 weeks. Both drugs were effective and no significant differences we
patients taking dibenzepin and those taking imipramine (Fielding, 1969).

4.6.W Diclofenac

Cancer pain

Depression

4.6.W.1 Cancer pain

a) In a 1-week study, diclofenac plus placebo was as effective as diclofenac plus imipramine or diclofenac pl
cancer pain. This double-blind study enrolled 180 patients who were randomly assigned to receive diclofenac
(mg) 4 times daily with placebo, diclofenac with imipramine 10 or 25 mg 3 times daily (determined by patient
greater than 65 years), or diclofenac with codeine 40 mg 4 times daily. Efficacy was assessed at baseline an
100 millimeter(mm) visual analogue scale (VAS) (0=no pain; 100=worst possible pain); patients with acceptal
continued treatment for the remainder of the study. Significant differences were NOT detected between the 3
Results of this study are limited by the short duration of treatment which may have been insufficient to detect
of imipramine, lack of dose titration for codeine, concomitant use of morphine in 30 patients, and inclusion of
different cancer pain etiologies. Additional studies which address the limitations of this study are needed (Mir

4.6.W.2 Depression

a) Diclofensine is a isoquinoline derivative, structurally similar to nomifensine, that is a potent inhibitor of 5-hy
dopamine, and norepinephrine reuptake (Capponi et al, 1985). In a double-blind comparison with imipramine
dose = 65 milligrams/day) and high dose (average dose = 97.6 milligrams/day) diclofensine therapy was sho
effective as imipramine therapy (average dose = 102.9 milligrams/day) during the 6-week study period. Durin
weeks of therapy diclofensine therapy was more effective, but by the completion of the 6-week study period t
difference between the treatment groups. Whether or not a difference in onset of action would have been obs
initial doses of imipramine were used is unknown. Diclofensine therapy was better tolerated than the imipram
even if higher doses of imipramine were used it would have resulted in an even higher incidence of side effec

4.6.X Dothiepin

4.6.X.1 Depression

a) Dothiepin and imipramine appear to be equally efficacious in the treatment of depression. In a double-blin
patients with existing depression received either dothiepin or imipramine. Therapy was initiated with 25 milligi
which was increased to a maximum of 250 milligrams/day based on clinical response. Although both dothiepi
groups showed similar improvement, dothiepin was associated with fewer adverse effects, including dry mou
(Eilenberg, 1980). Similar results were seen in another study (Sheth et al, 1979).

4.6.Y Doxepin

4.6.Y.1 Depression

a) Imipramine may be slightly more effective than doxepin in the treatment of depression. Ninety-nine patien
depression received imipramine 100 to 200 milligrams/day or doxepin 100 to 200 milligrams/day for 4 weeks
study. Imipramine was superior in 24 of 27 parameters. Imipramine was shown to be superior to doxepin in ir
symptoms of anxiety/depression; global evaluations showed improvement in 39 of 48 (81%) of imipramine pa
49 (69%) of doxepin patients (Finnerty et al, 1978).
b) In a study involving 79 patients, a higher socioeconomic status and shorter duration of illness were indicat
response to imipramine, whereas a higher response rate to doxepin was found in male patients (Finnerty & G
c) Amitriptyline was superior to imipramine and doxepin in relation to their effects on interpersonal learning ir
inpatients (Gillis, 1981). All subjects performed better, according to quantitative indices of learning tasks, thar
received antipsychotic or neuroleptic drugs but no antidepressants. Amitriptyline patients scored significantly
imipramine or doxepin patients.

d) No significant differences in overall efficacy of the 2 drugs was reported in one study (Kimura, 1972), but
mg daily was superior to imipramine 150 mg daily in neurotic depression, whereas imipramine appeared to b
doxepin in endogenous depression (Pinder et al, 1977a).
e) Similar antidepressant effects of doxepin and imipramine were reported; however, imipramine had a more
action. Doxepin appeared to have more sustained effects (Hasan & Akhtar, 1971).

4.6.Y.2 Efficacy

a) In elderly patients doxepin produces less orthostatic effects than imipramine (10.5 mmHg vs 25.9 mmHg).
effect observed with imipramine was weakly related to dose and did not correlate with pretreatment orthostati
with duration of treatment (Neshkes et al, 1985).

4.6.Z Electroconvulsive therapy

4.6.Z.1 Depression

a) A double-blind, randomized, controlled trial compared electroconvulsive therapy (ECT) with imipramine th
patients suffering from depression (Gangadhar et al, 1982). Group I received modified bilateral ECT using thi
250 mg, succinylcholine 20 to 30 mg, and atropine 0.65 mg during the procedure. ECT was administered eve
during the first 2 weeks for a total of 6 treatments and then once a week for the next 2 weeks. Following this
maintenance ECTs were administered in the next 8 weeks. During the course of this treatment the patients re
identical to the imipramine group. Group II received imipramine 75 milligrams/day during week one and 150 r
second through the eleventh week. The dose was reduced to 75 mg/day during the twelfth week. During the
each patient received a simulated course of ECT therapy at the same frequency as the ECT-treated group. T
patients completed the study period (5 patients in the ECT group and 3 patients in the imipramine group were
the study during the first 6 weeks). Both treatments produced equally significant improvement which was mai
6-month follow-up period. The rate of improvement was quicker in those patients receiving ECT therapy. ECT
fewer side effects than imipramine therapy. There was no lasting organic brain dysfunction associated with th
previously thought.

4.6.AA Encainide

4.6.AA.1 Cardiac dysrhythmia - Myocardial infarction with complication, Post

a) Encainide and flecainide were more effective in suppressing ventricular arrhythmias than moricizine, imipr
placebo during the dose titration phase of a 1-year, multicenter, randomized, double-blind, placebo-controllec
patients (Anon, 1988a). Patients were eligible for this study if they had an acute myocardial infarction within 6
entrance to the study, were less than 75 years of age and demonstrated either an average of 10 or more ven
complexes (VPCs) per hour, or 5 or more episodes of unsustained ventricular tachycardia during a 24-hour a
recording. The total daily doses of the study drugs were encainide 105 to 180 milligrams, flecainide 200 to 40
150 to 375 milligrams, and moricizine 600 to 900 mg. Efficacy was defined as 70% or more suppression in VI
more than 90% suppression of runs of VPC when compared with baseline. The efficacy rates were 83% for fl
encainide, 66% for moricizine, 52% for imipramine, and 37% for placebo during the dose titration phase of th
incidence of adverse effects was 49% for encainide, 55% for flecainide, 67% for imipramine, 64% for moricizi
placebo. Imipramine was the drug most associated with patient withdrawal due to adverse effects. This study
VPC suppression efficacy at the 1-year follow-up.

4.6.AB Flecainide

4.6.AB.1 Cardiac dysrhythmia - Myocardial infarction with complication, Post

a) Encainide and flecainide were more effective in suppressing ventricular arrhythmias than moricizine, imipr
placebo during the dose titration phase of a 1-year, multicenter, randomized, double-blind, placebo-controllec
patients (Anon, 1988). Patients were eligible for this study if they had an acute myocardial infarction within 6
entrance to the study, were less than 75 years of age and demonstrated either an average of 10 or more ven
complexes (VPCs) per hour, or 5 or more episodes of unsustained ventricular tachycardia during a 24-hour a
recording. The total daily doses of the study drugs were encainide 105 to 180 milligrams, flecainide 200 to 40
150 to 375 milligrams, and moricizine 600 to 900 mg. Efficacy was defined as 70% or more suppression in VI
more than 90% suppression of runs of VPC when compared with baseline. The efficacy rates were 83% for fl
encainide, 66% for moricizine, 52% for imipramine, and 37% for placebo during the dose titration phase of th
incidence of adverse effects was 49% for encainide, 55% for flecainide, 67% for imipramine, 64% for moricizi
placebo. Imipramine was the drug most associated with patient withdrawal due to adverse effects. This study
VPC suppression efficacy at the 1-year follow-up.

4.6.AC Fluoxetine

4.6.AC.1 Depression

a) SUMMARY: Fluoxetine has been as effective as imipramine in the treatment of depression, while producii
incidence of side effects. Overall cost of therapy, clinical efficacy, and patient quality of life have been shown
after six months of treatment.
b) In a double-blind, randomized, parallel group study, fluoxetine was better tolerated although not more effe
imipramine in the treatment of major depression with atypical features. A total of 154 patients (age 18 to 65 y
DSM-IV criteria for major depression for at least 1 month and also met the Columbia criteria for atypical depre

randomized to receive fluoxetine, imipramine, or placebo for 10 weeks. Fluoxetine was administered as 20 m for 4 weeks, 40 mg daily for week 5, and 60 mg daily for the remaining weeks. Imipramine was administered the first week, increasing by 50 mg/day each week until a maximum of 300 mg daily was reached. Mean daily of the study were 51.4 mg/day for fluoxetine and 204.9 mg/day for imipramine. Fluoxetine and imipramine did one another based on the Clinical Global Impression (CGI) scale improvement scores following 10 weeks of t Fluoxetine and imipramine were significantly more effective than placebo in the intention-to-treat (p less than respectively) and completer groups (p less than 0.03 and 0.001, respectively). Imipramine-treated patients de significantly higher dropout rate than fluoxetine-treated patients (p=0.04). In the intention-to-treat group, depr measures including the 17-item and 28-item Hamilton Depression Rating Scale and Patient Global Improvem no differences between fluoxetine and imipramine and a consistent clinical benefit of both treatment groups c placebo. Adverse effects significantly more common for imipramine than for fluoxetine included dry mouth (8 respectively), somnolence (42% versus 24%, respectively), and dizziness (44% versus 25%, respectively); co pain occurred at a significantly higher incidence in fluoxetine- versus imipramine-treated patients (McGrath et

c) For the initial treatment of depression, imipramine and fluoxetine are equivalent in terms of overall treatme and quality of life. In a randomized, controlled trial, patients with newly diagnosed depression (n=536) were p fluoxetine or a tricyclic antidepressant (imipramine or desipramine) and assessed at 1, 3, and 6 months for bo antidepressant regimen as measured by the Hamilton Depression Rating Scale and the Hopkins Symptom C of life. Drug cost and total health care costs were also measured. Clinical efficacy and quality of life were sim two groups; however, patients treated with fluoxetine had fewer adverse effects, were less likely to require a medication, and had less outpatients visits. Although drug costs were higher, total treatment costs were sligh fluoxetine group; however, this difference was not statistically significant (Simon et al, 1996).

d) Controlled studies have demonstrated that oral fluoxetine in doses of 40 to 80 milligrams daily is as effect 150 to 250 milligrams daily in the treatment of major depression (Cohn & Wilcox, 1985; Stark & Hardison, 198 1987a). Fluoxetine was as effective as imipramine doses of 150 to 300 milligrams/day (Byerly et al, 1988). He report (Bremner, 1984), fluoxetine was reported superior to imipramine in several depression scales in a 5-we study involving 40 depressed outpatients. In all studies, the incidence of side effects (anticholinergic effects, drowsiness, dry mouth, cardiovascular effects) was less with fluoxetine as compared with imipramine; fluoxet associated with a greater incidence of anxiety or nervousness, insomnia, and excessive sweating. In another sweating (as well as nausea) was higher with fluoxetine than imipramine (Stark & Hardison, 1985). Of signific has occurred during fluoxetine therapy, as compared to generally no change in body weight or increases in w imipramine. The onset of antidepressant action of each drug has been similar, generally within one week.

e) Imipramine and fluoxetine had similar efficacy in multicenter, double-blind, placebo-controlled, outpatient s the treatment of major depressive disorder (Stark & Hardison, 1985). Five hundred forty patients were randor receive either fluoxetine 60 to 80 milligrams daily, imipramine 150 to 300 milligrams daily (the majority of pati Patients were treated for up to 6 weeks in double-blind fashion. Imipramine and fluoxetine were both superior measures (Hamilton Psychiatric Rating Scale for Depression total, Raskin Severity of Depression Scale, Clin Impressions Severity of Illness Scale, Global Improvement and secondary symptom measures). Fluoxetine a were similarly effective on all general measures of improvement. Anorexia and nausea occurred to a significa in fluoxetine-treated patients; constipation, dizziness, drowsiness, dry mouth, somatosensory disturbances, a sweating were reported more frequently with imipramine.

f) The efficacy and safety of fluoxetine and imipramine was compared in 40 depressed outpatients in a doub parallel trial (Bremner, 1984). Fluoxetine was given in doses increasing from 20 to 40 milligrams daily, then to daily, during the first week; imipramine doses were increased from 75 to 100 milligrams daily, then to 125 mil During the second and third weeks, the maintenance dose of each drug was determined, with fluoxetine bein up to 80 milligrams daily and imipramine up to 300 milligrams daily. During the fourth and fifth weeks of the st maintenance dose was achieved; the maintenance dose for most fluoxetine patients was 60 milligrams daily, milligrams daily for imipramine. Fluoxetine was reported superior to imipramine in the total Hamilton Psychiat Depression, as well as the HAM-D scales for anxiety/somatization, retardation and sleep disturbance. Fluoxe reported more beneficial than imipramine in the Raskin Severity of Depression Scale and Covi Anxiety Scale. HAM-D total score, and the Raskin and Covi scales, fluoxetine was statistically superior to imipramine only du of the study (week 5). The Clinical Global Impressions demonstrated the superiority of fluoxetine over imipran depression but not global improvement. Weight loss (average, 3.8 pounds) occurred with fluoxetine during tre increase in weight being seen with imipramine (average, 0.7 pounds). Heart rate increased significantly with i compared to slight decreases with fluoxetine. Blood pressure decreased with fluoxetine as compared with inc imipramine, and fluoxetine was associated with a lesser degree of gastrointestinal disturbances, dizziness, an mouth occurred in one of 20 fluoxetine patients and in 9 of 20 imipramine-treated patients, with nervousness fluoxetine-treated patients and in two imipramine-treated patients.

4.6.AD Fluvoxamine

4.6.AD.1 Depression

a) SUMMARY: Fluvoxamine and imipramine appear to be equally efficacious in the treatment of depression 1987; Guelfi et al, 1983; Guy et al, 1984; Itil et al, 1983); (March, 1990)(Lydiard et al, 1989).

b) Fluvoxamine demonstrated a trend toward superiority over imipramine in treating 63 patients with major d 4- to 6-week, randomized, placebo-controlled, double-blind study (Lapierre et al, 1987). All drugs were starte milligrams/day, and were gradually increased to a maximum of 300 mg/day. The mean daily dose of fluvoxam of the study was 207 mg, and 192 mg for imipramine. At the end of the study, the total Hamilton Rating Scale (HAM-D) score had decreased by 75%, 55%, and 6% in the fluvoxamine-, imipramine-, and placebo-treated g

respectively. At the end of the study there were 8, 3, and 1 responders from the fluvoxamine, imipramine, and
respectively. Only 1 patient in each active treatment group withdrew from the study because of adverse effec
c) Fluvoxamine was comparable to imipramine in antidepressant activity during a 4-week, double-blind, mult
151 patients (Guelfi et al, 1983). Drug therapy was administered in twice daily dosing in the range of 100 to 3
for fluvoxamine and 50 to 200 milligrams daily for imipramine. At the end of the study there was a mean impr
Hamilton Rating Scale for Depression (HAM-D) of 67.2% in the fluvoxamine-treated group and a 62.1% impr
imipramine-treated group. A similar improvement was detected with both drugs on the Clinical Global Impress
end of the study, the mean daily dose of fluvoxamine was 221 mg and 112 mg for imipramine. A total of 37 pa
from the study prematurely; 19 on fluvoxamine and 18 on imipramine. The reasons for early withdrawal appe
between both drugs.
d) Fluvoxamine and imipramine were comparable in efficacy for the treatment of depression in 36 patients di
unipolar or bipolar depression during a 4- to 6-week, randomized, double-blind study (Guy et al, 1984). Both
administered at bedtime with a maximal dosage range between 150 to 225 milligrams/day. In the unipolar de
fluvoxamine-treated patients, 92% were judged "improved" at the end of the study compared to 81% of the im
However, the imipramine-treated group appeared to have a higher percent of patients rated as "much" or "ve
improved, 75% compared to 54% of the fluvoxamine group.
e) A double-blind comparative study of fluvoxamine and imipramine was carried out in 20 outpatients with de
Patients received randomly-assigned medication over a 4-week period in a dosage range of 50 of 300 mg giv
doses. There was a significant symptom severity reduction in both groups at the end of 4 weeks, and fluvoxa
effective than imipramine in reducing suicidal ideas and anxiety/somatic symptoms. Anticholinergic-type adve
predominated for imipramine and gastrointestinal effects for fluvoxamine (Gonella et al, 1990).
f) In a 6-week, double-blind, placebo-controlled, variable-dose study assessing the comparative antidepressa
fluvoxamine (FLU), imipramine (IMI), and placebo (PBO), 45 patients with major depressive disorder were ev
response and side effects. Dosage ranged between 100 to 300 milligrams/day for active medications. No stat
differences between either the FLU (N=17) and PBO or the FLU and IMI groups were found. Side effects wer
three groups: IMI(N=18): constipation (83%), dry mouth (55%), and sweating, dizziness, and nausea, all 39%
diarrhea, headache, dry mouth, all 41%, nausea (35%), and flatus (29%). PBO(N=18): pruritus (29%, nausea
(18%), asthenia and somnolence, both 12%. This study revealed a high placebo response, with a 50% impro
Thus, it is difficult to show differences from active medication unless the study is carried out for a longer time.
numbers of patients are too small to detect a true difference. Second, patients seemed to either respond or n
while the response to IMI appeared to be more graded. This may reflect a subgroup of depressed patients th
serotonin-deficient type of depression (Lydiard et al, 1989).
g) Other double-blind, placebo-controlled studies comparing imipramine and fluvoxamine have only demons
improvement in depression with either drug when compared with placebo (Dominguez et al, 1985; Norton et a

4.6.AD.2 Adverse Effects

a) SUMMARY: Fluvoxamine produces less cardiovascular and anticholinergic adverse effects than imipramin
nausea and vomiting are more common with fluvoxamine therapy (Benfield & Ward, 1986; Roos, 1983; Salet
et al, 1993).
b) Adverse effects data was pooled from the results of 10 double-blind, placebo-controlled trials comparing f
(n=222) with imipramine (n=221) (Benfield & Ward, 1986). Anticholinergic effects such as dry mouth, dizzines
sweating, and abnormal accommodation were much more prevalent in patients receiving imipramine. Nausea
only adverse effect to be much more prevalent in the fluvoxamine-treated patients.
c) The cardiac effects of tricyclic antidepressants were compared with fluvoxamine. The major cardiac adver
observed with tricyclic antidepressants include postural hypotension, heart rate increase, and slight prolongat
intraventricular conduction time and QT interval. The only cardiac effect observed with fluvoxamine was a sta
clinically, significant slowing of heart rate (Roos, 1983).
d) Fluvoxamine produced less psychomotor impairment than imipramine. Fluvoxamine was superior to imipr
milligrams in regards to concentration, reaction time, mood, psychomotor activity, and affectivity. Following th
fluvoxamine 75 milligrams to 10 healthy volunteers, psychometric tests demonstrated a tendency towards an
psychomotor activity, concentration, attention, after-effect, and mood and a significant increase in critical flick
frequency when compared to placebo (Saletu et al, 1980).

4.6.AE Gepirone

4.6.AE.1 Depression

a) Gepirone extended-release 10 to 60 mg daily was only marginally superior to placebo at some time points
and tended to be less effective than imipramine 50 to 300 mg daily in one double-blind study involving patien
depression (Feiger, 1996).

4.6.AF Haloperidol

4.6.AF.1 Schizophrenia

a) Haloperidol was compared with placebo, chlorpromazine, diazepam, and imipramine as prophylactic ager
relapse of schizophrenic patients. At the end of the three-year trial, haloperidol and chlorpromazine significan
remission as compared to the other three treatments. Daily doses of haloperidol were 3 milligrams; chlorprom
75 mg (Nishikawa et al, 1982).

4.6.AG Lithium

4.6.AG.1 Depression

a) Lithium was more effective in the treatment of unipolar and bipolar depression in 63 female in-patients in a controlled study. The patients received either lithium in doses producing serum levels of 0.8 to 1.2 mmole/L o milligrams/day in divided doses. Improvement occurred more quickly with imipramine (between days 1 and 8) (days 8 to 22); however, all patients treated with lithium improved, but not all imipramine-treated patients did 1979).

4.6.AH Lofepramine

4.6.AH.1 Depression

a) A meta-analysis of 7 studies comparing lofepramine (n=372) with imipramine (n=372) concluded that lofep comparable with imipramine in efficacy and superior in tolerance (Kerihuel & Dreyfus, 1991). Overall, there w difference between the number of lofepramine-treated patients (64%) and imipramine-treated patients (58%) during the trials that ranged from 4 to 8 weeks. Significantly fewer patients reported side effects with lofepram imipramine (55% vs 68%; p less than 0.0001). Lofepramine doses ranged from 25 to 225 milligrams/d, and in ranged from 25 to 150 milligrams/d.

b) Lofepramine is a tricyclic antidepressant that is structurally similar to imipramine, but has an improved lipo et al, 1982).

c) Lofepramine and imipramine had similar efficacy in a randomized, double-blind, placebo-controlled clinica al, 1982). Of the 139 patients initially enrolled in the study, 89 completed the full 6 weeks of treatment (34 lofe imipramine, and 21 placebo). Dropout rates for the lofepramine and imipramine group were similar when com treatment failures and side effects. There was a significantly high placebo dropout rate, with the majority of pa out due to a lack of clinical efficacy. Lofepramine and imipramine were both significantly better than placebo i primary depression. There was no significant difference between the imipramine and lofepramine group with Lofepramine therapy was associated with significantly lower incidence of severe and/or moderate side effects with 66.7% observed in the imipramine group), and a lower incidence of side effects in general.

d) Lofepramine and imipramine were compared in a double-blind placebo-controlled study involving 158 dep outpatients. Both drugs were equally efficacious and superior to placebo therapy. Lofepramine therapy produ incidence of sedation and anticholinergic effects than imipramine therapy (Rickels et al, 1982).

4.6.AI Maprotiline

4.6.AI.1 Depression

a) SUMMARY: Maprotiline is considered very similar to imipramine in therapeutic efficacy (VanderVelde, 198 1977; Lehmann et al, 1976; Singh et al, 1976; Levine, 1975; Middleton, 1975; Rieger et al, 1975; Balestrieri e Maprotiline therapy may be associated with a quicker onset of action (VanderVelde, 1981); (Clayhorn, 1977).

b) Maprotiline 50 milligrams orally 3 times/day was administered to a maximum of 300 mg/day or imipramine milligrams orally per day to 341 patients with manic depressive illness. Patients ranged in age from 19 to 64 y treatment for 4 weeks. Improvement was based on Hamilton's and Self-Rating scales. Sixty-seven percent of receiving maprotiline were reported as improved compared with 66% of the patients who received imipramine system effects, dry mouth, tremor, blurred vision, and gastrointestinal effects were reported but were significa maprotiline-treated group (Logue et al, 1979).

c) Maprotiline was superior to imipramine in a double-blind, randomized controlled trial of 25 inpatients with p disorder (Rieger et al, 1975). The dose of maprotiline and imipramine was 50 milligrams three times a day for by a flexible dosing schedule for three weeks. Results of the 16 patients completing the trial showed the Ham Scores for the maprotiline group to be significantly better (p less than 0.05) than those for the imipramine gro the trial. The Zung Depression Scale favored maprotiline (p less than 0.01) on day seven and at the end of th than 0.10). Overall rating of global impression (p less than 0.05) and global improvement at endpoint (p less t indicated maprotiline to be superior to imipramine. Dropouts from the study included five maprotiline patients, hospital against medical advice, one improving so as to warrant discontinuation of therapy, and one due to in response. Two patients from the imipramine group dropped out due to toxicity, one due to deterioration after treatment, and one because of physician intervention. Side effects were prevalent on day three but decrease day 14. Common complaints in both groups were dry mouth, blurred vision, drowsiness, and nasal congestio reported only in the imipramine group.

4.6.AJ Melitracen

4.6.AJ.1 Depression

a) Four-week, double-blind trial; 29 patients with chronic schizophrenic or neurotic depression; melitracen 75 (mg)/day vs imipramine 50 to 150 mg/day. Brief Psychiatric Rating Scale, Hamilton Psychiatric Rating Scale Impression: some improvement in both treatment groups, efficacy of imipramine superior to melitracen (not s significant). Melitracen better tolerated than imipramine: 46 adverse effects (drowsiness, dry mouth, increase tinnitus, agitation) for melitracen vs 69 for imipramine. Quicker average onset of therapeutic effect for melitra 2.2 weeks (Biros et al, 1969).

4.6.AK Methscopolamine

4.6.AK.1 Nocturnal enuresis

a) Methscopolamine is ineffective in the treatment of enuresis. In a study with 40 severely enuretic boys, me bromide was used to determine whether some subgroups of enuretic children might respond to the peripher muscarinic receptors. The effects of treatment with imipramine, desipramine, methscopolamine bromide, and compared; the tricyclic antidepressants were superior to methscopolamine and placebo (Rapoport et al, 198

4.6.AL Mianserin

Depression

Nocturnal enuresis

4.6.AL.1 Depression

a) Studies to date suggest that there is no significant difference in overall efficacy between imipramine and n treatment of depression in both inpatients and outpatients (Pichot et al, 1978; Murphy et al, 1976; Murphy, 19 several deficiencies are apparent in clinical trials to date, and 1 study has indicated that improvements seen imipramine were equivalent to those observed with placebo (Perry et al, 1978). (However, these patients wer weeks, which may have been insufficient time for therapeutic effects from either drug to occur).

b) Mianserin therapy (20 to 60 milligrams/day) in elderly depressed patients (n=50, age 60 to 80 years) is as imipramine therapy (75 to 150 milligrams/day) (Eklund et al, 1985). The incidence of dry mouth, dizziness, fa weakness was greater in the imipramine group than in the mianserin group, however the total number of side by each group was not significantly different. From these results the authors concluded that mianserin may b imipramine in the treatment of depression in elderly patients because of its lower incidence of side effects. H number of mianserin treated patients withdrew from the study due to confusion, worsening of the condition, o Considering this, it is to early to conclude that mianserin is superior to imipramine in the treatment of depress

4.6.AL.2 Nocturnal enuresis

a) Imipramine was superior to mianserin and placebo in achieving dry nights and reducing wetness scores (mianserin was not superior to placebo. This was a multicenter, randomized, double-blind study involving 80 c al, 1996).

4.6.AM Milnacipran

4.6.AM.1 Depression

a) SUMMARY: Milnacipran offers no efficacy advantage over tricyclic antidepressants

b) Milnacipran 50 to 100 mg twice daily has been comparable to or less effective than imipramine 100 to 15 amitriptyline 150 mg daily, and clomipramine 75 to 150 mg daily in the treatment of major depressive disorde endpoints were improvements on the Hamilton and Montgomery-Asberg scales (Tignol et al, 1998; Leinonen Kasper et al, 1996; Anon, 1997a; Von Frenckell et al, 1990; Ansseau et al, 1989). A more rapid onset of actio observed with clomipramine and amitriptyline (Leinonen et al, 1997; Ansseau et al, 1989).

c) Greater improvement of CGI-3 scores (therapeutic index, incorporating efficacy and tolerance) was report milnacipran in a manufacturer-prepared meta analysis of tricyclic antidepressant comparative trials (Anon, 19 1996), and this appears in manufacturer product information. However, statistical significance between treatm demonstrated (Anon, 1997a).

4.6.AN Moclobemide

4.6.AN.1 Depression

a) SUMMARY: Moclobemide and imipramine have been similarly effective in the treatment of depression; ac generally been greater with imipramine.

b) Moclobemide 300 to 600 milligrams orally daily has been as effective as imipramine 100 to 200 milligrams treatment of endogenous and non-endogenous depression in controlled clinical trials (Baumhackl et al, 1989; 1990; Versiani et al, 1989a; Versiani et al, 1989; Versiani et al, 1990a; Stabl et al, 1989; Lecrubier & Guelfi, 1 1990). However, a trend (not statistically significant) toward the superiority of imipramine over moclobemide i or neurotic depression has been observed by some investigators (Biziere & Berger, 1990; Versiani et al, 198 rapid response was reported with moclobemide in 1 study (Udabe et al, 1990).

c) In 1 study, the response rate to imipramine and moclobemide was similar in both males and females. How tended to be less effective in depressed patients over 60 years of age as compared with patients under 60 (E 1990).

d) Moclobemide and imipramine were equally efficacious in a placebo-controlled, 6-week study (Versiani et the largest trials to date (n=490) involving patients with a major depressive episode (50% with endogenous d reduction in the average Hamilton Rating Scale for Depression (HRSD) was observed with moclobemide 300 daily, as compared with 28% with placebo, during 6 weeks of treatment. Imipramine (100 to 200 milligrams d for comparison in this study, and was as effective as moclobemide, producing a 56% reduction in HRSD scor final assessments of efficacy by the investigators, good to very good responses were reported in 70% of pati

moclobemide, 70% treated with imipramine, and 28% treated with placebo. When subgroups of patients with non-endogenous depression were analyzed, both drugs were similarly effective and superior to placebo in ea Overall tolerability assessments favored moclobemide over imipramine (Versiani et al, 1989).

4.6.AN.2 Adverse Effects

a) Adverse effects have generally been less with moclobemide compared to imipramine, particularly dry mou tremor, sweating, and blurred vision (Stabl et al, 1989).

4.6.AO Moricizine

4.6.AO.1 Cardiac dysrhythmia - Myocardial infarction with complication, Post

a) Encainide and flecainide were more effective in suppressing ventricular arrhythmias than moricizine, imipr placebo during the dose titration phase of a 1-year, multicenter, randomized, double-blind and placebo-contro patients (Anon, 1988b). Patients were eligible for this study if they had an acute myocardial infarction within 6 entrance to the study, were less than 75 years of age and demonstrated either an average of 10 or more ven complexes (VPCs) per hour or 5 or more episodes of unsustained ventricular tachycardia (3 to 9 consecutive of 100/minute or more) during a 24-hour ambulatory ECG recording. The total daily doses of the study drugs to 180 milligrams for encainide, from 200 to 400 milligrams for flecainide, from 150 to 375 milligrams for imipr 600 to 900 milligrams for moricizine. Efficacy was defined as 70% or more suppression in VPC frequency and suppression of runs of VCP when compared to baseline. The efficacy rates were 83% for flecainide, 79% for moricizine, 52% for imipramine, and 37% for placebo during the dose titration phase of the study. The incider effects was 49% for encainide, 55% for flecainide, 67% for imipramine, 64% for moricizine, and 60% for place was the drug most associated with patient withdrawal due to adverse effects. This study did not address VPC efficacy at the 1-year follow-up.

4.6.AP Nefazodone

4.6.AP.1 Depression

a) Nefazodone was comparable overall to imipramine in a 6-week double-blind, placebo-controlled study inv with major depression. Average doses at the end of 6 weeks were 180 and 158 milligrams daily, respectively drugs were not always significantly superior to placebo in improving Hamilton Rating Scale for Depression (H imipramine tended to be superior to nefazodone on the visit-wise (observed case) analysis of HAM-D; in this imipramine was statistically superior to placebo at weeks 4 through 6 of treatment, whereas nefazodone was effective only at week 5. Neither agent proved statistically more effective than placebo on the Clinical Global (clinician's rating). Although adverse effects tended to be less with nefazodone, specific effects induced by ei not presented. This study did not provide a direct statistical comparison of imipramine and nefazodone (Feigh

b) Meta-analysis of 6 placebo-controlled, double blind studies showed that nefazodone and imipramine were treating major depression and the accompanying symptoms of anxiety, and nefazodone was superior to imipr treatment of agitation (Fawcett et al, 1995). Nefazodone (100 to 600 milligrams/day; mean endpoint dose=39 n=184), imipramine (25 to 300 milligrams/day; mean endpoint dose=178 milligrams; n=288), and placebo (n= compared in four 6-week and two 8-week studies. Both agents were significantly better than placebo in treati Anxiety symptoms were significantly improved by both agents compared with placebo; nefazodone resulted i both psychic anxiety and somatic anxiety as measured by the HAM-D scale, whereas imipramine had no effe anxiety. Nefazodone was significantly better than placebo in relieving agitation at weeks 1 and 3 through end showed a significant difference from placebo only at endpoint.

c) In a randomized, double-blind, placebo-controlled trial, nefazodone and imipramine were compared in 180 depression (Fontaine et al, 1994). Nefazodone was comparable in antidepressant efficacy to imipramine; sign improvement was evident in self-report anxiety symptoms as early as week 1 for nefazodone patients in eithe therapeutic dose range of nefazodone was found to be 100 to 500 milligrams/day, with most patients ultimate 500 milligrams/day. In this trial, nefazodone-treated patients experienced significantly fewer adverse events t The dose of imipramine ranged from 50 to 250 milligrams/day with the average dose being 214.4 milligrams/

4.6.AP.2 Adverse Effects

a) With acute phase- or long-term use of therapeutic doses of nefazodone or imipramine for depression, sign imipramine-treated patients than nefazodone-treated patients experienced clinically significant weight gain (g body weight). A retrospective analysis of pooled data from 3 studies comparing nefazodone (n=225) and imip showed that, at some time during the long-term phase of treatment, 9.5% of those taking nefazodone and 24 imipramine had clinically significant weight gain. At study endpoint, 2.9% and 19.7%, respectively (p=0.001) s gain. Percentages of patients with weight gain during acute-phase treatment were 0.9% for nefazodone and 4 imipramine (p=0.02) (Sussman et al, 2001).

4.6.AQ Nomifensine

4.6.AQ.1 Depression

a) SUMMARY: Nomifensine and imipramine appear similarly effective in the treatment of depression in inpat outpatients, including the elderly; comparative doses for each have been 75 to 150 milligrams/day. In genera nomifensine is less than imipramine (Merideth et al, 1984; Bremner et al, 1984; Cohn et al, 1984; Amin et al, 1978b; Forrest et al, 1977).

b) Nomifensine was as effective as imipramine in 20 patients with endogenous over-reactive depression (An Patients received 147.9 milligrams (mean) nomifensine daily or 158.3 milligrams (mean) imipramine daily in a

controlled, double-blind study. The incidence of anticholinergic side effects was lower with nomifensine than i
Nomifensine and imipramine, each in doses of 75 to 150 mg/day for 6 weeks, were equally effective in the tre
depressed patients. Autonomic side effects with nomifensine occurred less frequently than with imipramine (A
c) Nomifensine was equally efficacious as imipramine in 28 patients who received a daily dose of 150 to 200
period of 20 to 30 days. Side effects associated with nomifensine were lower than those associated with imip
al, 1974).
d) Based on the Hamilton rating scale and the Beck depression inventory, nomifensine and imipramine were
efficacious in the treatment of 30 outpatients with depression. Side effects of nomifensine and imipramine we
(Forrest et al, 1977).
e) Nomifensine in average doses of 150 milligrams orally daily was reported similarly effective as imipramine
the treatment of depression in outpatients in a 4-week controlled study (Bremner et al, 1984). However, toxici
mouth and sedation) was more frequent in imipramine patients.

4.6.AR Nortriptyline

4.6.AR.1 Depression

a) Most studies have indicated that there are no significant differences between nortriptyline and other antide
the tricyclic category such as amitriptyline (Rose et al, 1965; Leahy & Martin, 1967; Mendels, 1968; Martin &
Malitz & Kanzler, 1971), desipramine (Levy, 1966; Arieff, 1966; Stewart & Mitchell, 1968; Haider, 1968), protr
1966), and imipramine (Kessell & Holt, 1970).

4.6.AR.2 Efficacy

a) The effects of imipramine and nortriptyline on left ventricular function and blood pressure were studied du
ranging study of 20 patients with ventricular arrhythmias. Ten consecutive patients with more than 30 ventricu
depolarizations (VPDs) were treated with imipramine starting at 1 milligram/kilogram/day, increased by 1 mg/
second day, to a maximum dose of 5 mg/kg/day. Nortriptyline was administered to 10 similar patients beginni
milligram/kilogram/day, increased by 0.5 mg/kg/day every third day to a maximum of 3.5 mg/kg/day. The 2 gr
in terms of age, sex distribution, etiology of heart disease and NYHA functional class. At a mean effective dos
imipramine suppressed VPDs by 74%; VPDs were suppressed 85% by a maximally effective nortriptyline dos
Ejection fraction was slightly decreased with imipramine (from 33% to 31%) and with nortriptyline (from 43 to
decreases in orthostatic systolic pressure were greater following imipramine (26 mmHg) than after nortriptylin
significant change in supine systolic or diastolic blood pressure was noted after either drug. No significant rel
change in standing systolic blood pressure and daily dose, plasma drug concentration, or NYHA functional cl
demonstrated with either drug. Changes in standing systolic pressure were related to patient age with patient
old experiencing greater reductions in systolic pressure following administration of both drugs. To determine i
exist between imipramine and nortriptyline in terms of antiarrhythmic efficacy, studies in cardiac patients who
crossed-over, and randomized to double-blind treatment are needed (Giardina et al, 1985).

4.6.AS Paroxetine

Anxiety

Bipolar disorder, depressed phase

Depression

4.6.AS.1 Anxiety

a) In an uncontrolled trial, paroxetine and imipramine were as effective as 2- chlordesmethyldiazepam, a ben
treating generalized anxiety disorder (Rocca et al, 1997). Patients (n=81) received paroxetine 20 milligrams(r
imipramine 50 to 100 mg/day, or 2-chlordesmethyldiazepam 3 to 6 mg/day for 8 weeks. Over the first 2 week
with 2-chlordesmethyldiazepam showed greater improvement; however, after 4 weeks for paroxetine and 8 w
imipramine, the anti-depressants were more effective. Adverse effects consisted primarily of anticholinergic e
imipramine, nausea for paroxetine, and drowsiness for 2-chlordesmethyldiazepam. Larger, blinded, controlle
needed to confirm the results of this study.

4.6.AS.2 Bipolar disorder, depressed phase

a) Neither paroxetine nor imipramine was more effective than placebo in treating BIPOLAR DEPRESSION ir
stabilized on lithium if their serum lithium levels were above 0.8 milliequivalents per liter (meq/L). However, pa
serum lithium concentration was less than 0.8 meq/L showed greater improvement with 8 weeks of antidepre
than with placebo treatment (p=0.05 for paroxetine, p=0.04 for imipramine). In a double-blind study, patients
according to serum lithium concentration and then randomized to receive paroxetine (n=35), imipramine (n=3
(n=43) for 10 weeks. Among all completers of the study, therapeutic response (Hamilton depression scale sc
was achieved by 56%, 48%, and 54% of patients receiving paroxetine, imipramine, and placebo, respectively
accounted for study discontinuation in 1 patient in the paroxetine group (3%), 12 in the imipramine group (30
placebo group (12%). No patient in the paroxetine group experienced induction to mania, whereas 3 patients
imipramine and 1 treated with placebo developed treatment-emergent mania (Nemeroff et al, 2001).

4.6.AS.3 Depression

a) SUMMARY: Paroxetine, a selective serotonin reuptake inhibitor, and imipramine appear to be similarly eff treatment of major depression. The decision as to which drug to use should be based on patient-related char anxiety disorders, sleep disturbances, cardiovascular disease), potential drug interactions, and side effects.

b) Paroxetine, imipramine, and placebo were compared in 120 outpatients with moderate-to-severe major de (Feighner & Boyer, 1989). Following a 4- to 14-day single-blind, placebo washout period, patients were assig either paroxetine, imipramine, or placebo for 6 weeks. The dose of paroxetine and imipramine could be incre maximum of 50 milligrams and 275 milligrams daily, respectively. Paroxetine was superior to placebo in 5 of evaluated (HAMD scale, Raskin depression scale, MADRS, CGI scale, Covi anxiety scale); no improvement compared to placebo in the 56-item Symptom Checklist (SCL-56). Imipramine was also statistically superior t HAMD, Raskin, MADRS, and the CGI scale, but not on the Covi anxiety scale or the SCL-56. The only outco improved to a significantly greater degree with paroxetine was the HAMD total score. A high number of patie therapy (approximately 50%), which limits evaluation of efficacy. If only the patients completing the study are imipramine and paroxetine appear to be equally effective. Based upon the number of dropouts due to advers paroxetine appeared to be better tolerated than imipramine: 10% versus 30%. The most common adverse ef paroxetine were sedation and gastrointestinal effects, whereas anticholinergic adverse effects (dry mouth, co symptoms) were the most common with imipramine. However, a detailed incidence of all adverse effects was making it difficult to fully compare these agents.

c) Paroxetine was more effective than placebo in the short-term (6-week) treatment of depression; however, less effective than imipramine. The study was double-blinded and 122 patients with a major depressive disor randomized to receive either paroxetine (dose range 20 to 50 milligrams/day), imipramine (dose range 65 to milligrams/day) or placebo. At the end of the study, the imipramine-treated patients demonstrated consistentl both objective and subjective, on all depression rating scales when compared to paroxetine. Overall there wa rate to imipramine, a 48% response rate to paroxetine, and a 33% response rate to placebo (Peselow et al, 1

d) A multicenter, double-blind, placebo-controlled evaluation of paroxetine and imipramine in the outpatient t depression was conducted (Dunbar et al, 1991). After a 4- to 14-day placebo run-in period, patients were ran treatment groups; 240 to the paroxetine group, 237 to the imipramine group, and 240 to the placebo group. T started at 20 milligrams paroxetine and 80 milligrams imipramine. Dosage adjustment, if necessary, was don intervals over the six-week treatment phase. Drop-out rates were high for all groups; paroxetine 42.5%, imipr placebo 53.6%. Lack of efficacy (10%, 7%, and 33%, respectively) and side effects (23%, 36%, and 9%, resp most common reasons stated for dropping out of the study. Imipramine and paroxetine were equally superior produced similar efficacy results. However, paroxetine therapy was associated with less sedation, cardiovasc anticholinergic side effects.

e) Newer clinical trials have continued to support the previous findings that imipramine and paroxetine are si effectiveness. The major differences between the two compounds are the frequency of side effects, types of frequency of patients withdrawing from the clinical trials secondary to side effects from the study medications paroxetine therapy is better tolerated and associated with lower withdrawal rates (Ohrberg et al, 1992; Feighr (Arminen et al, 1994).

f) A 6-week, double-blind study was continued for 1 year by crossing over all patients who had failed to resp treatment to the other drug (Peselow et al, 1989a). Patients first treated with placebo were crossed over to pa total of 15 patients initially treated with paroxetine switched to imipramine, while 10 imipramine patients were paroxetine. Of the patients who initially failed on paroxetine, 73% responded to imipramine, while 50% of the initially failed on imipramine responded to paroxetine. Similar studies have shown paroxetine to be at least as imipramine with fewer side effects (Fabre, 1992; Cohn & Wilcox, 1992; Shrivastava et al, 1992; Feighner & B

4.6.AT Phenelzine

Depression

Posttraumatic stress disorder

4.6.AT.1 Depression

a) SUMMARY: Phenelzine and imipramine have been found to be equally effective in treating depression an imipramine was more effective in the treatment of hostility and paranoia, whereas phenelzine was more effec panic attacks (Davidson et al, 1981; Davidson et al, 1987; Isberg, 1981). Phenelzine therapy is superior to im treatment of atypical depression (Liebowitz et al, 1984; Stewart et al, 1989; Quitkin et al, 1988; Quitkin et al, 1990; Quitkin et al, 1993; McGrath et al, 1991). In one case report, phenelzine treatment was found to relieve obsessive-compulsive disorder (OCD) when treatment with amitriptyline and imipramine had failed.

b) Imipramine (median, 150 milligrams daily) had comparable efficacy with phenelzine (median, 75 milligram treatment of major depression in a 5-week, controlled, outpatient study. However, phenelzine was reported s imipramine in patients also presenting with panic attacks (Davidson et al, 1987).

c) Phenelzine, imipramine, and placebo were compared in a double-blind study in 74 patients with probable depression (Quitkin et al, 1988). Sixty patients completed the study. Dropout was similar among treatment gr weeks, 28% of the placebo-treated group, 50% of imipramine group, and 71% of the phenelzine group were

responders. Patients with reactive mood and only one associated symptom appeared to get more benefit with
During the next 6 weeks of the study, 41% of the placebo patients, 21% of the imipramine patients, and 7% o
patients experienced a relapse, despite continued drug therapy. Patients with definite atypical depression and
attacks responded well to drug therapy; after 6 weeks, response was observed in 60% of the placebo patient
imipramine patients, and 64% of the phenelzine patients. Patients with definite atypical depression without a
attacks did not respond as well; after 6 weeks, response was observed in 7% of the placebo group, 44% in th
group, and 83% in the phenelzine group.

d) A comparison of the results of one study were contrasted with previously published data from 180 patients
depression (Quitkin et al, 1988; Quitkin et al, 1989). Both imipramine and phenelzine were equally effective in
simple mood reactive depressive patients. Patients with atypical depression tended to respond better to phen
imipramine and 66% that had failed imipramine therapy responded with phenelzine therapy.

e) Replication of a previous study (Quitkin et al, 1988) substantiated the previous finding that phenelzine is s
imipramine and placebo in the treatment of atypical depression (Quitkin et al, 1990). This study used the sam
minor changes in dose schedule as in the 1988 study and included 90 patients with atypical depression which
included in the previous study population. Comparison of both groups found no significant difference between
population.

f) A six-week comparison of imipramine, phenelzine, and placebo was conducted in 194 nonmelancholic dep
with features of atypical depression (Stewart et al, 1989). The overall response rates was 71% with phenelzin
73 milligrams/day), 48% with imipramine (mean dose was 265 milligrams/day), and 26% with placebo (mean
tablets/day). Patients with dysrhythmic disorder tended to respond better than those with major depression. A
relationship was found in the placebo group between response and chronicity of the disorder.

g) Double-blind trials demonstrated that some patients may require chronic treatment with antidepressants to
remission from atypical depression. Patients who improved after 6 months of imipramine therapy were rando
either placebo or their same imipramine dose for a further 6 months in a double-bind fashion. A similar double
done in patients who had been maintained successfully on phenelzine. In the imipramine trial (n=32), the recu
continued imipramine (41%) and placebo (47%) was not significantly different. However, in the phenelzine tri
recurrence rate of 87% in the placebo treated patients was significantly higher (p=0.001) than those continue
(23%). Comparison of the results between imipramine and phenelzine is limited by the absence of blinding be
and baseline differences, with earlier onset and longer history of depressive illness in the phenelzine group p
to the high recurrence in those switched from phenelzine to placebo (Stewart et al, 1997).

4.6.AT.2 Posttraumatic stress disorder

a) A double-blind, placebo-controlled study of 60 male veterans found phenelzine to be better than imipramin
of combat-induced post-traumatic stress disorder (Kosten et al, 1991). Patients were treated with an average
milligrams imipramine and 68 milligrams phenelzine for 8 weeks. Dropout rates were high in all three groups
placebo, 60.9% with imipramine, and 21.1% with placebo, 60.9% with imipramine, and 21.1% with phenelzine
common reason being failure to return for clinic visits (50%, 50%, and 25%, respectively). At the end of 8 wee
and phenelzine produced greater improvement than placebo and phenelzine was demonstrated more effectiv
in improving Impact of Event Scale scores and post-traumatic stress disorder symptoms.

4.6.AU Reboxetine

4.6.AU.1 Depression

a) Reboxetine exhibited similar efficacy to, better tolerability than, and earlier onset of effect than imipramine
of major depression in a short-term study (6 weeks) (Berzewski et al, 1997). Patients (n=256) were randomiz
with reboxetine 4 milligrams (mg) twice daily or imipramine 50 mg twice daily with the evening dose increased
weeks of treatment. According to scores on the Hamilton Depression rating scale (HAM-D), response rates fo
with reboxetine or imipramine were 68.5% and 56.2% (statistically significant difference) respectively, and re
last assessment were 52% and 45.5%, respectively. On the Clinical Global Impression Severity of Illness and
Improvement scales (CGI-SI and CGI-GI), the percentage of reboxetine-treated patients classified as "norma
increased more rapidly than the group treated with imipramine, indicating an earlier onset of response. The M
Asberg Depression Rating Scale (MADRS) demonstrated no difference between the two treatment groups. In
adverse events described as probably or definitely related to treatment were 31.9% and 39% for patients trea
reboxetine or imipramine, respectively.

4.6.AV Ritanserin

4.6.AV.1 Depression

a) Ritanserin, a serotonin-2 antagonist, was compared with imipramine in a double-blind, placebo-controlled
patients with mild chronic depression (dysthymic disorder). At the end of the study imipramine was slightly mo
ritanserin based on the Hamilton Depression Rating Scale and the Zerssen Self-Rating Scale but was associ
frequency of side effects and a greater attrition rate (Bakish et al, 1994).

4.6.AW Rolipram

4.6.AW.1 Depression

a) Imipramine was superior to rolipram in patients with major depressive disorder in one double-blind study (
et al, 1989).

4.6.AX Sertraline

Depression

Dysthymia

Mixed anxiety and depressive disorder

4.6.AX.1 Depression

a) More than 50% of chronically depressed patients who were nonresponders to an antidepressant responde to an antidepressant of another class. Patients who had completed a randomized, 12-week, double-blind trial sertraline or imipramine for treatment of chronic depression and had failed to respond were switched to the a for 12 more weeks of double-blind treatment. Fifty-one patients were switched from imipramine to sertraline a sertraline to imipramine. Mean dosages at study end were 221 milligrams (mg) per day for imipramine and 16 sertraline. Ten percent of those switched to sertraline and 25% of those switched to imipramine dropped out. dropout rate was mainly due to intolerable adverse effects of imipramine. Those who switched to imipramine significant reductions in 3 adverse effects but significant increases in 8 adverse effects, whereas those who s sertraline had significant decreases in 6 adverse effects and significant increases in one:

	SERTRALINE TO IMIPRAMINE	IMIPRAMINE TO SE
DECREASED INCIDENCE		
	Insomnia	Dry mout
	Diarrhea	Somnolen
	Abdominal Pain	Increased sw
		Constipati
		Dizzines
		Urinary comp
INCREASED INCIDENCE		
	Dry mouth	Insomnia
	Increased sweating	
	Constipation	
	Dizziness	
	Tremor	
	Abnormal taste	
	Increased appetite	
	Urinary complaints	

b) The intent-to-treat response rates were 60% for sertraline and 44% for imipramine (p=0.03). Among comp response rates were 63% and 55%, respectively (p=0.16). After averaging across the study weeks and adjus status, depression type, and baseline value, there were no significant differences between groups in outcome improvement over time did not differ for the 2 groups (Thase et al, 2002).
c) In a double-blind study of major depression with or without dysthymia, response to sertraline was highest response with imipramine was highest in men. Patients meeting DSM III-R criteria for chronic major depressi

400 women) were randomized to 12-week treatment with sertraline or imipramine in a 2:1 ratio. Both drugs w milligrams (mg) daily and titrated to a maximum of 300 mg for imipramine and 200 mg for sertraline. Althoug response to sertraline was similar to imipramine, a statistically significant gender and treatment interaction wa highest response rates occurred in women taking sertraline and in men taking imipramine. More women resp (147/260; 57%) than to imipramine (61/133; 46%); and more men responded to imipramine (43/69; 62%) tha (73/161; 45%). Gender differences also occurred in the types of adverse events reported, and more women v imipramine group than from the sertraline group; however, withdrawal rates by men were not significantly diff drugs. A significant interaction was also seen between menopausal status and treatment. Withdrawal from tre highest in premenopausal women taking imipramine and postmenopausal women taking sertraline. The mecl these gender differences is unknown, and may relate to interaction of female sex hormones and serotonin ac al, 2000)

4.6.AX.2 Dysthymia

a) Sertraline and imipramine are equally effective for the treatment of dysthymia; however, sertraline is bette randomized trial, sertraline and imipramine were compared and evaluated in a group of 416 patients with ear dysthymia. Outcome was based on response based on clinical evaluation (Hamilton Rate Scale for Depressi Asberg Depression Rating Scale, Hopkins Symptom Checklist) and patient-rated version of the Inventory of D Symptoms. Improvement of scores of Clinical Global Impressions of 1 or 2 (very much or much improved) de response rates of 59% for sertraline, 64% for imipramine, and 44% for placebo. The mean dose of required f was 89.5 milligrams (mg) for sertraline and 159.7 milligrams for imipramine (Thase et al, 1996).

b) Of the 416 patients described in the study above by Thase et al, 355 had completed the Tridimensional P Questionnaire before and after treatment, and the results revealed that temperament scores improved with in dysthymia. At baseline, temperament in dysthymic patients was abnormal, with higher mean harm avoidance Tridimensional Personality Questionnaire than that reported for a community population. After 12 weeks of tr avoidance scores decreased significantly, with no significant differences between the sertraline, imipramine, Scores decreased for those achieving remission and those who did not; however, decreases were significant the remitters. Thus, improvement in temperament was mainly related to disease improvement regardless of t results revealed some gender and treatment effects, and further studies using multiple measures, rather than measure used in this study, would be needed to determine treatment effects on temperament and personality 2000).

4.6.AX.3 Mixed anxiety and depressive disorder

a) Imipramine and sertraline were equally effective in the treatment of anxiety and depression in patients witl disorder and major depressive disorder. In an randomized, multicenter, double-blind study, patients with full A disorder with concurrent major depressive disorder with a minimum of 4 panic attacks in the 4 weeks prior to baseline Montgomery-Asberg Depression Rating Scale (MADRS) score of at least 20 received either sertralir 100 milligrams (mg), mean dose, 65.4 mg/day) or imipramine (n=69; 100 to 200 mg, mean dose 144.2 mg/da Sertraline was given at an initial dose of 25 mg/day for 1 week, then titrated to 50 mg/day for 4 weeks, at whi could be increased to 100 mg, if needed. The initial dose of imipramine was 25 mg/day, increased at weekly 100 mg, and 150 mg. If needed, the dose could be increased again to 200 mg or reduced to 100 mg. Primary measures were weekly panic attack frequency and MADRS score. Sertraline and imipramine produced simila the mean baseline (28.5 vs 28.7, respectively) to endpoint (11.1 vs 11.2, respectively) total MADRS score an baseline (7.1 vs 7, respectively) to endpoint (2.9 vs 2.3, respectively) weekly panic attack frequency. Howeve treated patients reported significantly fewer adverse effects as compared with imipramine-treated patients (23 respectively; p=0.005) and fewer discontinued treatment (11% vs 22%, respectively; p=0.04). Nausea and dia frequently reported with sertraline treatment, while dizziness, dry mouth, sweating, tremor, and constipation w with imipramine administration (Lepola et al, 2003).

4.6.AY Sotalol

4.6.AY.1 Ventricular arrhythmia

a) Sotalol has been shown to be superior to procainamide, quinidine, mexiletine, propafenone, pirmenol, and ability to prevent death and the recurrence of ventricular arrhythmias in selected patients with ventricular tach Patients with a history of ventricular fibrillation or flutter with inducible, sustained ventricular tachyarrhythmias study drugs in random order until one was predicted effective by either Holter monitor assessment or progran stimulation (PES). Long-term therapy with the first effective drug was followed to one of three primary endpoi recurrence, sudden death, or unmonitored syncope. By PES, sotalol was predicted effective in 35% of a total compared to 16% for all other drugs. Although not significant, Holter assessment predicted sotalol effective fo suppression in 41% versus 45% for all other drugs combined. After two years of follow-up on chronic therapy pooled data for all the other drugs, sotalol had the lowest mortality rate (13% to 22%), lowest VT recurrence r and lowest drug withdrawal rate (38% compared to 75% to 80%). Since there was no control group, it is unkn sotalol improved survival or identified a population with a good prognosis (Prod Info Betapace(R), 1996; Mas 1989b).

4.6.AZ Tranylcypromine

4.6.AZ.1 Depression

a) Tranylcypromine is superior to imipramine in the treatment of patients with anergic bipolar depression (Hir

1991). Fifty-six patients with bipolar depression (with 73% meeting the criteria for anergic depression) were ra
to treatment with tranylcypromine 20 to 80 milligrams or imipramine 100 to 400 milligrams/day in a double-bli
study. The mean dose at the end of six weeks was 36.8 mg of tranylcypromine and 245.5 mg of imipramine.
anergic bipolar depression who did not respond to therapy in the initial phase (n=16) were then enrolled in a
with the same doses of each drug (Thase et al, 1992). Nine of the 12 patients who were switched to tranylcyp
to therapy and only one out of four patients switched to imipramine improved. Hypomania and mania develop
drugs, but occurred earlier (5.8 weeks vs 9.2 weeks) in those receiving imipramine.
b) In a double-blind study of 137 patients with psychotic depression, tranylcypromine 10 milligrams three tim
administered for an average of 22 weeks. Patients were also randomly allocated to receive phenelzine or imi
weeks of therapy, 47% of tranylcypromine patients were improved, and after termination of the study 44% we
Tranylcypromine was slightly less effective than imipramine, but more effective than phenelzine (Haydu et al,

4.6.BA Trazodone

4.6.BA.1 Depression

a) Trazodone is not therapeutically superior to imipramine, but its side effects are less troublesome (Fabre e
Feighner, 1980; Gerner et al, 1980; Escobar et al, 1980; Workman & Short, 1993a; Gershon, 1984). Anticholi
occurred more frequently in patients treated with imipramine than those treated with trazodone in a multi-cent
Newton, 1980).
b) A multicenter trial involving 379 patients treated with trazodone 200 to 600 milligrams (mg) per day imipra
mg/day or placebo for 21 to 24 days demonstrated imipramine and trazodone to be of equal efficacy (Gersho
1980). Another study involving 28 patients with endogenous depression receiving an average trazodone dose
an average imipramine dose of 140 mg/day for 28 days also demonstrated equal effectiveness between the 2
al, 1979). The results of a double-blind study involving 45 patients suggested that trazodone 200 to 600 mg/d
more rapid and prolonged improvement than did imipramine 100 to 300 mg/day (Feighner, 1980). In a double
study of 40 patients with endogenous depression, imipramine (maximum daily dose 300 mg) produced more
Hamilton depression scale scores on days 14 and 28 than trazodone (maximum daily dose 600 mg) (Escoba
c) Seventy-four patients were enrolled in a nonrandomized study with placebo baseline treatment to evaluate
imipramine, alprazolam, and trazodone in the treatment of agoraphobia (Charney et al, 1986). Twenty-nine p
assigned to imipramine, 28 to trazodone, and 26 to alprazolam treatment. All patients were treated with place
and then blindly switched to active treatment for clinical response and side effects. Both imipramine and alpra
effective in controlling the agoraphobia, however, alprazolam had a faster onset of action. Clinical responses
within one week with alprazolam therapy and were generally not observed in imipramine treated patients unti
week of therapy. Trazodone therapy was considered not effective in the treatment of agoraphobia.
d) In a double-blind controlled study, imipramine and placebo were compared with trazodone in the treatmer
patients with primary depression. The mean doses received during this study were 6.26 capsules/day of 50 m
trazodone, 6.37 capsules/day of imipramine 25 mg or 10.67 capsules/day of placebo. Three of 17 patients in
groups experienced a 50% reduction in the Hamilton total score on or before day 7 of therapy. On day 14, 8 p
trazodone group achieved this level of improvement. Of the imipramine- treated patients, no one in the group
improvement at day 7. However, by day 14, eight patients in the group had also experienced at least a 50% r
Hamilton differences in the subjects tested through the structured clinical interview. Clinical global impression
significant difference between trazodone and placebo in the proportion of improved patients at the end of 28
Global ward behavior indicated that trazodone was significantly (p less than 0.01) better than placebo for tens
inwardly distressed behavior and difficulty in sleeping. It was significantly (p less than 0.05) better for tired, w
energy behavior and anxious, worried, afraid behavior and concern for bodily health. Trazodone was slightly
0.10) for irritable, annoyed, impatient or angry behavior. Drowsiness was the most frequent side effect experi
trazodone treated patients. Anticholinergic effects were the most common effects in the imipramine group (Fe
e) Ten institutions participated in a multi-center, double-blind, placebo-controlled evaluation of either trazodo
in 263 in-patients. Inclusion criteria included primary depression of the endogenous type, minimum score of 1
Rating Scale for depression (HAM-D) and at least 7 of 21 symptoms in 3 of 5 categories of the symptom prof
Initial doses were 200 mg and 100 mg daily for trazodone or imipramine. At the end of 28 days, 113 patients
lack of efficacy or side effects. Drop out rates were 37% each for imipramine and trazodone and 58% for plac
were statistically superior to placebo in improvement of HAM- D and clinical global interview. There was no si
difference between trazodone and imipramine. Both trazodone and placebo caused statistically significantly f
anticholinergic side effects, 19% and 14% compared WITH imipramine 52% (Gershon, 1981).

4.6.BB Trimipramine

4.6.BB.1 Depression

a) One study showed trimipramine to be slightly superior to imipramine. Thirty-nine inpatients with endogeno
received either imipramine or trimipramine increased over 14 days to a maximum of 300 milligrams at bedtim
another 2 weeks. There were fewer adverse reactions (tremor, drowsiness, insomnia and dry mouth) than wi
however, nasal congestion occurred more frequently during trimipramine therapy (Rifkin et al, 1980).
b) Imipramine was compared with trimipramine in 44 patients with psychotic depression (average duration o
year) (Burns, 1965). Trimipramine was administered in doses of 25 mg three times daily for 1 week followed
times daily for 2 more weeks. Overall recovery was reported in 18 patients receiving trimipramine (in 8.7 days
10 patients receiving imipramine (8.9 days). In addition, anxiety and insomnia responded much better in patie
trimipramine. Similar results have been reported by others (Salzmann, 1965).

4.6.BC Tryptophan

4.6.BC.1 Depression

a) L-tryptophan 6 grams and imipramine 150 milligrams/day were effective in relieving endogenous and non-
depression in 59 patients. Imipramine improved agitation, while L-tryptophan improved work and activities in
endogenous depression. Imipramine therapy improved suicidal feelings in patients with non-endogenous dep
et al, 1979).

4.6.BD Venlafaxine

4.6.BD.1 Depression

a) Venlafaxine and imipramine resulted in similar improvement in depression with melancholia in hospitalize
weeks; however, venlafaxine produced an earlier response than imipramine on 1 test (Benkert et al, 1996). C
dose of venlafaxine was rapidly increased from 75 to 375 milligrams(mg)/day; this dose was continued until d
then decreased to 150 mg/day. The dose of imipramine was increased from 50 to 200 mg/day over 5 days ar
at this dose for the remainder of the study. The time to a 50% response rate was similar for the Montgomery-
Depression Rating Scale (MADRS), but for the 21-item Hamilton Rating Scale for Depression (HAM-D), the ti
was 1 week earlier with venlafaxine than imipramine (p=0.036). Adverse effects were reported in 69% and 76
treated with venlafaxine and imipramine, respectively. Statistically significant differences in dry mouth and tre
for imipramine (p less than 0.05) and nausea for venlafaxine (p=0.011). While this study enrolled 167 patients
than planned, and only 115 patients completed the 6-week study. Additional studies are needed to provide co
for a more rapid onset of effect with venlafaxine.

b) Venlafaxine was found to have antidepressant efficacy comparable to imipramine in outpatients with mod
depression. Venlafaxine was compared to imipramine in a 6 week, double-blind placebo controlled study in 2
depression of moderate to marked severity. Baseline and weekly efficacy measurements were obtained utiliz
Hamilton Rating Scale for Depression (HAM-D), the Montgomery-Asberg Depression Rating Scale (MADRS)
Global Impression severity and improvement scales (CGI). The mean maximal total daily dose of venlafaxine
48 milligrams and the mean maximal total daily dose of imipramine was 176 milligrams and +/- 56 mg. All stu
were administered in a three times a day schedule after meals. Venlafaxine showed a significant clinical adva
imipramine at the week 6 endpoint on the Ham-D total score. It was noted that this effect was probably due to
attrition rate for imipramine as compared to venlafaxine. Attrition rates due to adverse effects were 25% and
imipramine and venlafaxine respectively. Nausea, sedation, dry mouth, and dizziness were the most promine
adverse effects for venlafazine (Schweizer et al, 1994).

4.6.BE Viloxazine

Depression

Nocturnal enuresis

4.6.BE.1 Depression

a) SUMMARY: Several controlled studies have reported the equivalent efficacy of viloxazine 150 to 450 milli
imipramine 75 to 225 milligrams daily in the treatment of depression in inpatients and outpatients (Santonasta
Davies et al, 1977; McEvoy et al, 1982; Battistini et al, 1980; Nair & Schwartz, 1982; Floru et al, 1976; Bayliss
Side effects in some of these reports, primarily anticholinergic, were less with viloxazine; however, others hav
similar incidence as imipramine (McEvoy et al, 1982).

b) At least 2 studies have reported a similar clinical response to placebo as with viloxazine and imipramine ir
neurosis (Petrie et al, 1980; Guy et al, 1982). These data do not necessarily indicate the inefficacy of viloxazi
in this patient group, but rather reflect the methodological problems of placebo responsiveness in neurotic po
effects may also explain the reported early onset of effects with viloxazine in some clinical studies, both neur
endogenous depression.

c) Better scores were reported on the Hamilton Depression Scale in patients treated with viloxazine 50 millig
times/day compared to those treated with imipramine 25 milligrams three times/day (Elwin, 1980). The double
involved 59 depressed patients. However, this data was not reproduced in 40 depressed patients treated with
mg/day or imipramine 150 mg/day (Battistini et al, 1980), nor in 28 depressed patients (Santonastaso et al, 1

d) Viloxazine was compared with imipramine in the treatment of endogenous depression in a double-blind st
patients (McEvoy et al, 1982). Patients were randomly assigned to viloxazine 150 to 450 milligrams (mg) dail
to 225 milligrams daily (10 patients in each group). Flurazepam or chloral hydrate were given for sleep as nee
global impressions indicated that 7 viloxazine patients (70%) and 7 imipramine patients (70%) improved durir
patients receiving viloxazine and 3 receiving imipramine remained unchanged and 1 patient receiving viloxaz
Hamilton Psychiatric Rating Scale for Depression indicated improvement with both drugs with no differences
Imipramine had a faster onset of action for depression (1 week versus 2 weeks). The Hamilton Psychiatric Ra
Anxiety also showed similar degrees of improvement, however, viloxazine had a more rapid onset (1 week ve
Viloxazine had no effect on improving sleep disturbances as determined by the Hamilton Depression Scale, a

compared with other reports. Side effects were similar for both drugs with 1 patient in each group developing treatment (both patients had abnormal EKGs at initiation of treatment).

e) Viloxazine and imipramine has similar efficacy in a 5-week study involving 49 patients with endogenous d Schwartz, 1982). Viloxazine was initiated in oral doses of 50 milligrams (mg) three times a day with meals, wi being given at 5 p.m. Imipramine was given initially in doses of 25 milligrams orally three times a day in a sim dose was increased starting in the second week of the study to a maximum of viloxazine 400 mg daily and im daily by the fourth and fifth weeks. The mean daily dosage by the fifth week of the study was 380 mg daily fo 192 mg daily for imipramine. Both drugs resulted in improvement based upon Clinical Global Impressions, the Scale for Depression, the Hamilton Rating Scale for Anxiety, and the Brief Psychiatric Rating Scale. Based u Impressions, 12 of 24 viloxazine patients were very much improved, with 5 much improved; 13 of 25 imipram very much improved, with 7 being much improved. Side effects occurred more frequently in imipramine patie side effects of dry mouth, constipation, blurred vision, sweating, and sedation occurred more frequently in the However, nausea and vomiting occurred only in viloxazine patients.

4.6.BE.2 Nocturnal enuresis

a) Viloxazine was evaluated in the treatment of nocturnal enuresis in a controlled study with imipramine and children (Attenburrow et al, 1984). The drugs were randomly assigned for a 7-week period. Viloxazine 100 m bedtime was administered to children between 5 and 10 years of age. Imipramine was given in doses of 50 a respectively. At week 7, significantly more dry nights occurred with both viloxazine and imipramine as compa with no statistically significant difference between the two active agents. Toxicity was greater in the imipramin consisting of, primarily anticholinergic effects. These data suggest the efficacy of viloxazine in enuretic childre prove to be a useful alternative to imipramine in children who develop side effects during imipramine therapy.

4.6.BE.3 Adverse Effects

a) The most frequent side effects associated with viloxazine therapy are nausea and vomiting (Elwan, 1980; 1980), and the incidence of anticholinergic side effects is much lower than with imipramine.

b) Viloxazine appears to cause less impairment of psychomotor performance than imipramine. The driving o was tested after multiple doses of viloxazine 50 milligrams three times/day, imipramine 25 milligrams three tir or nothing. The group treated with imipramine demonstrated significantly worse performance in the gap acce subsidiary task responses. There was no effect on driving skills noted 2 hours after the first dose of each drug 1977).

4.6.BF Zimeldine

Agoraphobia

Depression

4.6.BF.1 Agoraphobia

a) A double-blind comparison of zimeldine, imipramine, and placebo in the treatment of 44 patients with agor attacks revealed that zimeldine was better, (not statistically significant), than imipramine and placebo therapy 1986). In fact, the imipramine therapy was not considered to be superior to placebo. Previous positive results (Mavissakalian & Perel, 1985; Cohen et al, 1984) would indicate that the dose of imipramine used in this stud mmilligrams/day) or the group of patients studied is not indicative of all patients with agoraphobia and panic a further studies are conducted the utilization of zimeldine in the treatment of agoraphobia should be limited to

4.6.BF.2 Depression

a) Zimeldine 100 milligrams orally twice a day was compared with oral imipramine 50 milligrams three times treatment of primary major depressive disorders (endogenous) in 95 patients in a controlled study (Hiramatsu During the 4-week study, zimeldine produced similar antidepressant activity as imipramine as evaluated on th Depression Scale. Zimeldine was reported more effective in patients over the age of 40, patients whose initia over 40 years, patients with mild-to-moderate depression and patients who had previously failed to show an a response to other antidepressants. Zimeldine was less toxic than imipramine, primarily with regard to anticho

b) Zimeldine demonstrated significantly lower Hamilton Depression scale total scores compared with imipran forty depressed patients were administered zimeldine, imipramine, and matching placebo in doses of 50 milli Fewer adverse effects were reported in the zimeldine group (Merideth & Feighner, 1983).

4.6.BF.3 Adverse Effects

a) Zimeldine did not differ in psychomotor or cognitive function tests in 18 healthy volunteers. In a double-bli fashion, each subject received zimeldine 100 milligrams, imipramine 50 milligrams, or matching placebo. A ba not exhibit a significant difference between active drugs (Ferris et al, 1980).

b) Zimeldine in therapeutic doses (200 milligrams/day) produces more pronounced anticholinergic effects, as accommodation width and salivary secretion rate, than imipramine in therapeutic doses (75 milligrams/day) (V 1981).

960. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999c.
961. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999d.
962. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999e.
963. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999f.
964. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999g.
965. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999h.
966. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999i.
967. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999j.
968. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999k.
969. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999l.
970. Product Information: Elavil(R), amitriptyline. Merck & Co, Inc, West Point, PA, 1999m.
971. Product Information: Enablex, darifenacin. Pfizer Inc., Brooklyn, New york, USA, 2004.
972. Product Information: FORADIL(R) AEROLIZER(R) inhalation powder, formoterol fumarate inhalation powder. Sche Kenilworth, NJ, 2006.
973. Product Information: Factive(R), gemifloxacin mesylate tablets. LG Life Sciences, Ltd., Seoul, Korea, 2003.
974. Product Information: Foscavir(R), foscarnet. AstraZeneca, Inc., Alexandria, VA, 1998.
975. Product Information: GEODON(R) oral capsules, IM injection, ziprasidone hcl oral capsules, ziprasidone mesylate I Pfizer,Inc, New York, NY, 2007.
976. Product Information: GenESA(R), arbutamine hydrochloride. Gensia Automedics, Inc., San Diego, CA, 1997.
977. Product Information: Halfan(R), halofantrine hydrochloride. Research Triangle Park, NC, 1998.
978. Product Information: Hismanal(R), astemizole. Janssen Pharmaceutica, Inc., Titusville, NJ, 1996.
979. Product Information: Hylorel(R), guanadrel. Fisons Corporation, Rochester, NY, 1995.
980. Product Information: Inapsine(R), droperidol. Akorn, Inc., Decatur, IL, 2002.
981. Product Information: Invirase(R), saquinavir mesylate. Roche Pharmaceuticals, Nutley, NJ, 2003.
982. Product Information: LEXIVA(R) oral solution, oral tablets, fosamprenavir calcium oral solution, oral tablets. GlaxoS

Research Triangle Park, NC, 2009.
983. Product Information: Manerix(R), Moclobemide. Hoffmann-La Roche Limited, Mississauga, Ontario, Canada, 2001.
984. Product Information: Marplan(R), isocarboxazid. Roche Laboratories Inc., Nutley, NJ, 1998.
985. Product Information: Matulane(R), procarbazine. Roche Laboratories Inc., Nutley, NJ, 1997.
986. Product Information: Mellaril(R), thioridazine. Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, 20
987. Product Information: NARDIL(R) Tablets, USP, phenelzine sulfate tablets, USP. Parke-Davis, New York, NY, 2005.
988. Product Information: NIRAVAM(TM) orally disintegrating tablet, alprazolam orally disintegrating tablet. Schwarz Pha WI, 2003.
989. Product Information: Naropin(TM), ropivacaine injection. Astra USA, Inc., Westborough, MA, 1996.
990. Product Information: Norpramin(R), desipramine hydrochloride tablets. Aventis Pharmaceuticals Inc., Kansas City,
991. Product Information: Norvir(R), ritonavir. Abbott Laboratories, North Chicago, IL, 1999.
992. Product Information: Orap(R) pimozide. TEVA Pharmaceuticals, Sellersville, PA, 1999.
993. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 1999.
994. Product Information: Orap(R), pimozide. Gate Pharmaceuticals, Sellersville, PA, 1999a.
995. Product Information: Orlaam(R), levomethadyl. Roxane Laboratories, Inc., 2001.
996. Product Information: PCE(R), erythromycin particles in tablets. Abbott Laboratories, North Chicago, IL, 1997.
997. Product Information: Pamelor(R), nortriptyline. Mallinkroft Inc., St. Louis, MO, 2001.
998. Product Information: Parnate(R), tranylcypromine sulfate tablets. GlaxoSmithKline, Research Triangle Park, NC, 20
999. Product Information: Paxil CR(TM), paroxetine. GlaxoSmithKline, Research Triangle Park, NC, 2003.
1000. Product Information: Posicor(R), mibefradil dihydrochloride. Roche Laboratories Inc., Nutley, NJ, 1997.
1001. Product Information: Propulsid(R), cisapride. Janssen Pharmaceutica Inc., Titusville, NJ, 2000.
1002. Product Information: Prozac(R), fluoxetine. Eli Lilly and Company, Indianapolis, IN, 2001.
1003. Product Information: Quinaglute(R), quinidine gluconate. Berlex Laboratories, Inc., Wayne, NJ, 1999.
1004. Product Information: Raxar(R), grepafloxacin hydrochloride. Glaxo Wellcome Inc., Research Triangle Park, NC, 19
1005. Product Information: Reyataz(TM), atazanavir. Bristol-Myers Squibb Company, Princeton, NJ, 2003.
1006. Product Information: SEREVENT(R) DISKUS(R) inhalation powder, salmeterol xinafoate inhalation powder. GlaxoS Research Triangle Park, NC, 2006.
1007. Product Information: Sandostatin(R), octreotide. Novartis Pharmaceuticals, East Hanover, NJ, 1999.
1008. Product Information: Serentil(R), mesoridazine. Novartis Pharmaceuticals Corporation, East Hanover, NJ, 2001.
1009. Product Information: Solian(R), amisulpride tablets. Lorex Synthelabo, Maidenhead, Berkshire, UK, 1999.
1010. Product Information: Stelazine(R), trifluoperazine hydrochloride. GlaxoSmithKline, Research Triangle Park, NC, 20
1011. Product Information: Strattera(TM), atomoxetine. Eli Lilly and Company, Indianapolis, IN, 2002.
1012. Product Information: Syprine(R), trientine hydrochloride. Merck & Co., Inc., West Point, PA, 2001.
1013. Product Information: TOFRANIL(R) tablets, imipramine hydrochloride tablets. Mallinckrodt Inc., St. Louis, MO, 2005
1014. Product Information: TOFRANIL-PM(R) capsules, imipramine pamoate capsules. Novartis Pharmaceuticals Corpor Hanover, NJ, 2005.
1015. Product Information: TOFRANIL-PM(R) oral capsule, imipramine pamoate oral capsule. Mallinckrodt Inc, St. Louis,
1016. Product Information: TOFRANIL-PM(R) oral capsules, imipramine pamoate oral capsules. Mallinckrodt,Inc, Hazelw
1017. Product Information: Tambocor(R) flecainide acetate. 3M Pharmaceuticals, Northridge, CA, 1998.
1018. Product Information: Tequin(TM), gatifloxacin. Bristol-Myers Squibb Company, Princeton, NJ, 1999.
1019. Product Information: Thorazine(R), chlorpromazine. Smithkline Beecham Pharmaceuticals, Philadelphia, PA, 2002.
1020. Product Information: Tofranil(R), Imipramine. Geigy Pharmaceuticals, Summit, NJ, 1995.
1021. Product Information: Tofranil(R), Imipramine. Geigy Pharmaceuticals, Summit, NJ, 1995a.
1022. Product Information: Tofranil(R), Imipramine. Geigy Pharmaceuticals, Summit, NJ, 1995b.
1023. Product Information: Trisenox(R), arsenic trioxide. Cell Therapeutics, Inc., Seattle, WA, 2000.
1024. Product Information: Trisenox(R), arsenic trioxide. Cell Therapeutics, Inc., Seattle, WA, 2000a.
1025. Product Information: Ultram(R), tramadol hydrochloride. Ortho-McNeil Pharmaceutical, Raritan, NJ, 1998.
1026. Product Information: VYVANSE(TM) oral capsules, lisdexamfetamine dimesylate oral capsules. New River Pharma Blacksburg, VA, 2007.
1027. Product Information: Vascor(R), bepridil hydrochloride. Ortho-McNeil Pharmaceuticals, Raritan, NJ, 2000.
1028. Product Information: Vivactil(R), protriptyline. Merck & Co Inc, Westpoint, PA, 1999.
1029. Product Information: Wellbutrin XL(TM), bupropion hydrochloride extended-release tablets. GlaxoSmithKline, Rese NC, 2003.
1030. Product Information: ZYVOX(R) IV injection, oral tablets, oral suspension, linezolid IV injection, oral tablets, oral su Pharmacia & Upjohn Company, New York, NY, 2008.
1031. Product Information: Zagam(R), sparfloxacin. Rhone-Poulenc Rorer Pharmaceuticals Inc, Collegeville, PA, 1998.
1032. Product Information: Zagam(R), sparfloxacin. Rhone-Poulenc Rorer Pharmaceuticals Inc, Collegeville, PA, 1998a.
1033. Product Information: Zoloft(R), sertraline hydrochloride. Roerig Division of Pfizer Inc, New York, NY, 1999.
1034. Product Information: Zomig(R), zolmitriptan tablets. AstraZeneca Pharmaceuticals, Wilmington, DE, 2001.
1035. Product Information: Zyban(R), bupropion hydrochloride. Glaxo Wellcome, Inc., Research Triangle Park, NC, 2000.
1036. Product Information: imipramine hcl oral tablets, imipramine hcl oral tablets. Par Pharmaceutical Companies,Inc, S 2007.
1037. Product Information: imipramine hydrochloride oral tablet, imipramine hydrochloride oral tablet. Par Pharmaceutical Valley , NY, 2003.
1038. Product Information: selegiline hydrochloride oral tablet, USP, selegiline hydrochloride oral tablet, USP. Par Pharm Spring Valley, NY, 2003.
1039. Product Information: tapentadol immediate release oral tablets, tapentadol immediate release oral tablets. Ortho-M Pharmaceuticals Inc, Raritan, NJ, 2008.

1040. Product Information: venlafaxine extended release oral tablets, venlafaxine extended release oral tablets. Upstate F Rochester, NY, 2008.

DRUGDEX® Evaluations

OXCARBAZEPINE

0.0 Overview

1) Class

a) This drug is a member of the following class(es):

Anticonvulsant

Dibenzazepine Carboxamide

2) Dosing Information

a) Adult

1) Partial seizure, monotherapy

a) initiation of monotherapy, 300 mg ORALLY twice a day, then increas by 300 mg/day every third day to 1200 mg/day OR 2400 mg/day in patie from other antiepileptic drug therapy to oxcarbazepine monotherapy (Pr TRILEPTAL(R) oral tablets, oral suspension, 2005)

b) conversion to monotherapy, initial, 300 mg ORALLY twice a day; ma dosage by up to 600 mg/day at weekly intervals to 2400 mg/day reache weeks while simultaneously reduce the dose of concomitant antiepilepti 3-6 weeks (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005

2) Partial seizure; Adjunct

a) initial, 300 mg ORALLY twice a day; may increase dosage by up to 6 weekly intervals to 1200 mg/day (Prod Info TRILEPTAL(R) oral tablets, suspension, 2005)

b) Pediatric

1) with adjunctive therapy, children 2 to less than 4 years of age may require the oxcarbazepine dose per body weight compared to adults; and children 4 equal to 12 years of age may require a 50% higher oxcarbazepine dose per compared to adults (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2

a) Partial seizure, monotherapy

1) 4 to 16 year old, initiation of monotherapy, 8-10 mg/kg/day ORA divided doses; may increase dose by 5 mg/kg/day every 3 days to t recommended maintenance dose (Prod Info TRILEPTAL(R) oral tab suspension, 2005)

2) 4 to 16 year old, conversion to monotherapy, initial, 8-10 mg/kg/ in 2 divided doses; may increase doses by up to 10 mg/kg/day at w to the recommended maintenance dose; simultaneously reduce the concomitant antiepileptic drugs over 3-6 weeks (Prod Info TRILEPT tablets, oral suspension, 2005)

3) 4 to 16 year old, maintenance, 600 to 900 mg/day for 20 kg chil 1200 mg/day for 25 to 30 kg; 900 to 1500 mg/day for 35 to 40 kg ch 1500 mg/day for 45 kg children; 1200 to 1800 mg/day for 50 to 55 k 1200 to 2100 mg/day for 60 to 70 kg children (Prod Info TRILEPTA tablets, oral suspension, 2005)

b) Partial seizure; Adjunct

1) 4 to 16 years old, initial, 8-10 mg/kg/day ORALLY in 2 divided d 600 mg/day(Prod Info TRILEPTAL(R) oral tablets, oral suspension,

2) 4 to 16 years old, maintenance, target maintenance dose of oxc should be achieved over 2 weeks, and is dependent upon patient w 29 kg, 900 mg/day); (29.1 to 39 kg, 1200 mg/day); and (greater tha mg/day) (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 20

3) 2 to less than 4 years old, initial, 8-10 mg/kg/day ORALLY in 2 d MAX: 600 mg/day; patients under 20 kg, consider initial dose of 16- in 2 divided doses (Prod Info TRILEPTAL(R) oral tablets, oral suspe

4) 2 to less than 4 years old, maintenance, should be titrated over 2
MAX: 60 mg/kg/day in 2 divided doses (Prod Info TRILEPTAL(R) or
suspension, 2005)

3) Contraindications
a) hypersensitivity to oxcarbazepine, or to any product component (Prod Info TR
oral tablets, suspension, 2007)

4) Serious Adverse Effects
a) Anaphylaxis
b) Angioedema
c) Hyponatremia
d) Immune hypersensitivity reaction, multiorgan
e) Stevens-Johnson syndrome
f) Toxic epidermal necrolysis

5) Clinical Applications
a) FDA Approved Indications
1) Partial seizure, monotherapy
2) Partial seizure; Adjunct

1.0 Dosing Information

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referri
Tradename List (Product Index)

B) Synonyms
Oxcarbazepine

C) Physicochemical Properties
1) Molecular Weight
a) 252.27 (Prod Info Trileptal™, 00)
2) Solubility
a) Systemic: Oxcarbazepine is slightly soluble in acetone, chloroform,
dichloromethane, and methanol. It is practically insoluble in ethanol, eth
(Prod Info Trileptal™, 00)

1.2 Storage and Stability

A) Oral route
1) Oral suspension of oxcarbazepine should be stored between 15 and 30 d
Celsius (59 and 86 degrees Fahrenheit) (Prod Info Trileptal(R), 2003).

1.3 Adult Dosage

1.3.1 Normal Dosage

Oral route

Trigeminal neuralgia

1.3.1.A Oral route

Partial seizure, monotherapy

Partial seizure; Adjunct

1.3.1.A.1 Partial seizure, monotherapy

a) Conversion

1) For conversion of therapy from other antiepileptic drugs (AE
oxcarbazepine monotherapy, oxcarbazepine therapy should be
a dose of 600 milligrams/day (mg/day) in two divided doses; sir
reduction of the dosage of the concomitant AEDs should begin.
oxcarbazepine dose may be increased at weekly intervals, as c
indicated, by a maximum of 600 mg/day to achieve a daily dose
mg/day. The maximum dose of oxcarbazepine should be reach
approximately 2 to 4 weeks while therapy with concomitant AEI
terminated gradually over approximately 3 to 6 weeks. Close m
the patient is recommended during the transition phase (Prod I
TRILEPTAL(R) oral tablets, oral suspension, 2005).

b) Initiation

1) In patients not currently treated with any antiepileptic drugs,
oxcarbazepine therapy should be initiated at a dose of 600 milli
(mg/day) in two divided doses. This dose is then increased eve
300 mg/day to achieve a dose of 1200 mg/day (Prod Info TRILI
tablets, oral suspension, 2005).

c) Withdrawal

1) Withdrawal of oxcarbazepine therapy should be gradual (Pr
TRILEPTAL(R) oral tablets, oral suspension, 2005).

1.3.1.A.2 Partial seizure; Adjunct

a) Oxcarbazepine should be initiated with a dose of 600 milligrams
(mg/day), in two divided doses. This dose may be increased at wee
as clinically indicated, by a maximum of 600 mg/day. The recomme
maintenance dose of oxcarbazepine for adjunctive use is 1200 milli
(mg/day) in 2 divided doses. Although daily doses greater than 120
more effective, most patients are not able to tolerate the 2400 mg/d
to adverse central nervous system effects. Close monitoring of the p
plasma concentrations of concomitant antiepileptic drugs is recomm
the titration phase, especially at doses greater than 1200 mg/day (P
TRILEPTAL(R) oral tablets, oral suspension, 2005).

1.3.1.B Trigeminal neuralgia

1) Effective oral doses of oxcarbazepine in the treatment of trigeminal n
been 300 milligrams 2 to 4 times daily initially, with the dose increased w
adequate pain control was achieved (Zakrzewska & Patsalos, 1989b).

2) Daily maintenance doses associated with pain relief have ranged fro
milligrams/day (Zakrzewska & Patsalos, 1989b; Farago, 1987b). In one
required for effective relief of pain were less than 10 milligrams/kilogram
patients, 11 to 20 milligrams/kilogram/day in 46%, and greater than 20
milligrams/kilogram/day in 31% (Farago, 1987b).

1.3.1.C Equivalent Doses

1) Oxcarbazepine oral suspension and film-coated tablets may be interc
equal doses (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 200

1.3.2 Dosage in Renal Failure

A) For patients with impaired renal function (creatinine clearance less than 3
milliliters/minute), oxcarbazepine therapy should be initiated at 300 milligram
half the usual starting dose, and increased at a slower rate than usual based
response (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005).

1.3.3 Dosage in Hepatic Insufficiency

A) Dose adjustments are generally not required in patients with mild to mode impairment (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005).

1.3.4 Dosage in Geriatric Patients

A) No specific guidelines exist for oxcarbazepine dosing in the elderly. Maxi concentrations and values for area under the concentration-time curve were higher in elderly volunteers (60 to 82 years of age) than in younger volunteer years of age). Differences are presumed to be due to age-related reductions clearance (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005). Be oxcarbazepine is initiated at a low dosage and titrated until a maintenance d reached, these pharmacokinetic differences are felt to have no significant cli implications (van Heiningen et al, 1991).

1.3.6 Dosage in Other Disease States

A) Pregnancy

1) Dose-normalized plasma concentrations of oxcarbazepine and mono carbazepine (MHD), the active metabolite, decreased during pregnancy to return to prepregnancy levels during the postpartum period in a pharm study in 5 pregnant women on oxcarbazepine monotherapy. Although p concentrations were not available in any of the women, plasma concent MHD and oxcarbazepine were measured during each trimester in 4 wom the last trimester in 1 woman, and at least once during the 3 months afte all women. The lowest dose-normalized concentrations were noted after gestation-week. Furthermore, postpartum dose-normalized plasma conc MHD and oxcarbazepine increased between 1.7 to 2.9 fold compared w trimester in 4 of the 5 pregnant women. The postpartum increase was ob soon as 7 to 8 days after delivery. In 1 out of the 5 women no increase i postpartum concentrations were noted (Tomson & Battino, 2007).

1.4 Pediatric Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

1.4.1 Normal Dosage

1.4.1.A Oral route

Partial seizure, monotherapy

Partial seizure; Adjunct

1.4.1.A.1 Partial seizure, monotherapy

a) Conversion

1) For conversion of therapy from other antiepileptic drugs (AE oxcarbazepine monotherapy in children 4 to 16 years, oxcarba should be initiated with a dose of 8 to 10 milligrams/kilogram/da in two divided doses; simultaneously, reduction of the dosage c concomitant AEDs should begin. The oxcarbazepine dose may at weekly intervals, as clinically indicated, by a maximum of 10 achieve the recommended daily dose. Concomitant AEDs shou terminated gradually over approximately 3 to 6 weeks. Close m the patient is recommended during the transition phase. The re total daily dose of oxcarbazepine is as follows (Prod Info Trilep

Patient Weight (in kg)	Target Maintenance Dose Range
20	600 to 900
25	900 to 1200

30	900 to 1200
35	900 to 1500
40	900 to 1500
45	1200 to 1500
50	1200 to 1800
55	1200 to 1800
60	1200 to 2100
65	1200 to 2100
70	1500 to 2100

b) Initiation

1) In children 4 to 16 years not currently treated with any antiep oxcarbazepine therapy should be initiated at 8 to 10 milligrams/ (mg/kg/day) in two divided doses. Doses should be increased b mg/kg/day every 3 days until the recommended daily dose is re recommended total daily dose of oxcarbazepine is as follows (F Trileptal(R), 2003a):

Patient Weight (in kg)	Target Maintenance Dose Rang (mg/day)
20	600 to 900
25	900 to 1200
30	900 to 1200
35	900 to 1500
40	900 to 1500
45	1200 to 1500
50	1200 to 1800
55	1200 to 1800
60	1200 to 2100
65	1200 to 2100
70	1500 to 2100

1.4.1.A.2 Partial seizure; Adjunct

a) 4 to 16 Year Olds

For adjunctive therapy in pediatric patients aged between 4 to oxcarbazepine should be initiated at a daily dose of 8 to 10 milligrams/kilogram/day (mg/kg/day) in two divided doses, usua exceed 600 mg/day. The target maintenance dose, according t below, should be attained within 2 weeks. The median dose rea clinical trials was 31 mg/kg/day (6 to 51 mg/kg/day) (Prod Info T (R) oral tablets, oral suspension, 2005):

Patient Weight (in kg)	Target Maintenance Dose (mg/day)
20 to 29	900
29.1 to 39	1200
greater than 39	1800

Children 4 to less than or equal to 12 years of age may require oxcarbazepine dose per body weight compared to adults. Child higher dose per body weight relative to adults because the app clearance increases with decreasing age (Prod Info TRILEPTA tablets, oral suspension, 2005).

b) 2 to 4 Year Olds

1) For adjunctive therapy in pediatric patients 2 years old to les years old, oxcarbazepine should be initiated at a daily dose of 8 milligrams/kilogram/day (mg/kg/day) in two divided doses, usua exceed 600 mg/day. For patients under 20 kilogram, a starting 20 mg/kg/day in 2 divided doses may be considered. The maxi maintenance dose of oxcarbazepine should be achieved over 2 and should not exceed 60 mg/kg/day in two divided doses. The reached during clinical trials in children 2 to 4 years of age was (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005).

2) Children 2 to less than 4 years of age may require up to twic oxcarbazepine dose per body weight compared to adults. Child

higher dose per body weight relative to adults because the app clearance increases with decreasing age (Prod Info TRILEPTA tablets, oral suspension, 2005).

3) Children 2 to 4 years of age may require up to twice the oxc dose per body weight compared to adults. Children require a hi body weight relative to adults because the apparent clearance decreasing age (Prod Info TRILEPTAL(R) oral tablets, oral sus 2005).

c) In children beginning oxcarbazepine therapy, doses have been t 30 milligrams/kilogram/day (mg/kg/day) over 1 to 3 weeks (Gaily et those switching from carbamazepine, an overnight change of 1.5 tin carbamazepine dose has been utilized. The mean effective dose fo achieving at least a 50% decrease in seizures has been 47 mg/kg/d range of 21 to 75 mg/kg/day.

1.4.1.B Equivalent Doses

1) Oxcarbazepine oral suspension and film-coated tablets may be interc equal doses (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 200

1.4.2 Dosage in Renal Failure

A) For patients with impaired renal function (creatinine clearance less than 3 milliliters/minute), oxcarbazepine therapy should be initiated at one-half the u dose, and increased slowly according to the clinical response (Prod Info TRIL oral tablets, oral suspension, 2005).

1.4.3 Dosage in Hepatic Insufficiency

A) Dose adjustments are generally not required in patients with mild to mode impairment (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005).

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Initial Response

a) Trigeminal neuralgia, oral: 24 hours (Zakrzewska & Patsalos, 1989).

2.2 Drug Concentration Levels

A) Therapeutic Drug Concentration

1) Epilepsy, not established (Zakrzewska & Patsalos, 1989).

B) Time to Peak Concentration

1) Oral: 4.5 hours (tablets), 6 hours (suspension) (Prod Info TRILEPTAL(R) oral suspension, 2005).

a) After the administration of a single dose of oxcarbazepine tablets, un conditions, in healthy, male volunteers, the median time to peak concent was 4.5 hours (range 3 to 13 hours). The median Tmax was 6 hours in h volunteers administered a single-dose of oxcarbazepine suspension, un conditions (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005) metabolite, 10-hydroxy-carbazepine, reaches peak levels at 4.5 to 8 hou 1990; Kristensen et al, 1983; Theisohn & Heimann, 1982a).

b) After the administration of a single dose of oxcarbazepine oral suspe fasted conditions, in healthy, male volunteers, the median time to peak c (Tmax) was 6 hours (Prod Info Trileptal(R), 2003b).

2) Steady-state plasma concentrations of 10-hydroxy-carbazepine, the activ are achieved within 2 to 3 days with twice-a-day dosing (Prod Info TRILEPTA tablets, oral suspension, 2005).

3) Maximum serum concentrations of the S- and R- enantiomers of 10-hydro carbazepine were 4.49 and 0.99 mg/L, respectively, but the median time to p concentration was similar for both (Volosov et al, 1999).

C) Area Under the Curve

1) 129.8 mg/L/hr (S-enantiomer); 26.3 mg/L/hr (R-enantiomer) (Volosov et a
a) Approximately 5-fold greater AUC for S-10-hydroxy-carbazepine thar hydroxy-carbazepine (Volosov et al, 1999).
b) AUC values were 30% to 60% higher in elderly volunteers (60 to 82 y than in younger volunteers (18 to 32 years of age). Differences are presi due to age-related reductions in creatinine clearance (Prod Info Trileptal
c) Dose adjusted AUC values were 30% to 40% lower in children below years than in children above 8 years of age (Prod Info Trileptal(R), 2003

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Bioavailability
1) Oral: rapidly absorbed (Anon, 1990; Theisohn & Heimann, 1982a).
B) Effects of Food
1) none (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005).

2.3.2 Distribution

A) Distribution Sites
1) Protein Binding
a) 40% to 60% (Prod Info TRILEPTAL(R) oral tablets, oral suspens Patsalos et al, 1990a).
1) Approximately 33% to 40% of 10-hydroxy-carbazepine is bc proteins, predominantly albumin (Prod Info TRILEPTAL(R) oral suspension, 2005; Patsalos et al, 1990a).
2) Serum concentration within the therapeutically relevant rang influence protein binding (Prod Info TRILEPTAL(R) oral tablets, suspension, 2005).
3) No difference in binding between males and females was ob (Patsalos et al, 1990a).
2) OTHER DISTRIBUTION SITES
a) SALIVA, correlates to serum concentrations (Kristensen et al, 19
1) A good correlation between saliva and serum concentration hydroxy-carbazepine has been reported from 8 to 72 hours follc administration of oxcarbazepine (Kristensen et al, 1983).
B) Distribution Kinetics
1) Volume of Distribution
a) 49 L (10-hydroxy-carbazepine) (Prod Info Trileptal(R), 2003b)

2.3.3 Metabolism

A) Metabolism Sites and Kinetics
1) LIVER, rapid and extensive metabolism (Faigle & Menge, 1990; Anor Schutz et al, 1986a; Theisohn & Heimann, 1982a).
a) Metabolized via stereoselective reduction by cystolic enzymes o group in position 10 of oxcarbazepine (Faigle & Menge, 1990; Anon Schutz et al, 1986a; Theisohn & Heimann, 1982a).
b) Lacks auto-inducing properties (Anon, 1990; Brodie et al, 1989a
c) Dose-dependent enzyme induction has been reported with highe producing effects similar to carbamazepine (Patsalos et al, 1990d).
B) Metabolites
1) 10-monohydroxy-carbazepine, active (Prod Info TRILEPTAL(R) oral suspension, 2005; Faigle & Menge, 1990; Anon, 1990; Schutz et al, 198 & Heimann, 1982a).
a) Primarily responsible for the therapeutic effects of oxcarbazepine

TRILEPTAL(R) oral tablets, oral suspension, 2005; Faigle & Menge
Patsalos et al, 1990d; Anon, 1990; Anon, 1989; Theisohn & Heimar
b) The metabolite 10-hydroxy-carbazepine is primarily excreted in t
the glucuronide conjugate (Dickinson et al, 1989; Anon, 1989; Schu
1986a; Theisohn & Heimann, 1982a).

2) Two isomeric 10,11-diols, inactive (Dickinson et al, 1989; Anon, 1989
1986a; Theisohn & Heimann, 1982a).

a) The trans-diol (10,11-dihydro-10,11-trans-dihydroxy-carbamazep
predominates (Dickinson et al, 1989; Anon, 1989; Schutz et al, 1986
& Heimann, 1982a).

3) Other minor metabolic pathways include direct O-glucuronidation and
with the enol form (Anon, 1990).

2.3.4 Excretion

A) Kidney

1) Renal Excretion (%)

a) 95% to 96% (Prod Info TRILEPTAL(R) oral tablets, oral suspens
Schutz et al, 1986a).

2) Only small amounts of unchanged oxcarbazepine are recovered (less
and the majority of renal excretion is accounted for by 10-hydroxy-carba
80%), primarily as the glucuronide conjugate. Only negligible amounts o
and cis-10,11-diol are found in the urine (approximately 3%) (Prod Info T
oral tablets, oral suspension, 2005; Anon, 1990; Schutz et al, 1986a).

B) Total Body Clearance

1) The younger and lower in weight the faster the weight-adjusted clear
monohydroxy-carbazepine (MHD). In children 2 years to less than 4 yea
weight-adjusted clearance is approximately 80% higher on average than
adults. When treated with a similar weight-adjusted dose, the correspon
exposure in these children is expected to be about 50% of adult exposu
4 to 12 years of age, weight-adjusted clearance is approximately 40% hi
average than that of adults. When treated with a similar weight-adjusted
corresponding MHD exposure in these children is expected to be about
exposure. The weight-adjusted MHD clearance in children 13 years and
expected to reach that of adults (Prod Info TRILEPTAL(R) oral tablets, o
suspension, 2005).

C) Other

1) OTHER EXCRETION

a) FECES, less than 4% (Prod Info TRILEPTAL(R) oral tablets, ora
2005).

2.3.5 Elimination Half-life

A) Parent Compound

1) ELIMINATION HALF-LIFE

a) 1 to 2.5 hours (Prod Info TRILEPTAL(R) oral tablets, oral suspen
Dickinson et al, 1989).

1) The half-life is prolonged to 19 hours in patients with renal in
(creatinine clearance less than 30 mL/min) (Prod Info TRILEPT
tablets, oral suspension, 2005).

B) Metabolites

1) 10-hydroxy-carbazepine, 8 to 11 hours (Prod Info TRILEPTAL(R) ora
suspension, 2005; Anon, 1990; Dickinson et al, 1989; Theisohn & Heima

a) The half-life of 10-monohydoxy-carbazepine was 9 hours (Prod I
TRILEPTAL(R) oral tablets, oral suspension, 2005).

b) Half-lives of the R- and S- enantiomers were 11.9 and 13 hours,
(Volosov et al, 1999).

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.1 Contraindications

A) hypersensitivity to oxcarbazepine, or to any product component (Prod Info TR oral tablets, suspension, 2007)

3.2 Precautions

A) anaphylaxis and angioedema of larynx, glottis, lips, and eyelids may occur; in fatalities if laryngeal involvement (Prod Info TRILEPTAL(R) oral tablets, suspensi
B) concomitant alcohol consumption; may cause additive sedative effect (Prod Ir TRILEPTAL(R) oral tablets, suspension, 2007)
C) concomitant medications known to decrease serum sodium levels; hyponatre Info TRILEPTAL(R) oral tablets, suspension, 2007)
D) concomitant use with hormonal contraceptives; therapy renders hormonal cor less effective (Prod Info TRILEPTAL(R) oral tablets, suspension, 2007)
E) decreases in T4 may occur; without decreases in T3 or TSH (Prod Info TRILE tablets, suspension, 2007)
F) hypersensitivity to carbamazepine (25% to 35% of those hypersensitive to car also have hypersensitivity reaction to oxcarbazepine) (Prod Info TRILEPTAL(R) c suspension, 2007)
G) hyponatremia (sodium less than 125 mmol/L); especially during the first 3 mo therapy, but may occur more than 1 year after therapy initiation (Prod Info TRILE tablets, suspension, 2007)
H) multiorgan hypersensitivity reactions have occurred; median time to detection (Prod Info TRILEPTAL(R) oral tablets, suspension, 2007)
I) rapid withdrawal of oxcarbazepine therapy; may result in increased seizure fre Info TRILEPTAL(R) oral tablets, suspension, 2007)
J) renal impairment (creatinine clearance less than 30 mL/minute); elimination of metabolite is slowed resulting in a 2-fold increase in exposure (Prod Info TRILEP tablets, suspension, 2007)
K) serious skin reactions, including Stevens-Johnson syndrome and toxic epider necrolysis, have occurred (median time to onset 19 days) (Prod Info TRILEPTAL tablets, suspension, 2007)
L) suicidality, increased risk of; based on data analysis of 199 placebo-controllec antiepileptic drugs, small elevated risk occurred as early as 1 week after starting continued to at least 24 weeks (US Food and Drug Administration, 2008)

3.3 Adverse Reactions

Dermatologic Effects

Endocrine/Metabolic Effects

Gastrointestinal Effects

Hematologic Effects

Hepatic Effects

Immunologic Effects

Neurologic Effects

Ophthalmic Effects

Psychiatric Effects

Renal Effects

Reproductive Effects

Respiratory Effects

Other

3.3.2 Dermatologic Effects

Cutaneous hypersensitivity

Dermatological finding

Erythema multiforme

Rash

Stevens-Johnson syndrome

Toxic epidermal necrolysis

3.3.2.A Cutaneous hypersensitivity

1) Summary

a) Allergic skin reactions are described with the administration of ox
(Dam et al, 1989a; Dam, 1990a; Houtkooper et al, 1987c); (Zakrzev
1988)(Houtkooper et al, 1987c; Zakrzewska & Patsalos, 1989a; And
Watts & Bird, 1991).

2) LITERATURE REPORTS

a) Desensitization to oxcarbazepine, following the development of a
pruritic rash, was accomplished using a dose of 0.1 milligram (mg) o
doubling the dose every 2 days until a therapeutic dosage was reac
Bird, 1991).

b) Allergic skin reactions have been reported less frequently with ox
as compared to carbamazepine in some clinical studies (Dam et al,
1990a; Houtkooper et al, 1987c).

c) There is evidence that oxcarbazepine can be used safely as an a
some patients with carbamazepine induced hypersensitivity (Zakrze
Ivanni, 1988)(Houtkooper et al, 1987c; Zakrzewska & Patsalos, 198

d) In 1 Danish study, a cross-reaction to oxcarbazepine was seen i
47 patients (25%) with allergic skin reactions to carbamazepine (An

3.3.2.B Dermatological finding

1) Skin rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, u
allergic skin reactions have been reported with the administration of oxc

3.3.2.C Erythema multiforme

1) Summary

a) Although not observed in controlled clinical trials, erythema multi
been observed in post-marketing studies or named patient program
oxcarbazepine (Prod Info Trileptal(R), 2003).

3.3.2.D Rash

1) Summary

a) Skin rash has been a frequently described adverse effect of oxc
therapy, also occurring with the discontinuation of oxcarbazepine th
may be associated with a mild eosinophilia, and was reported in 7%
on oxcarbazepine monotherapy in one study (Prod Info Trileptal(R),
al, 1993a; Watts & Bird, 1991).

3.3.2.E Stevens-Johnson syndrome

1) A 9-year-old Taiwanese boy developed Stevens-Johnson syndrome
14 days of initiating oxcarbazepine for treatment of seizures. The patient
of seizures first occurring at the age of 6 months and was treated with pl
several months and then the phenytoin was discontinued without recurre

seizures until he was 9 years old. Upon presentation, the patient's seizu
characterized by clonic movement of his hands and legs, with loss of co
The results of the electroencephalogram and physical examination were
unremarkable. The patient was started on oxcarbazepine 300 milligrams
and the dose was increased to 600 mg daily after one week. Fourteen d
beginning therapy with oxcarbazepine, the patient developed maculopap
his face and thigh along with high fever. Two days later, he developed b
thigh, multiple oral ulcers and hyperemic conjunctivae. The patient was
the emergency department with the diagnosis of presumed SJS. Labora
revealed leukocytosis (white blood cell (WBC) 13,930/mcL; normal rang
10,000/mcL), elevated C-reactive protein (50.59 mcg/mL; range, 0 to 5 r
Human leukocyte antigen (HLA) genotyping showed HLA-B*1518/B*400
pathology finding revealed lymphohistiocytic infiltration around the blood
scanty eosinophils, which was consistent with SJS. The patient improve
and antihistamine treatment for 7 days and was discharged 12 days late
concluded that similar to carbamazepine-induced SJS, the role of the HL
may be associated with the development of oxcarbazepine-induced SJS
2009).

2) Serious, sometimes life-threatening, cases of Stevens-Johnson synd
been reported with the use of oxcarbazepine in children and adults. Som
have required hospitalization, and rare cases of death have been report
Additionally, re-challenge with the drug has resulted in recurrence of the
reactions. The rate at which these dermatologic events have been repor
association with oxcarbazepine use exceeds the rate at which these eve
reported in the general population by 3- to 10-fold. The median time of o
reported cases was 19 days. Discontinuation of oxcarbazepine should b
in any patient who develops a skin reaction while using the drug (Prod Ir
TRILEPTAL(R) oral tablets, suspension, 2007).

3.3.2.F Toxic epidermal necrolysis

1) Serious, sometimes life-threatening, cases of toxic epidermal necroly
reported with the use of oxcarbazepine in children and adults. Some pat
required hospitalization, and rare cases of death have been reported. Ac
challenge with the drug has resulted in recurrence of the dermatologic re

skin reaction while using the drug(Prod Info TRILEPTAL(R) oral tablets,
2007).

3.3.3 Endocrine/Metabolic Effects

Abnormal thyroid hormone

Acute intermittent porphyria

Body temperature above normal

Hormone level - finding, Reproductive

Hyperlipidemia

Hyponatremia

Hypothermia

Weight gain

3.3.3.A Abnormal thyroid hormone

1) Summary

a) Use of oxcarbazepine has been associated with decreases in T4

or thyroid stimulating hormone (TSH) (Prod Info TRILEPTAL(R) ora suspension, 2007).

2) LITERATURE REPORTS

a) One study found that carbamazepine and oxcarbazepine both de serum thyroxine (T4) and free thyroxine (FT4) in girls with epilepsy. were reversible upon discontinuation of therapy. Patients, between and 18 years, were compared to 54 age-matched controls. Mean T4 levels in patients receiving carbamazepine (n=19) was 11.5 nM and compared to 14.4 nM and 96.6 nM in the control group (p less than 0.001, respectively). Mean T4 and FT4 in patients receiving oxcarba (n=18) were 11.3 nM and 74.9 nM (p less than 0.001 for both meas compared control). Thyrotropin and free triiodothyronine levels were significantly different. A second evaluation, taken a mean of 5.8 yea performed. Thyroid hormone levels in patients who had discontinue carbamazepine patients and 10 oxcarbazepine patients) did not sig from the controls. Patients had been off therapy for a mean of 5 and respectively (Vainionpaa et al, 2004).

3.3.3.B Acute intermittent porphyria

See Drug Consult reference: DRUGS CONSIDERED UNSAFE- ACUTE PORPHYRIAS

3.3.3.C Body temperature above normal

1) Case report- Despite several changes in drug therapy, a fever was re 20-year-old female which persisted for a follow-up period of approximate following the initial occurrence during oxcarbazepine therapy. The autho that the patient had actually experienced a change in "set point" for body regulation rather than having a febrile reaction. The oxcarbazepine dose milligrams (mg) twice a day for 2 weeks then increased to 300 milligrams times a day. The patient's body temperature had steadily ranged betwee 36.8 degrees Celsius (C) for several years. After oxcarbazepine treatme achieved good seizure control, but her temperature rose to over 37 degr oxcarbazepine was gradually reduced and valproate 1500 milligrams (m substituted resulting into a gradual return to pre-treatment temperature b increase in simple seizures. After a return to temperatures over 37 degre 37.6 degrees C) 4 months later, the valproate was reduced to 800 milligr (mg/day) and vigabatrin 1500 mg was added. Eventually, good seizure c achieved with doses of lamotrigine up to 150 mg/day and vigabatrin 200 however, the patient's temperature never returned to the pre-treatment r mechanism for this effect was hypothesized to be the influence of antiep on ion concentration, as the inherent ratio of sodium to calcium ions in th hypothalamus has been suggested as the physiological basis for the "se temperature control (Gatzonis et al, 1999).

3.3.3.D Hormone level - finding, Reproductive

1) LITERATURE REPORTS

a) Antiepileptic agents have been associated with changes in serur concentrations of male reproductive hormones. When compared to controls (n=41), carbamazepine treated men with partial epilepsy (n lower serum dehydroepiandrosterone sulfate concentrations (3068 r controls versus 1952 ng/mL for carbamazepine; p less than 0.001). statistically significant differences in dehydroepiandrosterone levels detected between controls and oxcarbazepine treated (n=18) or valp treated (n=27) men with generalized epilepsy. It was also found that valproic acid group had higher androstendione levels (5.9 ng/mL) w to the control group (2.2 ng/mL; p less than 0.001) whereas the othe not. Serum testosterone, sex hormone binding globulin, free androg luteinizing hormone, follicle stimulating hormone, prolactin and inhib measurements were not statistically significantly different between a Whether the differences in reproductive hormones are epilepsy-indu or antiepileptic agent-induced changes remains to be determined (Is 2004).

b) Reproductive hormone levels in men with epilepsy may be affec valproic acid or carbamazepine, with some effect shown by oxcarba doses. In valproate-treated men (n=21), androstenedione levels we increased compared with controls (n=25) (p less than 0.001), and m of the cohort taking valproate (57%) had serum concentrations of te

androstenedione, or dehydroepiandrosterone (DHEA) above the ref
(p less than 0.001). Follicle stimulating hormone levels were abnorm
valproate- treated men (p less than 0.05). Among carbamazepine-tr
(n=40), serum concentrations of DHEA were low (p less than 0.001)
hormone-binding globulin (SHBG) levels were high (p less than 0.05
taking high doses of oxcarbazepine (900 milligrams/day (mg/day) o
concentrations of testosterone, luteinizing hormone, and SHBG wer
(p=0.008, p=0.02, p=0.005, respectively). The authors noted that se
levels were high across all groups (Rattya et al, 2001).

3.3.3.E Hyperlipidemia

1) Case report - increased serum lipids, specifically low-density lipoprot
serum cholesterol were reported in 16-year-old girl. High-density lipopro
triglycerides, and liver function tests remained within normal limits. Oxca
metabolized primarily by ketone reductase and glucuronosyltransferase
minimal hepatic enzyme-induction in humans. An increase in lipid levels
previously in the patient when she was treated with carbamazepine, but
to be less probable with oxcarbazepine. The authors suggest monitoring
patients treated with oxcarbazepine as well as in those treated with carb
(Papacostas, 2000).

3.3.3.F Hyponatremia

1) Summary

a) Significant hyponatremia (sodium less than 125 mmol/L) genera
during the first 3 months of therapy, but may occur more than one y
therapy initiation. Dose reduction, therapy discontinuation, or restric
intake may be required. In patients who discontinued therapy in clin
sodium levels normalized within a few days without further treatmen
of serum sodium should be considered especially in patients at risk
who develop symptoms of hyponatremia. Patients are at risk if they
concomitant medications known to decrease serum sodium levels (
TRILEPTAL(R) oral tablets, suspension, 2007).

b) Hyponatremia has occurred with the administration of oxcarbaze
associated with a greater incidence of hyponatremia as compared w
carbamazepine (Dong et al, 2005). The mechanism is thought to be
antidiuretic hormone-like action on the kidney. HYPONATREMIC C
been described with oxcarbazepine use. Some investigators feel tha
hyponatremia from oxcarbazepine may severely limit its use as an a
Most patients with hyponatremia remain asymptomatic but some ma
drowsiness, increase in seizure frequency, and impaired consciousn
Hyponatremia with oxcarbazepine occurs most commonly in elderly
during administration of high doses of the drug (Kloster et al, 1998;
Amelsvoort et al, 1994; Steinhoff et al, 1992; Anon, 1990b; Pendleb
1989; Houtkooper et al, 1987c; Anon, 1989b; Zakrzewska & Patsalo
Johannessen & Nielson, 1987; Nielson et al, 1988).

2) Incidence: 2.5% to 29.9% (Dong et al, 2005; Prod Info TRILEPTAL(P
suspension, 2007)

3) LITERATURE REPORTS

a) The results of one study indicate that oxcarbazepine use is asso
greater incidence of hyponatremia as compared with the use of carb
In a cross-sectional study, the sodium levels of patients receiving tre
either oxcarbazepine (n=97; mean age, 36.3 years) or carbamazepi
mean age, 38.2 years) were evaluated for the presence of hyponatr
Hyponatremia was defined as a sodium level less than or equal to 1
milliequivalents/liter (mEq/L); severe hyponatremia was defined as a
less than or equal to 128 mEq/L. Hyponatremia was observed in a s
greater number of oxcarbazepine-treated patients, as compared wit
receiving carbamazepine therapy (29.9% (29/97) vs 13.5% (61/451)
p less than 0.0001). The incidence of severe hyponatremia was also
oxcarbazepine group as compared with the carbamazepine group (
vs 2.8%(13/451), respectively). Severe hyponatremia accounted for
(12/29) of all hyponatremia cases in oxcarbazepine-treated patients
accounting for 21.3% (13/61) of all hyponatremia cases reported in
receiving carbamazepine therapy (p less than 0.0001). The investig
found that, for both groups, hyponatremia was more likely to occur i
patients. Hyponatremia was observed in 62.2% and 20.6% of oxcar
carbamazepine-treated patients 40 years of age or older, as compa

and 7.9% of oxcarbazepine- and carbamazepine-treated patients le
years of age, respectively (p less than 0.0001, both values) (Dong e
b) In controlled epilepsy clinical studies, 38 of 1524 patients (2.5%)
oxcarbazepine developed clinically significant hyponatremia (sodiur
125 millimoles/liter (mmol/L), generally within the first 3 months of tr
patients who developed the condition were asymptomatic, but patie
frequently monitored and some had their oxcarbazepine dose reduc
discontinued or had their fluid intake restricted. When oxcarbazepin
discontinued, serum sodium concentrations generally returned to nc
few days without additional treatment (Prod Info Trileptal(R), 2003).
c) Hyponatremia, defined as at least one serum sodium measurem
micromoles/liter (mcmol/L), was observed in 8 of 34 children (24%)
intellectual disability given oxcarbazepine (Gaily et al, 1998).
d) Two cases of impaired water homeostasis and death after inges
oxcarbazepine are reported (Kloster et al, 1998).
e) In a study involving children, hyponatremia occurred in 7 out of 5
given oxcarbazepine (Gaily et al, 1997).
f) Hyponatremia was reported in 80 of 350 (23%) patients whose s
concentrations were monitored during oxcarbazepine therapy. Ten
patients had low serum sodium prior to receiving oxcarbazepine tre
et al, 1993a).
g) Hyponatremic coma, with a serum sodium level of 115 millimole
(mmol/L), was reported in a 50-year-old female following almost one
therapy with oxcarbazepine 2100 milligrams/day (mg/day). On disc
the drug, serum sodium levels improved after 2 days, with resolutio
somnolence and coma (Steinhoff et al, 1992).
h) Significant reductions in mean serum sodium levels (less than 1
millimoles/liter (mmol/L) have been reported in 50% to 80% of patie
studies. Available data suggests that the incidence of hyponatremia
oxcarbazepine may be greater than that observed with carbamazep
(Pendlebury et al, 1989; Nielson et al, 1988).

3.3.3.G Hypothermia

1) Transient hypothermia has been reported rarely during administratio
oxcarbazepine (Sillanpaa & Pihlaja, 1989).

3.3.3.H Weight gain

1) Weight gain has been reported as a relatively frequent adverse effec
oxcarbazepine therapy (Anon, 1990b).

3.3.4 Gastrointestinal Effects

Diarrhea

Gastrointestinal tract finding

Nausea and vomiting

3.3.4.A Diarrhea

1) Summary

a) Diarrhea is described with the administration of oxcarbazepine ir
patients, which stopped as therapy continued (Anon, 1990b; Farago
Sillanpaa & Pihlaja, 1989; Philbert et al, 1986a; Steinhoff et al, 1992
et al, 1989).

3.3.4.B Gastrointestinal tract finding

1) Summary

a) CONSTIPATION, ANOREXIA and a sensation of heat in the sto
described with the administration of oxcarbazepine (Steinhoff et al,
1990b; Pendlebury et al, 1989; Sillanpaa & Pihlaja, 1989; Farago, 1
et al, 1986a).

2) Nausea and vomiting, diarrhea, constipation, anorexia, and a sensati
the stomach are described with the administration of oxcarbazepine.

3.3.4.C Nausea and vomiting

1) Summary

a) Nausea and vomiting are described with the use of oxcarbazepi series, nausea and vomiting occurred with the discontinuation of ox therapy. In another trial, nausea and vomiting occurred with oxcarb at the maximum dosage (2400 mg/day) (Prod Info Trileptal(R), 200

3.3.5 Hematologic Effects

3.3.5.A Thrombocytopenia

1) A case report described thrombocytopenia in a 63-year-old woman a treated with oxcarbazepine. The patient, who had a history of depressio psychotic features and multiple psychiatric hospitalizations, presented to with increasingly disorganized behavior and paranoid ideation. Platelet c of admission was 300,000/microliter. Initial treatment with nortriptyline a was unsuccessful, and the patient was switched to aripiprazole and venl an inadequate response, oxcarbazepine 300 milligrams twice daily was ongoing treatment of aripiprazole and venlafaxine. The patient responde displaying an improvement in mood and energy levels. Following oxcarb therapy for a few days, the patient developed a low-grade fever and plat dropped to 208,000/microliter. Idiopathic thrombocytopenic purpura was partial thromboplastin time, prothrombin time, and international normaliz within normal limits. Platelet count continued to drop and was 18,000/mi 10 of treatment. Oxcarbazepine was discontinued and 4 days later, plate increased to 250,000/microliter and was within normal limits 7 days after oxcarbazepine (Mahmud et al, 2006).

3.3.6 Hepatic Effects

Increased liver function test

Liver finding

3.3.6.A Increased liver function test

1) Summary

a) Elevations in serum gamma-glutaryl transpeptidase (GGT) have observed in some patients treated with oxcarbazepine or 10-hydrox (Farago, 1987b). Although no severe hepatotoxic reactions have be monitoring of liver function tests is advised during therapy.

3.3.6.B Liver finding

1) Elevated liver function tests are described with the administration of oxcarbazepine.

3.3.7 Immunologic Effects

Anaphylaxis

Cross sensitivity reaction

Immune hypersensitivity reaction, multiorgan

3.3.7.A Anaphylaxis

1) Rare cases of anaphylaxis have been reported in patients following i subsequent oxcarbazepine use. In the event of this reaction, therapy sh discontinued and the patient should not be rechallenged with oxcarbaze Info TRILEPTAL(R) oral tablets, suspension, 2007).

3.3.7.B Cross sensitivity reaction

1) Summary

a) Cross-sensitivity reactions are described with the administration oxcarbazepine (Anon, 1990b; Prod Info Trileptal(R), 2003; Beran, 1

2) LITERATURE REPORTS

a) In 1 Danish study, a cross-reaction to oxcarbazepine was seen i patients (25%) with allergic skin reactions to carbamazepine (Anon,

b) Caution is advised in using oxcarbazepine in patients with a hist sensitivity to carbamazepine (Prod Info Trileptal(R), 2003).

c) Although only a 25% cross-sensitivity has been reported betwee oxcarbazepine and carbamazepine, dermatological reactions occur patients treated with oxcarbazepine who had previously discontinue carbamazepine because of the development of skin reactions. Two developed a pruritic skin rash and 1 patient developed exfoliative de following 2 or 3 doses of oxcarbazepine (Beran, 1993).

3.3.7.C Immune hypersensitivity reaction, multiorgan

1) Although the number of cases has been limited, multiorgan hypersen disorders, often considered life-threatening and resulting in hospitalizatic reported in association with the initiation of oxcarbazepine therapy (med detection 13 days, range 4-60 days). Multiorgan hypersensitivity reactior characterized by features such as rash, fever, lymphadenopathy, abnorr function tests, hepatitis, thrombocytopenia, neutropenia, eosinophilia, pr nephritis, oliguria, hepato-renal syndrome, asthenia, and arthralgia. Oxc treatment should be discontinued and replaced with an alternative thera hypersensitivity reaction is suspected. Although there are no reports tha sensitivity with other agents (ie, carbamazepine) has caused this reactio possibility cannot be ruled out (Prod Info TRILEPTAL(R) oral tablets, sus 2007).

3.3.9 Neurologic Effects

Encephalopathy

Neurological finding

Seizure

3.3.9.A Encephalopathy

1) Summary

a) Metabolic encephalopathy has been reported in a patient due to oxcarbazepine-induced hyponatremia (Rosendahl & Friis, 1991).

3.3.9.B Neurological finding

1) Summary

a) Severe HEADACHE (2.9%), DROWSINESS, DIZZINESS (6.4% (5.2%), TREMOR (1.8%), ABNORMAL GAIT (1.7%), and FATIGUE the most frequent adverse effects observed during therapy with oral oxcarbazepine and oral 10-hydroxy carbazepine and were among tl most commonly associated with discontinuation of oxcarbazepine ir studies. Sedation, DIFFICULTY IN CONCENTRATION, and MEMO IMPAIRMENT are also described with the administration of oxcarba is some evidence that the incidence and severity of central nervous effects, including sedation, is less with oxcarbazepine than with carl (Prod Info Trileptal(R), 2003; Anon, 1990b; Dam, 1990a; Sillanpaa & 1989; Farago, 1987b; Houtkooper et al, 1987c; Bulau et al, 1987a; I 1986a; Dickinson et al, 1988; Anon, 1989b; Farago, 1987b; Zakrzev Patsalos, 1989a; Curran & Java, 1993).

2) Headache, drowsiness, dizziness, ataxia, tremor, abnormal gait, fatig encephalopathy, and oculogyric crises are described with the administra oxcarbazepine. Psychomotor slowing, concentration difficulties, speech problems, somnolence or fatigue and coordination abnormalities such as disturbances have also been associated with oxcarbazepine use.

3) LITERATURE REPORTS

a) The incidence of dizziness, drowsiness, headache, and ataxia ha similar with oxcarbazepine as compared to carbamazepine in other 1990a; Houtkooper et al, 1987c).

b) In one study, substitution of carbamazepine with oxcarbazepine

receiving polytherapy was associated with increased alertness and to concentrate (Anon, 1990b).

3.3.9.C Seizure

1) Summary

a) In a case report, a 9-year-old female developed absence-like sei after initiating oxcarbazepine therapy. The patient had been diagnos benign focal epilepsy of childhood with centrotemporal spikes and h language delay. Her seizures were activated by drowsiness and we generalized tonic-clonic or hemi-clonic seizures with occasional pos paralysis. Over a 6-month period, she had 3 nocturnal seizures follc multiple nocturnal seizures over 3 days. She was then prescribed o monotherapy. Soon after, she developed multiple daily episodes of fluttering with loss of awareness. A 30-minute electroencephalogran recorded 6 seizures and benign focal epileptiform discharges of chil (BFEDC) occurring at a rate of 9 per minute. Oxcarbazepine was th discontinued and a 24-hour EEG was performed. BFEDC decrease minute and no seizures were recorded. The patient remained off an medications for 6 months and did not experience a recurrence of ab seizures (Chapman et al, 2003).

3.3.10 Ophthalmic Effects

Eye / vision finding

Oculogyric crisis

3.3.10.A Eye / vision finding

1) Summary

a) DIPLOPIA and ABNORMAL VISION were among the adverse ef frequently associated with discontinuation of oxcarbazepine therapy trials. Diplopia has been a relatively frequent adverse effect of oxca clinical trials abnormal vision and diplopia have been reported in 14 respectively, of patients treated with oxcarbazepine (n=86) (Prod In (TM), 2002)(Anon, 1990b).

2) Visual changes including diplopia, abnormal vision, and oculogyric cr described with the administration of oxcarbazepine.

3.3.10.B Oculogyric crisis

1) Summary

a) CASE REPORT - Oculogyric crisis, which occurred with carbam ceased following its discontinuance, recurred following onset of ther oxcarbazepine in a 31-year-old male. The oculogyric crisis occurrec related event, with as many as 30 episodes daily at higher oxcarbaz of 1800 milligrams/day (mg/day). Following implantation of a vagus stimulator, oculogyric crisis ceased, although oxcarbazepine therap continued (Gatzonis et al, 1999).

b) Dose-related oculogyric crisis has been described with the admi oxcarbazepine (Gatzonis et al, 1999).

3.3.12 Psychiatric Effects

3.3.12.A Suicidal thoughts

1) Data reviewed by the US Food and Drug Administration suggest an i of suicidal behavior or ideation may exist in patients receiving therapy w antiepileptic drugs (AEDs). The analysis included 199 placebo-controllec studies covering 11 different AEDs used for several different indications epilepsy, selected psychiatric illnesses, and other conditions, including n neuropathic pain syndromes. The analysis included 27,863 patients trea and 16,029 patients who received placebo, and patients were aged 5 ye There were 4 completed suicides among patients in the AED treatment g (vs) none in the placebo groups. Suicidal behavior or ideation occurred i patients in the AED treatment groups compared to 0.22% of patients in t groups. This corresponded to an estimated 2.1 per 1000 (95% confidenc to 4.2) more patients in the AED treatment groups having suicidal behav

than the placebo groups. The increased risk of suicidality was noted at 1 starting an AED and continued to at least 24 weeks. When compared to results were generally consistent among the drugs and were seen in all subgroups. Patients treated for epilepsy, psychiatric disorders, or other were all at an increased risk for suicidality compared to placebo. Closely patients treated with AEDs for emergence or worsening of depression, s other unusual changes in behavior, which may include symptoms such a agitation, hostility, mania, and hypomania (US Food and Drug Administr

3.3.13 Renal Effects

3.3.13.A Urogenital finding

1) When compared to healthy controls (n=41), valproic acid treated mer generalized epilepsy (n=27) had smaller testicular volumes (p=0.01). Wi study however, the testicular volumes of carbamazepine treated men wi epilepsy (n=15) or oxcarbazepine treated men with partial epilepsy (n=1 differ from controls. When further examined, valproic acid treated men w sperm morphology had smaller testicular volumes than control whereas volumes of valproic acid treated men with normal sperm were similar to (Isojarvi et al, 2004).

3.3.14 Reproductive Effects

3.3.14.A Semen exam: abnormal

1) Antiepileptic agents have been associated with changes in sperm mo motility. A lower frequency of morphologically normal sperm was found i carbamazepine treated men with partial epilepsy (n=15), in valproic acid with generalized epilepsy and in oxcarbazepine treated men with genera (n=18) (p less than 0.01 for carbamazepine and valproic acid and p less oxcarbazepine) compared to healthy controls (n=41). A statistically signi decrease in the frequency of motile sperm was also found with all treatm combined when compared to the healthy controls (p less than 0.05). Wit various treatment groups, valproic acid treated patients had a statisticall decrease in the frequency of motile sperm than in the control group (p le Carbamazepine treated men had high frequencies of abnormally low spe concentration (p less than 0.001) and poorly motile sperm (p less than 0 compared to controls (Isojarvi et al, 2004).

3.3.15 Respiratory Effects

Respiratory finding

Respiratory tract infection

3.3.15.A Respiratory finding

1) Upper respiratory tract infection has been reported with the administr oxcarbazepine.

3.3.15.B Respiratory tract infection

1) Summary

a) Upper respiratory tract infection has been reported in 7% of patie clinical trials (Prod Info Trileptal(TM), 2002).

3.3.16 Other

Angioedema

Withdrawal sign or symptom

3.3.16.A Angioedema

1) Rare cases of angioedema involving the larynx, glottis, lips, and eyel reported in patients following initial or subsequent oxcarbazepine use ar fatalities in cases with laryngeal involvement . In the event of this reactio

should be discontinued and the patient should not be rechallenged with oxcarbazepine (Prod Info TRILEPTAL(R) oral tablets, suspension, 2007

3.3.16.B Withdrawal sign or symptom

1) Rapid withdrawal of antiepileptic drugs including oxcarbazepine may increased seizure frequency (Prod Info TRILEPTAL(R) oral tablets, susp 2007).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy

1) U.S. Food and Drug Administration's Pregnancy Category: Category C (P TRILEPTAL(R) oral tablets, suspension, 2007a) (All Trimesters)

a) Either studies in animals have revealed adverse effects on the fetus (embryocidal or other) and there are no controlled studies in women or st women and animals are not available. Drugs should be given only if the benefit justifies the potential risk to the fetus.

2) Australian Drug Evaluation Committee's (ADEC) Category: D (Australian Department of Health and Ageing Therapeutic Goods Administration, 2006)

a) Drugs which have caused, are suspected to have caused, or may be cause an increased incidence of human fetal malformations or irreversib These drugs may also have adverse pharmacological effects. Accompar should be consulted for further details.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

3) Crosses Placenta: Unknown

4) Clinical Management

a) There are no adequate and well-controlled clinical studies in pregnar Limited data on the safety of oxcarbazepine during pregnancy demonstr evidence of toxicity (Gentile, 2003; Friis et al, 1993). Animal studies hav demonstrated developmental toxicities in the offspring at oral oxcarbaze similar to the maximum recommended human dose. Because oxcarbaze structurally similar to carbamazepine, which is considered to be teratoge humans, it is likely that oxcarbazepine is a human teratogen. Use oxcarb during pregnancy only if the potential benefit outweighs the potential risk (Prod Info TRILEPTAL(R) oral tablets, suspension, 2007a).

5) Literature Reports

a) In a case report of a 34-year-old woman with a 2-year history of idiop (subtype partial seizures evolving to secondary generalized seizures), tr oxcarbazepine 600 mg twice daily before and during pregnancy resulted spontaneous, uncomplicated vaginal delivery of a female infant without a effects. The patient began oxcarbazepine treatment after her diagnosis a seizure-free following the first month of therapy. During week 4 of the 39 gestation and 13 months after she started oxcarbazepine, pregnancy wa According to the patient, there was no other drug intake, no history of sm alcohol or caffeine use or infections during pregnancy. Obstetrical findin fetoprotein concentration, and three ultrasounds at weeks 22, 26, and 3(were all normal. Oxcarbazepine therapy was continued. The patient gav spontaneous and uncomplicated vaginal delivery to a female infant weig and measuring 49 cm with Apgar scores of 8 and 9 at one minute and 5 respectively, and no adverse effects. There was no exacerbation of seiz delivery (Gentile, 2003)

b) No congenital malformations were reported in 9 infants born to mothe oxcarbazepine during the first trimester of pregnancy (Friis et al, 1993).

c) Fetal structural abnormalities and other developmental toxicities were the offspring of rats and rabbits treated with either oral oxcarbazepine or monohydroxy metabolite during pregnancy at doses similar to the maxim recommended human dose. Maternal toxicity was also reported in the ra oxcarbazepine use during pregnancy (Prod Info TRILEPTAL(R) oral tabl suspension, 2007a). In mice, a malformation incidence of 8% was report pregnant mice were given the highest tolerable oxcarbazepine dose of 1 mg/kg/day on days 6 through 18 of gestation compared with a 5% incide mice given no drugs (Bennett et al, 1996)

d) .

B) Breastfeeding

1) Thomson Lactation Rating: Infant risk cannot be ruled out.

a) Available evidence and/or expert consensus is inconclusive or is inac determining infant risk when used during breastfeeding. Weigh the poter of drug treatment against potential risks before prescribing this drug duri

breastfeeding.

2) Clinical Management

a) Oxcarbazepine and its active metabolite, 10-hydroxy metabolite (MH excreted in human breast milk. The milk-to-plasma concentration ratio w be 0.5 for both drug and metabolite. Due to the potential for serious adv the nursing infant, a decision should be made to discontinue oxcarbazep discontinue nursing taking into consideration the importance of the drug mother (Prod Info TRILEPTAL(R) oral tablets, suspension, 2007a; Genti

3) Literature Reports

a) In a case report of a 34-year-old woman with a 2-year history of idiop (subtype partial seizures evolving to secondary generalized seizures), tr oxcarbazepine 600 mg twice daily before and during pregnancy and lact demonstrated no developmental abnormalities in the nursing infant after breast-feeding. The patient began oxcarbazepine treatment after her dia was seizure-free following the first month of therapy. During week 4 of th gestation and 13 months after she started oxcarbazepine, pregnancy wa Oxcarbazepine treatment was maintained throughout gestation. The pat via spontaneous and uncomplicated vaginal delivery to a female infant w kg and measuring 49 cm with Apgar scores of 8 and 9 at one minute an respectively, and no adverse effects. There was no exacerbation of seiz delivery and breast-feeding was successfully initiated with concomitant c treatment. During the first four months of nursing, the infant's developme normal (Gentile, 2003).

3.5 Drug Interactions

3.5.1 Drug-Drug Combinations

Carbamazepine

Clopidogrel

Cyclosporine

Ethinyl Estradiol

Etonogestrel

Evening Primrose

Felodipine

Fosphenytoin

Ginkgo

Lamotrigine

Levonorgestrel

Mestranol

Norelgestromin

Norethindrone

Norgestrel

Phenobarbital

Phenytoin

Selegiline

Simvastatin

Tolvaptan

Valproic Acid

Verapamil

3.5.1.A Carbamazepine

1) Interaction Effect: decreased plasma concentration of the active 10-n
metabolite of oxcarbazepine

2) Summary: Concurrent administration of oxcarbazepine and carbama
has resulted in a 40% decrease in the plasma concentration of the active
monohydroxy derivative (MHD) of oxcarbazepine (Prod Info TRILEPTAL
tablets, oral suspension, 2005). Although the exact mechanism for this c
unknown, it is believed to be partially due to the potential induction of ox
metabolism by CBZ, which is strong inducer of cytochrome P450 enzym
al, 1994). Although, the clinical significance of this interaction is unknow
plasma MHD concentrations may result in a potential loss of oxcarbazep
oxcarbazepine and carbamazepine are administered concurrently, clinic
oxcarbazepine may need to be monitored.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: established

6) Clinical Management: Coadministration of oxcarbazepine and carbar
result in a decreased concentration of the active 10-monohydroxy metab
oxcarbazepine. Monitor patients for clinical response to oxcarbazepine.

7) Probable Mechanism: potential induction of cytochrome P450-mediat
oxcarbazepine metabolism

8) Literature Reports

a) In a randomized, double-blind, placebo-controlled trial in adults,
coadministration of carbamazepine (CBZ) and oxcarbazepine result
decreased levels of the pharmacologically active 10-monohydroxy c
(MHD) of oxcarbazepine. Patients (n=12) being treated with a mear
1025 milligrams (mg) (range 400 to 2000 mg) were administered a s
oral dose of oxcarbazepine and were randomized, a week later, to r
300 mg oxcarbazepine three times daily or matched placebo for 3 w
controls (n=7) were untreated patients who received the single 600
oxcarbazepine dose and 3 weeks active treatment. Study results sh
area under the concentration-time curve (AUC) for MHD at steady s
reduced by 40% (90% confidence interval: 17% decrease, 57% dec
CBZ-treated group compared to the active controls (p less than 0.05
for CBZ did not alter significantly. Although the exact mechanism fo
decrease is unknown, it was partially attributed to a potential inducti
oxcarbazepine metabolism by carbamazepine, a strong inducer of c
P450 enzymes (McKee et al, 1994; Prod Info TRILEPTAL(R) oral ta
suspension, 2005).

3.5.1.B Clopidogrel

1) Interaction Effect: reduction in clinical efficacy of clopidogrel

2) Summary: Clopidogrel is metabolized to its active metabolite by CYP
Concomitant use of CYP2C19 inhibitors, such as oxcarbazepine, would
to result in reduced levels of the active metabolite, and therefore a reduc
clinical efficacy of clopidogrel. Concomitant use of CYP2C19 inhibitors w
clopidogrel is discouraged (Prod Info PLAVIX(R) oral tablet, 2009).

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Concomitant use of clopidogrel and oxcarbaze
discouraged (Prod Info PLAVIX(R) oral tablet, 2009).

7) Probable Mechanism: inhibition of CYP2C19- mediated clopidogrel m
oxcarbazepine

3.5.1.C Cyclosporine

1) Interaction Effect: decreased cyclosporine concentrations
2) Summary: Cyclosporine is extensively metabolized by CYP3A isozyn
Coadministration with oxcarbazepine, a CYP3A inducer, may result in de
cyclosporine concentrations. If concomitant therapy is required, the clinic
monitor circulating cyclosporine levels and make appropriate cyclosporin
adjustments (Prod Info ESTRADERM(R) transdermal system, 2005).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of cyclosporine and oxcarbaz
result in decreased cyclosporine plasma concentrations. If concurrent th
required, monitor circulating cyclosporine levels and make appropriate d
adjustments as necessary (Prod Info ESTRADERM(R) transdermal syst
Monitor the patient for decreased response to cyclosporine.
7) Probable Mechanism: induction of CYP3A-mediated cyclosporine me

3.5.1.D Ethinyl Estradiol

1) Interaction Effect: decreased contraceptive effectiveness
2) Summary: In studies conducted with oral contraceptives, concurrent
of oxcarbazepine with an oral contraceptive has decreased plasma conc
2 hormonal components: ethinyl estradiol (EE) and levonorgestrel (LNG)
TRILEPTAL(R) oral tablets, oral suspension, 2005). Contraceptive effec
be reduced when hormonal contraceptives (oral, transdermal, or vaginal
coadministered with some drugs, such as oxcarbazepine, that increase t
metabolism of contraceptive steroids. This could result in unintended pre
breakthrough bleeding. Caution is advised when oxcarbazepine is admi
concurrently with hormonal contraceptives (Prod Info ORTHO EVRA(R)
system, 2005). Patients should be advised about using additional contra
methods (Prod Info NUVARING(R) vaginal ring, 2005).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concurrent use of oxcarbazepine with hormon
contraceptives (oral, transdermal, or vaginal ring) may result in decrease
contraceptive efficacy, leading to unintended pregnancy or breakthrough
Use caution if oxcarbazepine is administered concomitantly with a comb
contraceptive.
7) Probable Mechanism: increased metabolism of contraceptive steroid
8) Literature Reports
a) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics o
estradiol (EE) and levonorgestrel (LNG) were studied in 10 healthy
had taken triphasic oral contraceptives for at least three menstrual c
300 mg was administered once on day 16 of the first study cycle, tw
day 17, and three times daily from day 18 of the first cycle through c
second cycle. Combined use resulted in a significant decrease in th
the concentration-time curve (AUC) for both EE (3 +/- 1.2 vs 1.6 +/-
and LNG (29.3 +/- 94.6 vs 189.5 +/- 71.7 nmol/h) (p = 0.006 for both
not a significant change in mean maximum concentration (Cmax) va
EE or LNG. Progesterone levels were low throughout the study indi
anovulation, but one subject had prolonged menstrual bleeding and
experienced breakthrough bleeding which indicates a potential loss
contraceptive efficacy (Klosterskov-Jensen et al, 1992).
b) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics o
estradiol (EE) and levonorgestrel (LN) were studied on 16 healthy w
18 to 44 years in a randomized double-blind cross-over design. Dur
different menstrual cycles, each woman was given placebo or 1200
in random sequence for 26 consecutive days with a one cycle wash
between. An oral contraceptive containing 50 mcg EE and 250 mcg
for the first 21 days of each cycle. Plasma concentrations of EE and
measured at regular intervals on days 21 to 23 of each cycle. Comp
placebo, a 47% decrease in area under the concentration-time curv
both EE and LN was seen during OCBZ treatment. Peak plasma EE
concentrations decreased from 180 pg/ml to 117 pg/ml during the p

OCBZ cycle, respectively (p less than 0.01) and the LN concentratic
from 10.2 to 7.7 ng/ml (p less than 0.01). In addition, the half-lives o
decreased from 13.6 to 7.9 hours (p less than 0.01) and from 28.8 t
respectively (p less than 0.01) (Fattore et al, 1999).
c) Concurrent administration of oxcarbazepine with an oral contrac
affected plasma concentrations 2 hormonal components: ethinyl est
and levonorgestrel (LNG). In studies conducted with oral combinatic
contraceptives, the mean area under the concentration-time curve (
for EE were reduced by 48% (90% confidence interval (CI): 22 to 65
and 52% (90% CI: 38 to 52) in another study. The mean AUC value
were reduced by 32% (90% CI: 20 to 45) in one study and 52% (90
52) in another study (Prod Info TRILEPTAL(R) oral tablets, oral sus
2005).

3.5.1.E Etonogestrel

1) Interaction Effect: decreased contraceptive effectiveness
2) Summary: In studies conducted with oral contraceptives, concurrent
of oxcarbazepine with an oral contraceptive has decreased plasma conc
2 hormonal components: ethinyl estradiol (EE) and levonorgestrel (LNG)
TRILEPTAL(R) oral tablets, oral suspension, 2005). Contraceptive effec
be reduced when hormonal contraceptives (oral, transdermal, or vaginal
coadministered with some drugs, such as oxcarbazepine, that increase
metabolism of contraceptive steroids. This could result in unintended pre
breakthrough bleeding. Caution is advised when oxcarbazepine is admi
concurrently with hormonal contraceptives (Prod Info ORTHO EVRA(R)
system, 2005). Patients should be advised about using additional contra
methods (Prod Info NUVARING(R) vaginal ring, 2005).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concurrent use of oxcarbazepine with hormon
contraceptives (oral, transdermal, or vaginal ring) may result in decrease
contraceptive efficacy, leading to unintended pregnancy or breakthrough
Use caution if oxcarbazepine is administered concomitantly with a comb
contraceptive.
7) Probable Mechanism: increased metabolism of contraceptive steroid
8) Literature Reports
a) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics c
estradiol (EE) and levonorgestrel (LNG) were studied in 10 healthy
had taken triphasic oral contraceptives for at least three menstrual c
300 mg was administered once on day 16 of the first study cycle, tw

both EE and LN was seen during OCBZ treatment. Peak plasma EE
concentrations decreased from 180 pg/ml to 117 pg/ml during the p
OCBZ cycle, respectively (p less than 0.01) and the LN concentratic
from 10.2 to 7.7 ng/ml (p less than 0.01). In addition, the half-lives o
decreased from 13.6 to 7.9 hours (p less than 0.01) and from 28.8 t
respectively (p less than 0.01) (Fattore et al, 1999).
c) Concurrent administration of oxcarbazepine with an oral contrac
affected plasma concentrations 2 hormonal components: ethinyl est

and levonorgestrel (LNG). In studies conducted with oral combinatic contraceptives, the mean area under the concentration-time curve (for EE were reduced by 48% (90% confidence interval (CI): 22 to 6 and 52% (90% CI: 38 to 52) in another study. The mean AUC value were reduced by 32% (90% CI: 20 to 45) in one study and 52% (90 52) in another study (Prod Info TRILEPTAL(R) oral tablets, oral sus 2005).

3.5.1.F Evening Primrose

1) Interaction Effect: reduced anticonvulsant effectiveness

2) Summary: Theoretically, evening primrose oil may reduce the effecti anticonvulsants by lowering the seizure threshold. Evening primrose oil i contraindicated in patients with epilepsy (Barber, 1998; Newall et al, 199

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Avoid concomitant use of evening primrose oil anticonvulsants.

7) Probable Mechanism: evening primrose oil may reduce the seizure th

3.5.1.G Felodipine

1) Interaction Effect: decreased felodipine exposure

2) Summary: Oxcarbazepine and its active 10-monohydroxy metabolite subgroup of cytochrome P450 3A family of enzymes which are utilized ir metabolism of felodipine. A small study indicated that repeated coadmin felodipine and oxcarbazepine decreased exposure to felodipine; howeve plasma concentrations remained within the recommended therapeutic ra et al, 1993; Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005 and oxcarbazepine are coadministered, it is advisable to monitor clinical felodipine.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Coadministration of felodipine and oxcarbazep resulted in decreased exposure to felodipine. If felodipine and oxcarbaze administered concurrently, monitor clinical response to felodipine.

7) Probable Mechanism: induction of cytochrome P450-mediated felodi metabolism

8) Literature Reports

a) A pharmacokinetic study was conducted with seven healthy subj were given felodipine 10 mg daily for 13 days; on day 6 oxcarbazep was given and was increased to 450 mg twice daily from day 7 to 1 dose of oxcarbazepine had no effect on felodipine pharmacokinetic compared with felodipine alone, but the week-long coadministration decrease of felodipine area under the concentration-time curve (AU (110.2 +/- 35.9 vs 79.2 +/- 25.7; p less than 0.05) and maximum pla concentration by 34% (9.7 +/- 3.2 vs 6.4 +/- 2 nmol/L). Similar result obtained for the inactive felodipine pyridine metabolite. Despite thes in felodipine AUC and Cmax, the felodipine plasma concentrations r within the recommended therapeutic range (Zaccara et al, 1993).

3.5.1.H Fosphenytoin

1) Interaction Effect: an increased risk of phenytoin toxicity (ataxia, hype nystagmus, tremor)

2) Summary: Fosphenytoin is a prodrug of phenytoin and the same inte occur with phenytoin are expected to occur with fosphenytoin (Prod Info 1999). When phenytoin in doses of 250 mg to 500 mg daily was combin oxcarbazepine in doses of 600 mg to 1800 mg daily, there was less thar change in the concentration of phenytoin. Additionally, concentrations of monohydroxy metabolite (MHD) of oxcarbazepine, which possesses pha activity, were decreased by 30%. This effect is most likely due to inducti cytochrome P450 enzyme system by phenytoin. When the same doses were combined with oxcarbazepine in doses greater than 1200 mg daily to a 40% increase in plasma phenytoin concentrations (Prod Info Trilept

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Patients should be monitored for phenytoin tox
receiving oxcarbazepine concurrently, especially when oxcarbazepine d
1200 mg daily. A decrease in the phenytoin dose may be required.
7) Probable Mechanism: inhibition of cytochrome P450 2C19-mediated
metabolism
8) Literature Reports
a) In polypharmacy studies employing add-on oxcarbazepine and
carbamazepine, increased serum levels of valproic acid and phenyt
observed with patients receiving oxcarbazepine. This was attributec
enzyme induction (Bulau et al, 1987; Houtkooper et al, 1987). Alterr
dependent enzyme induction has been reported by some investigat
doses of oxcarbazepine produced enzyme induction that was simila
carbamazepine (Patsalos et al, 1990a). Further studies are requirec
if oxcarbazepine will offer a significant advantage over carbamazep
regard to enzyme induction.

3.5.1.l Ginkgo

1) Interaction Effect: decreased anticonvulsant effectiveness
2) Summary: In a case report, 2 patients with epilepsy previously well c
valproate sodium developed a recurrence of seizures after ingesting ginl
Seizure control was regained after ginkgo was withdrawn (Granger, 200
developed seizures after exposure to 4'-O-methylpyridoxine arising from
ginkgo seeds (Yagi et al, 1993a). The compound 4'-O-methylpyridoxine,
is found in ginkgo seeds (used as food in Japan) as well as in leaves, th
component from which commercially available extracts are derived (Arer
1996a). The majority of ginkgo leaf products should not contain sufficien
4'-O-methylpyridoxine to cause seizures. However, ginkgo products are
assayed to assure that 4'-O-methylpyridixone is not contained in the con
product. Of concern are those instances where, depending on the harve
the potential introduction of contamination, 4'-O-methylpyridoxine may b
sufficient amounts to be problematic in vulnerable populations (eg, infan
with known seizure disorders).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Avoid concomitant use of ginkgo and anticonv
patients with epilepsy. If seizures occur for the first time or recur in patie
controlled by anticonvulsant medication, inquire about the use of ginkgo
extract. If possible, an assay should be conducted on the specific produc
if 4'-O-methylpyridoxine is present.
7) Probable Mechanism: neurotoxin 4'-O-methylpyridoxine (found in lea
seeds of ginkgo biloba) may cause seizures
8) Literature Reports
a) The serum of a 21-month-old patient with gin-nan food poisoning
for 4'-O-methylpyridoxine levels. The serum concentration was 0.9
micrograms/milliliter (mcg/mL) at 8.5 hours after ingesting ginkgo se
decreasing to 0.05 mcg/mL at 15.5 hours. The authors concluded th
methylpyridoxine content was responsible for the tonic/clonic convu
loss of consciousness observed. They further observed that infants
particularly vulnerable (Yagi et al, 1993).
b) Four to six milligrams of the neurotoxin 4'-O-methylpyridoxine ha
isolated from 2 kilograms of Ginkgo biloba leaves which is the sourc
commercially-available products. Highest amounts were found in se
micrograms (mcg)/seed) and leaves (5 mcg/leaf) derived from the tr
of July and beginning of August. The albumen of the seed can conta
mcg/gram dry weight, but this is reduced to 0.75-1.32 mcg/gram dry
boiled. The unprocessed seed coats contain from 5.44-7.15 mcg/gr
The neurotoxin in ginkgo leaf was detected in medications and it wa
detectable in homeopathic preparations. Specifically, 8.13 mcg/mL
methylpyridoxine was found in Tebonin Forte(R), 9.77 mcg/mL in R
mcg/mL in Kaveri Forte(R), and 7.18 mcg/mL in Gingium(R). Based
recommended daily intake, this translates into a maximum daily inta
methylpyridoxine of 48.78 mcg, 58.62 mcg, 11.40 mcg, and 43.08 m
Tebonin Forte(R), Rokan(R), Kaveri Forte(R), and Gingium(R), resp
Among the homeopathic products, Ginkgo biloba Urtinktur Hanosar
Ginkgo biloba Urtinktur DHU(R) contained 0.301 mcg/mL and 0.589
4'-O-methylpyridoxine, respectively. However, the authors note that

contained in medicinal extracts of ginkgo leaves may be too low to b
significance. Concern remains with the variance in 4'-O-methylpyrid
depending on the season during which the ginkgo was harvested (A
1996).

c) Seizures recurred in 2 patients, both with epilepsy that was well
prior to ingesting ginkgo biloba (Gb). The patients (an 84-year-old w
78-year-old man) had been free of seizures for at least 18 months p
beginning therapy with Gb 120 milligrams daily to treat cognitive de
patients developed seizures within 2 weeks of beginning Gb therapy
remained seizure-free (without changing anticonvulsant therapy) aft
discontinuing Gb (Granger, 2001).

3.5.1.J Lamotrigine

1) Interaction Effect: reduced lamotrigine concentrations and possible lo
control

2) Summary: Oxcarbazepine is structurally similar to carbamazepine bu
form an epoxide metabolite, which is considered responsible for the neu
of carbamazepine. When lamotrigine and oxcarbazepine were administe
concurrently to 14 epileptic patients, plasma concentrations of lamotrigin
decreased 28.7% compared to lamotrigine monotherapy (May et al, 199
patients who had received lamotrigine and oxcarbazepine concurrently,
occurred several weeks after oxcarbazepine discontinuation or dose red
Induction of lamotrigine metabolism by oxcarbazepine was postulated to
mechanism, such oxcarbazepine discontinuation or a dose reduction ma
resulted in a slow increase in lamotrigine levels, thereby increasing its to
& deLeon, 2007). Concomitant use of lamotrigine and oxcarbazepine ma
monitoring the patient closely for seizure control and increasing the lamo
as necessary. Conversely, in patients receiving these agents concurrent
oxcarbazepine is discontinued or its dose is reduced, lamotrigine doses
be reduced. Additionally, the patient may need to be monitored over sev
signs/symptoms of lamotrigine toxicity.

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Monitor seizure control and anticipate a possib
increase lamotrigine doses if oxcarbazepine is added to therapy. Conver
oxcarbazepine is withdrawn from therapy or if dosage is reduced, lamotr
may need to be reduced and the patient may need to be monitored over
weeks for symptoms of lamotrigine toxicity.

7) Probable Mechanism: hepatic induction by oxcarbazepine of lamotrig
metabolism

8) Literature Reports

a) Two patients, receiving lamotrigine and oxcarbazepine concurre
experienced oral ulcers several weeks after oxcarbazepine discontin
dose reduction. In the first case, a 35-year-old woman being treated
disorder (BD II), hypothyroidism, gastritis, migraines, and asthma w
after experiencing one week of worsening depression and two days
thoughts and treated with oxcarbazepine 600 mg/day, topiramate, fl
aripiprazole, quetiapine, lithium, naproxen, pantoprazole, amoxicillin
levothyroxine. On day 2, lamotrigine 50 mg/day was initiated and titr
200 mg/day by day 6. Oxcarbazepine dose was decreased and stop
and she was discharged on day 8 with lamotrigine 200 mg, topirama
aripiprazole, escitalopram, naproxen, pantoprazole, levothyroxine, a
hydroxyzine. On day 42 (41 days after starting lamotrigine and 39 d
stopping oxcarbazepine), she developed painful tongue ulcers. Sub
lamotrigine was stopped and the ulcers resolved in 4 days. In the se
36-year-old man with BD II, hypertension, and GERD was admitted
suicide attempt and prescribed oxcarbazepine 600 mg/day, phenyto
venlafaxine, mirtazapine, metoprolol, and famotidine. Lamotrigine 5
initiated on day 11 and titrated up to 100 mg/day by day 14. He was
on day 14 with lamotrigine 100 mg and oxcarbazepine 1200 mg (alo
medications); however, he reduced the oxcarbazepine dose to 600
discharge. On day 44 (22 days after oxcarbazepine dose decrease)
developed several painful mouth sores on his lips, gums, and tongu
lamotrigine and oxcarbazepine were discontinued and the ulcers res
completely (O'Neill & deLeon, 2007).

b) Lamotrigine serum concentrations from 222 patients receiving la

monotherapy (n = 64) or combination therapy with another antiepile
were evaluated. Fourteen patients were being treated with lamotrigi
oxcarbazepine. In the lamotrigine monotherapy group, the lamotrigi
concentration was 7.14 mcg/mL while the mean dose was 7.27 mg/
lamotrigine level-to-dose ratio (LDR) in this group calculated out to
mcg/mL/mg/kg. In the subjects receiving oxcarbazepine in addition
the plasma concentration was 4.73 mcg/mL while the mean dose w
mg/dose/kg. The lamotrigine LDR in this group was 0.71 mcg/mL/m
demonstrating the inducing properties of oxcarbazepine on lamotrig
metabolism (May et al, 1999).

3.5.1.K Levonorgestrel

1) Interaction Effect: decreased contraceptive effectiveness

2) Summary: In studies conducted with oral contraceptives, concurrent
of oxcarbazepine with an oral contraceptive has decreased plasma conc
2 hormonal components: ethinyl estradiol (EE) and levonorgestrel (LNG)
TRILEPTAL(R) oral tablets, oral suspension, 2005). Contraceptive effec
be reduced when hormonal contraceptives (oral, transdermal, or vaginal
coadministered with some drugs, such as oxcarbazepine, that increase
metabolism of contraceptive steroids. This could result in unintended pre
breakthrough bleeding. Caution is advised when oxcarbazepine is admi
concurrently with hormonal contraceptives (Prod Info ORTHO EVRA(R)
system, 2005). Patients should be advised about using additional contra
methods (Prod Info NUVARING(R) vaginal ring, 2005).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Concurrent use of oxcarbazepine with hormon
contraceptives (oral, transdermal, or vaginal ring) may result in decrease
contraceptive efficacy, leading to unintended pregnancy or breakthrough
Use caution if oxcarbazepine is administered concomitantly with a comb
contraceptive.

7) Probable Mechanism: increased metabolism of contraceptive steroid

8) Literature Reports

a) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics o
estradiol (EE) and levonorgestrel (LNG) were studied in 10 healthy
had taken triphasic oral contraceptives for at least three menstrual c
300 mg was administered once on day 16 of the first study cycle, tw
day 17, and three times daily from day 18 of the first cycle through c
second cycle. Combined use resulted in a significant decrease in th
the concentration-time curve (AUC) for both EE (3 +/- 1.2 vs 1.6 +/-
and LNG (29.3 +/- 94.6 vs 189.5 +/- 71.7 nmol/h) (p = 0.006 for both
not a significant change in mean maximum concentration (Cmax) va
EE or LNG. Progesterone levels were low throughout the study indi
anovulation, but one subject had prolonged menstrual bleeding and
experienced breakthrough bleeding which indicates a potential loss
contraceptive efficacy (Klosterskov-Jensen et al, 1992).

b) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics o
estradiol (EE) and levonorgestrel (LN) were studied on 16 healthy w
18 to 44 years in a randomized double-blind cross-over design. Dur
different menstrual cycles, each woman was given placebo or 1200
in random sequence for 26 consecutive days with a one cycle wash
between. An oral contraceptive containing 50 mcg EE and 250 mcg
for the first 21 days of each cycle. Plasma concentrations of EE and
measured at regular intervals on days 21 to 23 of each cycle. Comp
placebo, a 47% decrease in area under the concentration-time curv
both EE and LN was seen during OCBZ treatment. Peak plasma EE
concentrations decreased from 180 pg/ml to 117 pg/ml during the p
OCBZ cycle, respectively (p less than 0.01) and the LN concentratio
from 10.2 to 7.7 ng/ml (p less than 0.01). In addition, the half-lives o
decreased from 13.6 to 7.9 hours (p less than 0.01) and from 28.8 t
respectively (p less than 0.01) (Fattore et al, 1999).

c) Concurrent administration of oxcarbazepine with an oral contrac
affected plasma concentrations 2 hormonal components: ethinyl est
and levonorgestrel (LNG). In studies conducted with oral combinatio
contraceptives, the mean area under the concentration-time curve (
for EE were reduced by 48% (90% confidence interval (CI): 22 to 65

and 52% (90% CI: 38 to 52) in another study. The mean AUC value were reduced by 32% (90% CI: 20 to 45) in one study and 52% (90 52) in another study (Prod Info TRILEPTAL(R) oral tablets, oral sus 2005).

3.5.1.L Mestranol

1) Interaction Effect: decreased contraceptive effectiveness

2) Summary: In studies conducted with oral contraceptives, concurrent of oxcarbazepine with an oral contraceptive has decreased plasma conc 2 hormonal components: ethinyl estradiol (EE) and levonorgestrel (LNG) TRILEPTAL(R) oral tablets, oral suspension, 2005). Contraceptive effec be reduced when hormonal contraceptives (oral, transdermal, or vaginal coadministered with some drugs, such as oxcarbazepine, that increase t metabolism of contraceptive steroids. This could result in unintended pre breakthrough bleeding. Caution is advised when oxcarbazepine is admi concurrently with hormonal contraceptives (Prod Info ORTHO EVRA(R) system, 2005). Patients should be advised about using additional contra methods (Prod Info NUVARING(R) vaginal ring, 2005).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Concurrent use of oxcarbazepine with hormon contraceptives (oral, transdermal, or vaginal ring) may result in decrease contraceptive efficacy, leading to unintended pregnancy or breakthrough Use caution if oxcarbazepine is administered concomitantly with a comb contraceptive.

7) Probable Mechanism: increased metabolism of contraceptive steroid

8) Literature Reports

a) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics o estradiol (EE) and levonorgestrel (LNG) were studied in 10 healthy had taken triphasic oral contraceptives for at least three menstrual c 300 mg was administered once on day 16 of the first study cycle, tw day 17, and three times daily from day 18 of the first cycle through c second cycle. Combined use resulted in a significant decrease in th the concentration-time curve (AUC) for both EE (3 +/- 1.2 vs 1.6 +/- and LNG (29.3 +/- 94.6 vs 189.5 +/- 71.7 nmol/h) (p = 0.006 for both not a significant change in mean maximum concentration (Cmax) va EE or LNG. Progesterone levels were low throughout the study indi anovulation, but one subject had prolonged menstrual bleeding and experienced breakthrough bleeding which indicates a potential loss contraceptive efficacy (Klosterskov-Jensen et al, 1992).

b) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics o estradiol (EE) and levonorgestrel (LN) were studied on 16 healthy w 18 to 44 years in a randomized double-blind cross-over design. Dur different menstrual cycles, each woman was given placebo or 1200 in random sequence for 26 consecutive days with a one cycle wash between. An oral contraceptive containing 50 mcg EE and 250 mcg for the first 21 days of each cycle. Plasma concentrations of EE and measured at regular intervals on days 21 to 23 of each cycle. Comp placebo, a 47% decrease in area under the concentration-time curv both EE and LN was seen during OCBZ treatment. Peak plasma EE concentrations decreased from 180 pg/ml to 117 pg/ml during the p OCBZ cycle, respectively (p less than 0.01) and the LN concentratio from 10.2 to 7.7 ng/ml (p less than 0.01). In addition, the half-lives o decreased from 13.6 to 7.9 hours (p less than 0.01) and from 28.8 t respectively (p less than 0.01) (Fattore et al, 1999).

c) Concurrent administration of oxcarbazepine with an oral contrac affected plasma concentrations 2 hormonal components: ethinyl est and levonorgestrel (LNG). In studies conducted with oral combinatio contraceptives, the mean area under the concentration-time curve (for EE were reduced by 48% (90% confidence interval (CI): 22 to 65 and 52% (90% CI: 38 to 52) in another study. The mean AUC value were reduced by 32% (90% CI: 20 to 45) in one study and 52% (90 52) in another study (Prod Info TRILEPTAL(R) oral tablets, oral sus 2005).

3.5.1.M Norelgestromin

1) Interaction Effect: decreased contraceptive effectiveness
2) Summary: In studies conducted with oral contraceptives, concurrent
of oxcarbazepine with an oral contraceptive has decreased plasma conc
2 hormonal components: ethinyl estradiol (EE) and levonorgestrel (LNG)
TRILEPTAL(R) oral tablets, oral suspension, 2005). Contraceptive effec
be reduced when hormonal contraceptives (oral, transdermal, or vaginal
coadministered with some drugs, such as oxcarbazepine, that increase
metabolism of contraceptive steroids. This could result in unintended pre
breakthrough bleeding. Caution is advised when oxcarbazepine is admi
concurrently with hormonal contraceptives (Prod Info ORTHO EVRA(R)
system, 2005). Patients should be advised about using additional contra
methods (Prod Info NUVARING(R) vaginal ring, 2005).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concurrent use of oxcarbazepine with hormon
contraceptives (oral, transdermal, or vaginal ring) may result in decrease
contraceptive efficacy, leading to unintended pregnancy or breakthrough
Use caution if oxcarbazepine is administered concomitantly with a comb
contraceptive.
7) Probable Mechanism: increased metabolism of contraceptive steroid
8) Literature Reports
a) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics o
estradiol (EE) and levonorgestrel (LNG) were studied in 10 healthy
had taken triphasic oral contraceptives for at least three menstrual c
300 mg was administered once on day 16 of the first study cycle, tw
day 17, and three times daily from day 18 of the first cycle through c
second cycle. Combined use resulted in a significant decrease in th
the concentration-time curve (AUC) for both EE (3 +/- 1.2 vs 1.6 +/-
and LNG (29.3 +/- 94.6 vs 189.5 +/- 71.7 nmol/h) (p = 0.006 for both

and 52% (90% CI: 38 to 52) in another study. The mean AUC value
were reduced by 32% (90% CI: 20 to 45) in one study and 52% (90
52) in another study (Prod Info TRILEPTAL(R) oral tablets, oral sus
2005).

3.5.1.N Norethindrone

1) Interaction Effect: decreased contraceptive effectiveness
2) Summary: In studies conducted with oral contraceptives, concurrent
of oxcarbazepine with an oral contraceptive has decreased plasma conc
2 hormonal components: ethinyl estradiol (EE) and levonorgestrel (LNG)
TRILEPTAL(R) oral tablets, oral suspension, 2005). Contraceptive effec
be reduced when hormonal contraceptives (oral, transdermal, or vaginal

coadministered with some drugs, such as oxcarbazepine, that increase t
metabolism of contraceptive steroids. This could result in unintended pre
breakthrough bleeding. Caution is advised when oxcarbazepine is admi
concurrently with hormonal contraceptives (Prod Info ORTHO EVRA(R)
system, 2005). Patients should be advised about using additional contra
methods (Prod Info NUVARING(R) vaginal ring, 2005).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Concurrent use of oxcarbazepine with hormon
contraceptives (oral, transdermal, or vaginal ring) may result in decrease
contraceptive efficacy, leading to unintended pregnancy or breakthrough
Use caution if oxcarbazepine is administered concomitantly with a comb
contraceptive.

7) Probable Mechanism: increased metabolism of contraceptive steroid

8) Literature Reports

a) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics c
estradiol (EE) and levonorgestrel (LNG) were studied in 10 healthy
had taken triphasic oral contraceptives for at least three menstrual c
300 mg was administered once on day 16 of the first study cycle, tw
day 17, and three times daily from day 18 of the first cycle through c
second cycle. Combined use resulted in a significant decrease in th
the concentration-time curve (AUC) for both EE (3 +/- 1.2 vs 1.6 +/-
and LNG (29.3 +/- 94.6 vs 189.5 +/- 71.7 nmol/h) (p = 0.006 for both
not a significant change in mean maximum concentration (Cmax) va
EE or LNG. Progesterone levels were low throughout the study indi
anovulation, but one subject had prolonged menstrual bleeding and
experienced breakthrough bleeding which indicates a potential loss
contraceptive efficacy (Klosterskov-Jensen et al, 1992).

b) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics c
estradiol (EE) and levonorgestrel (LN) were studied on 16 healthy w
18 to 44 years in a randomized double-blind cross-over design. Dur
different menstrual cycles, each woman was given placebo or 1200
in random sequence for 26 consecutive days with a one cycle wash
between. An oral contraceptive containing 50 mcg EE and 250 mcg
for the first 21 days of each cycle. Plasma concentrations of EE and
measured at regular intervals on days 21 to 23 of each cycle. Comp
placebo, a 47% decrease in area under the concentration-time curv
both EE and LN was seen during OCBZ treatment. Peak plasma EE
concentrations decreased from 180 pg/ml to 117 pg/ml during the p
OCBZ cycle, respectively (p less than 0.01) and the LN concentratio
from 10.2 to 7.7 ng/ml (p less than 0.01). In addition, the half-lives o
decreased from 13.6 to 7.9 hours (p less than 0.01) and from 28.8 t
respectively (p less than 0.01) (Fattore et al, 1999).

c) Concurrent administration of oxcarbazepine with an oral contrac
affected plasma concentrations 2 hormonal components: ethinyl est
and levonorgestrel (LNG). In studies conducted with oral combinatio
contraceptives, the mean area under the concentration-time curve (
for EE were reduced by 48% (90% confidence interval (CI): 22 to 65
and 52% (90% CI: 38 to 52) in another study. The mean AUC value
were reduced by 32% (90% CI: 20 to 45) in one study and 52% (90
52) in another study (Prod Info TRILEPTAL(R) oral tablets, oral sus
2005).

3.5.1.O Norgestrel

1) Interaction Effect: decreased contraceptive effectiveness

2) Summary: In studies conducted with oral contraceptives, concurrent
of oxcarbazepine with an oral contraceptive has decreased plasma conc
2 hormonal components: ethinyl estradiol (EE) and levonorgestrel (LNG)
TRILEPTAL(R) oral tablets, oral suspension, 2005). Contraceptive effec
be reduced when hormonal contraceptives (oral, transdermal, or vaginal
coadministered with some drugs, such as oxcarbazepine, that increase t
metabolism of contraceptive steroids. This could result in unintended pre
breakthrough bleeding. Caution is advised when oxcarbazepine is admi
concurrently with hormonal contraceptives (Prod Info ORTHO EVRA(R)
system, 2005). Patients should be advised about using additional contra
methods (Prod Info NUVARING(R) vaginal ring, 2005).

3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concurrent use of oxcarbazepine with hormon contraceptives (oral, transdermal, or vaginal ring) may result in decrease contraceptive efficacy, leading to unintended pregnancy or breakthrough Use caution if oxcarbazepine is administered concomitantly with a comb contraceptive.
7) Probable Mechanism: increased metabolism of contraceptive steroid
8) Literature Reports
a) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics c estradiol (EE) and levonorgestrel (LNG) were studied in 10 healthy had taken triphasic oral contraceptives for at least three menstrual c 300 mg was administered once on day 16 of the first study cycle, tw day 17, and three times daily from day 18 of the first cycle through c second cycle. Combined use resulted in a significant decrease in th the concentration-time curve (AUC) for both EE (3 +/- 1.2 vs 1.6 +/- and LNG (29.3 +/- 94.6 vs 189.5 +/- 71.7 nmol/h) (p = 0.006 for both not a significant change in mean maximum concentration (Cmax) va EE or LNG. Progesterone levels were low throughout the study indi anovulation, but one subject had prolonged menstrual bleeding and experienced breakthrough bleeding which indicates a potential loss contraceptive efficacy (Klosterskov-Jensen et al, 1992).
b) The effects of oxcarbazepine (OCBZ) on the pharmacokinetics c estradiol (EE) and levonorgestrel (LN) were studied on 16 healthy w 18 to 44 years in a randomized double-blind cross-over design. Dur different menstrual cycles, each woman was given placebo or 1200 in random sequence for 26 consecutive days with a one cycle wash between. An oral contraceptive containing 50 mcg EE and 250 mcg for the first 21 days of each cycle. Plasma concentrations of EE anc measured at regular intervals on days 21 to 23 of each cycle. Comp placebo, a 47% decrease in area under the concentration-time curv both EE and LN was seen during OCBZ treatment. Peak plasma EE concentrations decreased from 180 pg/ml to 117 pg/ml during the p OCBZ cycle, respectively (p less than 0.01) and the LN concentratic from 10.2 to 7.7 ng/ml (p less than 0.01). In addition, the half-lives o decreased from 13.6 to 7.9 hours (p less than 0.01) and from 28.8 t respectively (p less than 0.01) (Fattore et al, 1999).
c) Concurrent administration of oxcarbazepine with an oral contrac affected plasma concentrations 2 hormonal components: ethinyl est and levonorgestrel (LNG). In studies conducted with oral combinatic contraceptives, the mean area under the concentration-time curve (for EE were reduced by 48% (90% confidence interval (CI): 22 to 65 and 52% (90% CI: 38 to 52) in another study. The mean AUC value were reduced by 32% (90% CI: 20 to 45) in one study and 52% (90 52) in another study (Prod Info TRILEPTAL(R) oral tablets, oral sus 2005).

3.5.1.P Phenobarbital
1) Interaction Effect: decreased concentration of the active 10-monohyc metabolite of oxcarbazepine and potential loss of oxcarbazepine efficacy
2) Summary: Concurrent administration of oxcarbazepine (600 to 1,800 (mg)/day) in patients receiving treatment with phenobarbital (100 to 150 resulted in a 25% decrease (90% confidence interval (CI), 12% decrease decrease) in the plasma concentration of oxcarbazepine's 10-monohydr (MHD) and a 14% increase (90% confidence interval (CI), 2% increase t increase) in the phenobarbital concentration (Prod Info TRILEPTAL(R) c oral suspension, 2005). Although the clinical significance of this interacti unknown, MHD is the pharmacologically active metabolite of oxcarbazep decreased plasma MHD concentrations may result in potential loss of ox efficacy. If oxcarbazepine and phenobarbital are administered concurrer response to oxcarbazepine may need to be monitored.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Coadministration of oxcarbazepine and pheno resulted in decreased concentrations of the active 10-monohydroxy met

oxcarbazepine. Monitor patients for clinical response to oxcarbazepine.
7) Probable Mechanism: potential induction of cytochrome P450-mediat oxcarbazepine metabolism

3.5.1.Q Phenytoin

1) Interaction Effect: an increased risk of phenytoin toxicity (ataxia, hype nystagmus, tremor)
2) Summary: Coadministration of phenytoin and oxcarbazepine (600 to milligrams (mg)/day) resulted in decreased levels of the pharmacologica monohydroxy derivative (MHD) of oxcarbazepine while oxcarbazepine d 1200 to 2400 mg/day resulted in increased levels of phenytoin plasma c Patients should be monitored for signs of phenytoin toxicity (ataxia, hype nystagmus, tremor) when receiving oxcarbazepine concurrently, especia oxcarbazepine doses exceed 1200 mg daily. A decrease in the phenytoi be required (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 200
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Concurrent administration of oxcarbazepine ar have resulted in increased plasma levels of phenytoin. Monitor patients f phenytoin toxicity (ataxia, hyperreflexia, nystagmus, tremor) when receiv oxcarbazepine concurrently, especially when oxcarbazepine doses exce daily. A decrease in the phenytoin dose may be required.
7) Probable Mechanism: potential inhibition of cytochrome P450 -media metabolism
8) Literature Reports
a) Administration of phenytoin in doses of 250 to 500 milligrams (m patients concurrently receiving oxcarbazepine in doses of 600 to 18 resulted in a less than 10% change in the concentration of phenytoi concentrations of the active 10-monohydroxy derivative (MHD) of ox were decreased by 30% (90% confidence interval (CI): 3% decreas decrease). When the same doses of phenytoin were combined with oxcarbazepine in doses greater than 1200 to 2400 mg daily, there v 40% increase (90% CI: 12% increase to 60% increase) in phenytoir concentrations (Prod Info TRILEPTAL(R) oral tablets, oral suspensi
b) In polypharmacy studies employing add-on oxcarbazepine and carbamazepine, increased serum levels of valproic acid and phenyt observed with patients receiving oxcarbazepine. This was attributec enzyme induction (Bulau et al, 1987; Houtkooper et al, 1987a). Alte dose-dependent enzyme induction has been reported by some inve higher doses of oxcarbazepine produced enzyme induction that was carbamazepine (Patsalos et al, 1990b). Further studies are required if oxcarbazepine will offer a significant advantage over carbamazep regard to enzyme induction.

3.5.1.R Selegiline

1) Interaction Effect: an increase in selegiline plasma concentration
2) Summary: In subjects who had received carbamazepine 400 mg/day slightly increased levels of selegiline and its metabolites were seen after application of selegiline transdermal patch 6 mg/24 hr. Changes in the s plasma levels were nearly 2-fold and variable across the subject populat EMSAM(R) transdermal patch, 2008). Although not studied with oxcarba similar interaction would be expected. Concomitant use of oxcarbazepin selegiline is contraindicated. It is recommended that selegiline be discor minimum of 14 days prior to initiation of oxcarbazepine when necessary EMSAM(R) transdermal patch, 2008).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of oxcarbazepine and selegil contraindicated. Selegiline should be discontinued for a minimum of 14 d oxcarbazepine therapy is initiated (Prod Info EMSAM(R) transdermal pa
7) Probable Mechanism: unknown

3.5.1.S Simvastatin

1) Interaction Effect: reduced simvastatin exposure
2) Summary: Oxcarbazepine is a molecular derivative of carbamazepin

a similar ability to induce cytochrome P450/3A4. Theoretically, oxcarbaz
expected to induce the metabolism of simvastatin, a cytochrome P450/3
In a controlled study, the concurrent administration of carbamazepine wi
significantly reduced maximum serum concentration, serum half-life, and
the concentration-time curve for both simvastatin and its active metaboli
acid (Ucar et al, 2004).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor cholesterol levels in patients receiving
therapy with oxcarbazepine and simvastatin. Simvastatin dose may nee
adjusted.
7) Probable Mechanism: induction of CYP3A4-mediated first-pass meta
simvastatin by oxcarbazepine
8) Literature Reports
a) Concurrent administration of simvastatin with carbamazepine (a
anticonvulsant chemically related to oxcarbazepine) significantly rec
simvastatin exposure. In a randomized, crossover study with a 2-we
period, healthy subjects (n=12) received either no drug or carbamaz
milligrams (mg) once daily for 2 days, after which the active drug gr
carbamazepine 300 mg twice daily for the next 12 days. On day 15
after the last carbamazepine dose), subjects fasted for 2 hours prio
single dose of simvastatin 80 mg. Serial blood samples were obtain
immediately prior to and for 24 hours after simvastatin administratio
Carbamazepine co-administration significantly reduced the mean m
serum concentration for both simvastatin and its active metabolite s
acid (from 18.7 nanograms/milliliter (ng/mL) to 6.0 ng/mL and from
1.1 ng/mL, respectively; p less than 0.01, both values). Simvastatin
simvastatin acid mean areas under the concentration-time curves (A
declined from 88.8 ng/mL x hour to 22.6 ng/mL x hour and from 33.
hour to 6.8 ng/mL x hour, respectively (p less than 0.001, both value
Concurrent administration with carbamazepine also significantly red
simvastatin acid serum mean half-life (from 5.9 hours to 3.7 hours, p
0.01) (Ucar et al, 2004).

3.5.1.T Tolvaptan

1) Interaction Effect: decreased tolvaptan plasma concentrations
2) Summary: Concomitant use of tolvaptan (primarily metabolized by CY
oxcarbazepine (a CYP3A inducer) may reduce tolvaptan exposure and s
avoided. If concomitant use is required, tolvaptan dose increases may b
to achieve the same clinical effect (Prod Info SAMSCA(TM) oral tablets,
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Concomitant use of oxcarbazepine and tolvapt
avoided due to a risk of reduced plasma concentrations of tolvaptan. If c
use is required, the dose of tolvaptan may need to be increased to achie
clinical effect (Prod Info SAMSCA(TM) oral tablets, 2009).
7) Probable Mechanism: induction of CYP3A-mediated tolvaptan metab
oxcarbazepine

3.5.1.U Valproic Acid

1) Interaction Effect: decreased plasma concentration of the active 10-m
metabolite of oxcarbazepine
2) Summary: Concurrent administration of oxcarbazepine (600 to 1,800
(mg)/day) in patients receiving treatment with valproic acid (400 to 2,800
resulted in a 18% decrease (90% confidence interval, 13% decrease to
decrease) in the plasma concentration of oxcarbazepine's 10-monohydr
(MHD) and a less than 10% change in the valproic acid concentration (P
TRILEPTAL(R) oral tablets, oral suspension, 2005). Although, the clinica
of this interaction is unknown, decreased plasma MHD concentrations m
potential loss of oxcarbazepine efficacy. If oxcarbazepine and valproic a
administered concurrently, clinical response to oxcarbazepine may neec
monitored.
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable

6) Clinical Management: Coadministration of oxcarbazepine and valproi result in a decreased concentration of the active 10-monohydroxy metab oxcarbazepine. Monitor patients for clinical response to oxcarbazepine.
7) Probable Mechanism: unknown

3.5.1.V Verapamil

1) Interaction Effect: decreased plasma levels of the active 10-monohyc metabolite of oxcarbazepine and potential loss of oxcarbazepine efficacy
2) Summary: Concurrent administration of oxcarbazepine (OCBZ) and v resulted in a 20% decrease in the plasma concentration of 10-monohydr (MHD) (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005; Ba 1994). Although the clinical significance of this interaction is unknown, M active metabolite of OCBZ and decreased plasma MHD concentrations r potential loss of OCBZ efficacy. If OCBZ and verapamil are administered clinical response to OCBZ may need to be monitored.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: Coadministration of oxcarbazepine and verapa in decreased plasma levels of the active 10-monohydroxy metabolite of oxcarbazepine. Although the clinical significance of this interaction is unl oxcarbazepine and verapamil are coadministered, monitor clinical respo oxcarbazepine.
7) Probable Mechanism: unknown
8) Literature Reports
a) Concurrent administration of oxcarbazepine (OCBZ) and verapa decreased plasma concentration of the 10-monohydroxy derivative active metabolite of OCBZ. In healthy volunteers (n=10), upon titrati to 900 milligrams/day (mg/day), verapamil (240 mg/day) was admin week. The area under the concentration-time curve (AUC) of MHD c 20%; however, AUC was unchanged for OCBZ. The mechanism for in MHD plasma concentration and its clinical significance are unkno al, 1994).

4.0 Clinical Applications

4.1 Monitoring Parameters

A) Therapeutic

1) Laboratory Parameters

a) In patients with epilepsy, therapeutic serum levels have not been ade established.
b) In women who plan on becoming pregnant, obtaining concentrations oxcarbazepine and mono-hydroxy-carbazepine (MHD) before becoming during the pregnancy may be beneficial. Although, therapeutic concentra not been established, prepregnancy concentrations in an optimally-treat provide a reference concentration for comparison to concentrations duri when concentrations decrease due to changes in the pharmacokinetic c of oxcarbazepine. Possible sampling times could be once monthly, with in patients with mild and stable epilepsy, and every 3 to 4 days for 2 wee delivery in patients who had their dosage adjusted during pregnancy (To Battino, 2007).

c) In patients with trigeminal neuralgia, therapeutic serum concentration metabolite of oxcarbazepine (10-hydroxy-carbazepine) have ranged fror micromoles/L (Zakrzewska & Patsalos, 1989a).

2) Physical Findings

a) In patients with epilepsy, seizure frequency and electroencephalogra

b) A reduction or elimination of pain is indicative of a therapeutic respor with trigeminal neuralgia.

B) Toxic

1) Laboratory Parameters

a) Serum sodium, during maintenance treatment, particularly if the patie receiving other medications known to decrease serum sodium levels or i hyponatremia (nausea, malaise, headache, lethargy, confusion, obtunda increase in seizure frequency or severity) (Prod Info TRILEPTAL(R) oral suspension, 2005)

b) Liver function tests

c) Blood counts

d) Serum lipid levels

e) Serum levels of concomitant antiepileptic drugs (AEDs) during oxcarb titration. Levels of AEDs may change, especially at oxcarbazepine doses than 1200 milligrams/day (Prod Info TRILEPTAL(R) oral tablets, oral sus 2005)

2) Physical Findings

a) Body weight

b) Temperature

c) Blood pressure

d) Data reviewed by the US Food and Drug Administration suggest an i of suicidal behavior or ideation may exist in patients receiving therapy w antiepileptic drugs (AEDs). The increased risk of suicidality was noted at starting an AED and continued to at least 24 weeks. Patients treated for psychiatric disorders, or other conditions were all at an increased risk for compared to placebo. Closely monitor patients treated with AEDs for em worsening of depression, suicidality, and other unusual changes in beha may include symptoms such as anxiety, agitation, hostility, mania, and h (US Food and Drug Administration, 2008).

4.2 Patient Instructions

A) Oxcarbazepine (By mouth)

Oxcarbazepine

Treats seizures caused by epilepsy in adults and children.

When This Medicine Should Not Be Used:
You should not use this medicine if you have had an allergic reaction to oxca

How to Use This Medicine:
Tablet, Liquid

Your doctor will tell you how much of this medicine to use and how often may need to be changed several times in order to find out what works be not use more medicine or use it more often than your doctor tells you to.
You may take this medicine with or without food.
Measure the oral liquid medicine with a marked measuring spoon, oral s medicine cup.
Shake the oral liquid well just before using. You can take the medicine d the oral syringe, or you can mix the medicine in a glass with a small amo
If you mix the medicine, drink the mixture right away. Do not save any m later.

If a Dose is Missed:

If you miss a dose or forget to use your medicine, use it as soon as you almost time for your next dose, wait until then to use the medicine and s dose. Do not use extra medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:

Store the medicine in a closed container at room temperature, away fror moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to d outdated medicine or medicine no longer needed. Dispose of any leftove

medicine 7 weeks after you open the bottle.
Keep all medicine away from children and never share your medicine wi

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including ov
medicines, vitamins, and herbal products.
Make sure your doctor knows if you are also using any other medicines
seizures. Seizure medicine includes carbamazepine (Tegretol®), phenol
phenytoin (Dilantin®), or valproic acid (Depakote®).
Tell your doctor if you also use felodipine (Plendil®) or verapamil (Calan
Do not drink alcohol while you are using this medicine.

Warnings While Using This Medicine:
Make sure your doctor knows if you are pregnant or breast feeding.
Tell your doctor if you have kidney disease, or if you have ever had an a
reaction to carbamazepine (Tegretol®).
Birth control pills may not work while you are using oxcarbazepine. To k
getting pregnant, use another form of birth control. Other forms include c
diaphragm, or contraceptive foam or jelly.
This medicine may make you dizzy or drowsy. Avoid driving, using mach
anything else that could be dangerous if you are not alert.
Do not stop using this medicine suddenly without asking your doctor. Yo
slowly decrease your dose before stopping it completely.

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swellin
your mouth or throat, chest tightness, trouble breathing.
Blistering, peeling, red skin rash.
Blurred vision or double vision.
Change in how much or how often you urinate.
Confusion, weakness, and muscle twitching.
Fast, slow, or pounding heartbeat.
Fever with rash, swollen glands in your neck.
Nausea, vomiting, loss of appetite, pain in your upper stomach.
Rapid eye movements (especially in children).
Seizures.
Trouble walking, speaking, or controlling body movement.
Uncontrollable shaking.
Unusual bleeding, bruising, or weakness.
Visual changes.

If you notice these less serious side effects, talk with your doctor:
Dizziness or drowsiness.
Headache.
Joint pain.
Mild nausea, vomiting, stomach pain, belching, or gas.
Stomach pain or indigestion

If you notice other side effects that you think are caused by this medicine, tel

4.3 Place In Therapy

A) Oxcarbazepine appears to be as effective as carbamazepine in the treatment and slightly better tolerated. It should be considered an alternative in epileptic pat to tolerate carbamazepine, including those with hypersensitivity, although caution these patients.

B) In the treatment of trigeminal neuralgia, oxcarbazepine has been effective in p unresponsive to, or intolerant of, carbamazepine, which is currently the drug of ch superiority of oxcarbazepine over carbamazepine has been suggested, but these employed small numbers of patients and were not adequately controlled.

C) Dose-dependent enzyme induction has been reported by some investigators, doses of oxcarbazepine producing effects similar to carbamazepine (Patsalos et the optimal dose of oxcarbazepine remains undefined, further studies will also be determine if the drug will offer a significant advantage in regard to enzyme induct autoinduction.

D) Hyponatremia is a concern with oxcarbazepine therapy, and may limit its use anticonvulsant and antineuralgic. The use of oxcarbazepine in diabetes insipidus

suggested, although data is not available for this indication (Pendlebury et al, 198

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) Oxcarbazepine, an anticonvulsant, is the 10-keto derivative of carbamaze Chemically, oxcarbazepine is 10,11-dihydro-10-oxo-5H-dibenz(b,f)azepine 5 (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005; Anon, 1989; A The metabolite 10-hydroxy-carbazepine is primarily responsible for the pharr activity of oxcarbazepine. However, the exact mechanism of action for its ant is unknown. In vitro electrophysiological studies suggest that drug-induced bl voltage-sensitive sodium channels may prevent repetitive neuronal firing and stabilization of hyperexcited neural membranes and the diminution of synapti propagation. Increased potassium conductance and high-voltage calcium cha modulation may also play a role (Prod Info TRILEPTAL(R) oral tablets, oral s 2005).

2) Animal studies have demonstrated that the mechanism of action of oxcarl similar to that of carbamazepine, which is inhibition of seizure propagation via posttetanic potentiation of synaptic transmission (Baltzer & Schmutz, 1978; A Anon, 1990). The spectrum of antiepileptic activity of each agent is also simil Schmutz, 1978; Anon, 1989). Antineuralgic properties of oxcarbazepine have demonstrated (Farago, 1987; Zakrzewska & Patsalos, 1989).

B) REVIEW ARTICLES

1) Dosages and formulations of antiepileptic drugs used to treat pediatric ep been reviewed (Bourgeois, 2002).

2) The pharmacology and therapeutic use of oxcarbazepine has been reviev 1999; Grant & Faulds, 1992; Bulau & Froscher, 1991; Perucca, 1993; Benete

3) A review of newer antiepileptic medications, including a summary of clinic and recommendations for use, has been published (Dichter & Brodie, 1996).

4) The pharmacokinetic interaction profile of oxcarbazepine and its importan has been reviewed (Baruzzi et al, 1993).

4.5 Therapeutic Uses

Antineoplastic adverse reaction - Peripheral neuropathy; Prophylaxis

Bipolar disorder

Panic disorder

Partial seizure, monotherapy

Partial seizure; Adjunct

Spasticity

Trigeminal neuralgia

4.5.A Antineoplastic adverse reaction - Peripheral neuropathy; Prophylaxis

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RA

2) Summary:

A randomized, open-label trial (n=40) found that oxcarbazepine may oxaliplatin-induced peripheral neuropathy symptoms (Argyriou et al,

3) Adult:

a) A randomized, open-label trial found that oxcarbazepine may preven induced peripheral neuropathy symptoms. Adult patients (age 61.8 years deviation (SD) +/- 9.1) with advanced colon cancer were randomly assig chemotherapy with the FOLFOX-4 regimen plus oxcarbazepine (150 mil (mg) /day initially, doubled weekly for 4 weeks to a maximum dose of 60

daily), or the FOLFOX-4 regimen alone. The oxcarbazepine titration peri
followed by a 20-week maintenance period. The primary endpoint meas
incidence of peripheral neuropathy. Investigators also evaluated differen
total neuropathy scores (TNS; 1-11 = mild, 12-23 = moderate, greater th
severe), neurologic disability scores (NDS) and neurologic symptom sco
The incidence of oxaliplatin-induced neuropathy among the patients who
the trial (n=32) was 5 of 16 patients receiving oxcarbazepine (31.2%) , w
incidence of oxaliplatin-induced neuropathy occurred in 12 of 16 of the c
(75%). This represents a relative risk of 0.42 (95% confidence interval (C
0.91, p=0.033). The intention-to-treat analysis (n=40) also demonstrated
significant results favoring oxaliplatin (p=0.05). The mean TNS scores w
in the patients treated with oxacarbazepine vs 11.2 +/- 9.05 in the patien
with oxcarbazepine (p=0.016). The mean NDS (5.1 +/- 8.2 vs 20 +/- 23.1
and the mean NSS (0.6 +/- 0.9 vs 1.5 +/- 1.3, p=0.025) were both lower
treated with oxcarbazepine. Adverse effects were mild to moderate in se
occurred at similar rates in both treatment groups; the most common effe
diarrhea, myelosuppression, dizziness, nausea, vomiting, and headache
Two patients in the oxcarbazepine group experienced acute headache a
during the titration period that caused them to withdraw from the study; t
symptoms improved shortly after oxcarbazepine discontinuation (Argyric

4.5.B Bipolar disorder

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RA

2) Summary:

Comparable results to other mood stabilizing agents (Ghaemi et al,
et al, 1983)
Limited data on usefulness as add-on therapy to lithium (Vieta et al,
Benedetti et al, 2004; Vieta et al, 2008)

3) Adult:

a) In a 52-week, multicenter, double-blind, randomized, placebo-control
prophylaxis trial (n=55), the addition of oxcarbazepine as adjunctive trea
maintenance lithium therapy of bipolar I and II disorder did not significan
onset of first relapse. Patients (aged 43.5 +/- 12 years, 65% female) with
of bipolar I or II disorder, who were not in an acute phase, but had at lea
episodes in the past year (with the last episode over 6 months prior to en
study) and receiving concomitant lithium (lithium levels greater than or e
milliequivalents/liter) during the past year were assigned to adjunctive ox
(n=26) treatment or placebo (n=29). Oxcarbazepine was started at 300 m
(mg) once a day for 3 days and titrated up by 300 mg increments every
administered twice a day, to a total daily dose of 1200 mg per day. After
week titration, the dose was maintained until the end of the study. Lithiu
administered open label throughout the study with levels monitored for a
months. Patients were required to stop all psychoactive, antipsychotic an
antidepressant medications 72 hours before the start of the study. Loraz
allowed as a concomitant medication up to 5 mg per day for insomnia or
primary efficacy variable was the length of the remission period (time to
manic or depressive episode). Based on an intent-to-treat analysis, the a
until first relapse of any type was not significantly different with the additi
oxcarbazepine compared with placebo (19.2 weeks vs 18.6 weeks; p=0.
of 38.5% and 58.6% patients in the oxcarbazepine and placebo arm, res
relapsed (p=0.1354). The number needed to treat (NNT) with oxcarbaze
any kind of relapse was 5 (odds ratio 0.44; 95% confidence interval, 0.1
study showed a statistically significant difference on the Barratt Impulsiv
Scale (BIS) (p=0.044) with a positive effect of oxcarbazepine in preventi
impulsivity. Overall, oxcarbazepine was well tolerated with no statistical
incidence of adverse events between the 2 groups. Larger trials are nee
evaluating oxcarbazepine in bipolar disorder (Vieta et al, 2008).

b) Adjunctive oxcarbazepine may be useful in the treatment of bipolar d
satisfactorily controlled by lithium. In an open-label study, patients with b
disorder taking lithium for at least 1 month (lithium levels ranging from 0.
milliequivalents/liter) were prescribed oxcarbazepine 300 milligrams/day
Doses of oxcarbazepine were increased to a maximum dose of 2400 mg

maintenance dose 919 mg/day). Patients had bipolar I (n=16) or bipolar
had a Clinical Global Impression Severity score of 4 to 6 at baseline. Oth
psychotropic agents were allowed but were not modified or changed dur
weeks of study. Sedation (66.7%), increased appetite (50%), weight gai
tremors (27.8%), constipation (16.7%), nausea/vomiting (16.7%), dry mo
and insomnia (11.1%) were reported with the use of oxcarbazepine. The
Clinical Global Impression-Bipolar Version Improvement (CGI-BP-I) scor
significantly from baseline at week 2, 4 and 8 (p less than 0.0001). Of th
61.1% were considered to be "responders" (CGI-BP-I score of 2 or 1 at
(Benedetti et al, 2004).

c) Authors of a retrospective chart review concluded that adjunctive or
oxcarbazepine was useful as a mood stabilizer in patients with bipolar di
Charts of patients treated with either adjunctive (n=31) or monotherapy
oxcarbazepine in a private practice clinic were reviewed. The mean oxca
dose was 1056.6 milligrams/day (mg/day) (range 150 to 2400 mg/day).
length ranged from 1 to 71 weeks (mean 16.2 weeks). Clinical response
assessed retrospectively using the Clinical Global Impressions-Improver
the patients receiving monotherapy oxcarbazepine, 36% experienced no
worsening of their symptoms, and 64% experienced mild to marked impr
patients receiving adjunctive oxcarbazepine, 39% experienced a worser
effect, and 61% experienced mild to marked improvement. Overall, 52%
discontinued treatment; 29% due to side effects and 24% due to lack of
Reported side effects included: sedation (40%), dizziness (7%), headacl
cognitive difficulty (5%), paresthesia, twitching, tactile impairment, diplop
nausea, weight gain and leg edema (2% each) (Ghaemi et al, 2003).

d) Comparable results to other mood stabilizing agents was found with
oxcarbazepine in 6 patients with acute mania (Emrich et al, 1983). Dose
2100 milligrams daily produced average decreases in the mania rating o
Multidimensional Psychiatric Scale of 50%.

4.5.C Panic disorder

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RA

2) Summary:

Effective in one case report (Windhaber et al, 1997)

3) Adult:

a) A 23-year-old man with alcohol-related seizures developed panic dis
was successfully treated with an increased dose of oxcarbazepine (Winc
1997). The patient was already receiving oxcarbazepine 600 milligrams
this was increased to 900 mg/day. The patient remained symptom-free o
month follow-up period.

4.5.D Partial seizure, monotherapy

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes; Pediatric, yes (4 years and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RA

2) Summary:

Indicated for use as monotherapy in the treatment of partial seizures
children 4 years and older (Prod Info TRILEPTAL(R) oral tablets, or
2005)

In an observational study (n=673; mean age 42.5 years) of adult ma
with partial epilepsy, oxcarbazepine improved sexual dysfunction in
preexisting sexual function disorders at baseline (Luef et al, 2009).

3) Adult:

a) Oxcarbazepine (OXC) was an effective monotherapeutic substitute w
to replace antiepileptic drugs (AED) used to maintain patients with medi
refractory partial epilepsy, in a randomized, double-blind, multicenter clir
compared two doses of oxcarbazepine (OXC 300 milligrams (mg)/day a
mg/day). Patients with a history of 2 to 40 seizures per 28-day period re

OXC 300 mg/day (n=46), or OXC 2400 mg/day (n=41) throughout a 126
treatment phase; all prior AED's were tapered and discontinued by day 4
receiving 2400 mg/day were titrated from an initial dose of 1200 mg up t
dose in 600 mg weekly increments; those patients unable to tolerate the
dose were adjusted to either 2100 mg or 1800 mg daily. Efficacy was me

b) Oxcarbazepine, 2400 milligrams/day (mg/day) in 2 divided doses, wa
monotherapy for the treatment of refractory partial seizures in 102 patien
62 years of age) in a placebo-controlled, double-blind trial. The primary e
variable was time to meet one of the exit criteria, defined as: completion
treatment phase; 4 partial seizures; 2 new-onset secondarily generalized
serial seizures; or status epilepticus. This variable was statistically signif
of oxcarbazepine (p=0.0001; by day 2.5 of the study period, 75% of the p
treated patients had met one of the exit criteria versus (vs) 25% of the pa
with oxcarbazepine. The secondary efficacy variable was the percentage
meet one of the exit criteria and was also statistically significantly lower (
0.0001) for the patients treated with oxcarbazepine (47%) vs 84% for the
treated group (Schachter et al, 1999).
c) Oxcarbazepine initiated at 600 milligrams/day, titrated to 1200 milligr
dosages in 2 daily divided doses), and maintained at the higher dose for
statistically significantly superior to placebo (p=0.046) in previously untre
(n=67; 8 to 69 years of age). The primary efficacy measure was a compa
to first seizure (Prod Info Trileptal(R), 2003a).
d) In 2 trials comparing oxcarbazepine in daily doses of 300 or 2400 mil
in patients previously treated with carbamazepine or other antiepileptic d
higher dose of oxcarbazepine was statistically significantly superior to th
(p=0.0001). Primary efficacy measures differed between the 2 studies; th
to meet exit criteria in 1 study and percentage of patients meeting exit cr
other (Prod Info Trileptal(R), 2003a).
e) Seizure frequency decreased in 32% to 48% of patients treated with
oxcarbazepine in a multicenter trial conducted over 10 years in 947 patie
al, 1993b). Patients were diagnosed with simple partial or complex partia
with or without secondary generalization and primary generalized seizur
daily doses employed were 30 milligrams/kilogram/day in children and 1
milligrams/kilogram/day in adults, usually given in 2 or 3 divided doses. (
patients experienced adverse reactions such as dizziness, sedation, fati
hyponatremia. Oxcarbazepine was used as monotherapy in 63% of the p
as part of polytherapy in 37%.
f) Similar decreases in seizure frequency were seen in a double-blind st
oxcarbazepine and carbamazepine in 16 epileptic patients inadequately
at least 1 anticonvulsant (other than carbamazepine) (Bulau et al, 1987b
patient had experienced at least 1 tonic-clonic or complex partial seizure
Oxcarbazepine or carbamazepine were added sequentially in randomize
during a 1-month titration period; therapy was continued for an additiona
Mean doses were 1111.5 and 788.5 milligrams daily for oxcarbazepine a
carbamazepine, respectively. Concomitant anticonvulsants were continu
the study. Seizure frequency was reduced by 90% during therapy with b
with 28% of all patients becoming seizure-free. Adverse effects were les
treated with oxcarbazepine. Increases in serum levels of valproic acid, p
primidone were observed in the oxcarbazepine group, presumably secon
lesser degree of enzyme induction as compared to carbamazepine.

1) Sexual Dysfunction Improvement in Male Patients with Epilepsy

a) In an observational study (n=673; mean age 42.5 years) of a
patients with partial epilepsy, oxcarbazepine improved sexual c
patients with preexisting sexual function disorders at baseline. I
received oxcarbazepine monotherapy either as initial treatment
changed from other antiepileptic drug (AED) pretreatment to ox

monotherapy; doses were titrated to the optimal therapeutic do
patients were assessed regarding their sexual dysfunction at ba
again 12 weeks later at the final examination. Seizure occurren
ratings of efficacy, and tolerability were also assessed. At base
dysfunction was reported in 228 (34%) patients, with 27 patient
antiepileptic pretreatment, 168 patients receiving enzyme-induc
pretreatment, and 33 patients receiving non-enzyme inducing A
pretreatment. Sexual dysfunction improvement was reported in
(n=181/228) of patients with preexisting sexual function disorde
months of treatment with oxcarbazepine, with no impairment re
10.1% (n=23/228) of patients at final assessment. The improve
most significant in patients receiving enzyme-inducing AED pre
Seizure occurrence per 28 days decreased during the retrospe
from a mean of 1.8 +/- 4.9 (95% CI, 1.43 to 2.17) to 0.4 +/- 1.8
to 0.54) after 3 months of therapy. Carbamazepine-treated pati
were excluded from results; however, in the patients who repor
dysfunction (n=147) with carbamazepine, 110 (75%) patients ir
switched to oxcarbazepine (Luef et al, 2009).

4) Pediatric:

a) An open-label study (n=92) failed to demonstrate the effectiveness o
oxcarbazepine monotherapy for children (1 month to 16 years of age) wi
inadequately-controlled or new-onset partial seizures; however, based o
pharmacokinetic and pharmacodynamic parameters, oxcarbazepine mo
was approved for children 4 years and older. Hospitalized children were
to either oxcarbazepine 10 milligrams/kilogram/day (mg/kg/day) or were
40 to 60 mg/kg/day within 3 days while withdrawing the previous antiepil
the second day of oxcarbazepine therapy. From day 3 to day 5, seizures
monitored by continuous video-electroencephalogram monitoring. The p
efficacy outcome was either completed the 5 day treatment or met one c
criteria. The exit criteria were: 1) 3 study specific seizures (ie, electrogra
seizures with a behavioral correlate) 2) a prolonged study specific seizu
children from both dose groups completed the 5-day study without exitin
between group comparison of the time to meet exit criteria was not statis
significant (p=0.904 for the difference between the curves). The manufa
the results were uninterpretable because of study limitations (no placebo
treatment and assessment period, and inadequate washout period) (Pro
TRILEPTAL(R) oral tablets, oral suspension, 2005).

b) Oxcarbazepine initiated at 600 milligrams/day, titrated to 1200 milligr
dosages in 2 daily divided doses), and maintained at the higher dose for
statistically significantly superior to placebo (p=0.046) in previously untre
(n=67; 8 to 69 years of age). The primary efficacy measure was a compa
to first seizure (Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2

c) Oxcarbazepine, 2400 milligrams/day (mg/day) in 2 divided doses, wa
monotherapy for the treatment of refractory partial seizures in 102 patier
62 years of age) in a placebo-controlled, double-blind trial. The primary e
variable was time to meet one of the exit criteria, defined as: completion
treatment phase; 4 partial seizures; 2 new-onset secondarily generalized
serial seizures; or status epilepticus. This variable was statistically signif
of oxcarbazepine (p=0.0001; by day 2.5 of the study period, 75% of the
treated patients had met one of the exit criteria versus (vs) 25% of the pa
with oxcarbazepine. The secondary efficacy variable was the percentage
meet one of the exit criteria and was also statistically significantly lower
0.0001) for the patients treated with oxcarbazepine (47%) vs 84% for the
treated group (Schachter et al, 1999).

d) Oxcarbazepine was found to be useful in both adjunctive use and mo
children with seizures during a chart review (Gaily et al, 1997a). Children
3.9 years, range 0.6 to 6.9 years) had either localization-related seizures
generalized epilepsy (n=9) with the main seizure types being complex pa
simple partial (n=4), epileptic spasm (n=9), and generalized tonic-clonic
children, an overnight change was made from carbamazepine to oxcarb
times their previous carbamazepine dose. The other children were titrate
milligrams/kilogram/day (mg/kg/day) over 1 to 3 weeks. Out of the childr
localization-related seizures, 12 of 44 became seizure-free while 16 ach
reduction in seizures. No child with generalized seizures became seizure
9 had a 50% reduction in seizures. In children who had previously had a
response to carbamazepine, 4 of 30 children become seizure-free while
reduction in seizures of at least 50%. Of the 23 children receiving monot

became seizure-free, and 7 had a 50% reduction in seizures. The mean
for children achieving at least a 50% decrease in seizures was 47 mg/kg
Hyponatremia occurred in 7 of the 53 children.

4.5.E Partial seizure; Adjunct

FDA Labeled Indication

1) Overview

FDA Approval: Adult, yes; Pediatric, yes (2 years and older)
Efficacy: Adult, Effective; Pediatric, Effective
Recommendation: Adult, Class IIa; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RA

2) Summary:

Indicated for use as adjunctive therapy in the treatment of partial se
adults and children 2 years and older (Prod Info TRILEPTAL(R) ora
suspension, 2005)
No evidence that oxcarbazepine was effective in children less than
(n=75) in an open-label, multicenter, rater-blind, randomized, paralle
(Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005)
During adjunctive therapy studies, median reductions in partial seizu
frequencies from baseline were 26% to 50% for oxcarbazepine and
placebo in adults, and 35% for oxcarbazepine and 9% for placebo i
(Prod Info TRILEPTAL(R) oral tablets, oral suspension, 2005)
No important differences in response due to gender were identified
adjunctive therapy trials (Prod Info TRILEPTAL(R) oral tablets, oral
2005)

3) Adult:

a) Efficacy for oxcarbazepine as adjunctive therapy for partial seizures i
demonstrated in a multicenter, double-blind, placebo-controlled trial (n=6
years of age). Patients who experienced 1 to 4 partial seizures per mont
baseline phase were randomized to receive placebo or fixed oxcarbazep
600, 1200, or 2400 milligrams/day (mg/day) in conjunction with 1 to 3 otl
antiepileptic drugs. A comparison between treatment groups of the perc
change in partial seizure frequency was the primary measure of efficacy
of oxcarbazepine were statistically significantly superior to placebo (p=0
high dose group, however, over 65% of patients discontinued treatment
adverse events (Prod Info TRILEPTAL(R) oral tablets, oral suspension,

b) Seizure frequency decreased in 32% to 48% of patients treated with
oxcarbazepine in a multicenter trial conducted over 10 years in 947 patie
al, 1993b). Patients were diagnosed with simple partial or complex partia
with or without secondary generalization and primary generalized seizur
daily doses employed were 30 milligrams/kilogram/day in children and 1
milligrams/kilogram/day in adults, usually given in 2 or 3 divided doses.
patients experienced adverse reactions such as dizziness, sedation, fati
hyponatremia. Oxcarbazepine was used as monotherapy in 63% of the
as part of polytherapy in 37%.

4) Pediatric:

a) Efficacy for oxcarbazepine as adjunctive therapy for inadequately-co
seizures in children was demonstrated in a multicenter, rater-blind, rand
parallel-group, open-label trial (n=128; 1 month to less than 4 years of a
criteria were at least 2 study specific seizures (ie, partial seizures identifi
electrograph with a behavioral correlate) during the 72 hour baseline pe
were randomized to either 10 milligrams/kilogram/day (mg/kg/day) or we
to 60 mg/kg/day within 26 days. After 9 days on their randomized target
seizures were monitored by continuous video-electroencephalogram mo
during the last 72 hours of the maintenance period. A between group co
the change in seizure frequency per 24 hours compared to the seizure f
baseline was statistically better (results and p value not provided) in the
group vs 10 mg/kg/day group. No evidence that oxcarbazepine was effe
children less than 2 years of age (n=75) (Prod Info TRILEPTAL(R) oral t
suspension, 2005).

b) Oxcarbazepine (OXC) was safe and effective when used as an adjur
antiepileptic agent in the treatment of partial seizures in children, in a ra
double-blind, parallel-group study. Pediatric patients (ages 3 to 17 years
inadequately controlled partial seizures treated with one or two antiepile
(AED) were assigned to receive 98-day regimens of either OXC (titrated
of 30 to 46 milligrams (mg)/kilogram (kg)/day) two times a day (n=138) o

(n=129) in addition to their pre-established AED regimen. Patients in the experienced a baseline median partial seizure frequency of 12 per 28-da median OXC dose administered was 31.4 mg/kg/day. The addition of OX preexisting AED regimen produced a significantly greater median percer from baseline in 28-day partial seizure frequency compared with placebo 9%, respectively; p=0.0001). Forty-one percent of patients OXC-group p recorded a seizure frequency reduction from baseline of 50% or more pe period compared with 22% of patients receiving placebo (p=0.0005), and group patients were seizure- free throughout the double-blind treatment compared with 1 patient receiving placebo. OXC-treated patients also ex significantly greater median percentage reduction in the occurrence of s generalized seizures compared with patients receiving placebo (78% ve respectively; p=0.0012). The frequency of adverse events was similar be groups; somnolence, headache, dizziness, nausea and vomiting were m reported, with the majority being considered mild to moderate in severity TRILEPTAL(R) oral tablets, oral suspension, 2005; Glauser et al, 2000).

c) Oxcarbazepine, in a mean dose of 56.7 milligrams/kilogram/day (mg/ found to be efficacious for adjunctive therapy in epilepsy in a retrospecti review of 46 children and adolescents (mean age 10.3 years; range 1.3 Oxcarbazepine doses ranged from 19 to 123 mg/kg twice a day, valproic most common co-medication (32 of 46 patients) and no patients were m more than one other drug besides oxcarbazepine. After follow-up for 1 y oxcarbazepine was found to be of some benefit in 50% of the patients. S children experienced an exacerbation of seizures and 17 children exhibi change, but 4 children became seizure-free, 18 experienced a 75% to 9 in seizures, and 1 had a 50% to 74% reduction in seizures; 4 patients we follow-up. Adverse effects tended to occur in patients with blood serum c of 35 to 40 mg/L 10-hydroxy-carbazepine, the active metabolite of oxcar (Borusiak et al, 1998).

d) In a small study (n=40) in children with intellectual disability and intra epilepsy, seizure frequency was reduced by at least 50% in 48% (19) of treated with oxcarbazepine 49 milligrams/kilogram/day (mg/kg/day) (mea dosage), given in 2 or 3 divided doses. Nine of the children received oxc monotherapy and 31 received it concomitantly with other antiepileptic dr including vigabatrin, benzodiazepines, valproate, lamotrigine, phenytoin, acetazolamide. Oxcarbazepine therapy was initiated using several strate Oxcarbazepine was initiated in 10 children as an overnight change from carbamazepine (at 1.5 times the carbamazepine dosage). In the remaini who weighed under 40 kg, the oxcarbazepine dose was titrated over 1 to 30/mg/kg/day and then increased as necessary. For the other children w 40 kg, oxcarbazepine was initiated at 20/mg/kg/day and titrated accordir response. A greater than 50% response was reported in 14 of 28 childre localization-related epilepsy and 5 of 12 children (42%) with generalized Oxcarbazepine dose reduction or discontinuation occurred in 8 children adverse effects and at least one adverse effect was reported in 40% of p Hyponatremia occurred in 24% (Gaily et al, 1998a).

e) Oxcarbazepine was found to be useful in both adjunctive use and mo children with seizures during a chart review (Gaily et al, 1997a). Children 3.9 years, range 0.6 to 6.9 years) had either localization-related seizures generalized epilepsy (n=9) with the main seizure types being complex pa simple partial (n=4), epileptic spasm (n=9), and generalized tonic-clonic children, an overnight change was made from carbamazepine to oxcarb times their previous carbamazepine dose. The other children were titrate milligrams/kilogram/day (mg/kg/day) over 1 to 3 weeks. Out of the childr localization-related seizures, 12 of 44 became seizure-free while 16 ach reduction in seizures. No child with generalized seizures became seizure 9 had a 50% reduction in seizures. In children who had previously had a response to carbamazepine, 4 of 30 children become seizure-free while reduction in seizures of at least 50%. Of the 30 children receiving polyth became seizure free and seizure reduction occurred in 14. The mean eff for children achieving at least a 50% decrease in seizures was 47 mg/kg Hyponatremia occurred in 7 of the 53 children.

4.5.F Spasticity

1) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive

Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RA

2) Summary:
Suggested efficacy in the treatment of spasticity related to cerebral lesions (Bittencourt & Silvado, 1985)

3) Adult:
a) Limited data have suggested the efficacy of oral oxcarbazepine in the spasticity related to cerebral epileptogenic lesions. Oxcarbazepine has b doses up to 3900 milligrams daily (Bittencourt & Silvado, 1985). Controll studies are needed to more fully evaluate the efficacy of the drug in spas

4.5.G Trigeminal neuralgia

1) Overview
FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RA

2) Summary:
Effective in the treatment of trigeminal neuralgia in patients unrespo intolerant of, carbamazepine (Zakrzewska & Patsalos, 1989b)

3) Adult:
a) Oxcarbazepine was effective in 6 patients with trigeminal neuralgia re carbamazepine therapy (Zakrzewska & Patsalos, 1989b). Oxcarbazepin administered in a dose of 300 milligrams 2 to 4 times daily, with prior me withdrawn over a 2-day period. The dose was adjusted weekly until adeq control was achieved, then patients were examined at 2 to 4 weekly inte were considered optimally managed after a pain free 2-week period; at t dose was reduced by 1 dose per week (300 milligrams). Re-titration was the event of relapse. Pain control was achieved in all patients, with onse effect being observed within 24 hours. Daily doses ranged from 600 to 2 milligrams. Both oxcarbazepine and 10-hydroxy-carbazepine serum leve with the dose and therapeutic effects. Effective pain relief was seen in al when serum levels of 10-hydroxy-carbazepine were between 50 and 11(micromoles/liter, corresponding to 1200 to 2400 milligrams daily of oxca

4.6 Comparative Efficacy / Evaluation With Other Therapies

Carbamazepine

Haloperidol

Lithium

Surgical procedure

4.6.A Carbamazepine

Epilepsy

Trigeminal neuralgia

4.6.A.1 Epilepsy

a) SUMMARY: Oxcarbazepine appears to be as effective as carbamaze treatment of epilepsy; severe adverse effects have occurred to a lesser oxcarbazepine in some studies. Further studies are needed to investigat inducing effects, particularly at higher doses.

b) Oxcarbazepine is similar in efficacy to carbamazepine as monothera therapy in epileptic patients (Dam et al, 1989; Reinikainen et al, 1987); (1987)(Houtkooper et al, 1987b; Houtkooper et al, 1984; Dam, 1990; Phil 1986; Anon, 1990a; Jensen, 1990). There is some evidence of efficacy i

unresponsive to carbamazepine. Doses associated with therapeutic equ
some studies have been 200 mg carbamazepine and 300 to 400 mg oxc
(Houtkooper et al, 1987b), however the ratio has been closer to 1:1 in ot
al, 1987).
c) Oxcarbazepine is at least as effective as carbamazepine in patients r
polytherapy, and oxcarbazepine may be better tolerated in some patient
efficacy of oxcarbazepine and carbamazepine was compared in 48 epile
poorly controlled on polytherapy, including carbamazepine, in a double-
crossover study (Houtkooper et al, 1987b). The types of seizures were g
patients), partial (10 patients), or both generalized and partial (29 patien
had at least 2 seizures/week despite therapy with 2 to 4 antiepileptic age
were randomly allocated to oxcarbazepine 300 mg/day or carbamazepir
mg/day. Following a titration period, where the dose of each was increas
optimal seizure control, therapy was continued for 12 weeks (steady- sta
trial period. As compared to carbamazepine, therapy with oxcarbazepine
total number of seizures by 9%; tonic-clonic and tonic seizures were furt
by 20% and 31%, respectively. In 5 patients, a shift from complex partial
partial seizures or atypical absence seizures was observed during oxcar
therapy. Other differences reported during oxcarbazepine therapy were
alertness and greater ability to concentrate in 5 patients and remission o
carbamazepine related allergic skin reactions in 2. Serum levels of valpr
phenytoin were higher in oxcarbazepine treated patients, and serum soc
concentration were lower. Other adverse effects were similar with each a
d) In a double-blind study, the efficacy of oxcarbazepine and carbamaz
epileptic patients inadequately controlled on at least 1 anticonvulsant (ot
carbamazepine) was evaluated (Bulau et al, 1987). Each patient had exp
least 1 tonic-clonic or complex partial seizure per month. Oxcarbazepine
carbamazepine were added sequentially in randomized fashion during a
titration period; therapy was continued for an additional 3 months. Mean
1111.5 and 788.5 mg daily for oxcarbazepine and carbamazepine, respe
Concomitant anticonvulsants were continued throughout. Seizure freque
reduced by 90% during therapy with both agents, with 28% of all patient
seizure-free. Adverse effects were less in oxcarbazepine treated patient
serum levels of valproic acid, phenytoin, and primidone were observed i
oxcarbazepine group, presumably secondary to a lesser degree of enzy
as compared to carbamazepine.

4.6.A.2 Trigeminal neuralgia

a) Oxcarbazepine and its 10-hydroxy-metabolite (10-hydroxy-carbazepi
dihydro-10-hydroxy carbamazepine) were compared with carbamazepin
patients with trigeminal neuralgia (Farago, 1987a). All patients had eithe
trigeminal neuralgia or other idiopathic facial neuralgias for at least 2 we
patients had been treated previously with carbamazepine. Oxcarbazepir
administered to 13 of the 24 patients for a mean of 11 months (mean ma
of 1100 milligrams daily), resulting in an adequate clinical response in 1(
moderate response in 3. Symptom recurrence, however, was seen in 1 p
months of treatment. Eleven patients were treated with the 10-hydroxy-n
oxcarbazepine (GP 47779) for a mean of 3.5 months (mean maximal do
milligrams daily), with 7 achieving alleviation of symptoms and 4 noticing
improvement. However, recurrence of symptoms occurred in 2 patients
and 2 months of treatment, respectively. In the 14 patients treated previc
carbamazepine, therapy with either oxcarbazepine or its metabolite was
be more effective than carbamazepine in 12; efficacy was considered ec
and worse in another. These overall results suggest the potential superi
oxcarbazepine over carbamazepine in trigeminal neuralgia. However, pl
controlled trials are required to confirm these findings.

4.6.A.3 Efficacy

a) The primary difference between oxcarbazepine and carbamazepine i
pharmacokinetic properties, which in turn affect the propensity of these a
adverse effects. Following absorption, oxcarbazepine is rapidly and exte
converted via reduction to 10-hydroxy-carbazepine, the active metabolite
excreted in the urine as the glucuronide conjugate. A portion of the 10-h
metabolite is hydroxylated to isomeric 10,11-diols, the trans-diol predom
(Theisohn & Heimann, 1982; Schutz et al, 1986; Anon, 1989a).
b) In contrast, carbamazepine is oxidized to the active carbamazepine-
epoxide; a portion of this metabolite is also converted to the inactive 10,
(Eichelbaum et al, 1985; Anon, 1989a; Anon, 1990a). The 10,11-epoxid

carbamazepine is responsible for dose-dependent adverse effects (Anon Anon, 1989a). Because an epoxide is not produced during oxcarbazepir metabolism, this drug is expected to be better tolerated than carbamaze 1990a).

4.6.A.4 Adverse Effects

a) A trend toward a lower incidence of severe adverse effects has been with oxcarbazepine as compared to carbamazepine in some studies (Bu 1987)(Dam, 1990; Houtkooper et al, 1987b), which at times reached sta significance (Dam, 1990).

b) Oxcarbazepine appears less likely than carbamazepine to influence processes, as the metabolism of oxcarbazepine is facilitated primarily by Studies have reported that oxcarbazepine lacks autoinducing properties carbamazepine, a feature which may decrease the incidence of breakthr (Anon, 1989a; Brodie et al, 1989; Anon, 1990a).

c) In some studies, oxcarbazepine has not influenced antipyrine kinetics an advantage with regard to drug interactions (Anon, 1989a). However, dependent enzyme induction has been reported by other investigators, v doses producing effects similar to carbamazepine (Patsalos et al, 1990c optimal dose of oxcarbazepine remains undefined, further studies will be determine if the drug will offer a significant advantage in regard to enzym and autoinduction.

4.6.B Haloperidol

4.6.B.1 Bipolar disorder

a) Oxcarbazepine has been compared with with haloperidol in 42 patien mania; mean doses used were 2400 mg/day and 42 mg/day respectively the response to oxcarbazepine was slower, by the end of the second we treatment, results were similar in both treatment groups. Haloperidol-trea had a significantly higher incidence of adverse effects (Emrich, 1990).

4.6.C Lithium

4.6.C.1 Bipolar disorder

a) In a review of the results of a double-blind multicenter trial comparing oxcarbazepine with lithium in 58 acutely manic patients, oxcarbazepine be equally effective but with a higher incidence of side effects. Onset wa slower with oxcarbazepine (Grant & Faulds, 1992a).

b) Conversely, a 3-year randomized study of oxcarbazepine vs lithium p 18 patients with bipolar disorder demonstrated no clear responders in th oxcarbazepine-treated group. A reduction in relapses was clearly seen i treated group. This study was flawed by poor patient selection and the tr lithium nonresponders with oxcarbazepine (Wildegrube, 1990).

4.6.D Surgical procedure

4.6.D.1 Trigeminal neuralgia

a) Oxcarbazepine was initially efficacious for relieving pain of intractable neuralgia, but eventually surgery was necessary in most patients. Fifteen had not found relief of trigeminal neuralgia pain or had experienced adve with carbamazepine, phenytoin, and baclofen, either as monotherapy or combination, were transferred from their current medication to oxcarbaz followed for 13 years. Over a period of 3 days, oxcarbazepine 300 millig was substituted for each 200 mg dose of carbamazepine or 100 mg dos phenytoin. Patients were free to discontinue medication during remissior patients used oxcarbazepine continuously, and 7 stopped during remiss periods of 2 to 7 months and, in one case, for 26 months. The mean dail 17.9 mg/kilogram (range 3.9 to 46.5 mg/kg). The mean duration of treatr years (range 2.4 months to 10.8 years). Oxcarbazepine gave pain relief, surgery was considered necessary in 12 of the 13 surviving patients. Su immediately successful in 8 of those patients but had to be repeated in 3 because of pain recurrence or complete failure. Repeat surgery was suc 2 with pain recurrence, but the one whose initial surgery completely faile medication for pain relief after the second surgery. Three of the patients underwent surgery had numbness and one had deafness as a conseque mean time for recurrence of pain after oxcarbazepine treatment was 10 (median 7 months); the mean time for recurrence after surgery was 28 n

time of this report, 8 patients continued to be pain free. Most patients fel
have had surgery earlier (Zakrzewska & Patsalos, 2002).

DRUGDEX® Evaluations

LISDEXAMFETAMINE

0.0 Overview

1) Class
- **a)** This drug is a member of the following class(es):
  Amphetamine (class)
  CNS Stimulant

2) Dosing Information
- **a)** Lisdexamfetamine Dimesylate
  - **1)** Adult
    - **a)** safety and efficacy have not been evaluated in the geriatric population (Prod Info VYVANSE(R) oral capsu
      - **1)** Attention deficit hyperactivity disorder
        - **a)** initial (lisdexamfetamine naive or switching from another medication): 30 mg ORALLY once daily capsules, 2008)
        - **b)** maintenance: may increase dose in increments of 10 mg or 20 mg ORALLY per day at approxim ORALLY per day (Prod Info VYVANSE(R) oral capsules, 2008)
  - **2)** Pediatric
    - **a)** long-term use of amphetamines has not been established in pediatric patients; effectiveness of lisdexamfe weeks duration (Prod Info VYVANSE(R) oral capsules, 2008)
    - **b)** lisdexamfetamine dimesylate has not been studied in children under the age of 6 years or adolescents; ar children under 3 years of age (Prod Info VYVANSE(R) oral capsules, 2008).
      - **1)** Attention deficit hyperactivity disorder
        - **a)** initial (lisdexamfetamine naive or switching from another medication): 30 mg ORALLY once daily capsules, 2008)
        - **b)** maintenance: may increase dose in increments of 10 mg or 20 mg ORALLY per day at approxim ORALLY per day (Prod Info VYVANSE(R) oral capsules, 2008)

3) Contraindications
- **a)** Lisdexamfetamine Dimesylate
  - **1)** cardiovascular disease, symptomatic (Prod Info VYVANSE(TM) oral capsules, 2007)
  - **2)** drug dependence, history of; potential for abuse (Prod Info VYVANSE(TM) oral capsules, 2007)
  - **3)** advanced arteriosclerosis (Prod Info VYVANSE(TM) oral capsules, 2007)
  - **4)** agitated states; may aggravate symptoms (Prod Info VYVANSE(TM) oral capsules, 2007)
  - **5)** concomitant use of monoamine oxidase inhibitors (MAOI), or within 14 days of MAOI use; hypertensive crisis r capsules, 2007)
  - **6)** glaucoma (Prod Info VYVANSE(TM) oral capsules, 2007)
  - **7)** hypersensitivity/idiosyncrasy to sympathomimetic amines (Prod Info VYVANSE(TM) oral capsules, 2007)
  - **8)** hypertension, moderate to severe (Prod Info VYVANSE(TM) oral capsules, 2007)
  - **9)** hyperthyroidism (Prod Info VYVANSE(TM) oral capsules, 2007)

4) Serious Adverse Effects
- **a)** Lisdexamfetamine Dimesylate
  - **1)** Cerebrovascular accident
  - **2)** Chest pain
  - **3)** Dead - sudden death
  - **4)** Gilles de la Tourette's syndrome
  - **5)** Myocardial infarction
  - **6)** Palpitations
  - **7)** Seizure
  - **8)** Stevens-Johnson syndrome
  - **9)** Tachycardia
  - **10)** Toxic epidermal necrolysis due to drug
  - **11)** Ventricular hypertrophy

5) Clinical Applications
- **a)** Lisdexamfetamine Dimesylate
  - **1)** FDA Approved Indications
    - **a)** Attention deficit hyperactivity disorder

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms

Lisdexamfetamine

Lisdexamfetamine Dimesylate

C) Physicochemical Properties

1) Lisdexamfetamine Dimesylate

a) Molecular Weight

1) 455.6 (Prod Info VYVANSE(TM) oral capsules, 2007)

b) Solubility

1) Lisdexamfetamine is soluble in water at 792 mg/mL (Prod Info VYVANSE(TM) oral capsules, 2007)

1.2 Storage and Stability

A) Lisdexamfetamine Dimesylate

1) Preparation

a) Oral route

1) Lisdexamfetamine dimesylate should be administered once daily in the morning. The dose may be ta swallowed whole, or the capsule may be opened and the entire contents dissolved in a glass of water to (Prod Info VYVANSE(R) oral capsules, 2008).

B) Lisdexamfetamine Dimesylate

1) Oral route

a) Capsule

1) Store at controlled room temperature, 25 degrees Celsius (77 degrees Fahrenheit); excursions permi 86 degrees Fahrenheit) (Prod Info VYVANSE(TM) oral capsules, 2007).

1.3 Adult Dosage

1.3.1 Normal Dosage

1.3.1.A Lisdexamfetamine Dimesylate

1.3.1.A.1 Oral route

1.3.1.A.1.a Attention deficit hyperactivity disorder

1) The recommended initial dose in lisdexamfetamine-naive patients or in patients switching from a once daily in the morning. According to therapeutic need and patient response, the initial dose may orally per day at approximately weekly intervals to a maximum of 70 mg orally per day. The lowest e should be periodically interrupted to determine the need for continued treatment (Prod Info VYVANS

2) Lisdexamfetamine dimesylate has not been studied in the geriatric population (Prod Info VYVANSE(R) ora

1.4 Pediatric Dosage

1.4.1 Normal Dosage

1.4.1.A Lisdexamfetamine Dimesylate

1.4.1.A.1 Oral route

1.4.1.A.1.a Attention deficit hyperactivity disorder

1) The recommended initial dose in lisdexamfetamine-naive patients or in patients switching from a once daily in the morning. According to therapeutic need and patient response, the initial dose may orally per day at approximately weekly intervals to a maximum of 70 mg orally per day. The lowest e should be periodically interrupted to determine the need for continued treatment (Prod Info VYVANS

2) The long-term effects of amphetamine use in the pediatric population have not been established. In clinica dimesylate was established for up to 4 weeks duration. Lisdexamfetamine dimesylate has not been studied ir adolescents. Amphetamines are not recommended for use in children under 3 years of age (Prod Info VYVAl

2.0 Pharmacokinetics

Drug Concentration Levels

ADME

2.2 Drug Concentration Levels

A) Lisdexamfetamine Dimesylate

1) Peak Concentration

a) When the dose of lisdexamfetamine dimesylate was normalized based on weight, the Cmax was 12% low
70 milligrams/day (mg/day) for 7 days. The weight/dose normalized Cmax were the same for girls and boys f
VYVANSE(TM) oral capsules, 2007).

2) Time to Peak Concentration

a) Oral, dextroamphetamine: 3.5 hours (Prod Info VYVANSE(TM) oral capsules, 2007)

b) Oral, lisdexamfetamine dimesylate: 1 hour (Prod Info VYVANSE(TM) oral capsules, 2007)

1) The Tmax of dextroamphetamine after a single oral 30, 50, or 70 milligram dose of lisdexamfetamine
(n=18; aged 6 to 12 years) after an 8-hour fast was approximately 3.5 hours. The Tmax of lisdexamfetan
Info VYVANSE(TM) oral capsules, 2007).

3) Area Under the Curve

a) After lisdexamfetamine dimesylate was administered as a solution and as capsules after an 8-hour fast, th
(Prod Info VYVANSE(TM) oral capsules, 2007).

b) When the dose of lisdexamfetamine dimesylate was normalized based on weight, the AUC was 22% lowe
70 milligrams/day (mg/day) for 7 days. The weight/dose normalized AUC were the same for girls and boys fo
VYVANSE(TM) oral capsules, 2007).

2.3 ADME

Absorption

Metabolism

Excretion

Elimination Half-life

2.3.1 Absorption

A) Lisdexamfetamine Dimesylate

1) Effects of Food

a) Increases Tmax by approximately 1 hr (Prod Info VYVANSE(TM) oral capsules, 2007).

b) Food has no effect on AUC or Cmax but does prolong the Tmax of dextroamphetamine by approxima
dose of lisdexamfetamine dimesylate was given to healthy adults after a high fat meal, the Tmax was 4.7
fasted state (Prod Info VYVANSE(TM) oral capsules, 2007).

2) Following oral administration, lisdexamfetamine dimesylate is rapidly absorbed from the gastrointestinal tr
2007).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) Lisdexamfetamine Dimesylate

a) Liver and/or intestinal metabolism (Prod Info VYVANSE(TM) oral capsules, 2007).

1) After oral administration, lisdexamfetamine dimesylate is converted to dextroamphetamine and L
intestinal and/or hepatic metabolism. Lisdexamfetamine dimesylate is not metabolized by CYP450 e
capsules, 2007).

B) Metabolites

1) Lisdexamfetamine Dimesylate

a) Dextroamphetamine, (active) (Prod Info VYVANSE(TM) oral capsules, 2007).

1) After oral administration, lisdexamfetamine dimesylate is converted to dextroamphetamine and L
intestinal and/or hepatic metabolism (Prod Info VYVANSE(TM) oral capsules, 2007).

b) L-lysine, (inactive) (Prod Info VYVANSE(TM) oral capsules, 2007)

1) After oral administration, lisdexamfetamine dimesylate is converted to dextroamphetamine and L
intestinal and/or hepatic metabolism (Prod Info VYVANSE(TM) oral capsules, 2007).

2.3.4 Excretion

A) Kidney

1) Lisdexamfetamine Dimesylate

a) Renal Excretion (%)

1) 96% (Prod Info VYVANSE(TM) oral capsules, 2007).

a) Following administration of a single 70 milligram dose of lisdexamfetamine dimesylate to 6 h

dose was recovered in the urine; 42% of which was amphetamine, 25% hippuric acid, and 2% i
(TM) oral capsules, 2007).

B) Feces
1) Lisdexamfetamine Dimesylate
a) 0.3% (Prod Info VYVANSE(TM) oral capsules, 2007).
1) Following administration of a single 70 milligram dose of lisdexamfetamine dimesylate to 6 healt
was recovered in the feces (Prod Info VYVANSE(TM) oral capsules, 2007).

2.3.5 Elimination Half-life

A) Parent Compound
1) Lisdexamfetamine Dimesylate
a) less than 1 hour (Prod Info VYVANSE(TM) oral capsules, 2007)
1) The elimination half-life of lisdexamfetamine dimesylate averaged less than one hour in studies i
VYVANSE(TM) oral capsules, 2007).

3.0 Cautions

Contraindications

Precautions

Adverse Reactions

Teratogenicity/Effects in Pregnancy/Breastfeeding

Drug Interactions

3.0.A Black Box WARNING
1) Lisdexamfetamine Dimesylate
a) Oral (Capsule)
1) Amphetamines have a high potential for abuse. Administration of amphetamines for prolonged periods of
attention should be paid to the possibility of subjects obtaining amphetamines for non-therapeutic use or distr
prescribed or dispensed sparingly.
2) Misuse of amphetamines may cause sudden death and serious cardiovascular adverse events (Prod Info

3.1 Contraindications

A) Lisdexamfetamine Dimesylate
1) cardiovascular disease, symptomatic (Prod Info VYVANSE(TM) oral capsules, 2007)
2) drug dependence, history of; potential for abuse (Prod Info VYVANSE(TM) oral capsules, 2007)
3) advanced arteriosclerosis (Prod Info VYVANSE(TM) oral capsules, 2007)
4) agitated states; may aggravate symptoms (Prod Info VYVANSE(TM) oral capsules, 2007)
5) concomitant use of monoamine oxidase inhibitors (MAOI), or within 14 days of MAOI use; hypertensive crisis r
capsules, 2007)
6) glaucoma (Prod Info VYVANSE(TM) oral capsules, 2007)
7) hypersensitivity/idiosyncrasy to sympathomimetic amines (Prod Info VYVANSE(TM) oral capsules, 2007)
8) hypertension, moderate to severe (Prod Info VYVANSE(TM) oral capsules, 2007)
9) hyperthyroidism (Prod Info VYVANSE(TM) oral capsules, 2007)

3.2 Precautions

A) Lisdexamfetamine Dimesylate
1) long duration of use; may lead to dependence (Prod Info VYVANSE(TM) oral capsules, 2007)
2) amphetamine misuse; may cause sudden death and serious cardiovascular events (Prod Info VYVANSE(TM)
3) bipolar disorder, comorbid; may precipitate a mixed/manic episode (Prod Info VYVANSE(TM) oral capsules, 2
4) cardiovascular conditions which may be compromised by increases in blood pressure or heart rate (eg, preexis
myocardial infarction, or ventricular arrhythmia) (Prod Info VYVANSE(TM) oral capsules, 2007)
5) EEG abnormalities, especially with history of; may lower convulsive threshold (Prod Info VYVANSE(TM) oral c
6) psychosis, preexisting; may exacerbate symptoms of behavior disturbance and thought disorder (Prod Info VY
7) seizures, especially with a history of; may lower convulsive threshold (Prod Info VYVANSE(TM) oral capsules,
8) structural cardiac abnormalities/conditions, serious, especially in children and adolescents; sudden death has
(Prod Info VYVANSE(TM) oral capsules, 2007)
9) tics, motor and phonic, history of; risk of exacerbation (Prod Info VYVANSE(TM) oral capsules, 2007)
10) Tourette's syndrome, history of; risk of exacerbation (Prod Info VYVANSE(TM) oral capsules, 2007)

3.3 Adverse Reactions

3.3.1 Cardiovascular Effects

3.3.1.A Lisdexamfetamine Dimesylate

3.3.1.A.1 Chest pain

a) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc
28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisde
reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.1.A.2 Dead - sudden death

a) Incidence: rare

b) Children and Adolescents - With Preexisting Cardiac Risk

1) Following administration of CNS stimulant drugs at usual doses, sudden death has been reporte
cardiac abnormalities or other serious heart problems and adults being treated for ADHD . Sudden d
administration of amphetamines (Prod Info VYVANSE(TM) oral capsules, 2007).

c) Children and Adolescents - Healthy

1) A retrospective, case-controlled study examines the association between stimulant medication, i

unexplained sudden death in healthy children and adolescents. In a collection of data from state vita States, 564 cases of sudden death in children and adolescents between the ages of 7 to 19 years w who died as passengers in motor vehicle accidents. The study determined that 1.8% (n=10) of youth were taking stimulant medication compared with only 0.4% (n=2) of youths in the motor vehicle acci 74.9; p=0.02). Limitations to this study included the time lag between the youths stimulant medicatio recall of information regarding clinical diagnoses, inconsistent postmortem inquiry, and the exclusion authors stated that this finding should be considered when evaluating the overall risk and benefit of adolescents (Gould et al, 2009). Given the limitations of this study, the U.S. Food and Drug Adminis and benefits associated with stimulant medications (US Food and Drug Administration, 2009).

3.3.1.A.3 Increased blood pressure

a) Incidence: adult patients, 3% (Prod Info VYVANSE(R) oral capsules, 2008)

b) Blood pressure increases were reported in 3% of adult patients who received lisdexamfetamine in fin compared with 0% of patients who received placebo (n=62) in a 4-week, double-blind, randomized, place patients diagnosed with ADHD (Prod Info VYVANSE(R) oral capsules, 2008).

c) Elevation of blood pressure has been reported following administration of amphetamines. Modest inc mmHg), and average heart rate (about 3 to 6 bpm) are associated with stimulant medications, but larger (R) oral capsules, 2008).

3.3.1.A.4 Increased heart rate

a) Incidence: adult patients, 2% (Prod Info VYVANSE(R) oral capsules, 2008)

b) Heart rate increases were reported in 2% of adult patients who received lisdexamfetamine in final dos compared with 0% of patients who received placebo (n=62) in a 4-week, double-blind, randomized, place patients diagnosed with ADHD (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.1.A.5 Myocardial infarction

a) Myocardial infarction (MI) has been reported in adults being treated with CNS stimulant drugs at usua following administration of amphetamines (Prod Info VYVANSE(TM) oral capsules, 2007).

3.3.1.A.6 Palpitations

a) Palpitations have been reported following administration of amphetamines (Prod Info VYVANSE(R) o

3.3.1.A.7 Summary

a) Serious cardiovascular events, including sudden cardiac death, myocardial infarction, and stroke hav including lisdexamfetamine. It is recommended that stimulant drugs not be used in patients who have kn serious heart rhythm irregularities, coronary artery disease, or other serious heart problems. Blood press regular intervals in patients receiving lisdexamfetamine (Prod Info VYVANSE(TM) oral capsules, 2007).

3.3.1.A.8 Tachycardia

a) Tachycardia led to discontinuation of therapy in 1% (3/358) of adult patients receiving lisdexamfetami rate compared with those receiving placebo (Prod Info VYVANSE(R) oral capsules, 2008).

b) Tachycardia has been reported following administration of amphetamines or lisdexamfetamine dimes 2008).

c) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc of 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisd reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.1.A.9 Ventricular hypertrophy

a) Ventricular hypertrophy led to discontinuation of therapy in 1% (2/218) of pediatric patients receiving l discontinuation rate compared with those receiving placebo (Prod Info VYVANSE(R) oral capsules, 2008

3.3.2 Dermatologic Effects

3.3.2.A Lisdexamfetamine Dimesylate

Rash

Stevens-Johnson syndrome

Toxic epidermal necrolysis due to drug

Urticaria

3.3.2.A.1 Rash

a) Incidence: pediatric patients, 3% (Prod Info VYVANSE(R) oral capsules, 2008)
b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), rash was reported in 3% of pediatric patients receiving lisdexamfetamine (n=218) compared wit the most frequent adverse events leading to discontinuation of therapy was rash with an incidence of 1% which was at least twice the rate compared with placebo (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.2.A.2 Stevens-Johnson syndrome
a) Stevens-Johnson syndrome has been reported following administration of amphetamines (Prod Info V

3.3.2.A.3 Toxic epidermal necrolysis due to drug
a) Toxic epidermal necrolysis has been reported following administration of amphetamines (Prod Info V

3.3.2.A.4 Urticaria
a) Urticaria has been reported following administration of amphetamines (Prod Info VYVANSE(R) oral c

3.3.3 Endocrine/Metabolic Effects

3.3.3.A Lisdexamfetamine Dimesylate

Decreased body growth

Diaphoresis

Problem of growth and development

Sexual dysfunction

Weight decreased

3.3.3.A.1 Decreased body growth
a) Suppression of growth has been reported with long-term use of stimulants in children and adolescent
b) It is recommended that pediatric patients being treated with lisdexamfetamine be monitored for growt (R) oral capsules, 2008).

3.3.3.A.2 Diaphoresis
a) Incidence: adult patients, 3% (Prod Info VYVANSE(R) oral capsules, 2008)
b) Hyperhidrosis was reported in 3% of adult patients who received lisdexamfetamine in final doses of 3 0% of patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, diagnosed with ADHD (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.3.A.3 Problem of growth and development
a) In patients receiving lisdexamfetamine 7 days per week for 1 year, there was a decrease in growth ra from baseline in percentile of -13.4 over 1 year. The average percentile at baseline was 60.6, and at 1 ye (R) oral capsules, 2008).
b) It is recommended that pediatric patients being treated with lisdexamfetamine be monitored for growt (R) oral capsules, 2008).

3.3.3.A.4 Sexual dysfunction
a) Changes in libido have been reported following administration of amphetamines (Prod Info VYVANSE

3.3.3.A.5 Weight decreased
a) Incidence: pediatric patients, 9% (Prod Info VYVANSE(R) oral capsules, 2008)
b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), a decrease in weight was reported in 9% of pediatric patients receiving lisdexamfetamine (n=21 (n=72) (Prod Info VYVANSE(R) oral capsules, 2008).
c) In a controlled trial in pediatric patients age 6 to 12 years, the mean weight loss from baseline after 4 pounds for patients receiving 30, 50, and 70 mg of lisdexamfetamine, respectively, compared with a 1 pc Higher doses of lisdexamfetamine were associated with greater weight loss during the 4 weeks of therap per week for 1 year, there was a decrease in growth rate (measured by body weight) from mean change The average percentile at baseline was 60.6, and at 1 year was 47.2 (Prod Info VYVANSE(R) oral capsu
d) In a 4-week, double-blind, randomized, placebo-controlled, parallel group trial of 420 adult patients di baseline after 4 weeks of therapy was 2.8, 3.1, and 4.3 pounds in adult patients who received lisdexamfe (n=358), respectively, compared with a mean weight gain of 0.5 pound in patients who received placebo 2008).

3.3.4 Gastrointestinal Effects

3.3.4.A Lisdexamfetamine Dimesylate

Constipation

Diarrhea

Loss of appetite

Nausea

Taste sense altered

Upper abdominal pain

Vomiting

Xerostomia

3.3.4.A.1 Constipation

a) Constipation has been reported following administration of amphetamines (Prod Info VYVANSE(R) o

3.3.4.A.2 Diarrhea

a) Incidence: adult patients, 7% (Prod Info VYVANSE(R) oral capsules, 2008)

b) Diarrhea was reported in 7% of adult patients who received lisdexamfetamine in final doses of 30 mg patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, paralle ADHD (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.4.A.3 Loss of appetite

a) Incidence: pediatric patients, 39%; adult patients, 27% (Prod Info VYVANSE(R) oral capsules, 2008)

b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), a decreased appetite was reported in 39% of pediatric patients receiving lisdexamfetamine (n=2 placebo (n=72) (Prod Info VYVANSE(R) oral capsules, 2008).

c) Decreased appetite was reported in 27% of adult patients who received lisdexamfetamine in final dos compared with 3% of patients who received placebo (n=62) in a 4-week, double-blind, randomized, place patients diagnosed with ADHD. In the same study, anorexia was reported in 5% of patients receiving lisc receiving placebo (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.4.A.4 Nausea

a) Incidence: pediatric patients, 6%; adult patients, 7% (Prod Info VYVANSE(R) oral capsules, 2008)

b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), nausea was reported in 6% of pediatric patients receiving lisdexamfetamine (n=218) compared Info VYVANSE(R) oral capsules, 2008).

c) Nausea was reported in 7% of adult patients who received lisdexamfetamine in final doses of 30 mg, patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, paralle ADHD (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.4.A.5 Taste sense altered

a) Unpleasant taste has been reported following administration of amphetamines (Prod Info VYVANSE(

3.3.4.A.6 Upper abdominal pain

a) Incidence: pediatric patients, 12%; adults, 5% or greater (Prod Info VYVANSE(R) oral capsules, 2008

b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), upper abdominal pain was reported in 12% of pediatric patients receiving lisdexamfetamine (n= placebo (n=72). Abdominal pain was also reported in at least 5% or more adults patients receiving lisdex VYVANSE(R) oral capsules, 2008).

c) Further, in a retrospective review of poison center databases in 8 states during the initial 10 months c in 7% (2 of 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse event not be reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.4.A.7 Vomiting

a) Incidence: pediatric patients, 9% (Prod Info VYVANSE(R) oral capsules, 2008)
b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), vomiting was reported in 9% of pediatric patients receiving lisdexamfetamine (n=218) compared Vomiting led to discontinuation of therapy in 1% (2/218) of pediatric patients receiving lisdexamfetamine, rate compared with those receiving placebo (Prod Info VYVANSE(R) oral capsules, 2008).
c) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisdexam determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.4.A.8 Xerostomia

a) Incidence: pediatric patients, 5%; adult patients, 26% (Prod Info VYVANSE(R) oral capsules, 2008)
b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), dry mouth was reported in 5% of pediatric patients receiving lisdexamfetamine (n=218) compar (Prod Info VYVANSE(R) oral capsules, 2008).
c) Dry mouth was reported in 26% of adult patients who received lisdexamfetamine in final doses of 30 of patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, para with ADHD (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.8 Musculoskeletal Effects

3.3.8.A Lisdexamfetamine Dimesylate

3.3.8.A.1 Muscle fasciculation

a) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisdex reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.9 Neurologic Effects

3.3.9.A Lisdexamfetamine Dimesylate

Cerebrovascular accident

Confusion, acute

Dizziness

Dystonia

Gilles de la Tourette's syndrome

Headache

Insomnia

Seizure

Somnolence

Tic

Tremor

3.3.9.A.1 Cerebrovascular accident

a) Stroke has been reported in adults being treated with CNS stimulant drugs at usual doses for ADHD. administration of amphetamines (Prod Info VYVANSE(TM) oral capsules, 2007).

3.3.9.A.2 Confusion, acute

a) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisdexam determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.9.A.3 Dizziness

a) Incidence: pediatric patients, 5% (Prod Info VYVANSE(TM) oral capsules, 2007)

b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), dizziness was reported in 5% of pediatric patients receiving lisdexamfetamine (n=218) compare (Prod Info VYVANSE(TM) oral capsules, 2007).

c) Further, in a retrospective review of poison center databases in 8 states during the initial 10 months c (2 of 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with be reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.9.A.4 Dystonia

a) Incidence: 29% (Spiller et al, 2008)

b) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisde reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.9.A.5 Gilles de la Tourette's syndrome

a) Exacerbation of Tourette's syndrome has been reported following administration of amphetamines. P be evaluated for Tourette's syndrome (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.9.A.6 Headache

a) Incidence: adult patients, 5% or greater (Prod Info VYVANSE(R) oral capsules, 2008)

b) Headache occurred in at least 5% or more patients receiving lisdexamfetamine during clinical trials, l (2/358) of adult patients , which was at least twice the discontinuation rate compared with those receiving capsules, 2008).

3.3.9.A.7 Insomnia

a) Incidence: pediatric patients, 19%; adult patients, 27% (Prod Info VYVANSE(R) oral capsules, 2008;

b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), insomnia was reported in 19% of pediatric patients receiving lisdexamfetamine (n=218) compar (Prod Info VYVANSE(R) oral capsules, 2008).

c) Insomnia was reported in 27% of adult patients who received lisdexamfetamine in final doses of 30 m of patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, para with ADHD. In the same trial, initial insomnia was reported in 4% of adult patient receiving lisdexamfetam placebo (Prod Info VYVANSE(R) oral capsules, 2008).

d) Insomnia led to discontinuation of therapy in 1% (2/218) of pediatric patients and 2% (8/358) of adult at least twice the discontinuation rate compared with those receiving placebo (Prod Info VYVANSE(R) o

e) Further, in a retrospective review of poison center databases in 8 states during the initial 10 months c (8 of 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with be reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.9.A.8 Seizure

a) Incidence: 4% (Spiller et al, 2008)

b) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisdexamfet concomitant trazodone and imipramine, but had not experienced any other seizures prior to the initiation

3.3.9.A.9 Somnolence

a) Incidence: pediatric patients, 2% (Prod Info VYVANSE(R) oral capsules, 2008)

b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), somnolence was reported in 2% of pediatric patients receiving lisdexamfetamine (n=218) comp (Prod Info VYVANSE(TM) oral capsules, 2007).

3.3.9.A.10 Tic

a) Incidence: pediatric patients, 2% (Prod Info VYVANSE(R) oral capsules, 2008)

b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), tics were reported in 2% of pediatric patients receiving lisdexamfetamine (n=218) compared wit the most frequent adverse events leading to discontinuation of therapy was exacerbation of motor and pl patients receiving lisdexamfetamine, which was at least twice the rate compared with placebo (Prod Info

c) Tics led to discontinuation of therapy in 1% (2/218) of pediatric patients receiving lisdexamfetamine, v compared with those receiving placebo (Prod Info VYVANSE(R) oral capsules, 2008).

d) Exacerbation of motor and phonic tics has been reported following administration of amphetamines. I should be evaluated for tics (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.9.A.11 Tremor

a) Incidence: adult patients, 2% (Prod Info VYVANSE(R) oral capsules, 2008)

b) Tremor was reported in 2% of adult patients who received lisdexamfetamine in final doses of 30 mg, patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, paralle ADHD (Prod Info VYVANSE(R) oral capsules, 2008).

c) Further, in a retrospective review of poison center databases in 8 states during the initial 10 months c of 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisc reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).
d) Tremor has been reported following administration of amphetamines (Prod Info VYVANSE(R) oral ca

3.3.10 Ophthalmic Effects

3.3.10.A Lisdexamfetamine Dimesylate

3.3.10.A.1 Blurred vision
a) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisde reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.12 Psychiatric Effects

3.3.12.A Lisdexamfetamine Dimesylate

Agitation

Anxiety

Dysphoric mood

Euphoria

Feeling nervous

Hallucinations

Irritability

Labile affect

Psychotic disorder

Restlessness

Summary

3.3.12.A.1 Agitation
a) Incidence: adult patients, 3% (Prod Info VYVANSE(R) oral capsules, 2008)
b) Agitation was reported in 3% of adult patients who received lisdexamfetamine in final doses of 30 mg patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, paralle ADHD (Prod Info VYVANSE(R) oral capsules, 2008).
c) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisde reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.12.A.2 Anxiety
a) Incidence: adult patients, 6% (Prod Info VYVANSE(R) oral capsules, 2008)
b) Anxiety was reported in 6% of adult patients who received lisdexamfetamine in final doses of 30 mg, patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, paralle ADHD. This led to a 1% discontinuation rate of lisdexamfetamine therapy (Prod Info VYVANSE(R) oral c

3.3.12.A.3 Dysphoric mood
a) Dysphoria has been reported following administration of amphetamines (Prod Info VYVANSE(R) oral

3.3.12.A.4 Euphoria
a) Euphoria has been reported following administration of amphetamines (Prod Info VYVANSE(R) oral c

3.3.12.A.5 Feeling nervous

a) Incidence: adult patients, 4% (Prod Info VYVANSE(R) oral capsules, 2008)
b) Feeling jittery was reported in 4% of adult patients who received lisdexamfetamine in final doses of 3
0% of patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled,
diagnosed with ADHD (Prod Info VYVANSE(R) oral capsules, 2008).
c) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc
(3 of 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with
be reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.12.A.6 Hallucinations

a) Incidence: 11% (Spiller et al, 2008)
b) In a retrospective review of poison center databases in 8 states during the initial 10 months of produc
of 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisc
reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.3.12.A.7 Irritability

a) Incidence: pediatric patients, 10%; adults, 5% or greater (Prod Info VYVANSE(R) oral capsules, 2008
b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric
(n=290), irritability was reported in 10% of pediatric patients receiving lisdexamfetamine (n=218) compar
(Prod Info VYVANSE(R) oral capsules, 2008).
c) Irritability was also reported in at least 5% or more adults patients receiving lisdexamfetamine during
1% (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.12.A.8 Labile affect

a) Incidence: pediatric patients, 3% (Prod Info VYVANSE(R) oral capsules, 2008)
b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric
(n=290), labile affect was reported in 3% of pediatric patients receiving lisdexamfetamine (n=218) compa
(Prod Info VYVANSE(TM) oral capsules, 2007).

3.3.12.A.9 Psychotic disorder

a) In multiple short term, placebo-controlled studies, psychotic episodes have been reported in 0.1% of
with recommended doses of methylphenidate or amphetamines compared with no patients receiving pla
2008).
b) Psychotic or manic symptoms may occur among patients without prior history of psychosis, or may w
(Prod Info VYVANSE(R) oral capsules, 2008).

3.3.12.A.10 Restlessness

a) Incidence: adult patients, 3% (Prod Info VYVANSE(R) oral capsules, 2008)
b) Restlessness was reported in 3% of adult patients who received lisdexamfetamine in final doses of 3
0% of patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled,
diagnosed with ADHD (Prod Info VYVANSE(R) oral capsules, 2008).

3.3.12.A.11 Summary

a) The use of stimulants may result in new-onset or worsening of existing psychotic disorders, even in p
aggressive behavior and evaluating the patient for bipolar disorder prior to stimulant use is recommende

3.3.14 Reproductive Effects

3.3.14.A Lisdexamfetamine Dimesylate

3.3.14.A.1 Impotence

a) Impotence has been reported following administration of amphetamines (Prod Info VYVANSE(R) oral

3.3.15 Respiratory Effects

3.3.15.A Lisdexamfetamine Dimesylate

3.3.15.A.1 Dyspnea

a) Incidence: adult patients, 2% (Prod Info VYVANSE(R) oral capsules, 2008)
b) Dyspnea was reported in 2% of adult patients who received lisdexamfetamine in final doses of 30 mg
patients who received placebo (n=62) in a 4-week, double-blind, randomized, placebo-controlled, paralle
ADHD. This led to a 1% discontinuation rate of lisdexamfetamine therapy (Prod Info VYVANSE(R) oral c

3.3.16 Other

3.3.16.A Lisdexamfetamine Dimesylate

3.3.16.A.1 Fever

a) Incidence: pediatric patients, 2% (Prod Info VYVANSE(R) oral capsules, 2008)

b) During a 4-week, double-blind, randomized, placebo-controlled, parallel-group clinical trial of pediatric (n=290), pyrexia was reported in 2% of pediatric patients receiving lisdexamfetamine (n=218) compared Info VYVANSE(TM) oral capsules, 2007).
c) Further, in a retrospective review of poison center databases in 8 states during the initial 10 months c 28) of patients between 4 and 44 years of age (median, 8 years) experiencing adverse events with lisdex reliably determined as concomitant drugs or conditions were not evaluated (Spiller et al, 2008).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding

A) Teratogenicity/Effects in Pregnancy
1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info VYVANSE(TM) oral capsule
a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other) studies in women and animals are not available. Drugs should be given only if the potential benefit justifies th
See Drug Consult reference: PREGNANCY RISK CATEGORIES
2) Crosses Placenta: Unknown
3) Clinical Management
a) There are no adequate and well-controlled studies with lisdexamfetamine in humans or animals. Studies v animals have shown adverse maternal and fetal effects. Until further data are available, it is recommended th only if the potential benefit justifies the potential risk to the fetus (Prod Info VYVANSE(TM) oral capsules, 200
4) Literature Reports
a) Reproduction studies with lisdexamfetamine (prodrug of dextroamphetamine) have not been conducted in of premature delivery and low birth weight in infants born to mothers dependent on amphetamine. Additionall agitation, and significant lassitude, may be present in such infants (Prod Info VYVANSE(TM) oral capsules, 2
b) In pregnant rats and rabbits, orally administered amphetamine (D to L enantiomer ratio of 3:1) at doses up not affect embryofetal development or survival. However, parenteral administration of dextroamphetamine at mice resulted in severe maternal toxicity and fetal malformations and death. Additionally, in several studies in clinically relevant amphetamine doses led to long-term neurochemical and behavioral effects, such as learnin activity, and changes in sexual function (Prod Info VYVANSE(TM) oral capsules, 2007).

B) Breastfeeding
1) Thomson Lactation Rating: Infant risk cannot be ruled out.
a) Available evidence and/or expert consensus is inconclusive or is inadequate for determining infant risk wh potential benefits of drug treatment against potential risks before prescribing this drug during breastfeeding.
2) Clinical Management
a) As amphetamines are excreted in human milk, breast-feeding women receiving lisdexamfetamine should VYVANSE(TM) oral capsules, 2007).

3.5 Drug Interactions

3.5.1 Drug-Drug Combinations

Amitriptyline

Amoxapine

Clomipramine

Clorgyline

Desipramine

Dothiepin

Doxepin

Furazolidone

Imipramine

Iproniazid

Isocarboxazid

Lofepramine

Moclobemide

Nialamide

Nortriptyline

Opipramol

Pargyline

Phenelzine

Procarbazine

Protriptyline

Rasagiline

Selegiline

Toloxatone

Tranylcypromine

Trimipramine

3.5.1.A Amitriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCA monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.B Amoxapine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.C Clomipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc
1969). However, a systemic review of stimulants in the treatment of depression concluded that although
ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt
appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.D Clorgyline

1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine
Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine met
norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis,
hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Lisdexamfetamine use during or within 14 days following the administration of a mo
hypertensive crises may occur (Prod Info VYVANSE(TM) oral capsules, 2007).
7) Probable Mechanism: increased norepinephrine availability

3.5.1.E Desipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported
from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with
Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m
most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sho
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
& Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs
monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf
capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if
closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen
amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet
VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab
2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism o
imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases in
effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb
methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th
pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g
fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical
doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc
1969). However, a systemic review of stimulants in the treatment of depression concluded that although
ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt
appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.F Dothiepin

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reported
from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with
Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m
most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sho
moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo
& Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs
monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho
increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf

capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.G Doxepin

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation

2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: theoretical

6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.

7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission

8) Literature Reports

a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).

b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).

c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).

d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.H Furazolidone

1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)

2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine me norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis, hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007). Furazolidone has significant MAOI activity (Pet Therefore, concurrent use of furazolidone with lisdexamfetamine should be avoided.

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Lisdexamfetamine use during or within 14 days following the administration of a mo contraindicated as hypertensive crises may occur (Prod Info VYVANSE(TM) oral capsules, 2007). As furazoli concurrent use with lisdexamfetamine.
7) Probable Mechanism: increased norepinephrine availability

3.5.1.I Imipramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs n most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCA monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.J Iproniazid

1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine me norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Lisdexamfetamine use during or within 14 days following the administration of a mo hypertensive crises may occur (Prod Info VYVANSE(TM) oral capsules, 2007).
7) Probable Mechanism: increased norepinephrine availability

3.5.1.K Isocarboxazid

1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine me norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Lisdexamfetamine use during or within 14 days following the administration of a mo hypertensive crises may occur (Prod Info VYVANSE(TM) oral capsules, 2007).
7) Probable Mechanism: increased norepinephrine availability

3.5.1.L Lofepramine

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs n most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been rep & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCA monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).

However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.M Moclobemide

1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine me norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Lisdexamfetamine use during or within 14 days following the administration of a mo hypertensive crises may occur (Prod Info VYVANSE(TM) oral capsules, 2007).
7) Probable Mechanism: increased norepinephrine availability

3.5.1.N Nialamide

1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine me norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Lisdexamfetamine use during or within 14 days following the administration of a mo hypertensive crises may occur (Prod Info VYVANSE(TM) oral capsules, 2007).
7) Probable Mechanism: increased norepinephrine availability

3.5.1.O Nortriptyline

1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur wit Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs n most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been rep

& Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.P Opipramol
1) Interaction Effect: hypertension, other cardiac effects, and CNS stimulation
2) Summary: Concomitant tricyclic antidepressant (TCA) and amphetamine administration has been reporte from the release of norepinephrine (Beaumont, 1973; Raisfeld, 1972). A similar reaction might also occur with Acute elevations in blood pressure have been noted (Flemenbaum, 1971a). Some amphetamine-like drugs m most combinations have not been studied. When amphetamine analogs are being used to treat obesity, it sh moderate weight gain (Russ & Ackerman, 1988). False positive urine tests for amphetamines have been repo & Browning, 1993). Caution is advised when concurrent administration of amphetamine-like agents and TCAs monitored for increased cardiovascular effects (hypertension and dysrhythmias).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Coadministration of amphetamines and tricyclic antidepressants or other sympatho increased cardiovascular effects, or CNS stimulation (Prod Info VYVANSE(TM) oral capsules, 2007; Prod Inf capsules, oral tablets, 2006; Prod Info ADDERALL(R) oral tablets, 2006; Flemenbaum, 1972). Use caution if closely for hypertension and dysrhythmias.
7) Probable Mechanism: synergistic effects on noradrenergic neurotransmission
8) Literature Reports
a) Amphetamines may increase the activity of tricyclic antidepressants (TCA) or sympathomimetic agen amphetamine with TCAs such as desipramine or protriptyline results in sustained increases in d-amphet VYVANSE(TM) oral capsules, 2007; Prod Info DEXEDRINE(R) sustained-release oral capsules, oral tab 2006).
b) Human pharmacologic studies have demonstrated that methylphenidate may inhibit the metabolism c imipramine, clomipramine, or desipramine (Prod Info DAYTRANA(TM) transdermal system, 2006).
c) Concomitant administration of tricyclic antidepressants and methylphenidate can result in increases i effects induced by TCAs may lead to blood pressures as high as 170/120 mmHg within one day of comb methylphenidate usually results in the blood pressure returning to normotensive levels; reinstitution of th pressure elevation (Flemenbaum, 1971; Flemenbaum, 1972).
d) Fifteen patients with DSM-III major depression, who failed to respond to treatment with desipramine g fenfluramine 40 mg to 120 mg daily for two weeks but did not result in any transient or sustained clinical doubled steady-state plasma levels of desipramine (Price et al, 1990).
e) There have been claims based on uncontrolled studies that a better antidepressant response may oc 1969). However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

3.5.1.Q Pargyline
1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine

Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine met
norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis,
hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Lisdexamfetamine use during or within 14 days following the administration of a mo
hypertensive crises may occur (Prod Info VYVANSE(TM) oral capsules, 2007).
7) Probable Mechanism: increased norepinephrine availability

3.5.1.R Phenelzine
1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine
Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine met
norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis,
hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: Lisdexamfetamine use during or within 14 days following the administration of a mo
hypertensive crises may occur (Prod Info VYVANSE(TM) oral capsules, 2007).
7) Probable Mechanism: increased norepinephrine availability

3.5.1.S Procarbazine
1) Interaction Effect: hypertensive crisis (headache, hyperpyrexia, hypertension)
2) Summary: Use of lisdexamfetamine during or within 14 days following the administration of a monoamine
Amphetamines stimulate the release of norepinephrine, and the use of MAOIs slows down amphetamine met
norepinephrine and other monoamines from adrenergic nerve ending. This could result in hypertensive crisis,
hyperpyrexia (Prod Info VYVANSE(TM) oral capsules, 2007).

However, a systemic review of stimulants in the treatment of depression concluded that although ten placebo-controlled studies of stimulant drugs in primary depression, with one exception, indicated litt appear to be as effective as the conventional antidepressants in primary depression (Satel & Nelson, 19

4.0 Clinical Applications

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

4.1 Monitoring Parameters

A) Lisdexamfetamine Dimesylate
1) Therapeutic
a) Improvement in mental and behavioral symptoms of attention deficit hyperactivity disorder (ADHD), includ hyperactivity, and cognitive performance.
2) Toxic
a) Physical Findings
1) The American Academy of Pediatrics (AAP) does not recommend the routine use of electrocardiogra evaluations (which were previously recommended by the American Heart Association (AHA) scientific st place the child at risk for sudden cardiac death) before initiating stimulant therapy to treat attention-defici The APA cited specific reasons for changing the recommendation including: lack of evidence establishin treat ADHD and sudden cardiac death (SCD), the frequency of sudden unexpected deaths among patier in the general population of children, and lack of cost-effective analysis to support ECG screening or spe al, 2008).
2) Based on the American Academy of Pediatrics (AAP) and the American Heart Association (AHA) con monitoring recommendations have been established to assist clinicians in the evaluation of children treat lisdexamfetamine, for ADHD (Perrin et al, 2008; Vetter et al, 2008):
- Conduct a thorough examination prior to initiating lisdexamfetamine therapy for a diagnosis of ADH symptoms indicative of a cardiac condition, including palpitations, near syncope, or syncope.
- Obtain a complete family and patient history for conditions associated with SCD, and determine cu counter medications.
- Conduct a complete physical evaluation of the patient for hypertension, cardiac murmurs, physical signs of irregular cardiac rhythms.
- Perform further evaluation if family history, patient history or physical exam is suggestive of cardiac and if indicated, consult pediatric cardiologist .
- Continue to assess the patient for cardiac symptoms and any changes in family history at follow up
- Blood pressure and heart rate should be evaluated at baseline, during routine follow-up within 1 to months. Increases in blood pressure and heart rate have been reported with stimulant use.

b) It is not conclusive whether chronic use of stimulants in children may be associated with suppression of g during treatment (Prod Info VYVANSE(TM) oral capsules, 2007).

4.2 Patient Instructions

A) Lisdexamfetamine Dimesylate (By mouth)

Lisdexamfetamine Dimesylate

Treats attention deficit hyperactivity disorder (ADHD). This medicine is a stimulant.

When This Medicine Should Not Be Used:

You should not use this medicine if you or your child have had an allergic reaction to lisdexamfetamine dimesylate glaucoma, an overactive thyroid, high blood pressure, heart disease, or blood vessel problems. Do not use this m you are very nervous, tense, or agitated most of the time. You should not use this medicine if you have used a dru (MAOI), such as Eldepryl®, Marplan®, Nardil®, or Parnate®, in the past 14 days. Do not give this medicine to a c

How to Use This Medicine:

Capsule

Your doctor will tell you how much of this medicine to use and how often. Your dose may need to be changed best for you. Do not use more medicine or use it more often than your doctor tells you to.

This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your d Ask your pharmacist for the Medication Guide if you do not have one. Your doctor might ask you to sign som information.

You may take this medicine with or without food.

It is best to take this medicine in the morning. Taking this medicine in the afternoon or evening could make it

If you cannot swallow the capsule whole, you may open it and pour the medicine into a glass of water. Stir thi

This medicine is part of an ADHD treatment program that may also include counseling or special education. C all treatment measures.

If a Dose is Missed:

If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next d the missed dose. Do not use extra medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:

Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.

Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after need to throw away old medicine after the expiration date has passed.

Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:

Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a

Make sure your doctor knows if you are also using blood pressure medicines (such as atenolol, lisinopril, met medicines (such as meperidine, propoxyphene, Demerol®, or Darvon®), chlorpromazine (Thorazine®), cold haloperidol (Haldol®), lithium carbonate (Lithobid®), certain medicines for depression (such as amitriptyline, methenamine (Hiprex, Urex®), phenobarbital, or phenytoin (Dilantin®).

Warnings While Using This Medicine:

Make sure your doctor knows if you are pregnant or breastfeeding, or if you or your child have heart problems

Tell your doctor if you or your child have muscle tics or Tourette's syndrome, a condition that causes you to h not able to control.

Your doctor should know if you or your child have epilepsy, or a history of seizures, depression, or mental illn problems. Also tell your doctor if you or anyone in your family has tried to commit suicide.

This medicine may be habit-forming. If you feel that the medicine is not working as well, do not use more thar instructions.

This medicine may cause slow growth. If your child is using this medicine, the doctor will need to keep track o your child is growing properly.

This medicine may cause blurred vision or make you drowsy or dizzy. If any of these occur, do not drive, use dangerous if you are not alert or not able to see well.

Your doctor will need to check your progress at regular visits while you are using this medicine. Be sure to ke

Possible Side Effects While Using This Medicine:

Call your doctor right away if you notice any of these side effects:

Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, o

Blistering, peeling, red skin rash.

Blurred vision or trouble seeing.

Chest pain, shortness of breath, or fainting.

Fast, pounding, or irregular heartbeat.

Mood or mental changes, or unusual or disturbing thoughts.

Numbness or weakness in your arm or leg, or on one side of your body.

Seeing, hearing, or feeling things that are not there.
Seizures.
Tremors or shaking.
Uncontrollable muscle movements or twitching.

If you notice these less serious side effects, talk with your doctor:
Constipation, diarrhea, or upset stomach.
Dry mouth or bad taste in your mouth.
Feeling restless or nervous.
Headache or dizziness.
Loss of appetite or weight loss.
Nausea, vomiting, or stomach pain.
Problems having sex.
Trouble sleeping.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) Lisdexamfetamine Dimesylate

1) Lisdexamfetamine dimesylate is a pro-drug of dextroamphetamine, approved for the treatment of Attention-De placebo-controlled trials, lisdexamfetamine dimesylate showed improvement in behavior in children aged 6 to 12 v combined type or hyperactive-impulsive type. The long-term (greater than 4 weeks) efficacy of lisdexamfetamine assessed in controlled trials (Prod Info VYVANSE(TM) oral capsules, 2007).

4.4 Mechanism of Action / Pharmacology

A) Lisdexamfetamine Dimesylate

1) After oral administration, lisdexamfetamine dimesylate is rapidly absorbed in the gastrointestinal tract and conv responsible for the drug's activity. The mechanism of action of dextroamphetamine in the treatment of attention-de Amphetamines may block the reuptake of norepinephrine and dopamine at the presynaptic neuron and thus increa dopamine into the extraneuronal space (Prod Info VYVANSE(TM) oral capsules, 2007).

4.5 Therapeutic Uses

4.5.A Lisdexamfetamine Dimesylate

4.5.A.1 Attention deficit hyperactivity disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, yes (age 6 to 12 years)
Efficacy: Adult, Evidence favors efficacy; Pediatric, Effective
Recommendation: Adult, Class IIb; Pediatric, Class IIa
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Approved for the treatment of Attention-Deficit/Hyperactivity Disorder in children aged 6 to 12 and ac 2008)
In a 4-week, randomized, double-blind, placebo-controlled, parallel-group study (n=420), lisdexamfe in the treatment of adults meeting Diagnostic and Statistical Manual of Mental Disorders-Fourth Edit VYVANSE(R) oral capsules, 2008)
In a 4-week, multicenter, randomized, double-blind, fixed-dose study (n=290), lisdexamfetamine dim treatment of children aged 6 to 12 meeting Diagnostic and Statistical Manual of Mental Disorders-Fo or hyperactive-impulsive type ADHD (Biederman et al, 2007)

c) Adult:

1) Lisdexamfetamine mesylate was effective and well tolerated in the treatment of adult ADHD in a rand parallel-group study. Adults meeting the Diagnostic and Statistical Manual of Mental Disorders-Fourth Ed to receive fixed doses of either 30 milligrams (mg), 50 mg, or 70 mg of lisdexamfetamine (n=358) or plac Lisdexamfetamine was initiated at 30 mg and titrated in weekly increments of 20 mg to achieve the 50 ar ratings on the ADHD Rating Scale (ADHD-RS), significant improvements occurred for all lisdexamfetami Treatment-emergent adverse events occurring commonly and more frequently than placebo included dry nausea (7% vs 0%), decreased appetite (27% vs 3%), insomnia (27% vs 8%), and anxiety (6% vs 0%) (

d) Pediatric:

1) Lisdexamfetamine was effective and well tolerated for the treatment of children with combined type o Deficit/Hyperactivity Disorder (ADHD) in a multicenter, randomized, double-blind, fixed-dose study of 4 w 1.8 years) were included if their ADHD Rating Scale version IV (ADHD-RS-IV) was 28 or greater. Childre dimesylate 30 milligrams (mg) once in the morning for 4 weeks (n=71), 50 mg once in the morning (30 m to 4) for 4 weeks (n=74), 70 mg once in the morning (30 mg for 1 week, then titrated to 50 mg for week 2 (n=73), or placebo for 4 weeks (n=72). The primary efficacy endpoint was the mean change from baselir ADHD-RS-IV rated 18 symptoms on a scale of 0 (no symptoms) to 3 (severe symptoms) based on the in

and child. The majority of patients were male (69%), treatment-naive (59.2% to 69.9%), and diagnosed v
ADHD-RS-IV score improved 4- to 5-fold for each lisdexamfetamine dose group relative to the placebo (
improvement was demonstrated in the 70-mg dose group (-26.7 (standard deviation (SD), 1.54)) compar
0.001). Improvement was noticed for all dose groups during the first week with continued improvement th
Conners' Parent Rating Scale-Revised: Short Form (CPRS-R), a 27-question parent rating of the childs's
and ADHD index, at three times through the day (up to 6 PM). Compared with the placebo group, the CP
(morning, afternoon, and evening) improved significantly starting at week 1 through week 4 for all dose g
mg dose group experiencing the greatest improvement. Adverse events were primarily mild to moderate
mostly in the first week. The most common adverse events experienced in the lisdexamfetamine and pla
appetite (39% and 4%, p less than or equal to 0.05), insomnia (19% and 3%, p less than or equal to 0.05
significant), headache (12% and 10%, p = not significant), irritability (10% and 0%, p less than or equal t
significant), weight decrease (9% and 1%, p less than or equal to 0.05), and nausea (6% and 3%, p = no
demonstrated in mean ECG parameters (including QT intervals), laboratory values, or blood pressure fo
2007).

2) Treatment with lisdexamfetamine mesylate led to a significant difference in patient behavior compare
crossover design, analog classroom study in children aged 6 to 12 years (n=52) meeting the Diagnostic
Fourth Edition criteria for ADHD (combined type or hyperactive-impulsive type). Subsequent to a 3-week
amphetamine/dextroamphetamine (Adderall XR(R)) 10 to 30 milligrams (mg) daily, patients were randon
amphetamine/dextroamphetamine, lisdexamfetamine mesylate (30, 50, or 70 mg/day), or placebo once
lasted for 1 week. Efficacy was assessed as the mean of investigator ratings on the Swanson, Kotkin, Al
scores over 8 sessions of a 12 hour treatment day (Prod Info VYVANSE(R) oral capsules, 2008).

1.0 Dosing Information

Drug Properties

Storage and Stability

Adult Dosage

Pediatric Dosage

1.1 Drug Properties

A) Information on specific products and dosage forms can be obtained by referring to the Tradename List (Product In

B) Synonyms

Sertraline
Sertraline HCl
Sertraline Hydrochloride

C) Physicochemical Properties

1) Molecular Weight

a) Sertraline hydrochloride: 342.7 (Fleeger, 1996)

2) Solubility

a) Systemic: Sertraline hydrochloride is slightly soluble in water and sparingly soluble in ethyl alcohol (Prod I

1.2 Storage and Stability

A) Sertraline Hydrochloride

1) Preparation

a) Oral route

1) The oral concentrate formulation of sertraline should be diluted in 4 ounces (½ cup) using only water, (Prod Info ZOLOFT(R) tablets and oral concentrate, 2005).

B) Oral route

1) Tablets and oral concentrate should be stored at a controlled room temperature of 25 degrees Celsius (77 deg are permitted (Prod Info Zoloft(R), 2002).

1.3 Adult Dosage

Normal Dosage

Dosage in Renal Failure

Dosage in Hepatic Insufficiency

Dosage in Geriatric Patients

1.3.1 Normal Dosage

1.3.1.A Sertraline Hydrochloride

1.3.1.A.1 Oral route

Dysthymia

Major depressive disorder

Obsessive-compulsive disorder

Panic disorder

Posttraumatic stress disorder

Premenstrual dysphoric disorder

Social phobia

1.3.1.A.1.a Dysthymia

1) A dose of sertraline 50 milligrams (mg) daily orally as a single dose in the morning or the evening controlled trial. Dose increases up to a maximum of 200 mg/day were allowed (Ravindran et al, 200

1.3.1.A.1.b Major depressive disorder

1) The initial recommended dosage is 50 milligrams daily as a single dose in the morning or the eve recommended dosage of 200 milligrams daily (Prod Info Zoloft(R), 2002).

2) Sertraline oral concentrate contains 20 milligrams/milliliter (mg/mL). Immediately before taking se lemon/lime soda, lemonade, or orange juice. After mixing, a slight haze may appear; this is normal. contains dry natural rubber (Prod Info Zoloft(R), 2002).

a) DURATION OF THERAPY

1) Clinical trials have suggested that depressed patients responding during the first 8 weel term studies of sertraline efficacy have not been completed, treatment of depression gener unknown whether the dose of sertraline required to maintain euthymia is the same as that r

1.3.1.A.1.c Obsessive-compulsive disorder

1) The initial dosage is 50 milligrams once daily in the morning or evening. If 50 milligrams does not daily at intervals of at least 1 week (Prod Info Zoloft(R), 2002).

2) Sertraline oral concentrate contains 20 milligrams/milliliter (mg/mL). Immediately before taking se lemon/lime soda, lemonade, or orange juice. After mixing, a slight haze may appear; this is normal. contains dry natural rubber (Prod Info Zoloft(R), 2002).

a) DURATION OF THERAPY

1) Efficacy of sertraline therapy in obsessive compulsive disorder has not been documente disorder, therapy should be continued for responding patients. Periodic determination of th provide the patient with the lowest effective dose (Prod Info Zoloft(R), 2002).

1.3.1.A.1.d Panic disorder

1) The initial recommended dosage is 25 milligrams (mg) once daily, taken in the morning or evenir still inadequate, the dosage may be increased at intervals of 1 week to a maximum of 200 mg/day (

2) Sertraline oral concentrate contains 20 milligrams/milliliter (mg/mL). Immediately before taking se lemon/lime soda, lemonade, or orange juice. After mixing, a slight haze may appear; this is normal. contains dry natural rubber (Prod Info Zoloft(R), 2002).

a) DURATION OF THERAPY

1) Efficacy of sertraline therapy in panic disorder has not been documented for longer thar therapy should be continued for responding patients. Periodic determination of the need fo patient with the lowest effective dose (Prod Info Zoloft(R), 2002).

1.3.1.A.1.e Posttraumatic stress disorder

1) The initial recommended dosage is 25 milligrams (mg) once daily, taken in the morning or evenir still inadequate, the dosage may be increased at intervals of 1 week to a maximum of 200 mg/day (

2) Sertraline oral concentrate contains 20 milligrams/milliliter (mg/mL). Immediately before taking se lemon/lime soda, lemonade, or orange juice. After mixing, a slight haze may appear; this is normal. contains dry natural rubber (Prod Info Zoloft(R), 2002).

1.3.1.A.1.f Premenstrual dysphoric disorder

1) CONTINUOUS DOSING

a) Premenstrual dysphoric disorder (PMDD) may be treated with sertraline either throughout th dosing). For continuous dosing, sertraline should be started at 50 milligrams (mg) per day (mor day. Dosage adjustments, if needed, should be made in 50 mg increments at the onset of each

2) LUTEAL PHASE DOSING

a) Premenstrual dysphoric disorder (PMDD) may be treated with sertraline either throughout th dosing). For luteal phase dosing, sertraline should be started at 50 milligrams (mg) per day (mo day. For doses higher than 50 mg, use a 50 mg/day titration step for three days at the beginnin

1.3.1.A.1.g Social phobia

1) The initial recommended dosage is 25 milligrams (mg) once daily, taken in the morning or evenir still inadequate, the dosage may be increased at intervals of 1 week to a maximum of 200 mg/day (

a) DURATION OF THERAPY

1) Sertraline in doses of 50 to 200 milligrams per day was effective in the treatment of adu trials. Dosages should be adjusted to the lowest effective dose and periodic determinations

1.3.1.A.2 MAXIMUM DOSE

a) Recommended maximum is 200 milligrams daily (Prod Info Zoloft(R), 2002).

1.3.2 Dosage in Renal Failure

A) Sertraline Hydrochloride

1) In patients with renal impairment, dosage adjustment is NOT necessary. Sertraline is extensively metabol Zoloft(R), 2002).

1.3.3 Dosage in Hepatic Insufficiency

A) Sertraline Hydrochloride

1) Sertraline is extensively metabolized in the liver. In patients with hepatic impairment or cirrhosis, a lower c

1.3.4 Dosage in Geriatric Patients

A) Sertraline Hydrochloride

1) Although no specific dosage adjustments have been recommended for sertraline use in geriatric patients, patients treated with a dose of 100 milligrams daily for 14 days. Steady-state clearance is achieved in 2-3 we but not in females (Prod Info Zoloft(R), 2002). Since steady state may take longer to achieve in elderly, dose

1.4 Pediatric Dosage

Normal Dosage

Dosage in Hepatic Insufficiency

1.4.1 Normal Dosage

1.4.1.A Sertraline Hydrochloride

1.4.1.A.1 Oral route

1.4.1.A.1.a Obsessive-compulsive disorder

1) The initial recommended dose is 25 milligrams (mg) once daily in children 6 to 12 years of age o 200 mg/day in clinical trials which established efficacy in the pediatric population; however, dosage may be administered in the morning or evening (Prod Info Zoloft(R), 2002).

2) Sertraline oral concentrate contains 20 milligrams/milliliter (mg/mL). Immediately before taking se lemon/lime soda, lemonade, or orange juice. After mixing, a slight haze may appear; this is normal. contains dry natural rubber (Prod Info Zoloft(R), 2002).

1.4.3 Dosage in Hepatic Insufficiency

A) Sertraline Hydrochloride

1) In patients with hepatic impairment, a lower or less frequent dosage interval should be used (Prod Info Zo

2.0 Pharmacokinetics

Onset and Duration

Drug Concentration Levels

ADME

2.1 Onset and Duration

A) Onset

1) Initial Response

a) Depression, regular release: 2 weeks (Reimherr et al, 1988).

2) Peak Response

a) Depression, regular release: 6 weeks (Amin et al, 1989a; Doogan & Caillard, 1988).

2.2 Drug Concentration Levels

A) Time to Peak Concentration

1) Oral, regular release: 4 to 8 hours (Prod Info Zoloft(R), 2002w; Doogan & Caillard, 1988; Saletu et al, 1986).

a) The Cmax after continuous administration of sertraline 200 mg/day was 165 ng/mL (children 6 to 12 years

b) A study of 22 young (less than 45 years) and elderly (greater than 65 years) healthy male and female volu and elderly groups after continuous administration of 200 mg for 21 days (Ronfeld et al, 1997).

c) The time of administration (morning versus evening) did NOT affect mean peak plasma sertraline concent single doses of 100 mg. Although no specific recommendation can be made, it appears that sertraline may b 1997a).

d) A mean peak plasma sertraline concentration of 54.5 ng/mL was observed 4 hours after a single 100-milli were 105.4 and 253.2 ng/mL, respectively, at 6 hours post-dosing (Saletu et al, 1986).

B) Area Under the Curve

1) 2296 to 3107 ng-hr/mL (Prod Info Zoloft(R), 2002w).

a) The AUC was 3107 ng-hr/mL (children 6 to 12 years), 2296 ng-hr/mL (adolescents 13 to 17 years), and 2

2002w).

2.3 ADME

Absorption

Distribution

Metabolism

Excretion

Elimination Half-life

Extracorporeal Elimination

2.3.1 Absorption

A) Bioavailability

1) Oral, regular release: complete (Prod Info Zoloft(R), 2002w; Doogan & Caillard, 1988).

a) Single dose bioavailability studies have shown that the tablets and oral solution are approximately eq

b) The time of day of administration (morning versus evening) did NOT affect the area under the curve (mean terminal elimination half-life, or mean elimination rate constant, in 22 healthy male volunteers who appears that sertraline may be administered in the morning or evening without bioavailability differences

B) Effects of Food

1) small (Prod Info Zoloft(R), 2002w).

a) For the tablet, food increased the mean peak plasma concentration by 25%, and it decreased the tim (Prod Info Zoloft(R), 2002w).

2.3.2 Distribution

A) Distribution Sites

1) Protein Binding

a) 99% (Doogan & Caillard, 1988).

B) Distribution Kinetics

1) Volume of Distribution

a) 20 L/kg (Doogan & Caillard, 1988).

2.3.3 Metabolism

A) Metabolism Sites and Kinetics

1) Liver, extensive (Prod Info Zoloft(R), 2002w).

a) Sertraline undergoes extensive first-pass metabolism (Prod Info Zoloft(R), 2002w).

b) Sertraline is primarily metabolized via N-demethylation to desmethylsertraline, which is weakly active hydroxylated. The alpha-hydroxy ketone metabolite is excreted in the urine and feces (Doogan & Caillard

B) Metabolites

1) Desmethylsertraline, weakly active (Doogan & Caillard, 1988).

2) Alcohol metabolites, inactive (Doogan & Caillard, 1988).

3) Oxime metabolites, inactive (Doogan & Caillard, 1988).

2.3.4 Excretion

A) Kidney

1) Renal Excretion (%)

a) 40% to 45% (Prod Info Zoloft(R), 2002w).

2) None of the dose is recovered as unchanged sertraline (Prod Info Zoloft(R), 2002w). The alpha-hydroxy k

B) Other

1) OTHER EXCRETION

a) Feces, 40% to 45% (Prod Info Zoloft(R), 2002w).

b) About 12-14% of sertaline is found unchanged in the feces along with the alpha-hydroxy ketone meta

2.3.5 Elimination Half-life

A) Parent Compound

1) ELIMINATION HALF-LIFE

a) 24 hours (Doogan & Caillard, 1988; Saletu et al, 1986).

1) The half-life after continuous administration of sertraline 200 mg/day was 26.2 hours (children 6 t 2002w).

2) A study of 22 young (less than 45 years) and elderly (greater than 65 years) healthy male and fe

exhibited a 50% shorter half-life (mean 22 hours) compared to the other groups (32 to 36 hours) (Rc
3) The time of day of administration (morning versus evening) did NOT affect mean terminal elimina
single doses of 100 mg (Ronfeld et al, 1997a).

B) Metabolites

1) Desmethylsertraline, 62 to 104 hours (Doogan & Caillard, 1988; Saletu et al, 1986; Prod Info Zoloft(R), 20

2.3.6 Extracorporeal Elimination

A) Hemodialysis

1) Dialyzable: No (Schwenk et al, 1995).

a) In 2 patients undergoing hemodialysis with a Baxter CA-110 hollow fiber dialysis filter, no sertraline w
the dialysis time was 4 and 3.63 hours for patient 1 and 2, respectively (Schwenk et al, 1995).

3.3.1.A Sertraline Hydrochloride

Angina

Cardiac dysrhythmia

Cardiovascular finding

EKG finding

Syncope

3.3.1.A.1 Angina

a) Summary

1) CASE REPORT - A case report notes the occurrence angina along with shortness of breath and were severe enough to warrant hospitalization and withdrawal of treatment. Authors postulate that ir vasoconstriction. This results from the inability of the endothelium to produce sufficient endothelium- al, 1997).

b) LITERATURE REPORTS

1) An 81-year-old woman developed nausea and severe, crushing, retrosternal chest pain with sho milligrams. The pain worsened over the subsequent 2 hours and required hospitalization. The cardio were also normal. The electrocardiogram revealed normal sinus rhythm with nonspecific ST-T wave

acetylsalicylic acid, intravenous (IV) heparin, IV nitroglycerin, and diltiazem; sertraline was stopped. coronary artery and circumflex artery, respectively. Although it is difficult to attribute angina to sertra atherosclerotic coronary arteries causes vasoconstriction. This results from the inability of the endot vasoconstriction caused by serotonin (Sunderji et al, 1997).

3.3.1.A.2 Cardiac dysrhythmia

a) Summary

1) In postmarketing evaluation, AV BLOCK and VENTRICULAR TACHYCARDIA, including TORSA sertraline (Prod Info Zoloft(R), 2002).

3.3.1.A.3 Cardiovascular finding

a) Summary

1) Sertraline has been associated with PALPITATIONS, CHEST PAIN, HYPERTENSION, HYPOTE

b) Arrhythmias, palpitations, electrocardiogram changes, chest pain, hypertension, hypotension, edema

c) In a large cohort study including 481,744 persons and 1487 cases of SUDDEN CARDIAC DEATH oc associated with an increased risk of sudden cardiac death (rate ratio, 0.95; 95% CI, 0.42 to 2.15). In con equivalent) had a 41% increased rate of sudden cardiac death (rate ratio, 1.41; 95% CI, 1.02 to 1.95) (R

3.3.1.A.4 EKG finding

a) Summary

1) Electrocardiographic abnormalities were noted in 2 of 8 patients taking sertraline, 200 milligrams clinically significant Q-T INTERVAL PROLONGATION. Additional data are necessary to establish a

3.3.1.A.5 Syncope

a) Three patients with neurally mediated syncope, which was exacerbated following the use of sertraline

3.3.2 Dermatologic Effects

3.3.2.A Sertraline Hydrochloride

Dermatological finding

Night sweats

Stevens-Johnson syndrome

3.3.2.A.1 Dermatological finding

a) Summary

1) Infrequently, RASH, ACNE, PRURITUS, ALOPECIA, DERMATITIS, and PHOTOSENSITIVITY F

b) Infrequently, rash, acne, pruritus, alopecia, dermatitis, and photosensitivity reaction have been assoc have also been noted.

3.3.2.A.2 Night sweats

a) Summary

1) CASE REPORT - Progressively worse night sweats developed in a young woman treated with se with progressive worsening of night sweats. The patient stopped sertraline abruptly and noted resolu noted mild daytime sweating. After switching sertraline to fluoxetine, she had no further episodes of

3.3.2.A.3 Stevens-Johnson syndrome

a) Summary

1) CASE REPORT - A 96-year-old woman developed cutaneous and mucosal eruptions 3 weeks a atypical flat lesions were found on the face, trunk, and proximal limbs. Painful, oral erosions and cor days after sertraline and arginine chlorhydrate were stopped, the skin lesions disappeared. The auth distribution, atypical flat appearance, and total necrolysis of the epidermis. Other medications or dis

Syndrome of inappropriate antidiuretic hormone secretion

3.3.3.A.1 Decreased uric acid level

a) Summary

1) A small decrease in serum uric acid (7%) has been occasionally associated with sertraline therap

3.3.3.A.2 Disorder of fluid AND/OR electrolyte

a) Hyponatremia, which in some cases may be related to syndrome of inappropriate antidiuretic hormon

3.3.3.A.3 Endocrine finding

a) A small decrease in serum uric acid has been occasionally associated with therapeutic sertraline use reported. Syndrome of inappropriate antidiuretic hormone (SIADH) has also been reported in patients of

3.3.3.A.4 Galactorrhea

a) Summary

1) Sertraline therapy has been associated with galactorrhea. The probable mechanism for SSRI-inc stimulation of postsynaptic serotonin receptors in the hypothalamus or presynaptic serotonin recepto

b) LITERATURE REPORTS

1) Galactorrhea associated with sertraline was reported in a 37-year-old woman with a 1-year histo intolerable nausea developed, she was switched to sertraline 50 mg daily. After 2 weeks, the dosag beginning treatment. Sertraline was discontinued, and lactation ceased 21 days later. She was rece Stahl, 1993). Sixteen anecdotal cases of galactorrhea associated with sertraline have been reported have been reported in approximately 36 patients (Pers Comm, 1994).

3.3.3.A.5 Gynecomastia

a) Summary

1) Gynecomastia has been reported with sertraline use (Prod Info Zoloft(R), 2002). BREAST PAIN,

3.3.3.A.6 Hyperglycemia

a) Summary

1) Hyperglycemia was reported following the administration of sertraline for the treatment of depres Following the initiation of sertraline (12.5 milligrams (mg)/day, titrated weekly to 50 mg/day), the wor 116.3 mg/deciliter (dL) to 180.3 mg/dL. Laboratory studies revealed an increase in fasting serum glu treatment. During sertraline therapy, the patient lost 4 pounds and reported a reduction in carbohydr

3.3.3.A.7 Hyponatremia

a) Summary

1) The use of sertraline by elderly patients has been associated with cases of clinically significant h antidiuretic hormone secretion (SIADH) has also been reported following therapy. This effect has be frequently in patients over 65 years of age (Pecora et al, 1997)(Jackson et al, 1995; Leung & Remic Resch, 1995).

b) Incidence: rare

3.3.3.A.8 Hypothyroidism

a) Summary

1) Patients with thyroid disease who are also receiving treatment for depression should have thyroi levels and small increases in serum thyrotropin levels after starting treatment with sertraline and oth

3.3.3.A.9 Metabolic finding

a) Summary

1) HYPOGLYCEMIA, or HYPERCHOLESTEROLEMIA, and HYPERTRIGLYCERIDEMIA have bee DECREASED WEIGHT was also reported in at least 2% of pediatric patients during clinical trials of

b) Weight loss, hypoglycemia, hypercholesterolemia, hyperglycemia, and hypertriglyceridemia has occu

3.3.3.A.10 Syndrome of inappropriate antidiuretic hormone secretion

a) Summary

1) Sertraline has been associated with syndrome of inappropriate antidiuretic hormone secretion (S occurs between 3 days and 4 month after beginning therapy (Woo & Smythe, 1997; Bradley et al, 1

b) LITERATURE REPORTS

1) Of the 25 case reports of selective serotonin reuptake inhibitor (SSRI)-induced SYNDROME OF published, the majority occurred in patients over 70 years of age. Based on published reports, the o included confusion, lethargy, dizziness, fatigue, anorexia, delirium, and abdominal pain. Abnormal la (milliosmole/liter) mOsm/L; range 214 to 272 mOsm/L), decreased serum sodium concentration (me (median 392.5 mOsm/L; 229 to 613 mOsm/L). In all but 1 case, the selective serotonin reuptake inh patient was also treated with sodium chloride 3%. Patients in their fifties generally recovered in 2 to the 6 patients rechallenged with an SSRI, 3 developed a decrease in serum sodium consistent with adequately report symptoms, laboratory results, and exclusion of other causes making it difficult to a

2) Three days after starting sertraline 50 milligrams daily, a 78-year-old woman was diagnosed with encephalopathic and had myoclonus. Her serum sodium decreased from 136 milliequivalents/liter (n 125 mEq/L and 474 milliosmoles/kilogram (mOsm/kg), respectively, compared to a plasma osmolali mL of sodium chloride 3%, (3) restricting fluid intake to 1000 mL/day, and (4) initiating demeclocyclin sodium returned to 138 mEq/L within 3 days. Other drugs and medical conditions were considered u reported although symptoms occurred later, after 5 days and 4 months; discontinuation of sertraline 1996).

3.3.4 Gastrointestinal Effects

3.3.4.A Sertraline Hydrochloride

Gastrointestinal hemorrhage

Gastrointestinal tract finding

Grinding teeth

Nausea and vomiting

Pancreatitis

Xerostomia

3.3.4.A.1 Gastrointestinal hemorrhage

See Drug Consult reference: CONCOMITANT USE OF SSRIs AND NSAIDs - INCREASED RISK OF GA

3.3.4.A.2 Gastrointestinal tract finding

a) Summary

1) During placebo-controlled clinical trials, the following were reported in adults at an incidence grea FLATULENCE (Prod Info Zoloft(R), 2002). Infrequently, sertraline has been reported to cause INDIG

b) Infrequently, sertraline has been reported to cause diarrhea, indigestion, dry mouth, abdominal pain, flatulence, nausea and vomiting have occurred more frequently. Minimal weight loss (mean 1-2 pounds)

3.3.4.A.3 Grinding teeth

a) Sertraline-induced bruxism has occurred after exposure to daily doses ranging from 6.25 to 150 mg, v Stanziani, 1993). Dose reduction from 25 mg/day to 6.25 mg/day failed to relieve symptoms in one 36-ye with longstanding anxiety disorder and depression had her 100 mg/day sertraline discontinued, with an 1 patient's mood deteriorated. Replacement of paroxetine with fluvoxamine (dosage not reported) resulted failed to alleviate her bruxism (Fitzgerald & Healy, 1995).

3.3.4.A.4 Nausea and vomiting

a) Summary

1) During placebo-controlled clinical trials, nausea, and vomiting were reported in adults with sertral vomiting were noted 4 to 6 hours after single doses of 100 milligrams in one study, and were reporte

b) LITERATURE REPORTS

1) The selective serotonin reuptake inhibitors (SSRIs) produce nausea and vomiting in 20% to 25% decreases or resolves over approximately 3 weeks. However, in others, reduction of the dose or dis for a few weeks may facilitate continued treatment with the SSRI. Limited data suggest that ondanse

with careful monitoring for arrhythmias may be more cost effective than ondansetron. The proposed the chemoreceptor trigger zone and area postrema in the brainstem, the primary areas within the br

3.3.4.A.5 Pancreatitis

a) Summary

1) Pancreatitis has been temporally associated with the use of sertraline (Prod Info Zoloft(R), 2002)

3.3.4.A.6 Xerostomia

a) Summary

1) Several studies have reported XEROSTOMIA as an occasional adverse effect of sertraline in the

3.3.5.A Sertraline Hydrochloride

Disorder of hemostatic system

Hematology finding

3.3.5.A.1 Disorder of hemostatic system

a) Summary

1) Rare occurrences (incidence less than 0.1%) of BRUISING, ECCHYMOSES, EPISTAXIS, PROL therapy. The majority of cases have been reported in patients taking fluoxetine but case reports are

b) LITERATURE REPORTS

1) INCIDENCE

a) Rare (incidence less than 0.1%). The majority of cases have been reported in patients takin (Berk & Jacobson, 1998).

2) OUTCOME

a) Mild (treatment continued with/without other management) (Berk & Jacobson, 1998).

3) ASSOCIATED SYMPTOMS

a) Symptoms include: bruising, ecchymoses, epistaxis, prolonged bleeding time, rectal bleedin

4) CLINICAL MANAGEMENT

a) PHARMACOLOGIC - For minor bleeding diatheses (ie, bruising), treatment is usually unnec clinically significant, occurs with other underlying medical illnesses, or fails to improve with time

5) PREDISPOSING RISK FACTORS

a) DOSE-RELATED

1) Yes. Many cases have occurred in patients taking doses at the higher end of the dose r

b) DISEASE STATES

1) Yes. More common in patients with underlying diseases; 1 case occurred in a patient w

6) PROBABLE MECHANISM

a) PHARMACOLOGIC (extension of the expected effects of the drug). Selective serotonin reup storage of serotonin is observed. Serotonin-mediated platelet aggregation may be decreased (E

7) DOCUMENTATION QUALITY

a) Fair

8) CASE REPORT

a) A case of prolonged bleeding time associated with ecchymoses and normal prothrombin and resolved spontaneously with drug cessation (Calhoun & Calhoun, 1996a).

3.3.5.A.2 Hematology finding

a) Summary

1) AGRANULOCYTOSIS, APLASTIC ANEMIA, and THROMBOCYTOPENIA have been reported a

b) Sertraline therapy has been associated with bruising, ecchymoses, epistaxis, prolonged bleeding tim thrombocytopenia. Rare cases of impaired platelet aggregation have been reported.

c) Purpura has been reported in at least 2% of pediatric patients treated with sertraline (Prod Info Zoloft

3.3.6 Hepatic Effects

3.3.6.A Sertraline Hydrochloride

Increased liver enzymes

Liver failure

Liver finding

3.3.6.A.1 Increased liver enzymes

a) Summary

1) Asymptomatic elevations in serum transaminases have been reported within the first 9 weeks of (Prod Info Zoloft(R), 2002).

3.3.6.A.2 Liver failure

a) Summary

1) Liver failure has been temporally associated with the use of sertraline (Prod Info Zoloft(R), 2002)

3.3.6.A.3 Liver finding

a) Elevated liver enzymes and liver failure have been noted occasionally with therapeutic sertraline use.

3.3.7 Immunologic Effects

3.3.7.A Sertraline Hydrochloride

3.3.7.A.1 Anaphylaxis

a) Summary

1) In postmarketing surveillance, ANAPHYLACTOID REACTIONS have been associated with use c

3.3.8 Musculoskeletal Effects

3.3.8.A Sertraline Hydrochloride

Arthralgia

Fracture of bone

Fracture of bone, Nonvertebral

Muscle weakness

Myalgia

Summary

3.3.8.A.1 Arthralgia

a) Incidence: 0.1% to 1% (Prod Info ZOLOFT(R) concentrate, oral tablets, 2009)

b) Arthralgia was reported in 0.1 to 1% of over 4000 adult patients exposed to multiple doses of sertralir concentrate, oral tablets, 2009).

3.3.8.A.2 Fracture of bone

a) In a case-control study including fracture cases (n=124,655) during the year 2000 and age- and gend participants who were using an average standard daily dose of sertraline (adjusted odds ratio (OR), 1.25 use was associated with an increased risk of hip fracture (adjusted OR, 1.76; 95% CI, 1.52 to 2.03), fore 1.74; CI, 1.26 to 2.41) (Vestergaard et al, 2008)

b) In a population-based, randomly selected, prospective cohort study adjusted for potential covariates, years of age and older who used daily SSRIs (n=137; mean age of 65.1 years), including sertraline, com use was associated with a significant 2.1-fold increased risk of fragility fracture (95% confidence interval fragility fracture (95% CI, 1.1 to 2.1). Daily SSRI users who were recurrent (ie, treated with SSRIs at bas (95% CI, 1.1 to 4.0). Fractures were reported at the following sites: forearm (40%), ankle and foot (21%), or fingers (Richards et al, 2007).

3.3.8.A.3 Fracture of bone, Nonvertebral

a) In a prospective, population-based, cohort study (n=7983) with a mean follow-up of 8.4 years, there w age (mean age of 77.5 years) who were currently using an SSRI (citalopram, escitalopram, fluoxetine, flu antidepressants. Current SSRI use was associated with an increased risk of nonvertebral fracture (adjus antidepressant use. Current SSRI use was also associated with an increased risk of nonvertebral fractur (n=1217). In addition, duration of SSRI use showed a 9% increase in fracture risk per extra month on an humerus, and pelvis were reported (Ziere et al, 2008).

3.3.8.A.4 Muscle weakness

a) Incidence: 0.1% to 1% (Prod Info ZOLOFT(R) concentrate, oral tablets, 2009)

b) Muscle weakness was reported in 0.1 to 1% of over 4000 adult patients exposed to multiple doses of (R) concentrate, oral tablets, 2009).

3.3.8.A.5 Myalgia

a) Incidence: 1% or greater (Prod Info ZOLOFT(R) concentrate, oral tablets, 2009)

b) Myalgia was reported in at least 1% of over 4000 adult patients exposed to multiple doses of sertralin concentrate, oral tablets, 2009).

3.3.8.A.6 Summary

a) Sertraline has been frequently associated with myalgia, and infrequently associated with arthralgia ar was associated with an increased risk of hip, forearm, and spine fracture in a case-controlled study (Ves prospective cohort study of SSRIs, including sertraline (Richards et al, 2007). An increased risk of nonve paroxetine, in adult participants older than 55 years of age (Ziere et al, 2008).

3.3.9.B.1 Agitation

a) Agitation is one of the most frequently reported adverse effects of sertraline (incidence greater than 5

3.3.9.B.2 Cognitive function finding

a) Summary

1) Increases in objective measurements of alertness were observed with sertraline in doses of 50, 7 (critical flicker fusion and choice reaction time tests) were performed on 10 patients after single dose 7.5 hours post-dosing. However, subjective drowsiness was reported with these doses (Hindmarch

3.3.9.B.3 Dizziness

a) Dizziness is one the most frequently reported adverse effects of sertraline (incidence greater than 5%

3.3.9.B.4 Dystonia

a) Incidence: rare (Prod Info Zoloft(R), 2002)

b) Sertraline has been infrequently associated with muscle dystonia (Prod Info Zoloft(R), 2002).

3.3.9.B.5 Dystonia, Mandibular

a) Summary

1) Mandibular dystonia has been noted in several case reports during therapeutic sertraline use. W abatement. Patients on multiple drug therapies should be carefully monitored for interactions or pote 1996b).

b) LITERATURE REPORTS

1) "Sneering" movements developed in the upper mouth area 7.5 months after sertraline was initiat painful pulling sensation of the upper lip. Other dyskinesias or tics were not identified. Symptoms re reappearance of the sneering movement 24 hours later. Two days after stopping sertraline, the abn after identification of this movement disorder (Stanislav & Childs, 1999).

2) A case of mandibular dystonia was reported two days after the addition of metoclopramide 10 mi months with sertraline 100 mg/day (Wilks, 1998b).

3) In a case report, DYSTONIA was reported in a 24-year-old man treated for posttraumatic stress then this dose was increased to 50 mg. Three days after starting the higher dosages, he presented jaw stiffness and feeling as if his face was "frozen." The symptoms were relieved by administration was noted over a year later after he began treatment with sertraline 25 mg, which was increased to common to both drugs, possibly associated with enhancement of serotonergic neurotransmission th

4) A 22-year-old woman developed mandibular dystonia characterized by periauricular pain, jaw tig (mg) daily. Symptoms were relieved by diphenhydramine 50 mg. A third dose of sertraline was admi taking metoclopramide 15 mg four times daily for gastroesophageal reflux which had caused no adv effect of sertraline and metoclopramide resulting in dystonia. This case is intended to alert clinicians (Christensen & Byerly, 1996b).

5) TORTICOLLIS and JAW STIFFNESS responsive to treatment with diphenhydramine, and akathi

3.3.9.B.6 Extrapyramidal sign

a) Summary

1) Extrapyramidal reactions (EPRs) including acute DYSTONIC REACTIONS, NEUROLEPTIC MA selective serotonin reuptake inhibitors (SSRI). The majority of case reports involve fluoxetine; howe

b) LITERATURE REPORTS

1) Extrapyramidal reactions occurred more frequently in women (about 75%) possibly due to more reports, the dose of the SSRI was increased to the maximum recommended dose within 7 days or during the second to fourth week of treatment. Possible mechanisms by which SSRIs cause Extrapy activity resulting in clinically significant effects; and (2) Concurrent use of an SSRI and antipsychotic combination of the two (Caley, 1997).

2) TREATMENT - The majority of extrapyramidal reactions (EPRs) occur within the first few days to during the first 4 weeks of treatment with selective serotonin reuptake inhibitors (SSRIs) and periodi stopping the SSRI (Caley, 1997; Gill et al, 1997). In a limited number of case reports, propranolol a to 90 milligrams (mg) daily, and the dose of clonazepam was 1.5 mg daily (Gill et al, 1997). In single trihexyphenidyl or diphenhydramine 50 mg. Parkinsonism characterized by increasing rigidity and tr a neuroleptic agent. In all cases, symptoms disappeared after reducing the dose or stopping the SS spontaneously over days to weeks after the SSRI is stopped (Gill et al, 1997).

3.3.9.B.7 Headache

a) Headache is one of the most frequently reported adverse effects of sertraline (incidence greater than

3.3.9.B.8 Hyperactive behavior

a) Hyperkinesia has been reported in at least 2% of pediatric patients treated with sertraline (Prod Info Z

3.3.9.B.9 Impaired psychomotor performance

a) Summary

1) Subjective drowsiness was reported with sertraline in a study testing psychomotor function, but t
chart review, nursing home patients treated with fluoxetine and other selective serotonin-reuptake in
risk of falls compared to patients who are not on antidepressants (Thapa et al, 1998).

b) LITERATURE REPORTS

1) A retrospective chart review of 2428 nursing home residents treated with antidepressants assess
were then compared to those not treated (n=847). Antidepressant treatment included tricyclic antide
treated patients was higher than that for patients who were not treated, both before and after the init
or related conditions are at a greater risk of falls than those without such conditions. Patients on TC
(CI), 1.8 to 2.2). The SSRIs had a adjusted rate ratio of 1.8 (1.6 to 2, p=0.001) and trazodone had a
among medications of the same class. It was, however, noted that patients receiving a dose of 20 m
significant increase in the incidence of falls than those receiving lower doses (Thapa et al, 1998).

2) The acute effects of single doses of sertraline 100 milligrams (mg), amitriptyline 50 mg, and plac
double-blind, placebo-controlled crossover study. While performance was clearly impaired by amitri
objective measures of alertness. Although subjective DROWSINESS was reported with both drugs,

3.3.9.B.10 Insomnia

a) Insomnia is one of the most frequently reported adverse effects of sertraline (incidence greater than 5

3.3.9.B.11 Parkinsonism

a) Summary

1) CASE REPORT - A case report notes the development of parkinsonism with symptoms of pill-rol
two weeks after his sertraline dose was increased. A rapid decrease of the dose resolved symptoms
Parkinsonism; therefore, the authors attribute the reaction to sertraline although no rechallenge at a

b) LITERATURE REPORTS

1) Two weeks after the dose of sertraline was increased to 150 milligram (mg) daily, a 90-year-old r
bradykinesia, and festinating gait; he fell twice. The dose of sertraline was rapidly tapered to 50 mg/
sertraline, mental and neurologic examination was normal. The only other medical conditions were s
treated with furosemide and enalapril. In this case, other medical conditions and medications were r
sertraline although rechallenge with the higher dose was not performed (Schechter & Nunes, 1997).

3.3.9.B.12 Restless legs syndrome

a) In a prospective, naturalistic study of patients (median age, 46 years; range, 18 to 87 years) treated v
syndrome (RLS) or worsening of preexisting RLS as a side effect related to treatment. Antidepressants i
duloxetine, reboxetine, and mirtazapine. Mirtazapine led to a marked decline of RLS in 28% of subjects
symptoms (newly occurred or deteriorated) at the rate of 5% to 10%. Subjects stated symptoms occurre

3.3.9.B.13 Seizure

a) Summary

1) CASE REPORT - A 34-year-old woman had a severe TONIC-CLONIC SEIZURE when her sertra
depression. Initial computerized tomography (CT) head scan and electroencephalogram (EEG) were
consistent with a postictal disturbance rather than epilepsy. Sertraline was switched to citalopram, a
predisposing risk factors for seizures such as previous seizures or sedative or alcohol abuse. For m
patient (Saraf & Schrader, 1999).

b) Incidence: rare

3.3.9.B.14 Sleep walking disorder

a) Summary

1) CASE REPORT - A 34-year-old HIV-positive woman developed somnambulism while being treat
milligram (mg) daily dose of paroxetine was gradually increased over 2 weeks to 20 mg daily. Three
according to witnesses. The somnambulism disappeared completely 1 week after the daily dose wa
increasing the dose to 20 mg/day, the sleepwalking reappeared. Paroxetine was discontinued and s
100 mg/day, she again began to sleepwalk. Her symptoms of depression and anxiety improved at th
(Alao et al, 1999).

3.3.9.B.15 Somnolence

a) Somnolence is one of the most frequently reported adverse effects of sertraline (incidence greater tha

3.3.9.B.16 Summary

a) Some of the most frequently reported adverse effects of sertraline are insomnia, headache, dizziness
in 0.4% of patients during clinical studies. Extrapyramidal reactions (EPRs) including acute dystonic reac
been associated with therapeutic use. Nursing home patients have an increased risk of falls compared to

3.3.9.B.17 Tic

a) Exacerbation of TICS in a patient with Tourette's Syndrome that responded to cessation of sertraline

3.3.9.B.18 Tremor

a) Tremor is one of the most frequently reported adverse effects of sertraline (incidence greater than 5%

3.3.10 Ophthalmic Effects

Eye / vision finding

Oculogyric crisis

3.3.10.A.1 Eye / vision finding

a) Summary

1) XEROPHTHALMIA, or DIPLOPIA, PHOTOPHOBIA, accommodation changes and CONJUNCTI evaluation, OPTIC NEURITIS and CATARACTS have been temporally associated with use of sertra

b) Rare reports of xerophthalmia, diplopia, photophobia, anterior chamber eye hemorrhage, accommod neuritis and cataracts have also been reported.

3.3.10.A.2 Oculogyric crisis

a) Summary

1) In postmarketing evaluation, oculogyric crisis has been temporally associated with use of sertrali

3.3.12 Psychiatric Effects

3.3.12.A Sertraline Hydrochloride

Depression, exacerbation

Hypomania

Psychiatric sign or symptom

Suicidal thoughts

3.3.12.A.1 Depression, exacerbation

a) Incidence: rare

b) Adult and pediatric patients who experience symptoms of anxiety, agitation, panic attacks, insomnia, hypomania, or mania may be at risk of worsening of their depression. This same concern applies to treat observed, therapy should be reevaluated and it may be necessary to discontinue medications when sym (Anon, 2004).

3.3.12.A.2 Hypomania

a) Summary

1) Two cases of hypomania were reported; one occurred after 5 weeks of sertraline 200 milligrams discontinuation of sertraline and treatment with short-term clonazepam or lithium (Laporta et al, 198

b) Incidence: rare

3.3.12.A.3 Psychiatric sign or symptom

a) Summary

1) Abnormal dreams, AGGRESSIVE BEHAVIOR, delusions, HALLUCINATIONS, EMOTIONAL LAI Info Zoloft(R), 2002; Reimherr et al, 1988b).

2) Aggressive reactions have been reported in at least 2% of pediatric patients treated with sertralir

b) Abnormal dreams, agitation, aggressive behavior, delusions, hallucinations, emotional lability, paranc associated with sertraline therapy.

c) LITERATURE REPORTS

1) Complex, colorful visual hallucinations have been reported less than 3 weeks after initiation of se seconds after awakening and resolved following discontinuation of sertraline (Bourgeois et al, 1998)

3.3.12.A.4 Suicidal thoughts

a) Summary

1) Adult and pediatric patients being treated with antidepressants for major depressive disorder wh

(aggressiveness), impulsivity, akathisia (psychomotor restlessness), hypomania, or mania may be a
treating patients with other psychiatric and nonpsychiatric disorders. If these symptoms are observe
when symptoms are severe, sudden in onset, or were not part of the patient's initial symptoms. Patie
this drug (Anon, 2004; Anon, 2004).
2) A causal role for antidepressants in inducing suicidality has been established in pediatric patients
this risk with the clinical need. In pooled analyses of 24 short-term, placebo-controlled trials of nine a
mirtazapine, nefazodone, and venlafaxine extended-release) including over 4400 pediatric patients
disorders, a greater risk of suicidal behavior or ideation during the first few months of therapy was d
respectively). The risk of suicidality was most consistently observed in the trials that included patient
psychiatric indications, such as obsessive compulsive disorder and social anxiety disorder. No suici
several months) in pediatric patients is not known. It is also unknown whether this risk extends to ad

3.3.14.B.2 Priapism

a) Summary

1) Therapeutic use of sertraline has resulted in rare case occurrence of priapism. The Adverse Eve 46 reports of priapism associated with sertraline (Rand, 1998) One case report noted a 47-year-old resolution occurred after tapering the patient off sertraline. The patient was started on nefazodone t

b) LITERATURE REPORTS

1) INCIDENCE

a) Rare (incidence less than 0.1%). The Adverse Events Reporting System maintained by the sertraline (Rand, 1998).

2) OUTCOME

a) Severe (hospitalization required for treatment) (Rand, 1998).

3) ASSOCIATED SYMPTOMS

a) Pain.

4) ONSET/DURATION

a) DURATION OF SYMPTOMS (with treatment)

1) Several weeks (1 case) (Rand, 1998).

5) CLINICAL MANAGEMENT

a) PHARMACOLOGIC

1) Initial treatment consisted of repeated intracorporeal injection of methoxamine which wa cavernosa and a Winter's shunt procedure which was partially effective. After several week (Rand, 1998).

6) PROBABLE MECHANISM

a) Pharmacologic (extension of the expected effects of a drug).

1) The proposed mechanism for this adverse effect is alpha- 1-adrenergic blockade. Amor alpha-1-adrenergic activity (Rand, 1998).

7) DOCUMENTATION QUALITY

a) Poor.

8) CASE REPORT

a) A 47-year-old man treated with sertraline 200 milligram (mg)/day and dextroamphetamine 1(several brief episodes over the past month. He came to the emergency department (ED) due to injection of methoxamine appeared effective; however, he returned to the ED and was admitted with injection of dilute epinephrine and a Winter's shunt procedure. At follow-up, several weeks was started on nefazodone (Rand, 1998).

3.3.14.B.3 Sexual dysfunction

a) Summary

1) During clinical trials, DELAYED EJACULATION (14%) and DECREASED LIBIDO (6%) were rep & Caillard, 1988c).

sertraline therapy. Symptoms have included: fatigue, nausea, abdominal cramps, diarrhea, shortnes
tinnitus, ataxia, abnormal sensations ("electric shocks", skin tingling sensations, and involuntary mo
reinstatement of sertraline therapy (Wolfe, 1997; Zajecka et al, 1997; Leiter et al, 1995; Louie et al,
b) LITERATURE REPORTS
1) PEDIATRIC
a) On the fourth day, following the abrupt discontinuation of sertraline (200 milligrams (mg) per
tremor, irritability, and insomnia. The patient was treated with paroxetine 20 mg/day (sertraline
resolved within 30 hours (Diler & Avci, 2002).
b) Withdrawal symptoms in a neonate after maternal sertraline therapy has been reported. Sym
enhanced startle reaction. The child had been well until one day postpartum and symptoms res
Laidlaw, 1995).

3.3.16.B.3 Fatigue
a) Fatigue is one of the most frequently reported adverse effects of sertraline (incidence greater than 5%

3.3.16.B.4 Fever
a) Fever has been reported in at least 2% of pediatric patients treated with sertraline (Prod Info Zoloft(R

3.3.16.B.5 Serotonin syndrome
a) Serotonin syndrome, including life-threatening cases, or neuroleptic malignant syndrome (NMS)-like
serotonin syndrome include mental status changes (eg, agitation, hallucination, coma), autonomic instab
hyperreflexia, incoordination) and/or gastrointestinal symptoms (eg, nausea, vomiting, diarrhea). Severe
rigidity, autonomic instability with possible rapid fluctuation of vital signs, and mental status changes. Se
including triptans, with drugs that impair metabolism of serotonin, including MAOIs, or with antipsychotics
b) Sertraline, a selective serotonin reuptake inhibitor, is capable, as other drugs in this class, of inducing
more drugs capable of enhancing CNS (central nervous system) serotonin activity. Often, patients with s
(Horowitz & Mullins, 1999; Lane & Baldwin, 1997).
c) A 43-year-old woman with severe mental retardation experienced serotonin syndrome (palpitations, c
hypertonicity of the lower limbs, diffuse hyperreflexia, hyperthermia, and leukocytosis) after taking 2 sub-
recovery for hospital discharge on the second day (Bhanji, 2000).

3.4 Teratogenicity/Effects in Pregnancy/Breastfeeding
A) Teratogenicity/Effects in Pregnancy
1) U.S. Food and Drug Administration's Pregnancy Category: Category C (Prod Info Zoloft(R), 2003a) (All Trimes

a) Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal or other) available. Drugs should be given only if the potential benefit justifies the potential risk to the fetus.

2) Australian Drug Evaluation Committee's (ADEC) Category: C(Australian Drug Evaluation Committee, 1999)

a) Drugs which, owing to their pharmacological effects, have caused or may be suspected of causing harmfu be reversible. Accompanying texts should be consulted for further details.

See Drug Consult reference: PREGNANCY RISK CATEGORIES

3) Crosses Placenta: Yes

4) Clinical Management

a) A population-based study found no increased risk of malformations, but the exposed infants were more lik SSRIs, including sertraline, after 20 weeks of gestation has been associated with an increased risk of persist significant association between the use of SSRIs in early pregnancy and the risks of birth defects, including c al, 2007). Sertraline is generally well tolerated in pregnancy and does not appear to pose an unusually high ri and in each case, these dangers must be weighed against the potential for teratogenic effects (Lamberg, 199

5) Literature Reports

a) Data from the case-controlled National Birth Defects Prevention Study (NBDPS), which included data from (defined as treatment with any SSRI from 1 month before to 3 months after conception) to SSRIs was associ confidence interval (CI), 1.1 to 5.1; P=0.02), craniosynostosis in 24 exposed infants out of 432 (adjusted OR 181 (adjusted OR 2.8; 95% CI, 1.3 to 5.7; P=0.005). However, early exposure did not significantly increase th SSRIs reported by control mothers were sertraline, fluoxetine, paroxetine, and citalopram (Alwan et al, 2007)

b) A case-control study found that the use of selective serotonin reuptake inhibitors (SSRIs) after 20 weeks o the newborn (PPHN). Fluoxetine, paroxetine, and sertraline were the specific SSRIs studied to carry this incr and their infants. Assessment of exposure was determined by telephone interview within 6 months of birth. A with an odds ratio of 6.1 (95% CI 2.2 to 16.8; p=0.001) of delivering an infant with PPHN relative to no use du antidepressants use at any gestation time was not associated with increased risk of PPHN development. The study, infants exposed to SSRIs after 20 weeks of gestation have a PPHN incidence of 0.6 to1.2% (Chamber

c) A population-based study of 1782 pregnant women exposed to selective serotonin reuptake inhibitors (SS neonatal intensive or special care unit, particularly with third trimester exposure. Using 1996-2001 data derive who had at least one purchase (a 3-months' supply) of an SSRI during the period of one month before pregn drug purchases during the same peripartum period. The mean age of both cohorts was 30 years (+/- 7). Ther artificial reproductive techniques in the SSRI group compared to controls (p less than 0.001), and mean lengt Malformations, however, were not more common in the SSRI group (p = 0.4). Purchases of SSRIs (citoprar trimester than later in pregnancy, with 118 women purchasing sertraline during the first trimester, 31 during th first trimester exposure, treatment in a special or intensive care unit was more common for the infants expose adjusting for confounding variables, this difference remained statistically significant (OR 1.6; 95% CI 1.1 to 2.

d) In a prospective, multicenter, controlled cohort study of 267 pregnant women taking 3 different SSRIs, 14 group (267 pregnant women exposed only to nonteratogens) no differences between the two groups were re stillbirth, prematurity, birth weight, and gestational age (Kulin et al, 1998).

e) A prospective study through the California Teratogen Information Service compared the outcomes of 112 teratogens. The rate of major anomalies in the two groups was similar (3.8% and 1.9%, respectively). Wome (16.3%) and their infants were more often admitted to the special care nursery (Chambers et al, 1999).

B) Breastfeeding

1) American Academy of Pediatrics Rating: Drugs for which the effect on nursing infants is unknown but may be

2) Thomson Lactation Rating: Infant risk is minimal.

a) The weight of an adequate body of evidence and/or expert consensus suggests this drug poses minimal r

3) Clinical Management

a) The selective serotonin-reuptake inhibitors, including sertraline, are lipid soluble and therefore excreted in manufacturer recommends that sertraline not be used by women while breastfeeding (Prod Info Zoloft(R), 20 should be monitored for anorexia, weight loss, irritability and insomnia.

4) Literature Reports

a) Low or undetectable levels of sertraline in human breast milk have been reported. A study of 3 nursing inf sertraline and the metabolite norsertraline were reported (Mammen et al, 1997). No adverse effects in the inf sertraline; neither drug was detectable in the infant serum (Altshuler et al, 1996).

b) One study involved 12 nursing infants whose mothers used sertraline while breastfeeding (Llewellyn & St adverse effects were noted. Similarly, sertraline was not detectable in the serum of 6 nursing infants whose m as reported by the mothers. The authors suggest that breastfeeding should generally not be discouraged in m

c) Although the clinical data suggest that the absolute dose of sertraline and the metabolite N-desmethylsert adverse outcomes, the effects of perinatal infant exposure to sertraline on long-term cognitive development o

d) Non-quantifiable (0 ng/mL to 2 ng/mL) concentrations of sertraline were detected in 7 of 9 nursing infants; ng/mL. The infant with a sertraline concentration of 64 ng/mL had an N-desmethylsertraline concentration of The infant did not experience any adverse events related to the high concentrations. Two infants had non-qua ng/mL to 6 ng/mL), and one infant had a level of 24 ng/mL, despite a low serum sertraline level. Because N-d Researchers could not conclude why the 1 infant had such high concentrations. Maternal doses of sertraline

e) Three and 6 infants had detectable serum concentrations of sertraline and desmethylsertraline, respective sertraline and desmethylsertraline were highest 7 to 8 hours and 5 to 11 hours, respectively, after the dose. C breast milk 7 to 8 hours after the maternal dose for an infant feeding every 3 hours. Breast milk concentration higher with higher maternal doses. This study was conducted in 12 mother-infant pairs; exposure to sertraline 150 mg daily (Stowe et al, 1997).

5) Drug Levels in Breastmilk

a) Parent Drug
1) Milk to Maternal Plasma Ratio
a) 1.0-3.6 (Buist & A, 2001)
b) Active Metabolites
1) Desmethylsertraline (Stowe et al, 1997)

b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.F Almotriptan

1) Interaction Effect: an increased risk of serotonin syndrome

2) Summary: Concomitant use of almotriptan and selective serotonin reuptake inhibitors (SSRI's) has been r
Concurrent use of a triptan and an SSRI may result in serotonin syndrome which may be life-threatening. Sy
coordination, fast heart beat, rapid changes in blood pressure, increased body temperature, overreactive refl
commonly used intermittently and that either the triptan or the SSRI may be prescribed by a different physicia
combination and monitor them closely for symptoms of serotonin syndrome (US Food and Drug Administratio

3) Severity: major

4) Onset: delayed

5) Substantiation: theoretical
6) Clinical Management: Coadministration of a triptan, such as almotriptan, and an SSRI may result in a life-
used intermittently and that either the triptan or the SSRI may be prescribed by a different physician. If these
monitor closely for symptoms of serotonin syndrome (restlessness, hyperthermia, hyperreflexia, incoordinatic
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation
8) Literature Reports
a) Concomitant administration of fluoxetine and almotriptan is well tolerated and fluoxetine has only a m
pharmacokinetics are not significantly affected. A randomized, open-label, two-way crossover study invo
treatments with a minimum 3-week washout between periods: (1) three 20 mg fluoxetine capsules on da
on day 8 with no treatment on days 1 through 7. Peak almotriptan concentrations were 18% higher follov
This difference was statistically significant (p equal 0.023). Mean almotriptan area under the concentratic
treatment groups. Mean half-life was not statistically different between the treatment groups. During fluo
almotriptan may have been increased by fluoxetine. The author concludes that based on the results of th
and fluoxetine can be safely used concomitantly in migraine management (Fleishaker et al, 2001).

3.5.1.G Alprazolam

1) Interaction Effect: an increased risk of psychomotor impairment and sedation
2) Summary: To date, limited information is available related to the effects of coadministered alprazolam and
metabolism (Von Moltke et al, 1994). It is theoretically possible that an interaction might occur because alpra
inhibit one or more P450 isoenzymes (DeVane, 1994). Current evidence indicates that alprazolam is metabol
inhibiting the CYP3A4 isoenzyme. However, a study involving ten healthy volunteers failed to show an alterat
sertraline (Hassan et al, 2000a).
3) Severity: moderate
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Caution is warranted if alprazolam and sertraline are to be coadministered. Monitor
may need to be reduced.
7) Probable Mechanism: inhibition of cytochrome P450 3A-mediated alprazolam metabolism
8) Literature Reports
a) Ten healthy white volunteers (eight women and two men) participated in a randomized, double-blind,
potential to impair alprazolam metabolism and to assess whether any potential impairment is dependent
sertraline 50 mg, 100 mg, or 150 mg daily. The alprazolam maximum concentration (Cmax), time to max
were not clinically significantly altered in the presence of sertraline. No pharmacodynamic interactions, a
recall, were detected between sertraline and alprazolam at any dose of sertraline. These in vivo findings
via cytochrome P450 3A4 enzymes (Hassan et al, 2000).

3.5.1.H Amitriptyline

1) Interaction Effect: elevated amitriptyline serum levels or possible serotonin syndrome (hypertension, hype
2) Summary: There is limited evidence suggesting that sertraline may inhibit tricyclic antidepressant (TCA) m
P450 2D6 enzyme activity and may increase the plasma concentrations of coadministered drugs that are me
2002o; Preskorn et al, 1994s; Lydiard et al, 1993i). There have been several reports of serotonin syndrome d
antidepressants, including one case report due to sertraline and amitriptyline coadministration (George & Goo
rare but potentially fatal condition of serotonergic hyperstimulation characterized by changes in mental status
1991k). Further clinical studies or case reports are necessary to determine the incidence and implications of
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: The combined use of tricyclic antidepressants (TCAs) and selective serotonin reupt
serotonin syndrome have also been reported with concurrent TCA and SSRI therapy. Caution should be obse
7) Probable Mechanism: inhibition of amitriptyline metabolism
8) Literature Reports
a) A 40-year old woman was admitted to the hospital after developing symptoms of serotonin syndrome
amitriptyline 75 mg was added to a regimen of sertraline 40 mg twice daily. Other medications at time of
examination, the patient had a fever of 38.0 degrees Celsius, was diaphoretic and showed signs of hype
resolved rapidly (Alderman & Lee, 1996).
b) Desipramine pharmacokinetics were studied in 18 healthy male volunteers. Study subjects received
mg daily) for 21 days. When sertraline was added to desipramine therapy, the mean maximum concentra
increased by 26%. Trough concentrations of desipramine were close to baseline one week after sertralin
interaction may not be clinically significant (Preskorn et al, 1994r).

3.5.1.I Amoxapine

1) Interaction Effect: modest elevation in amoxapine serum levels or possible serotonin syndrome (hypertens
2) Summary: There is limited evidence suggesting that sertraline may inhibit tricyclic antidepressant (TCA) m
P450 2D6 enzyme activity and may increase the plasma concentrations of coadministered drugs that are me
2002p; Preskorn et al, 1994u; Lydiard et al, 1993j). Effects of the interaction may have little or no clinical impa
were modest compared with those found when fluoxetine (another selective serotonin reuptake inhibitor) was
sertraline therapy for TCA toxicity (dry mouth, urinary retention, CNS depression). Amoxapine doses may nee
3) Severity: major

4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: The combined use of tricyclic antidepressants (TCAs) and selective serotonin reupt serotonin syndrome have also been reported with concurrent TCA and SSRI therapy. Caution should be obs
7) Probable Mechanism: inhibition of amoxapine metabolism
8) Literature Reports
a) The pharmacokinetics of desipramine have been studied in 18 healthy male volunteers. Study subjec sertraline (50 mg daily) for 21 days. When sertraline was added to desipramine therapy, the mean maxi concentration-time curve increased by 26%. Trough concentrations of desipramine were close to baseli were modest and the interaction may not be clinically significant (Preskorn et al, 1994t).

3.5.1.J Anagrelide

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control an been associated with an increased risk of bleeding. Bleeding events reported have included epistaxis, ecchy tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are given concurrently, monitor patient for PROZAC(R) oral capsules, delayed-release capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.K Ancrod

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control an anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alte coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin 1997a).
3) Severity: major
4) Onset: delayed

8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopran bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. T (95% CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI implicated in patients experienci addition of an SSRI was not associated with a change in warfarin dose or INR (p=0.48 and p=0.31 respe patient adherence, and exclusion of clopidogrel, dipyridamol, corticosteroids and anticoagulants other th
b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin. on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (O bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).
c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).
d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically th enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.N Ardeparin

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin 1997a).
3) Severity: major

4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d
7) Probable Mechanism: unknown
8) Literature Reports

Prothrombin time was measured prior to each dose of warfarin and periodically th enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.O Aspirin

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and been associated with an increased risk of bleeding. Bleeding events reported have included epistaxis, ecchy tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are given concurrently, monitor patient for PROZAC(R) oral capsules, delayed-release capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.P Astemizole

1) Interaction Effect: cardiotoxicity (QT interval prolongation, torsades de pointes, cardiac arrest)
2) Summary: Coadministered sertraline may inhibit astemizole metabolism, thereby leading to increased ast administration of astemizole and sertraline should be avoided (Prod Info Hismanal(R), 1998).
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Concomitant use of astemizole and sertraline is not recommended.
7) Probable Mechanism: inhibition of cytochrome P450-mediated metabolism of astemizole

3.5.1.Q Benoxaprofen

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hematom suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable

7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton

b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.U Bupropion

1) Interaction Effect: increased plasma levels of sertraline

2) Summary: It is recommended that sertraline, an antidepressant metabolized by the cytochrome P450 2D6 concomitantly with bupropion (Prod Info Wellbutrin XL(TM), 2003; Prod Info Zyban(R), 2000).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Coadministration of bupropion and sertraline should be approached with caution an to the treatment regimen of a patient already receiving sertraline, consider decreasing the dose of sertraline.

7) Probable Mechanism: inhibition of cytochrome P450 2D6-mediated sertraline metabolism

3.5.1.V Cannabis

1) Interaction Effect: manic symptoms

2) Summary: One case of mania following use of marijuana with fluoxetine therapy has been reported (Stoll symptoms could have resulted from the fluoxetine or marijuana alone. Caution is advised for patients using m

3) Severity: moderate

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: Caution patients taking selective serotonin reuptake inhibitors to avoid concomitant

7) Probable Mechanism: additive serotonergic stimulation

8) Literature Reports

a) A 21-year-old female presented with mania, agitation, and grandiose delusions following use of mariju reported smoking 2 "joints" during a 36-hour period. Over the next 24 hours, she developed increased en perphenazine were given for agitation and excitement which gradually resolved over 4 days. She remain prior to discharge. One week after discharge, she discontinued fluoxetine due to insomnia and feeling "h rapid switch to mania after smoking marijuana with fluoxetine, the manic symptoms were associated with from either fluoxetine or marijuana alone (Stoll et al, 1991).

3.5.1.W Carbamazepine

1) Interaction Effect: an increased risk of carbamazepine toxicity (ataxia, nystagmus, diplopia, headache, vo

2) Summary: Coadministration of sertraline and carbamazepine may cause reduced carbamazepine clearan possibly blood dyscrasias (Joblin & Ghose, 1994a). Similar interactions have been reported between carbam fluvoxamine (Pearson, 1990; Fritze et al, 1991). However, in two separate in vivo studies, coadministration of concentrations of carbamazepine (Prod Info Zoloft(R), 2002j). Two case reports of coadministration of carbar sertraline (Khan et al, 2000).

3) Severity: moderate

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: Due to the potential for elevated carbamazepine levels, patients should be closely f Consider measuring carbamazepine serum concentrations within two to three weeks of adding or discontinui metabolism of sertraline, sertraline levels may be lower than expected, which may result in lack of efficacy of

7) Probable Mechanism: inhibition of carbamazepine metabolism, increase in sertraline CYP3A4-mediated m

8) Literature Reports

a) A 24-year-old woman received maintenance carbamazepine 600 mg daily and flecainide 100 mg dail increased from 4.7 to 8.5 mg/L (normal range, 4 to 10 mg/L), and her blood counts were normal. Two mo white blood cell counts were abnormally low. Postoperatively her blood counts remained low, despite blo had missed one or more doses. On bone marrow examination, erythroid hyperplasia with megaloblastic counts began to improve five days after withdrawal of sertraline and carbamazepine; she was not rechall to inhibition of cytochrome P450 isoenzymes and carbamazepine protein binding displacement (Joblin &

b) Sertraline is suspected of inhibiting cytochrome P450IIIA4 (CYP3A4) enzyme activity (DeVane, 1994 have a potentially significant interaction with sertraline. Conversely, carbamazepine is also a known pote decreased sertraline concentrations (Spina et al, 1996).

c) Two cases have been reported in which concomitant use of sertraline and carbamazepine resulted in schizoaffective disorder who had been successfully treated with haloperidol and carbamazepine for 3 ye mg/day. A plasma level for carbamazepine and sertraline was obtained after sertraline initiation. Sertralin male diagnosed with posttraumatic stress disorder who had been successfully treated with carbamazepi disorder. Plasma levels were obtained for sertraline and carbamazepine during therapy. Sertraline levels mg/day (Kahn et al, 2000).

3.5.1.X Carprofen

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

approximately one month after adding selegiline to fluoxetine therapy. The patient improved 2 months af
involved diaphoresis, vasoconstriction, and cyanosis of the hands which occurred in close temporal relat
quick resolution of symptoms. Rechallenge with fluoxetine alone occurred without incident.

3.5.1.AG Clozapine

1) Interaction Effect: an increased risk of clozapine toxicity (sedation, seizures, hypotension)
2) Summary: Coadministration of clozapine with sertraline has been reported to result in increased clozapine
Chong et al, 1997a; Centorrino et al, 1996a). Clozapine is metabolized by the cytochrome P450 2D6 isoenzy
addition to being metabolized by CYP2D6 itself (Prod Info Zoloft(R), 1999g; DeVane, 1994e). Cytochrome P4
CYP3A4 (Chong & Remington, 1998).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor the therapeutic efficacy of clozapine and for any evidence of toxicity, partic
dosage may be required in some clinical situations.
7) Probable Mechanism: decreased clozapine metabolism
8) Literature Reports

a) Two case reports revealed the exacerbation of psychotic symptoms with the addition of a selective se
schizophrenia, had been taking clozapine 175 mg per day. Other medications included propranolol for ta
symptoms but continued compulsive behavior, sertraline 50 mg per day was added. Within four weeks, t
clozapine concentrations increased from 325 ng/mL before sertraline therapy to 695 ng/mL after sertralir
of clozapine 500 mg per day which was later increased to 600 mg per day. After fluvoxamine 50 mg per
ng/mL before fluvoxamine treatment to 2750 ng/mL after 28 days of fluvoxamine treatment. During this ti
worsened. The authors postulated that the worsening of psychotic symptoms could be due to SSRI inhib
serotonergic and dopaminergic blockade caused by coadministration of the two drugs (Chong et al, 1997

b) A study evaluated the serum concentrations of clozapine and norclozapine, the major metabolite, wh
paroxetine, and sertraline. Eighty outpatients receiving clozapine all had been diagnosed with schizophre
combination with clozapine. Of these 40 patients, 14 were receiving fluoxetine, 10 were receiving sertrali
serum concentrations of clozapine and norclozapine were 41.1% and 44.8% higher, respectively, than in
norclozapine concentration to dose was also 37.7% higher in patients receiving SSRIs, indicating clozap
study groups were too limited for an accurate statistical comparison between the individual SSRIs (Cento

3.5.1.AH Dalteparin

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and
anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp
reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter
coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin
1997a).

3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopram bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. T (95% CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI implicated in patients experienci addition of an SSRI was not associated with a change in warfarin dose or INR (p=0.48 and p=0.31 respe patient adherence, and exclusion of clopidogrel, dipyridamol, corticosteroids and anticoagulants other th
b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin. on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (O bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).
c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).
d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically th enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.AI Danaparoid

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin 1997a).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopram bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin. on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (O bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).
c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).
d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically th enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.AJ Darunavir

1) Interaction Effect: decreased sertraline exposure and plasma concentrations
2) Summary: Coadministration of darunavir/ritonavir with sertraline has resulted in significantly decreased se sertraline dose should be carefully titrated based on clinical response. When darunavir/ritonavir is initiated in sertraline (Prod Info PREZISTA(TM) oral tablets, 2006).

3) Severity: moderate
4) Onset: unspecified
5) Substantiation: established
6) Clinical Management: Concurrent administration of sertraline with darunavir/ritonavir significantly decreas carefully titrate the sertraline dose based on clinical response. When darunavir/ritonavir is initiated in patients
7) Probable Mechanism: unknown
8) Literature Reports
a) In a pharmacokinetics study, concurrent administration of sertraline and darunavir/ritonavir significant administered sertraline 50 mg orally once daily concurrently with darunavir 400 mg/ritonavir 100 mg orall mean ratio % 0.56; 90% confidence interval (CI), 0.49 to 0.63), a 49% decreased in sertraline AUC (LS r mean ratio % 0.51; 90% CI, 0.45 to 0.57). Darunavir pharmacokinetics were not significantly altered (Pro

3.5.1.AK Defibrotide

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin 1997a).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopram bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. (95% CI; 1.37 to 8.91, p=0.009) compared with warfarin only. b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin. on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (O bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).
c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).
d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically t enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.AL Dehydroepiandrosterone

1) Interaction Effect: development of manic symptoms
2) Summary: A case has been reported in which concomitant dehydroepiandrosterone (DHEA) and sertralin disorder (Dean, 2000a). DHEA was also noted to cause mania in a patient with no previous personal or famil found in patients with mental disorders; DHEA suppression has lead to improvement in psychotic symptoms to manic episodes (Majewska, 1995). DHEA is a precursor to androgenic steroids, which in high doses may p patients with a personal and/or family history of bipolar disorder should not take DHEA until further data is av serotonin reuptake inhibitors (SSRIs) should be avoided due to the potential additive precipitation of mania.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: Avoid concomitant use of dehydroepiandrosterone (DHEA) and selective serotonin irritability, aggressive behavior), determine if the patient is using DHEA and discontinue DHEA.
7) Probable Mechanism: serotonergic activity of dehydroepiandrosterone, possibly increased androgen level
8) Literature Reports
a) A 31-year-old male was admitted following threats to commit suicide and injure family members. He h depression. Sertraline had been prescribed 3 years prior when he was diagnosed with bipolar disorder, v 300 mg to 500 mg daily for the previous 2 months apparently for weight training. Following use of DHEA female friend and family members. He also drank alcohol occasionally and reportedly had difficulty contr valproic acid with the dose titrated to 500 mg twice daily. The combination of DHEA, sertraline, and alcol

3.5.1.AM Dermatan Sulfate

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin 1997a).

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d

7) Probable Mechanism: unknown

8) Literature Reports

a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopram bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. (95% CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI implicated in patients experienci addition of an SSRI was not associated with a change in warfarin dose or INR (p=0.48 and p=0.31 respe patient adherence, and exclusion of clopidogrel, dipyridamol, corticosteroids and anticoagulants other th

b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin. on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (O bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).

c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).

d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically th enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.AN Desipramine

1) Interaction Effect: modest elevation of desipramine serum levels or possible serotonin syndrome (hyperte

2) Summary: There is limited evidence suggesting that sertraline may inhibit tricyclic antidepressant (TCA) m P450 2D6 enzyme activity and may increase the plasma concentrations of coadministered drugs that are me Lydiard et al, 1993d; Prod Info Zoloft(R), 1999c). Effects of the interaction may have little or no clinical impact were modest compared with those found when fluoxetine (another selective serotonin reuptake inhibitor) was

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: The combined use of tricyclic antidepressants (TCAs) and selective serotonin reupt serotonin syndrome have also been reported with concurrent TCA and SSRI therapy. Caution should be obse

7) Probable Mechanism: inhibition of desipramine metabolism

8) Literature Reports

a) Desipramine pharmacokinetics was studied in 18 healthy male volunteers. Study subjects received o mg daily) for 21 days. When sertraline was added to desipramine therapy, the mean maximum concentra increased by 26%. Trough concentrations of desipramine were close to baseline one week after sertralin interaction may not be clinically significant (Preskorn et al, 1994h).

3.5.1.AO Desirudin

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin 1997a).

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d

7) Probable Mechanism: unknown

8) Literature Reports

a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl

fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopran bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. (95% CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI implicated in patients experienci addition of an SSRI was not associated with a change in warfarin dose or INR (p=0.48 and p=0.31 respe patient adherence, and exclusion of clopidogrel, dipyridamol, corticosteroids and anticoagulants other th

b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin. on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (O bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).

c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).

d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically t enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.AP Desvenlafaxine

1) Interaction Effect: increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, mental s

2) Summary: Concurrent use of desvenlafaxine and a selective serotonin reuptake inhibitor (SSRI) may resu may include restlessness, hallucinations, loss of coordination, fast heart beat, rapid changes in blood pressur (Prod Info PRISTIQ(TM) oral extended-release tablets, 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: theoretical

6) Clinical Management: Coadministration of desvenlafaxine and an SSRI may result in a life-threatening co serotonin syndrome with the patient and monitor closely for symptoms of serotonin syndrome (restlessness, increases (Prod Info PRISTIQ(TM) oral extended-release tablets, 2008).

7) Probable Mechanism: additive serotonergic effect

3.5.1.AQ Dexfenfluramine

1) Interaction Effect: serotonin syndrome (hypertension, hyperthermia, myoclonus, mental status changes)

2) Summary: Dexfenfluramine is a nonspecific serotonin agonist that both enhances the release of serotonin selective serotonin reuptake inhibitor, such as sertraline, has the potential to cause serotonin syndrome (Sch by symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, diaphoresis, shiverir Dexfenfluramine should not be used in combination with sertraline (Prod Info Redux(R), 1997).

3) Severity: major

4) Onset: rapid

5) Substantiation: theoretical

6) Clinical Management: Concurrent use of dexfenfluramine and sertraline may result in an additive increase (hypertension, hyperthermia, myoclonus, mental status changes). Dexfenfluramine should not be used in co

7) Probable Mechanism: additive serotonergic effects

3.5.1.AR Dexketoprofen

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton

5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are given concurrently, monitor patient for
PROZAC(R) oral capsules, delayed-release capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.AW Dipyrone

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and
associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator
suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent
were searched among 26,005 users of antidepressant medications and compared with the number of ho
amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t
12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The
SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.AX Dothiepin

1) Interaction Effect: modest elevations in dothiepin serum levels or possible serotonin syndrome (hypertens
2) Summary: There is limited evidence suggesting that sertraline may inhibit tricyclic antidepressant (TCA) m
P450 2D6 enzyme activity and may increase the plasma concentrations of coadministered drugs that are me
2002c; Preskorn et al, 1994a; Lydiard et al, 1993). Effects of the interaction may have little or no clinical impa
were modest compared with those found when fluoxetine (another selective serotonin reuptake inhibitor) was
sertraline therapy for TCA toxicity (dry mouth, urinary retention, CNS depression). Dothiepin doses may need
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: The combined use of tricyclic antidepressants (TCAs) and selective serotonin reupt
serotonin syndrome have also been reported with concurrent TCA and SSRI therapy. Caution should be obse
7) Probable Mechanism: inhibition of dothiepin metabolism
8) Literature Reports
a) Desipramine pharmacokinetics were studied in 18 healthy male volunteers. Study subjects received c
daily) for 21 days. When sertraline was added to desipramine therapy, the mean maximum concentration
increased by 26%. Trough concentrations of desipramine were close to baseline one week after sertralin
interaction may not be clinically significant (Preskorn et al, 1994).

3.5.1.AY Doxepin

1) Interaction Effect: modest elevations in doxepin serum levels or possible serotonin syndrome (hypertensio
2) Summary: There is limited evidence suggesting that sertraline may inhibit tricyclic antidepressant (TCA) m
P450 2D6 enzyme activity and may increase the plasma concentrations of coadministered drugs that are me
2002f; Preskorn et al, 1994e; Lydiard et al, 1993b). Effects of the interaction may have little or no clinical impa
were modest compared with those found when fluoxetine (another selective serotonin reuptake inhibitor) was
sertraline therapy for TCA toxicity (dry mouth, urinary retention, CNS depression). Doxepin doses may need t
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: The combined use of tricyclic antidepressants (TCAs) and selective serotonin reupt
serotonin syndrome have also been reported with concurrent TCA and SSRI therapy. Caution should be obse
7) Probable Mechanism: inhibition of doxepin metabolism
8) Literature Reports
a) Desipramine pharmacokinetics was studied in 18 healthy male volunteers. Study subjects received or
daily) for 21 days. When sertraline was added to desipramine therapy, the mean maximum concentration
increased by 26%. Trough concentrations of desipramine were close to baseline one week after sertralin
interaction may not be clinically significant (Preskorn et al, 1994d).

3.5.1.AZ Droperidol

1) Interaction Effect: an increased risk of cardiotoxicity (QT prolongation, torsades de pointes, cardiac arrest)
2) Summary: Any drug known to have the potential to prolong the QT interval should not be used together w potentially arrhythmogenic agents such as antidepressants that prolong the QT interval (Prod Info Inapsine(R
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Droperidol should be administered with extreme caution in the presence of risk fact
7) Probable Mechanism: additive cardiac effects

3.5.1.BA Droxicam

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BB Duloxetine

1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: Duloxetine is a selective serotonin and norepinephrine reuptake inhibitor. The concomitant use due to the potential for serotonin syndrome (Prod Info CYMBALTA(R) delayed-release oral capsules, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: theoretical
6) Clinical Management: The concomitant use of duloxetine and sertraline is not recommended due to the po oral capsules, 2008).
7) Probable Mechanism: additive serotonergic effects

3.5.1.BC Efavirenz

1) Interaction Effect: decreased sertraline plasma concentrations
2) Summary: Coadministration of efavirenz and sertraline resulted in significantly decreased concentrations sertraline doses based on clinical response (Prod Info SUSTIVA(R) oral capsules, tablets, 2008).
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: established
6) Clinical Management: The concomitant use of efavirenz and sertraline resulted in significantly reduced ex sertraline are coadministered. Sertraline doses may need to be increased based on clinical response (Prod In
7) Probable Mechanism: induction of CYP3A4-mediated sertraline metabolism by efavirenz
8) Literature Reports
a) In a pharmacokinetics study, concurrent administration of efavirenz and sertraline significantly decrea sertraline 50 mg orally once daily concurrently with efavirenz 600 mg orally once daily for 14 days. Resul 40%), a 39% decrease in sertraline AUC (90% CI, 27% to 50%), and a 46% decrease in sertraline Cmin was a mean 11% (90% CI, 6% to 16%) increase in efavirenz Cmax (Prod Info SUSTIVA(R) oral capsules

3.5.1.BD Eletriptan

1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: There have been case reports of weakness, hyperreflexia, and incoordination following concon specific reuptake inhibitor (SSRI) (Prod Info Imitrex(R) Nasal Spray, 2003). Because eletriptan is a 5HT 1B/1 (R), 2003). Concurrent use of a triptan and an SSRI may result in serotonin syndrome which may be life-threa of coordination, fast heart beat, rapid changes in blood pressure, increased body temperature, overreactive r commonly used intermittently and that either the triptan or the SSRI may be prescribed by a different physicia combination and monitor them closely for symptoms of serotonin syndrome (US Food and Drug Administratio
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Coadministration of a triptan, such as eletriptan, and an SSRI may result in a life-th used intermittently and that either the triptan or the SSRI may be prescribed by a different physician. If these monitor closely for symptoms of serotonin syndrome (restlessness, hyperthermia, hyperreflexia, incoordinatio

7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation

3.5.1.BE Enoxaparin

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin 1997a).

3) Severity: major

4) Onset: delayed

5) Substantiation: probable

6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d

7) Probable Mechanism: unknown

8) Literature Reports

a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopram bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. (95% CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI implicated in patients experienci addition of an SSRI was not associated with a change in warfarin dose or INR (p=0.48 and p=0.31 respe patient adherence, and exclusion of clopidogrel, dipyridamol, corticosteroids and anticoagulants other th

b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin. on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (O bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).

c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).

d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically t enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.BF Epoprostenol

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and been associated with an increased risk of bleeding. Bleeding events reported have included epistaxis, ecchy tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution, 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an antiplatelet agent are given concurrently, monitor patient for PROZAC(R) oral capsules, delayed-release capsules, solution, 2008)

7) Probable Mechanism: unknown

3.5.1.BG Eptifibatide

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and been associated with an increased risk of bleeding. Bleeding events reported have included epistaxis, ecchy tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution, 2008).

3) Severity: major

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an antiplatelet agent are given concurrently, monitor patient for PROZAC(R) oral capsules, delayed-release capsules, solution, 2008)

7) Probable Mechanism: unknown

3.5.1.BH Erythromycin

1) Interaction Effect: an increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, ment

2) Summary: Serotonin syndrome was precipitated in a pediatric patient taking sertraline when erythromycin status had significantly improved. Erythromycin induces cytochrome P450 3A (CYP3A), becomes demethylat formation of this inactive complex is associated with decreased CYP3A activity both in the liver and the small route of metabolism may result in elevated sertraline levels (Lee & Lee, 1999a).

3) Severity: major

4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: All patients receiving a serotonergic medication should be monitored for signs and s
7) Probable Mechanism: inhibition by erythromycin of cytochrome P450 3A4-mediated sertraline metabolism
8) Literature Reports
a) Sertraline 37.5 mg daily was prescribed for a 12-year-old boy with severe obsessive-compulsive diso adverse effects before erythromycin 200 mg twice daily was initiated. Within four days of concurrent ther restlessness, paresthesias, tremulousness, and confusion. Erythromycin and sertraline were both discon

3.5.1.BI Etodolac

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hematon suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BJ Etofenamate

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hematon suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BK Etoricoxib

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hematon suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BL Felbinac

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hematon suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu

3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BM Fenbufen
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BN Fenfluramine
1) Interaction Effect: serotonin syndrome (hypertension, hyperthermia, myoclonus, mental status changes)
2) Summary: Fenfluramine is a nonspecific serotonin agonist that both enhances the release of serotonin an serotonin reuptake inhibitor, such as sertraline, has the potential to cause serotonin syndrome (Schenck & M symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, diaphoresis, shivering, more data are available, fenfluramine should not be used in combination with sertraline.
3) Severity: major
4) Onset: rapid
5) Substantiation: theoretical
6) Clinical Management: Concurrent use of fenfluramine and sertraline may result in an additive increase in s (hypertension, hyperthermia, myoclonus, mental status changes). Fenfluramine should not be used in combi
7) Probable Mechanism: additive serotonergic effects

3.5.1.BO Fenoprofen
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BP Fentiazac
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate

4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BQ Flecainide
1) Interaction Effect: an increased risk of flecainide toxicity (cardiac arrhythmia)
2) Summary: No data are currently available related to concomitant flecainide - sertraline administration. Fle al, 1994). Sertraline inhibits the CYP2D6 isoenzyme (Prod Info Zoloft(R), 2002k; DeVane, 1994c). With flecai higher flecainide serum levels and possible flecainide toxicity. Controlled studies are needed to investigate th
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Coadministration of these agents should be approached with caution. Monitor the E need to be reduced.
7) Probable Mechanism: inhibition of flecainide metabolism

3.5.1.BR Floctafenine
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.BS Flufenamic Acid
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate

3.5.1.BV Fondaparinux
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and
anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp e
reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter
coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin
1997a).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig
closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl
fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien
with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopram
bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie
corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. T
(95% CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI implicated in patients experienci
addition of an SSRI was not associated with a change in warfarin dose or INR (p=0.48 and p=0.31 respe
patient adherence, and exclusion of clopidogrel, dipyridamol, corticosteroids and anticoagulants other tha
b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum
increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit
for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin.
on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (OI
bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).
c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject
given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb
findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).
d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se
study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize
mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically th
enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.BW Fosphenytoin
1) Interaction Effect: an increased risk of phenytoin toxicity (ataxia, hyperreflexia, nystagmus, tremor)
2) Summary: Fosphenytoin is a prodrug of phenytoin and the same interactions that occur with phenytoin are
sertraline with phenytoin has been reported to result in elevated serum phenytoin levels in two elderly patient
verify the extent of this interaction.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable

6) Clinical Management: Caution is warranted if fosphenytoin and sertraline are to be coadministered. Serun therapy or changing the sertraline dose. Monitor patients for signs and symptoms of phenytoin toxicity (ataxia downward.
7) Probable Mechanism: sertraline inhibition of phenytoin metabolism by cytochrome P450 isoenzymes
8) Literature Reports
a) Sertraline is known to be a moderate to weak inhibitor of the cytochrome P450IID6 isoenzyme (CYP2 metabolism of phenytoin may involve the cytochrome P450IID6 (Murray, 1992) and the CYP2C9 hepatic activity and pathways, it seems theoretically possible that concurrent sertraline may act to inhibit metabo
b) Two cases in which elderly patients developed elevated serum phenytoin concentrations during coad phenytoin 300 mg per day in addition to several other medications. After sertraline 25 mg every night for to 12.3 mcg/mL. After serial increases in the sertraline dose to 75 mg per day, the patient's serum pheny restarted at a dose of 200 mg per day. Sertraline 100 mg per day was also administered without further a levels (from 15.6 mcg/mL to 20 mcg/mL) after the addition of sertraline 25 mg every other day to phenyto within one week after starting sertraline therapy or initiating a change in sertraline dose (Haselberger et a

3.5.1.BX Frovatriptan
1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: There have been case reports of weakness, hyperreflexia, and incoordination following concon specific reuptake inhibitor (SSRI) (Prod Info Imitrex(R) Nasal Spray, 2003). Because frovatriptan is a 5HT 1B/ Frova(R), 2004). Concurrent use of frovatriptan and an SSRI may result in serotonin syndrome which may be hallucinations, loss of coordination, fast heart beat, rapid changes in blood pressure, increased body tempera that triptans may be commonly used intermittently and that either the triptan or the SSRI may be prescribed b prescribed this combination and monitor them closely for symptoms of serotonin syndrome (US Food and Dru
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Coadministration of a triptan, such as frovatriptan, and an SSRI may result in a life- used intermittently and that either the triptan or the SSRI may be prescribed by a different physician. If these monitor closely for symptoms of serotonin syndrome (restlessness, hyperthermia, hyperreflexia, incoordinatio
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation

3.5.1.BY Furazolidone
1) Interaction Effect: weakness, hyperreflexia, and incoordination
2) Summary: Although not its primary mechanism of action, furazolidone has monoamine oxidase inhibitor a receiving selective serotonin reuptake inhibitors (SSRI) in combination with monoamine oxidase inhibitors (M fluctuations of vital signs, and mental status changes that include extreme agitation progressing to delirium a SSRI, or within a minimum of 14 days of discontinuing therapy with a MAOI (Prod Info Furoxone(R), 1999).
3) Severity: contraindicated
4) Onset: delayed
5) Substantiation: theoretical
6) Clinical Management: If concurrent therapy with furazolidone and a selective serotonin reuptake inhibitor (excess (mental status changes, diaphoresis, fever, weakness, hyperreflexia, incoordination).
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation

3.5.1.BZ Ginkgo
1) Interaction Effect: increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, mental s
2) Summary: The addition of Ginkgo biloba and/or St. John's Wort to therapy with buspirone and fluoxetine r is unclear if Ginkgo or St. John's Wort, the combination of both, or other patient factors, contributed to the effe selective serotonin reuptake inhibitors (SSRIs). Caution is advised, especially when ginkgo is taken to counte (Sloley et al, 2000; White et al, 1996), and has demonstrated serotonergic activity in animals (Ramassamy et with SSRIs. The potential MAO inhibitory activity of ginkgo is questionable. A human study did not show MAO extract inhibited MAO-A/MAO-B in the rat brain in vitro (Sloley et al, 2000; White et al, 1996) and MAO-B in h following oral consumption (Porsolt et al, 2000).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients closely for symptoms of serotonin syndrome if ginkgo is combined
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation
8) Literature Reports
a) A 42-year-old female experienced symptoms consistent with a mixed hypomanic episode following co symptoms resolved following discontinuation of Ginkgo and St. John's Wort. The patient was being treate twice daily and buspirone 15 mg twice daily. Several weeks prior to presentation, buspirone was increase melatonin, and St. John's Wort in unspecified doses. Melatonin was considered unlikely to have contribu since they may potentiate antidepressants, and considering the temporal relationship between the use o symptoms. However, the brain injury was considered a possible contributor (Spinella & Eaton, 2002).

3.5.1.CA Heparin
1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and
anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp
reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter
coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin
1997a).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig

c) In one case report, a 36-year-old male experience symptoms of serotonin syndrome after concomitar transplant after receiving high-doses of cyclophosphamide, total body irradiation, and antihymocyte globu versus-host disease, thrombotic thrombocytic purpura, renal failure, and multiple pulmonary infections. C medications consisted of tacrolimus, corticosteroids, thalidomide 100 mg daily, sertraline 50 mg daily, mo restlessness, delirium and agitation. He developed hypertension and a high fever (40 degrees Celsius). V all medications with neurological effects were discontinued, including sertraline, thalidomide, alprazolam, and morphine were reinstated with no reoccurrence of symptoms (Hachem et al, 2003).

3.5.1.CR Lithium

1) Interaction Effect: possible increased lithium concentrations and/or an increased risk of SSRI-related sero
2) Summary: Concomitant use of lithium and various SSRIs has been associated with enhanced side effects resulted in neurotoxicity and increased lithium levels in one case report (Salama & Shafey, 1989a). Signs and who demonstrated therapeutic serum lithium levels while on concurrent fluoxetine and lithium (Muly et al, 199 interaction between lithium and citalopram (Gram et al, 1993a; Baumann et al, 1996a). Combined administra significant effect on the pharmacokinetics of citalopram or lithium. However, plasma lithium levels should be m clinical practice. Lithium may enhance the serotonergic effects of citalopram, therefore caution should be exe Concurrent use of fluvoxamine and lithium has led to case reports of increased lithium levels and neurotoxicit Spigset, 1993a; Evans & Marwick, 1990; Burrai et al, 1991a). No pharmacokinetic interference was apparent (TM), 2003). If these two agents are to be given concomitantly, the manufacturer suggests that caution be us have been reported when lithium was coadministered with fluoxetine and fluvoxamine (both in the same phar Spigset, 1993a; Salama & Shafey, 1989a).
3) Severity: moderate
4) Onset: delayed
5) Substantiation: established
6) Clinical Management: Monitor patients on concurrent lithium and selective serotonin reuptake inhibitor the and symptoms associated with serotonin syndrome (hypertension, hyperthermia, myoclonus, mental status c
7) Probable Mechanism: unknown
8) Literature Reports
a) Concomitant administration of oral lithium carbonate and oral fluoxetine resulted in increased lithium s (Salama & Shafey, 1989). Fluoxetine 20 mg daily was added to a regimen of lithium 1200 mg daily follow morning awakening. Lithium serum levels increased to 1.7 mEq/L from a range of 0.75 to 1.15 mEq/L pri resulted in a decrease in the lithium serum level within 48 hours to 1.2 mEq/L. The neurologic symptoms contribution of fluoxetine to lithium toxicity in this patient was obscured by the fact that the lithium was re
b) A 53-year old woman who had been taking fluoxetine 20 mg daily and lorazepam 0.5 mg four times d order to augment her response to fluoxetine. Within 48 hours, the patient became confused, ataxic, and degrees F, and laboratory values were normal except for an elevated leukocyte count and slightly elevat resolved over the next four days. At no point did the lithium levels reach a toxic level, suggesting that the et al, 1989).
c) Serotonin syndrome was precipitated when lithium 300 mg twice daily was added to a three-month re measured at 0.65 mEq/L and the dose was increased to 300 mg three times daily. Two days after this do tremor, diarrhea, and incoordination. After discontinuation of lithium and initiation of cyproheptadine thera of fluoxetine 40 mg per day without further symptoms of serotonin syndrome (Muly et al, 1993).
d) Eight healthy male volunteers completed three phases of an interaction study to determine the effects sparteine, indicating normal cytochrome P450 2D6 enzyme activity. Although lithium is not influenced by subject received citalopram 40 mg alone as a single daily dose for 10 days, lithium 30 mmol (1980 mg) a two weeks separated each treatment phase. Results showed that the concurrent administration of citalo 1993).
e) Twenty-four patients experiencing depression (DSM III criteria) were randomized under double-blind daily) or placebo. All of the subjects had failed to respond to four weeks of citalopram monotherapy. Lithi between lithium and citalopram was noted, and cotherapy was well tolerated (Baumann et al, 1996).
f) Serotonin syndrome was described in a 53-year-old patient who was stabilized on lithium 1400 mg da period the fluvoxamine dose was increased to 200 mg daily; tremor and difficulty with fine hand moveme bilateral hyperreflexia of biceps and knee jerks, and clonus in both ankles were seen. After 12 weeks of daily replaced fluvoxamine, and the neuromuscular symptoms abated over a 2-week period. After four w
g) Three cases of mania were reported in patients who were treated with lithium and fluvoxamine. The r begun. Fluvoxamine was discontinued and, in two of the three patients, the mania resolved, and success depression reappeared within a month of fluvoxamine discontinuation (Burrai et al, 1991).
h) In an open-labeled, placebo-controlled study, lithium 600 mg was administered to 16 subjects orally t sertraline 100 mg or placebo was given twice, ten hours and two hours prior to lithium dosing on day nin renal clearance increased by 6.9% (0.11 L/hour) when sertraline was coadministered. Seven subjects ex subjects who ingested placebo and lithium experienced side effects (Wilner et al, 1991).

3.5.1.CS Lofepramine

1) Interaction Effect: modest elevations in lofepramine serum levels or possible serotonin syndrome (hyperte
2) Summary: There is limited evidence suggesting that sertraline may inhibit tricyclic antidepressant (TCA) m P450 2D6 enzyme activity and may increase the plasma concentrations of coadministered drugs that are me 2002i; Preskorn et al, 1994m; Lydiard et al, 1993f). Effects of the interaction may have little or no clinical impa

were modest compared with those found when fluoxetine (another selective serotonin reuptake inhibitor) was sertraline therapy for TCA toxicity (dry mouth, urinary retention, CNS depression). Lofepramine doses may ne

6) Clinical Management: Coadministration of a triptan, such as naratriptan, and an SSRI may result in a life-t used intermittently and that either the triptan or the SSRI may be prescribed by a different physician. If these monitor closely for symptoms of serotonin syndrome (restlessness, hyperthermia, hyperreflexia, incoordinatic

7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation

3.5.1.DH Nialamide

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, hyperthermia, myoclonus, mental st

2) Summary: Concurrent administration or overlapping therapy with sertraline and a monoamine oxidase (M characterized by symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, diaph concomitant use of serotonin specific reuptake inhibitors and MAO inhibitors (Prod Info Zoloft(R), 1999h; Lap & de Vries, 1990i). Concomitant use is contraindicated.

3) Severity: contraindicated

4) Onset: rapid

5) Substantiation: probable

6) Clinical Management: Concurrent use of sertraline and a MAO inhibitor is contraindicated. Wait at least 1 least 14 days after discontinuing sertraline before initiating therapy with a MAO inhibitor.

7) Probable Mechanism: inhibition of serotonin metabolism by monoamine oxidase

8) Literature Reports

a) Concomitant use of SSRIs and monoamine oxidase inhibitors can produce a toxic reaction known as hyperstimulation and manifests as restlessness, myoclonus, changes in mental status, hyperreflexia, dia fatality can result.

b) A 26-year old woman who had been taking isocarboxazid for eight weeks stopped taking the drug for the patient became restless and developed leg twitches. The patients was later admitted to the emergen disturbances. After treatment with diazepam and propranolol the patient did not improve. The patient wa symptoms after the second dose (Lappin & Auchincloss, 1994j).

c) A drug interaction was reported in a 61-year old woman in which sertraline 100 mg twice daily was ac taking the first sertraline dose, the patient was found in a semicomatose state, with elevated body tempe Hg. After transportation to the hospital, the patient was misdiagnosed as having neuroleptic malignant sy sertraline and phenelzine. The authors suggest that monoamine oxidase inhibitor (MAOI) therapy should serotonin reuptake inhibitor (SSRI) and that before starting a MAOI, SSRI therapy should be discontinue 1994j).

d) Two cases reports suggested a possible interaction between fluoxetine and selegiline (Suchowersky approximately one month after adding selegiline to fluoxetine. The patient improved two months after bo involved diaphoresis, vasoconstriction, and cyanosis of the hands which occurred in close temporal relat quick resolution of symptoms. Rechallenge with fluoxetine alone occurred without incident.

3.5.1.DI Niflumic Acid

1) Interaction Effect: an increased risk of bleeding

2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control anc associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu

3) Severity: moderate

4) Onset: unspecified

5) Substantiation: probable

6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in

7) Probable Mechanism: unknown

8) Literature Reports

a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton

1) Interaction Effect: an increased risk of phenytoin toxicity (ataxia, hyperreflexia, nystagmus, tremor)
2) Summary: Coadministration of sertraline with phenytoin has been reported to result in elevated serum phe controlled studies are needed to verify the extent of this interaction.
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Caution is warranted if phenytoin and sertraline are to be coadministered. Serum pl therapy or changing the sertraline dose. Monitor patients for signs and symptoms of phenytoin toxicity (ataxia downward.
7) Probable Mechanism: sertraline inhibition of phenytoin metabolism by cytochrome P450 isoenzymes
8) Literature Reports
a) Sertraline is known to be a moderate to weak inhibitor of the cytochrome P450IID6 isoenzyme (CYP2 metabolism of phenytoin may involve the cytochrome P450IID6 (Murray, 1992a) and the CYP2C9 hepati activity and pathways, it seems theoretically possible that concurrent sertraline may act to inhibit metabo
b) Two elderly patients developed elevated serum phenytoin concentrations during coadministration wit addition to several other medications. After sertraline 25 mg every night for depression was added to his increases in the sertraline dose to 75 mg per day, the patient's serum phenytoin level rose to 30.9 mcg/m per day. Sertraline 100 mg per day was also administered without further adverse effects. Patient 2, an 8 mcg/mL) after the addition of sertraline 25 mg every other day to phenytoin 260 mg per day. The authors sertraline therapy or initiating a change in sertraline dose (Haselberger et al, 1997b).

3.5.1.DW Pimozide

1) Interaction Effect: an increase in plasma pimozide levels
2) Summary: Due to the narrow therapeutic index of pimozide and due to the interaction noted at low dose o Info Zoloft(R), 2002s).
3) Severity: contraindicated
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Concomitant use of sertraline in patients taking pimozide is contraindicated.
7) Probable Mechanism: unknown
8) Literature Reports
a) In a controlled trial of a single 2 mg dose of pimozide, sertraline 200 mg daily coadministration to stea time curve (AUC) and maximum plasma concentrations (Cmax) of about 40%, but was not associated w been evaluated in combination with sertraline, the effect on QT interval and pharmacokinetic parameters and observed interaction data with low doses, the combination should be avoided (Prod Info Zoloft(R), 2

3.5.1.DX Pirazolac

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.DY Piroxicam

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.DZ Pirprofen

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton

b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.EA Procarbazine

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, hyperthermia, myoclonus, mental sta
2) Summary: Concurrent administration or overlapping therapy with sertraline and a monoamine oxidase (MA characterized by symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, diaph concomitant use of serotonin specific reuptake inhibitors and MAO inhibitors (Prod Info Zoloft(R), 1999j; Lapp & de Vries, 1990q). Concomitant use is contraindicated.
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Concurrent use of sertraline and a MAO inhibitor is contraindicated. Wait at least 14 least 14 days after discontinuing sertraline before initiating therapy with a MAO inhibitor.
7) Probable Mechanism: inhibition of serotonin metabolism by monoamine oxidase
8) Literature Reports

a) Concomitant use of SSRIs and monoamine oxidase inhibitors can produce a toxic reaction known as serotonergic hyperstimulation and manifests as restlessness, myoclonus, changes in mental status, hype correctly treated, fatality can result.

b) A 26-year old woman who had been taking isocarboxazid for eight weeks stopped taking the drug for the patient became restless and developed leg twitches. The patients was later admitted to the emergen disturbances. After treatment with diazepam and propranolol the patient did not improve. The patient was symptoms after the second dose (Lappin & Auchincloss, 1994r).

c) A drug interaction was reported in a 61-year old woman in which sertraline 100 mg twice daily was ac taking the first sertraline dose, the patient was found in a semicomatose state, with elevated body tempe Hg. After transportation to the hospital, the patient was misdiagnosed as having neuroleptic malignant sy sertraline and phenelzine. The authors suggest that monoamine oxidase inhibitor (MAOI) therapy should serotonin reuptake inhibitor (SSRI) and that before starting a MAOI, SSRI therapy should be discontinue 1994r).

d) Two cases reports suggested a possible interaction between fluoxetine and selegiline (Suchowersky approximately one month after adding selegiline to fluoxetine. The patient improved two months after bot involved diaphoresis, vasoconstriction, and cyanosis of the hands which occurred in close temporal relat quick resolution of symptoms. Rechallenge with fluoxetine alone occurred without incident.

3.5.1.EB Propafenone

1) Interaction Effect: an increased risk of propafenone toxicity (cardiac arrhythmias)
2) Summary: No data are currently available related to concomitant propafenone - sertraline administration. I 2000). Sertraline inhibits the CYP2D6 isoenzyme (Prod Info Zoloft(R), 1999d). With propafenone - sertraline propafenone serum levels and possible propafenone toxicity. Controlled studies are needed to investigate the
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Coadministration of these agents should be approached with caution. Monitor the E may need to be reduced.
7) Probable Mechanism: inhibition of propafenone metabolism

3.5.1.EC Propranolol

1) Interaction Effect: an increased risk of chest pain
2) Summary: Sertraline is a moderate to weak inhibitor of the hepatic cytochrome P450IID6 isoenzyme (CYP report describes sudden chest pain when sertraline was added to existing propranolol therapy (Iruela, 1994a)
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients receiving propranolol and sertraline cotherapy for an increased inc coronary artery disease.
7) Probable Mechanism: endothelium vasoconstriction caused by serotonin
8) Literature Reports

a) A 53-year-old male physician was maintained on propranolol 160 mg daily and aspirin 200 mg daily fo depression, he experienced sudden precordial chest pain that was responsive to 2 mg of sublingual glyc occurred on the electrocardiogram. The next day, a similar reaction happened soon after the administrat nortriptyline 50 mg daily with no further episodes of chest pain. Possible mechanisms for this interaction artery disease (Iruela, 1994).

3.5.1.ED Propyphenazone

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate

4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.EE Proquazone

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 t 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.EF Protriptyline

1) Interaction Effect: modest elevations in protriptyline serum levels or possible serotonin syndrome (hyperte
2) Summary: There is limited evidence suggesting that sertraline may inhibit tricyclic antidepressant (TCA) m P450 2D6 enzyme activity and may increase the plasma concentrations of coadministered drugs that are me Lydiard et al, 1993a; Prod Info Zoloft(R), 1999a). Effects of the interaction may have little or no clinical impac were modest compared with those found when fluoxetine (another selective serotonin reuptake inhibitor) was sertraline therapy for TCA toxicity (dry mouth, urinary retention, CNS depression). Protriptyline doses may ne
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: The combined use of tricyclic antidepressants (TCAs) and selective serotonin reupt serotonin syndrome have also been reported with concurrent TCA and SSRI therapy. Caution should be obse
7) Probable Mechanism: inhibition of protriptyline metabolism
8) Literature Reports
a) Desipramine pharmacokinetics were studied in 18 healthy male volunteers. Study subjects received c daily) for 21 days. When sertraline was added to desipramine therapy, the mean maximum concentration increased by 26%. Trough concentrations of desipramine were close to baseline one week after sertralin interaction may not be clinically significant (Preskorn et al, 1994b).

3.5.1.EG Rasagiline

1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, hyperthermia, myoclonus, mental sta
2) Summary: Concurrent administration or overlapping therapy with selective serotonin reuptake inhibitors, in has been reported to cause serious, sometimes fatal reactions. Signs and symptoms included hyperthermia, status changes progressing to extreme agitation, delirium, and coma. Similar reactions have been reported w selegiline. Rasagiline clinical trials did allow concomitant use of sertraline in doses less than or equal to 100 m adequate to rule out the possibility of adverse events from the combination of rasagiline and sertraline, and s initiating therapy with sertraline (Prod Info AZILECT(R) oral tablets, 2006).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: Concurrent use of sertraline and rasagiline Should be avoided. Wait at least 14 day
7) Probable Mechanism: inhibition of serotonin metabolism by monoamine oxidase
8) Literature Reports
a) Concomitant use of serotonin specific reuptake inhibitors and monoamine oxidase inhibitors can prod syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness, myoclonus, cha not recognized and correctly treated, death can result.

3.5.1.EH Reviparin

1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and anticoagulants has been associated with an increased risk of bleeding (Wallerstedt et al, 2009; Schalekamp reported have included epistaxis, ecchymosis, hematoma, petechiae, and life-threatening hemorrhages. Alter coadministration of SSRIs with warfarin (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008). Prothrombin 1997a).
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: When sertraline and an anticoagulant are given concurrently, monitor patient for sig closely for altered anticoagulant effects, including increased bleeding, when sertraline therapy is initiated or d
7) Probable Mechanism: unknown
8) Literature Reports
a) According to a retrospective cohort study (n=234), there was an increased risk of clinically relevant bl fibrillation during concomitant SSRI therapy or within 2 weeks following SSRI therapy termination. Patien with randomly selected patients who received warfarin only (n=117). SSRI included fluoxetine, citalopram bleeding episodes during 213.9 treatment years in the warfarin plus SSRI group, and 10 patients experie corresponding total incidences of bleedings were 51.4 and 23.9 per 1000 treatment years, respectively. (95% CI; 1.37 to 8.91, p=0.009) compared with warfarin only. The SSRI implicated in patients experienci addition of an SSRI was not associated with a change in warfarin dose or INR (p=0.48 and p=0.31 respe patient adherence, and exclusion of clopidogrel, dipyridamol, corticosteroids and anticoagulants other th
b) A population-based, case-controlled study of new coumarin users (acenocoumarol and phenprocoum increased risk of hospitalization due to nongastrointestinal bleeding. Using national pharmacy and hospit for abnormal bleeding and compared them with 5818 control subjects who were also taking a coumarin. on SSRIs showed greater risk for hospitalization for nongastrointestinal bleeding (adjusted odds ratio (O bleeding (adjusted OR 0.8, 95% CI, 0.4 to 1.5) was not significantly different (Schalekamp et al, 2008).
c) Sertraline 50 mg to 200 mg daily for 21 days produced an 8% increase in prothrombin time in subject given prior to sertraline; this compared with a 1% decrease with placebo. Normalization of the prothromb findings is unknown (Prod Info ZOLOFT(R) oral tablets, concentrate, 2008).
d) In a non-blinded, randomized, placebo-controlled trial involving 12 healthy volunteers, the effect of se study, all participants received warfarin 0.75 mg/kg. Beginning on day 11, each volunteer was randomize mg/day to 200 mg/day. Prothrombin time was measured prior to each dose of warfarin and periodically th enhanced by sertraline to a clinically significant degree, despite the fact that sertraline was given in a hig

3.5.1.EI Rifampin

1) Interaction Effect: loss of sertraline efficacy
2) Summary: Sertraline is metabolized by cytochrome P450 3A4 enzymes, which are induced by rifampin the of selective serotonin reuptake inhibitor (SSRI) withdrawal syndrome following seven days of concurrent rifam
3) Severity: moderate
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Monitor patients for sertraline efficacy and signs of selective serotonin reuptake inh rifampin is given concomitantly.
7) Probable Mechanism: induction of cytochrome P450 3A4-mediated sertraline metabolism
8) Literature Reports
a) Rifampin administration was thought to precipitate selective serotonin reuptake inhibitor withdrawal sy concurrent therapy. The patient had been stabilized on sertraline 200 mg nightly for generalized anxiety mg was started for a methicillin-resistant Staphylococcus aureus skin infection. Seven days later, the pat a blood sample was drawn to determine the plasma sertraline concentration. Laboratory analysis reveale ng/mL. The patient finished the remainder of the 10-day course of rifampin. Seven days after rifampin wa an N-desmethylsertraline concentration of 136 ng/mL. Anxiety was still persistent in this patient, so sertra (Markowitz & DeVane, 2000).

3.5.1.EJ Rizatriptan

1) Interaction Effect: an increased risk of serotonin syndrome
2) Summary: There have been case reports of weakness, hyperreflexia, and incoordination following concon specific reuptake inhibitor (SSRI) (Prod Info Imitrex(R), 1998). Because rizatriptan is a 5HT 1B/1D receptor a 1998a). Concurrent use of a triptan and an SSRI may result in serotonin syndrome which may be life-threate coordination, fast heart beat, rapid changes in blood pressure, increased body temperature, overreactive refl commonly used intermittently and that either the triptan or the SSRI may be prescribed by a different physicia combination and monitor them closely for symptoms of serotonin syndrome (US Food and Drug Administratio
3) Severity: major
4) Onset: delayed
5) Substantiation: probable
6) Clinical Management: Coadministration of a triptan, such as rizatriptan, and an SSRI may result in a life-th used intermittently and that either the triptan or the SSRI may be prescribed by a different physician. If these monitor closely for symptoms of serotonin syndrome (restlessness, hyperthermia, hyperreflexia, incoordinatio
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation

8) Literature Reports
a) Twelve healthy volunteers received paroxetine 20 mg daily for two weeks and a single dose of rizatrip paroxetine (Prod Info Maxalt(R), 1998).

3.5.1.EK Rofecoxib
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and associated with an increased risk of bleeding. Bleeding events have included epistaxis, ecchymosis, hemator suspension, 2008) (Prod Info Lexapro(TM), 2003; Dalton et al, 2003a; Prod Info CELEXA (R) oral tablet, solu
3) Severity: moderate
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an NSAID are given concurrently, monitor patient for signs of in
7) Probable Mechanism: unknown
8) Literature Reports
a) SSRIs increase the risk of upper gastrointestinal bleeding and this effect is potentiated by concurrent were searched among 26,005 users of antidepressant medications and compared with the number of ho amount of upper GI bleeding episodes was 3.6 times more than expected (95% confidence interval, 2.7 12.2 (95% confidence interval, 7.1 to 19.5) and 5.2 (95% confidence interval, 3.2 to 8), respectively. The SSRIs. Combined use of SSRIs and NSAIDs or low-dose aspirin increased the risk even further (Dalton
b) Coadministration of ketorolac with psychoactive drugs (such as fluoxetine) has been associated with

3.5.1.EL Selegiline
1) Interaction Effect: CNS toxicity or serotonin syndrome (hypertension, hyperthermia, myoclonus, mental sta
2) Summary: Concurrent administration or overlapping therapy with sertraline and a monoamine oxidase (MA characterized by symptoms such as restlessness, myoclonus, changes in mental status, hyperreflexia, diaph Zoloft(R), 2002u; Lappin & Auchincloss, 1994u; Graber et al, 1994u; Bhatara & Bandettini, 1993j; Suchowers contraindicated, and a minimum of 14 days should elapse after discontinuing selegiline before initiating thera before initiating therapy with selegiline (Prod Info EMSAM(R) transdermal patch, 2006).
3) Severity: contraindicated
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Concurrent use of sertraline and selegiline is contraindicated. Wait at least 14 days after discontinuing sertraline before initiating therapy with selegiline.
7) Probable Mechanism: inhibition of serotonin metabolism by monoamine oxidase
8) Literature Reports
a) Concomitant use of serotonin specific reuptake inhibitors and monoamine oxidase inhibitors can prod syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness, myoclonus, cha not recognized and correctly treated, death can result.
b) A 26-year old woman who had been taking isocarboxazid for eight weeks stopped taking the drug for the patient became restless and developed leg twitches. The patients was later admitted to the emergen disturbances. The patient did not improve after treatment with diazepam and propranolol. The patient wa in symptoms after the second dose (Lappin & Auchincloss, 1994t).
c) A drug interaction was reported in a 61-year old woman in which sertraline 100 mg twice daily was ac taking the first sertraline dose, the patient was found in a semicomatose state, with elevated body tempe mmHg. After transportation to the hospital, the patient was misdiagnosed as having neuroleptic malignar between sertraline and phenelzine. The authors suggest that MAO inhibitor therapy should be discontinu inhibitor (SSRI) and that before starting a MAOI, SSRI therapy should be discontinued for at least 5 half-
d) Two case reports suggested a possible interaction between fluoxetine and selegiline (Suchowersky & approximately 1 month after adding selegiline to fluoxetine therapy. The patient improved 2 months after involved diaphoresis, vasoconstriction, and cyanosis of the hands which occurred in close temporal relat quick resolution of symptoms. Rechallenge with fluoxetine alone occurred without incident.

3.5.1.EM Sibrafiban
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and been associated with an increased risk of bleeding. Bleeding events reported have included epistaxis, ecchyr tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution, 2008).
3) Severity: major
4) Onset: unspecified
5) Substantiation: probable
6) Clinical Management: When an SSRI and an antiplatelet agent are given concurrently, monitor patient for PROZAC(R) oral capsules, delayed-release capsules, solution, 2008)
7) Probable Mechanism: unknown

3.5.1.EN Sibutramine
1) Interaction Effect: an increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, ment
2) Summary: Sibutramine inhibits the reuptake of norepinephrine, dopamine, and serotonin. In addition, the t

neurotransmitters. A hyperserotonergic state, termed serotonin syndrome, may result if sibutramine is given c
and selective serotonin reuptake inhibitors is not recommended (Prod Info Meridia(R), 1997).
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Sibutramine should not be administered with serotonergic agents, including selectiv
7) Probable Mechanism: additive pharmacologic effects resulting in excessive serotonergic stimulation
8) Literature Reports
a) Serotonin syndrome is a condition of serotonergic hyperstimulation and manifests as restlessness, m
the syndrome is not recognized and correctly treated, death can result (Sternbach, 1991b).

3.5.1.EO St John's Wort
1) Interaction Effect: an increased risk of serotonin syndrome (hypertension, hyperthermia, myoclonus, ment
2) Summary: Case reports describe the onset of serotonin syndrome-like symptoms, mania, and hypomania
(Spinella & Eaton, 2002c; Barbanel et al, 2000a; Waksman et al, 2000a; Lantz et al, 1999a). A patient exhibit
paroxetine therapy (Gordon, 1998a). St. John's Wort is thought to inhibit serotonin reuptake and may have m
which when added to selective serotonin reuptake inhibitors may result in serotonin syndrome.
3) Severity: major
4) Onset: rapid
5) Substantiation: probable
6) Clinical Management: Patients should be advised to wait two weeks after stopping St. John's Wort before
selective serotonin reuptake inhibitor (SSRI) therapy with St. John's Wort, the half-life of the specific SSRI sh
metabolized out of the body.
7) Probable Mechanism: additive serotonergic effect
8) Literature Reports
a) Five cases have been reported of serotonin syndrome in the elderly after combining prescription antic
headache 4 days after starting St. John's Wort 300 milligrams (mg) three times daily combined with sertr
2 developed nausea, epigastric pain and anxiety 3 days after starting St. John's Wort 300 mg twice daily
discontinuing both medications, and he resumed sertraline use without complications. The third case dev
mg twice daily combined with sertraline 50 mg daily. His symptoms improved in 4 to 5 days after stoppin
nausea, anxiety, restless, and irritability 2 days after starting St. John's Wort 300 mg three times daily co
seven days, and his symptoms improved in 1 week after stopping the medication. Cases 1 through 4 res
Case 5 developed nausea, vomiting and restlessness 3 days after starting St. John's Wort 300 mg three
John's Wort but discontinued the nefazodone and over 1 week her symptoms Improved. She refused to
moderate symptoms of depression and anxiety returned (Lantz et al, 1999).
b) A 50-year-old female taking St. John's Wort 600 mg daily experienced symptoms of sedative intoxica
slow-moving, and complained of nausea and weakness. Prior to starting St. John's Wort, she had been r
sleep, she returned to her baseline mental status (Gordon, 1998).
c) A 61-year-old female experienced restlessness and involuntary movements of her extremities after be
mg daily. The patient reported agitation and akathisia 8 hours after taking the first dose of paroxetine. Sh
hyperreflexia and rigidity. Blood pressure, heart rate, and temperature were normal. After admission, blo
minute. Creatine kinase increased from 212 units/liter (U/L) initially to 1024 U/L. The patient was manage
2000).
d) A 28-year-old male developed a manic syndrome following comedication with St. John's Wort and se
orchidectomy 2 years earlier, but testosterone levels were subtherapeutic. The patient was prescribed se
patient preference (dose not specified). Before sertraline was started, the patient was instructed to disco
improved mood so did not see his physician, believing that he did not need further treatment. Over 2 mo
afford, and was ultimately arrested for stealing fuel for the car. On arrest, he was referred to psychiatric s
distractible, have flight of ideas, and grandiose delusions, leading to a diagnosis of a manic episode. The
that St. John's Wort may have increased the risk as a result of monoamine oxidase inhibition. Since the
state was considered low. However, the patient had elevated gonadotropin levels (luteinizing hormone a
(Barbanel et al, 2000).
e) A 42-year-old female experienced symptoms consistent with a mixed hypomanic episode following co
symptoms resolved following discontinuation of Ginkgo and St. John's Wort. The patient was being treat
twice daily and buspirone 15 mg twice daily. Several weeks prior to presentation, buspirone was increas
melatonin, and St. John's Wort in unspecified doses. Melatonin was considered unlikely to have contribu
since they may potentiate antidepressants, and considering the temporal relationship between the use o
symptoms. However, the brain injury was considered a possible contributor (Spinella & Eaton, 2002b).

3.5.1.EP Sulfinpyrazone
1) Interaction Effect: an increased risk of bleeding
2) Summary: The release of serotonin by platelets is important for maintaining hemostasis. Case-control and
been associated with an increased risk of bleeding. Bleeding events reported have included epistaxis, ecchy
tablets, suspension, 2008; Prod Info PROZAC(R) oral capsules, delayed-release capsules, solution, 2008).
3) Severity: major
4) Onset: unspecified

Monitoring Parameters

Patient Instructions

Place In Therapy

Mechanism of Action / Pharmacology

Therapeutic Uses

Comparative Efficacy / Evaluation With Other Therapies

4.1 Monitoring Parameters

A) Sertraline Hydrochloride
1) Therapeutic
a) DEPRESSION
1) Improvement in target symptoms (depressed mood, suicidal thoughts or intent, change in appetite, la of excessive guilt/worthlessness, psychomotor retardation or agitation, difficulties in thinking/concentratic
2) Patients with thyroid disease who are also receiving treatment for depression should have thyroid fun and small increases in serum thyrotropin levels after starting treatment with sertraline and other antidepr
b) OBSESSIVE-COMPULSIVE DISORDER
1) Reduction or resolution of recurrent and persistent impulses, ideas or thoughts that are intrusive and
2) Reduction or resolution of repetitive and intentional behaviors performed in response to obsessive th
c) PANIC DISORDER
1) Reduction or resolution of signs/symptoms consistent with panic disorder (dyspnea, palpitations, trem experiencing an uncontrolled feeling).
2) Toxic
a) Physical Findings
1) Since EXTRAPYRAMIDAL REACTIONS including dystonic reactions, parkinsonian-like movement di weekly during the first 4 weeks of therapy is recommended (Gill et al, 1997).
2) Gastrointestinal adverse effects (nausea, vomiting) are common during initiation of therapy but usuall
3) Monitor patients receiving antidepressants for worsening of depression, suicidality, or unusual change decreases. Such monitoring should include at least weekly face-to-face contact with patients or their fam week for the next 4 weeks, then at 12 weeks, and then as clinically indicated beyond 12 weeks. Families observation) of patients and communication with the prescriber (Anon, 2004; Anon, 2004).
4) Patients who experience symptoms of anxiety, agitation, panic attacks, insomnia, irritability, hostility, depression or suicidality. If these symptoms are observed, therapy should be re-evaluated and it may be were not part of the patient's initial symptoms (Anon, 2004; Anon, 2004).

4.2 Patient Instructions

A) Sertraline (By mouth)
Sertraline

Treats depression, obsessive-compulsive disorder (OCD), posttraumatic stress disorder (PTSD), premenstrual dy is an antidepressant called a selective serotonin reuptake inhibitor (SSRI).

When This Medicine Should Not Be Used:

You should not use this medicine if you have had an allergic reaction to sertraline or if you are also using pimozid
such as Eldepryl®, Marplan®, Nardil®, or Parnate® within the past 14 days. Do not use the liquid form of sertralir

How to Use This Medicine:
Tablet, Liquid
Your doctor will tell you how much of this medicine to use and how often. Do not use more medicine or use it
Measure the oral liquid medicine with a marked measuring spoon, oral syringe, or medicine cup. The oral liqu
with 1/2 cup (4 ounces) of water, ginger ale, lemon-lime soda, lemonade, or orange juice. Do not mix this me
liquid until you are ready to take your dose. It is okay if the mixture looks hazy.
This medicine should come with a Medication Guide. Read and follow these instructions carefully. Ask your d
Guide if you do not have one. Your doctor might ask you to sign some forms to show that you understand this

If a Dose is Missed:
If you miss a dose or forget to use your medicine, use it as soon as you can. If it is almost time for your next d
medicine to make up for a missed dose.

How to Store and Dispose of This Medicine:
Store the medicine in a closed container at room temperature, away from heat, moisture, and direct light.
Ask your pharmacist, doctor, or health caregiver about the best way to dispose of any leftover medicine after
expiration date has passed.
Keep all medicine away from children and never share your medicine with anyone.

Drugs and Foods to Avoid:
Ask your doctor or pharmacist before using any other medicine, including over-the-counter medicines, vitamins, a
Make sure your doctor knows if you are also using cimetidine (Tagamet®), diazepam (Valium®), digitoxin, lin
sumatriptan (Imitrex®), tolbutamide, tramadol (Ultram®), tryptophan, or valproate (Depacon®). Tell your doct

Possible Side Effects While Using This Medicine:
Call your doctor right away if you notice any of these side effects:
Allergic reaction: Itching or hives, swelling in your face or hands, swelling or tingling in your mouth or throat, d
Blistering, peeling, red skin rash.
Change in how much or how often you urinate.
Chest pain.
Fast or pounding heartbeat.
Headache, trouble concentrating, memory problems, weakness, or unsteadiness.
Muscle stiffness, twitching, shaking, or uncontrolled muscle movements.
Painful, prolonged erection of your penis, or trouble having sex.
Severe confusion, sweating, diarrhea, or fever.
Unusual bleeding or bruising.
Unusual thoughts, behavior, restlessness, nervousness, aggressive behavior, or anger.

If you notice these less serious side effects, talk with your doctor:
Decreased interest in sex.
Dizziness or drowsiness.
Dry mouth.
Loss of appetite.
Mild diarrhea, constipation, nausea, vomiting, or stomach pain.
Tiredness.

Trouble sleeping.
Weight loss.

If you notice other side effects that you think are caused by this medicine, tell your doctor.

4.3 Place In Therapy

A) SUMMARY

1) Sertraline has received approval by the United States Food and Drug Administration for treating depression, o numerous other psychiatric disorders.

B) DEPRESSION

1) All of the selective serotonin reuptake inhibitors (SSRIs) are effective for treating depression although selected NOT have any major therapeutic benefits over other SSRIs; however, it has less potential for drug interactions an an SSRI is dependent on clinical judgement and response of patients to previous therapy (Edwards & Anderson,

2) Preliminary data suggest that a trial of a second serotonin reuptake inhibitor (SSRI) is a viable clinical alternati (Joffe et al, 1996). In a retrospective review of 55 patients who had failed to respond to at least five weeks of thera dosages), 51% did respond to a trial of an alternative agent. The choice of the second agent was based on clinicia

4.4 Mechanism of Action / Pharmacology

A) MECHANISM OF ACTION

1) Sertraline is a potent and selective inhibitor of synaptosomal serotonin reuptake in the brain. It has a higher de including clomipramine, fluoxetine, fluvoxamine, and zimeldine (Heym & Koe, 1988a). It appears to have little effe

2) Like most other antidepressants (except fluoxetine), sertraline also causes an indirect down-regulation of posts therapeutic effect and for its delay in clinical efficacy (Doogan & Caillard, 1988; Heym & Koe, 1988a).

B) REVIEW ARTICLES

1) A comparison of selective serotonin reuptake inhibitors with a guide to selection is provided (Edwards & Ander

2) Two reviews provide a discussion of the efficacy of selective serotonin reuptake inhibitors and other antidepres

3) The efficacy of antidepressants in reducing panic attack frequency, symptoms of depression, social avoidance

4) A review article discusses the rational treatment of depression and each class of antidepressants (Cohen, 199

5) A review article describes the treatment of panic disorder, including the role of selective serotonin reuptake inh

6) Treatment of elderly patients with selective serotonin reuptake inhibitors is discussed with emphasis on improv

7) Pharmacological and therapeutic information about sertraline has been summarized (Peruche & Schulz, 1997

8) Drug-interactions of antidepressants are reviewed in German language (Zapotoczky & Simhandl, 1995).

4.5 Therapeutic Uses

4.5.A Sertraline Hydrochloride

Aggressive behavior

Alcoholism

Alzheimer's disease; Adjunct

Alzheimer's disease - Depression

Anorexia nervosa

Binging - Eating disorder

Cerebrovascular accident, Post - Depression; Prophylaxis

Cerebrovascular accident, Post - Mood swings

Clozapine adverse reaction - Obsessive-compulsive disorder

Complication of hemodialysis - Hypotensive episode

Depression - Myocardial infarction, Post

Drug-induced depressive state

Dysthymia

Flashbacks

Generalized anxiety disorder

Intermittent explosive disorder

Major depressive disorder

Myocardial infarction; Prophylaxis

Night eating syndrome

Non-cardiac chest pain

Obsessive-compulsive disorder

Panic disorder

Pathological laughing

Posttraumatic stress disorder

Premature ejaculation

Premenstrual dysphoric disorder

Respiratory obstruction

Schizophrenia

Severe major depression with psychotic features

Social phobia

4.5.A.1 Aggressive behavior

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Sertraline has been effective in the treatment of severe aggressiveness and self-injurious behavior a
reports (Ranen et al, 1996; Hellings et al, 1996)

c) Adult:

1) Sertraline has been effective in the treatment of severe aggressiveness and self-injurious behavior as
reports (Ranen et al, 1996; Hellings et al, 1996). Because serotonergic mechanisms have been implicate
was attempted after multiple pharmacologic interventions had failed. Dosages in these cases ranged fro
mg to avoid akathisia or irritability. Marked improvement to complete cessation of aggressive behaviors
sertraline for this indication.

4.5.A.2 Alcoholism

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Helpful in alcoholic patients without lifetime depression but not in alcoholic patients with lifetime dep

c) Adult:

1) Sertraline treatment was more effective than placebo in reducing alcohol intake of alcoholic subjects were currently experiencing or had previously experienced depression ("lifetime depression"). One hund (n=53) and those without (n=47) before being randomly assigned to receive sertraline 200 milligrams/da noted for frequency of drinking; however, the interaction between lifetime depression status and treatme never-depressed groups (p=0.33), whereas placebo was favored over sertraline in the lifetime-depressio never-depressed groups; there was no difference between treatments in the lifetime depression groups. adverse reactions (sexual disturbance, fatigue, and headache) were significantly more frequent in the se 2001).

4.5.A.3 Alzheimer's disease; Adjunct

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

May be effective as an adjunctive therapy in the treatment of behavioral and psychological symptom severe symptoms (Finkel et al, 2004)

c) Adult:

1) Sertraline therapy was not effective in the treatment of behavioral and psychological symptoms in the analysis of a subgroup of patients with moderate to severe symptoms. In a randomized, double-blind, pla received 8 weeks of open label treatment with donepezil (5 to 10 milligram (mg)/day) followed by 12 wee dose, 125.7 mg/day) or placebo (n=120). Primary endpoints included scores for the Neuropsychiatric Inv (CGI-S) scale. In the initial analyses, no significant improvements were found for any of the primary endp However, in a post hoc analyses of a subgroup of patients with moderate to severe behavioral and psych sertraline treatment was associated with a significant improvement on the mean NPI Behavioral and Psy significantly more patients in the donepezil-plus-sertraline group were rated as responders on the NPI Be placebo group (60% vs 33%, respectively; p=0.006). Sertraline was well tolerated with only diarrhea occu

4.5.A.4 Alzheimer's disease - Depression

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Reduced depressive symptoms in patients with Alzheimer's disease in double-blind, placebo-control

c) Adult:

1) Sertraline therapy effectively reduced depressive symptoms in patients with Alzheimer's disease. In a disorder and probable Alzheimer's disease received sertraline (n=24; initial, 25 milligrams (mg)/day for 1 or placebo (n=20) for 12 weeks following a one-week placebo run-in phase. Response to treatment was Depression Rating Scale (HDRS). Significantly more sertraline-treated patients were full or partial respon Patients in the sertraline group also had significantly greater improvements on CSDD and HDRS scores Although not significant, sertraline-treated patients showed a stronger statistical trend toward stabilizatio Depression Rating Scale-ADL subscale, as compared with placebo. There was no difference between tr dizziness and gastrointestinal symptoms being the most frequently reported adverse events (Lyketsos et

2) Sertraline was more effective than placebo in reducing DSM-IV diagnosed major depressive disorder Alzheimer's disease and major depression were randomized to receive either sertraline (n=12) or placeb over 6 weeks to 150 mg/day or the maximum tolerated dose. Three of the 12 patients receiving sertraline response occurring by the third week of treatment. In the placebo group, there was one full responder an less than 0.05). Mean reductions in scores on the Cornell Scale for Depression were significantly greater placebo group reported nervous system side effects (tremor, restlessness) (Lyketsos et al, 2000).

4.5.A.5 Anorexia nervosa

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Pediatric, Evidence is inconclusive
Recommendation: Pediatric, Class III
Strength of Evidence: Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Not better than non-drug treatment for anorexia nervosa (Santonastaso et al, 2001)

c) Pediatric:

1) Addition of sertraline to a multidisciplinary treatment of anorexia nervosa was not more effective than

DSM-IV criteria for restricting-type anorexia nervosa, were treated with open-label sertraline 50 milligram whose response had been unsatisfactory. Eleven other similar subjects were given no medication. All pa per week. At 14 weeks, 6 patients in each group (55%) still had a diagnosis of a full eating disorder. Bod months, rates of full remission were 54% in the sertraline group and 27% in the control group (not signifi headache, and insomnia. No subject interrupted treatment because of side effects (Santonastaso et al, 2

4.5.A.6 Binging - Eating disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

A small double-blind study found sertraline to decrease the frequency of binges compared to placeb

c) Adult:

1) Sertraline reduced the frequency of binges, global clinical severity scores, and body mass index to a met DSM-IV criteria for binge eating disorder and had binge episodes at least 3 times weekly for 6 month placebo; doses were adjusted based on response up to 200 mg daily. Estimated mean weight loss was an underlying condition in most of the study patients. Of the 18 patients treated with sertraline, 11 had a disorder. In the 16 placebo-treated patients, 7 had a lifetime diagnosis and 3 had a current diagnosis of

4.5.A.7 Cerebrovascular accident, Post - Depression; Prophylaxis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Sertraline was more effective than placebo in the prevention of post-stroke depression (Rasmussen

c) Adult:

1) Sertraline treatment appeared to be more effective than placebo in the prevention of depression follo post-stroke patients received sertraline (n=70; initial, 50 milligrams (mg)/day for 2 weeks then titrated up months. The incidence rate of depression (assessed by the total score on the Hamilton Depression Scal placebo group (8.2% vs 22.8%, respectively). The depression occurrence rate as measured by scores o (11.5% vs 28%, respectively). Fewer sertraline-treated patients had Clinical Global Impression (CGI) sev given placebo (18% vs 29.8%, respectively; p=0.12). Sertraline was well tolerated and there were no sig

4.5.A.8 Cerebrovascular accident, Post - Mood swings

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

In a small study (n=28), sertraline reduced emotional lability after a stroke (Burns et al, 1999)

c) Adult:

1) More patients treated with sertraline than placebo experienced a reduction in emotional lability (Burns randomly assigned to receive placebo or sertraline 50 milligrams/day for 8 weeks. At 8 weeks, 93% of pa Clinician's Interview-based impression of change and the emotionalism/lability of mood questions (p=0.0 to placebo (p=0.041). Four patients did NOT complete the study; 2 patients receiving sertraline experien suggest that sertraline is useful for reducing emotional lability after stroke.

4.5.A.9 Clozapine adverse reaction - Obsessive-compulsive disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

In a single case, sertraline effectively treated obsessive-compulsive behavior induced by clozapine(

c) Adult:

1) Addition of sertraline to clozapine reduced obsessive compulsive behavior without adversely affecting effectively reduced treatment-refractory psychosis, the patient developed obsessive compulsive behavio to risperidone and clomipramine which were ineffective so treatment with clozapine was reinstituted alon

plasma concentrations which were likely due to competitive inhibition of cytochrome P450 isoenzymes b
regimen, his psychotic and obsessive-compulsive symptoms were well controlled (Rahman et al, 1998).

4.5.A.10 Complication of hemodialysis - Hypotensive episode

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Reduced the severity of hypotension during and after hemodialysis sessions (Yalcin et al, 2002)

c) Adult:

1) Sertraline treatment raised the systolic and diastolic nadirs during hemodialysis sessions and increas
hypotension. Of 12 patients selected for treatment, 3 were unable to tolerate sertraline at 100 milligrams
before sertraline treatment were compared to data from a 4-week sertraline period. The sertraline period
before data collection. Dry weights of the patients, ultrafiltration volumes, dialysate composition, dialysat
and diastolic blood pressure (DBP) were the same in the sertraline period as in the pre-sertraline period.
the pre-sertraline period to 87 in the sertraline period (p less than 0.05); the nadir of DSP rose from 51 to
than 0.005). Post-dialysis DPB did not change significantly (59 to 62). The need for therapeutic intervent
0.001) (Yalcin et al, 2002).

4.5.A.11 Depression - Myocardial infarction, Post

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Sertraline relieved depression without causing adverse cardiac effects (Shapiro et al, 1999)
Heart rate variability recovery following acute MI was facilitated by sertraline (McFarlane et al, 2001)

c) Adult:

1) Sertraline improved depressive symptoms in patients with a recent myocardial infarction (MI). In this
milligrams daily beginning a mean of 30 days after the MI. At 16 weeks, 74% of patients had a positive re
Hamilton rating decreased from 19.7 to 7.8 (p less than 0.001). Fifteen (78.9%) of 19 patients who comp

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
In a single patient, sertraline was effective for eliminating flashbacks associated with lysergic acid di

c) Adult:
1) Sertraline treatment, started at 25 milligrams (mg) daily and slowly titrated to a target dose of 100 mg and depressive symptoms in a single patient with an 8-month history of LSD intake and daily flashbacks days after each dose increase but then subsided. This patient had no history of seizures or migraines. H experience at a later time of the original effects of the hallucinogenic drug. The hallucinogen, LSD, is bel Sertraline decreased the typical physiologic responses to serotonergic agonists as well as attenuated the LSD which present as flashbacks (Young, 1997).

4.5.A.15 Generalized anxiety disorder

a) Overview
FDA Approval: Adult, no;
Efficacy: Adult, Evidence favors efficacy;
Recommendation: Adult, Class IIb;
Strength of Evidence: Adult, Category B; Pediatric, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Sertraline-treated adults had significant decreases in the total Hamilton Rating Scale for Anxiety sco dose study of 326 adults with moderate to severe primary generalized anxiety disorder (Brawman-M Sertraline therapy in combination with cognitive behavioral therapy (CBT) was shown to be superior were both superior to placebo in a randomized, controlled trial among children and adolescents with Reduced psychic and somatic symptoms in children with generalized anxiety disorder (Rynn et al, 2

c) Adult:
1) Sertraline-treated adult outpatients had significant decreases in the total Hamilton Rating Scale for An double-blind, flexible-dose study of 326 evaluable adults with moderate to severe, primary generalized a GAD, had a total HAM-A symptom score of 20 or greater, a score of 2 or greater on item 1 of the HAM-A Scale score. There was no placebo run-in phase, but patients could not receive psychotropic drugs withi baseline. Patients were randomized to receive either placebo (n=162), or sertraline 25 milligrams/day (m and 7, up to a maximum of 200 mg/day. Decreases in dose were permitted at any time with only one sub was 149.1 mg +/- 59 mg. The mean age of patients was approximately 40 years, including 8.3% of patie measurement, the mean change in total HAM-A at 10 weeks compared with baseline was -12.71 +/- 7.1 between groups of -1.8 +/- 0.8 (95% CI, -3.4 to -0.2, p=0.032). There were significant improvements in to 6 and lasting through week 10. An analysis of the HAM-A somatic subscale in sertraline-treated patients subscale did demonstrate significant improvements (p=0.011). The response rate (at least 50% reductio (p=0.05). Significant adverse events (p less than 0.001) in the sertraline group (n=165) compared with pl libido 17.6% vs 2.4%. Diastolic blood pressure increases of 1.59 mmHg +/- 8.83 mmHg occurred in the s (p=0.0204) (Brawman-Mintzer et al, 2006).

d) Pediatric:
1) Sertraline therapy) was shown to be superior t both superior to placebo in a randomized, controlled trial among children and adolescents with childhood 10.7 years; 74.2% under the age of 13), with a primary diagnosis of social phobia, separation or generali receive sertraline plus CBT (n=140), sertraline alone (n=133), CBT alone (n=139) or placebo (n=76). Sul subjects receiving sertraline alone and placebo therapy were not aware which therapy they were receivir titrated on a fixed-flexible schedule beginning with 25 mg per day and adjusted upward in the absence o sessions which included anxiety-management skills and behavioral exposure to anxiety-provoking situati +/- 59.8 mg and the mean daily dose for sertraline-only patients was 146 +/- 60.8 mg. The primary outco

improvement on the Clinical Global Impression-Improvement scale (a scale of 1 to 7 with lower scores in included all patients randomized. At week 12, a Clinical Global Impression-Improvement scale of 1 or 2 (86.4) of patients receiving sertraline in combination with CBT, 54.9% (95% CI, 46.4 to 63.1) of patients re 23.7% (95% CI, 15.5 to 34.5) of patients receiving placebo therapy (all p less than 0.001 vs placebo). Pa either sertraline alone (OR 3.4; 95% CI, 2 to 5.9; p less than 0.001) or CBT alone (OR 2.8; 95% CI, 1.6 t patients receiving sertraline alone or CBT alone (p=0.41). In the number needed to treat (NNT) analysis, event; treating 3 patients with sertraline alone or CBT alone prevented 1 additional event. The incidence in the sertraline group compared to the placebo group. There were no suicide attempts (Walkup et al, 20

2) Sertraline was safe and efficacious in the treatment of generalized anxiety disorder in children and ac DSM-IV diagnosis of generalized anxiety disorder were randomly assigned to receive sertraline or placel first week and 50 mg/day thereafter. Significant treatment differences in favor of sertraline were evident f Anxiety Rating Scale, as well as the psychic factor score, was significantly better in the sertraline group t factor). Ten of 11 patients receiving sertraline were rated as improved, while only 1 of the placebo patien marked improvement. There was no depression-by-treatment interaction effect, indicating that the obser age effects on treatment were observed. Patients receiving sertraline reported less dizziness, nausea, a and restlessness occurred more frequently among those treated with sertraline than among those receiv

4.5.A.16 Intermittent explosive disorder

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Three patients treated with sertraline noted a decrease in explosive behavior (Feder, 1999)

c) Adult:

1) Three patients (age range, 29 to 51 years old) who met DSM-IV diagnostic criteria for intermittent exp sertraline. Two patients received sertraline 50 milligrams daily while the third required sertraline 100 milli months to 2 years with continued treatment; family members and friends also observed the change. The which is corrected with sertraline (Feder, 1999).

4.5.A.17 Major depressive disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective; Pediatric, Evidence favors efficacy
Recommendation: Adult, Class I;
Strength of Evidence: Adult, Category B; Pediatric, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

More effective than placebo in relieving acute depression
In comparison to placebo, reduced recurrence of chronic depression in 18-month study of responde
Sertraline has more favorable adverse effect profile than amitriptyline
Possibly efficacious in adolescents with major depression
Safe and effective in the treatment of moderate to severe depression in children and adolescents ag
Sertraline was safe and effective in reducing depressive symptoms in elderly patients
In elderly patients with depression, sertraline did not provide protection against relapse when given

c) Adult:

1) Treatment with sertraline effectively reduced depressive symptoms in patients with late-life depressio (n=752), elderly patients (60 years and older) with major depressive disorder and with or without comorb included in the comorbid illness group (n=442) had a vascular morbidity (ie, cardiovascular, cerebrovasc endpoint, significantly greater score improvements for the Hamilton Depression scale (p=0.02), Clinical G (p=0.001) were seen in sertraline-treated patients as compared with patients who received placebo. Sign effective in the treatment of depression regardless of medical comorbidity. Sertraline was generally well t

2) Sertraline therapy following remission of depressive symptoms did not provide prophylaxis against re major depressive disorder (mean age, 77.6 years of age) received open-label treatment with sertraline (r achieving remission of depressive symptoms entered a randomized, double-blind, placebo- controlled, m received sertraline (at their final therapeutic dose; range, 50 to 100 mg/day) or placebo. Increases in dos in the prevention of recurrence of depression (Wilson et al, 2003).

3) Sertraline therapy was more effective than placebo in the treatment of symptoms associated with maj controlled study, geriatric patients (mean age, 69.8 years; range, 59 to 97 years) with major depressive d score of at least 18 received sertraline (n=371; initial, 50 milligrams (mg)/day for 4 weeks, then titrated to period of 4 to 14 days. From baseline to endpoint, sertraline treatment produced significantly greater cha p=0.01) and the Clinical Global Impressions (CGI) Severity score (-1 vs -0.8, respectively; p=0.009). Ser endpoint as compared with placebo (2.7 vs 2.9, respectively; p=0.02). The CGI response rate (defined as 35% for those taking placebo (p=0.005). The HAM-D response rate (defined as at least a 50% reduction placebo (35% vs 26%, respectively; p=0.007). Diarrhea, headache, somnolence, tremor, nausea, fatigue

(Schneider et al, 2003).

4) At the end of a 20-week continuation study, more patients receiving sertraline than placebo had a per sertraline-treated and 49% of placebo-treated patients withdrew or failed to complete the study. In this co with major depression. One hundred seven responders (66 sertraline; 41 placebo) from a 6-week acute p only responders had been entered into the continuation phase, a prospectively defined Clinical Global Im persistence of a treatment effect in this period (Olie, 1997).

5) After 6 weeks, sertraline produced significant improvement in depression compared to placebo at all compared to placebo in a double-blind, parallel study of 289 patients with depression.

6) In an 18-month continuation study of patients with chronic depression or dysthymic disorder with majo placebo. Following treatment for depression and a short continuation period, patients (n=161) who respo weeks; the maximum allowable dose was 200 milligrams (mg). The recurrence rate was 6% and 23% for recurrence of depressive symptoms compared to placebo. Of the 161 patients enrolled in the continuatio the patients treated with sertraline, the major reason for discontinuation was adverse effects, whereas in sertraline is useful for preventing recurrence or reemergence of depression in patients with chronic depre

d) Pediatric:

1) Sertraline therapy effectively treated depressive symptoms in children and adolescents with moderate placebo- controlled trials, pediatric patients (n=376; ages 6 to 17 years) with major depressive disorder c sertraline (50 to 200 milligrams (mg)/day; mean dose, 131 mg/day) or placebo for 10 weeks. Psychotrop allowed during the study. Response was defined as a 40% or greater reduction in the adjusted total scor Impression-Improvement (CGI-I) score of 2 or less ("very much" or "much" improved). From baseline to e significantly better for sertraline-treated patients as compared with placebo-treated patients (-22.84 vs -2 sertraline group as compared with placebo for both the CDRS-R (69% vs 59%, respectively; p=0.05) and with insomnia, diarrhea, anorexia, vomiting, agitation, purpura, and urinary incontinence being reported r ideation (3 patients) and aggressive reaction (1 patient) (Wagner et al, 2003).

2) In an uncontrolled, open-label study of adolescents (ages 12 to 18 years) with DSM-IV major depress depressive symptoms, although response patterns differed for MDD and DD. Patients (n=21) received se 200 mg/day. Response to treatment, as indicated by a 50% or greater improvement in the Hamilton-Dep was sustained to the end of the study (24 weeks). In the DD group (n=8), the HAM-D response rate was of a score of 2 or less on the Clinical Global Impression-Improvement Scale (CGI-I), the response rate re the end of the study. In the DD group, the CGI-I maximal response rate was 75% at week 6. That maxim were the most common adverse events, with of the DD group and 30% of the M of the MDD group. Two obese patients were withdrawn from the study for elevations in blood pressure a efficacious in the acute treatment of MDD and DD and in the continued treatment of MDD in adolescents

4.5.A.18 Myocardial infarction; Prophylaxis

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class III
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Associated with decreases in platelet/endothelial activation in depressed, post-acute coronary syndr
May confer a protective effect against first myocardial infarction (Sauer et al, 2001)

c) Adult:

1) Sertraline therapy was associated with a decrease in platelet/endothelial activation in patients experie placebo-controlled sub-study of the Sertraline Antidepressant Heart Attack Randomized Trial (SADHART placebo for 24 weeks. The use of aspirin, anticoagulants, and ADP- receptor inhibitors was allowed throu platelet/endothelial activation as compared with placebo and may offer further advantage for this patient et al, 2003).

2) In a case-control study comprised of 653 cases of first myocardial infarction (MI) and 2990 control sul protective effect against first MI. The subjects in this study were smokers, between the ages of 30 to 65 y SSRIs investigated in this study were fluoxetine, fluvoxamine, paroxetine, and sertraline; doses taken by first MI compared to controls (after adjustment for potential confounders) was 0.35 (95% CI 0.18, 0.68; p inhibitory effect on serotonin-medicated platelet activation or amelioration of other factors associated with

4.5.A.19 Night eating syndrome

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence favors efficacy
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Treatment with sertraline reduced the symptoms of night eating syndrome compared to placebo in a (O'Reardon et al, 2006)

c) Adult:

1) In an 8-week, randomized, double-blind, placebo-controlled study (n=34), treatment with sertraline re

(Leonard, 1997). Early studies used near maximal doses of an SSRI which resulted in a high incidence c
response in some patients and better tolerance in most (Leonard, 1997). While the optimal duration of tr
studies have shown relapse rates between 65% and 90% when pharmacologic treatment was stopped (I
doses of an SSRI and/or behavioral therapy are considered refractory to treatment. In about 20% of this

therapy with haloperidol or clonazepam may be beneficial (Rasmussen & Eisen, 1997).

4) Results of a study demonstrated significant improvement of obsessive compulsive disorder (OCD) on multicenter trial in 87 patients with OCD who did not meet criteria for depression, sertraline 200 milligram symptoms as measured by the Yale-Brown Obsessive-Compulsive Scale and the NIMH Scale. The Mau although there was a trend toward greater improvement in the sertraline-treated group; the physician-rat some improvement as compared with 26% of the placebo-treated group (Chouinard et al, 1990).

d) Pediatric:

1) Cognitive behavior therapy (CBT) either alone or in combination with sertraline was more effective in compared with sertraline monotherapy or placebo. In the randomized, controlled, multicenter Pediatric O age, 11.7 years) with a primary diagnosis of OCD and a Children's Young-Brown Obsessive-Compulsive over a 12-week period. Equal numbers of patients received either CBT alone, sertraline therapy alone, c titration schedule (25 to 200 milligrams/day over 6 weeks, after which no further dosage adjustments wer the 12-week study period. At 12 weeks, significantly greater reductions in CYBOCS scores were observe placebo (p less than 0.001). Monotherapy with sertraline or CBT was not significantly different when com scores as compared with placebo (p=0.007 and p=0.003, respectively). Significantly higher rates of clinic combination therapy (53.6%; 95% CI, 36% to 70%) as compared with sertraline (21.4%, 95% CI, 10% to differ from CBT alone (39.3%; 95% CI, 24% to 58%) (p=ns). As with reductions in CYBOCS scores, sert remission rates, however, CBT was superior to placebo (p=0.002) while sertraline was not (p=ns). Sertra attempt during the study. Common adverse effects included decreased appetite, diarrhea, enuresis, mot Team, 2004).

2) Sertraline was shown to be effective in a 12-week, multicenter, placebo-controlled, parallel group stud open extension study of 137 outpatients (ages 6 to 18) for the treatment of obsessive-compulsive disord score of 22 on the Children's Yale-Brown Obsessive-Compulsive Scale (CYBOCS). Children ages 6 to 1 to 17) were started on 50 mg/day. Doses were increased over the next four weeks to a maximum dose o sertraline group had a mean reduction of approximately 7 units on the CYBOCS total score which was si Response to treatment was not altered by either age or gender (Prod Info Zoloft(R), 2003a).

4.5.A.22 Panic disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class IIa
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Sertraline has reduced the frequency of panic attacks in blinded studies (Pohl et al, 1998; Londborg

c) Adult:

1) Sertraline is an effective therapy for panic disorder. In a 10-week, double-blind, multicenter study, 166 titration to a maximum dose of 200 mg daily; at study endpoint, the mean sertraline dose was 126 mg/da number of panic attacks per week decreased by 77% and 51% in the sertraline and placebo groups, resp (62%) than placebo (46%) were free of panic attacks (p=0.04). Investigators also noted significant impro (severity and improvement: p less than 0.001). Adverse effects resulted in study discontinuation in 9% a effects had a mild-to-moderate severity rating (Pohl et al, 1998).

2) Sertraline was significantly more effective than placebo in the treatment of panic disorder. Patients we 200 mg daily (n=44), or placebo (n=44) for 12 weeks. The primary measure of efficacy was the number o the number of weekly panic attacks compared to a 39% reduction with placebo. There were no significar decreased the frequency of situational and unexpected panic attacks, anticipatory anxiety, and limited sy After 12 weeks, more patients were panic-free with sertraline than placebo, 57% and 41%, respectively. 200 mg group, and 31% of the placebo group discontinued the study. A significantly greater number of p placebo. Because efficacy was independent of plasma concentrations, 50 mg of sertraline daily is the re (Londborg et al, 1998).

4.5.A.23 Pathological laughing

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category C

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Relieved pseudobulbar laughter in one patient (Okun et al, 2002)

c) Adult:

1) Sertraline resolved pseudobulbar laughter within 48 hours in a 46-year-old man who had suffered inju Parkinson's disease), the man underwent right gamma knife thalamotomy, targeting the ventral intermed numbness in his lip, which resolved, and numbness in his left hand, which persisted over the following ye symptoms of depression or elated mood. He was given sertraline 50 milligrams/day, which resolved the follow-up (Okun et al, 2002).

4.5.A.24 Posttraumatic stress disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective
Recommendation: Adult, Class I
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Effective for treating posttraumatic stress disorder (Rapaport et al, 2002)
Effectiveness maintained during extended treatment (Londborg et al, 2001)
Some nonresponders to acute treatment respond to longer treatment (Londborg et al, 2001)

c) Adult:

1) Quality of life (QOL) was significantly improved in patients with posttraumatic stress disorder (PSTD) In a manufacturer-funded study, 359 patients meeting DSM-III-R criteria for PTSD for at least 6 months v milligrams (mg) per day or placebo for 12 weeks. Completers of the acute phase (n=275), whether or not (n=234). Responders during the continuation phase (n=172) were eligible for a 28-week, randomized, do maintenance phase. In comparison to placebo treatment, acute sertraline treatment resulted in significan (Q-LES-Q) of patients without comorbid depression. Improvement in scores of those with comorbid depr measures of psychological functioning and well-being were significant (relative to placebo) for sertraline- occupational impairment scores were significantly better with sertraline than with placebo. During the cor the double-blind, maintenance phase, QOL and functioning scores deteriorated somewhat for both group

2) Effectiveness of sertraline for treating posttraumatic stress disorder (PTSD) was maintained in most p Furthermore, half of the nonresponders to acute treatment became responders during the 6 months of c the acute phase of 2 double-blind, placebo-controlled trials of sertraline for treatment of severe DSM-III-R during the acute phase. Blinding to acute-phase treatment was maintained throughout the open label stu (mg) daily for the first week. The dose was then increased to 50 mg/day, which was titrated on an individ sustained their initial response. Average scores on various investigator-completed and patient-completed patients who were nonresponders during the acute phase who became responders during the continuati response time was having a high baseline severity score (higher than 75) on the Clinician Administered I frequent moderate-to-severe treatment-related adverse events were headache, insomnia, dry mouth, an vital signs attributed to sertraline during the 24 weeks. Body weight increased by a mean of 0.8 kilogram

3) Sertraline was more effective than placebo in prevention of posttraumatic stress disorder (PTSD) rela for posttraumatic stress disorder (PTSD), were enrolled in this 28-week, double-blind, multicenter, placeb biweekly and were classified as relapsed if their Clinical Global Impression (CGI) improvement score inc increased by at least 30%, and there was significant worsening of the patient's clinical condition on two c relapse than the patients treated with sertraline (mean endpoint dose=137 milligrams). Forty percent of t 28-week trial (Davidson et al, 2001).

4) Sertraline was more effective than placebo for treating patients with chronic post-traumatic stress dis randomly assigned to sertraline 25 milligrams (mg)/day or placebo; after the first week, the sertraline dos patients who received treatment, 65 and 68 patients assigned to sertraline and placebo completed the tri follow-up. In patients completing the study, the mean daily dosage of sertraline was 151.3 mg. For 3 of th Clinical Global Impression-Severity scale (CGI-S), and the Clinical Global Impression-Improvement Scal 33 versus (vs) -23.2, p=0.02; CGI-S -1.2 vs -0.8, p=0.01; CGI-I 2.5 vs 3, p=0.01). In addition, a trend tow treated with sertraline versus placebo. About 70% of the reduction on the CAPS-2 and IES was achieved

4.5.A.25 Premature ejaculation

a) Overview

FDA Approval: Adult, no; Pediatric, no
Efficacy: Adult, Evidence is inconclusive
Recommendation: Adult, Class IIb
Strength of Evidence: Adult, Category B

See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:

Sertraline effectively increased time to ejaculation during a randomized, placebo-controlled trial (n=3

c) Adult:

1) Thirty-seven men were successfully treated with sertraline 50 mg daily for premature ejaculation. Dur (n=19) for 4 weeks. Patients then underwent a 4-week washout period and entered phase 2 which consi open-label trial to evaluate the long-term effects of sertraline on premature ejaculation and the effects of significantly compared to those in the placebo group, from a mean of 0.3 minutes to 3.2 minutes (P less drug, efficacy was lost after 6 to 13 days. This suggests that long-term treatment with sertraline may be r

4.5.A.26 Premenstrual dysphoric disorder

FDA Labeled Indication

a) Overview

FDA Approval: Adult, yes; Pediatric, no
Efficacy: Adult, Effective

Recommendation: Adult, Class I
Strength of Evidence: Adult, Category B
See Drug Consult reference: RECOMMENDATION AND EVIDENCE RATINGS

b) Summary:
Sertraline is effective for premenstrual dysphoric disorder (PMDD) (Prod Info Zoloft(R), 2002; Pearls
Administration during the luteal phase was as effective as continuous sertraline and more effective t
& Smoller, 1997)

c) Adult:

4.6.A Amisulpride

Burning mouth syndrome

Dysthymia

4.6.A.1 Burning mouth syndrome

a) Amisulpride, sertraline, and paroxetine were all effective in reducing the symptoms of burning mouth synd
serotonin reuptake inhibitors (SSRIs). In a randomized, single-blind study, 76 patients with BMS and without
mg/day, or sertraline 50 mg/day for 8 weeks. Pain scores decreased significantly in all groups, as did depres
Anxiety), by week 8. The only difference among treatments was the shorter latency to response in the amisul
paroxetine and 6% with sertraline) (Maina et al, 2002a).

4.6.A.2 Dysthymia

a) Although amisulpride and sertraline were equally effective for treatment of dysthymia at 12 weeks of treat

amisulpride than with sertraline. In a 12-week, randomized, double-blind study, patients between the ages of depression, were given amisulpride (n=156) or sertraline (n=150), each drug at a starting dose of 50 milligran were eventually increased to 100 mg/day). The median time to onset of partial response (corresponding to a score) was significantly shorter with amisulpride: 11 days versus 15 days (p less than 0.0091). Percentages c sertraline (p less than 0.01). Patients reported perceiving improvement earlier with amisulpride: 8.4 days vs 1 HAMD score) also occurred earlier with amisulpride. By week 4, 63% of patients in the amisulpride group and corresponding values were 82% and 69% (p=0.009). By week 12, the percentage of responders did not differ percentage of patients reporting adverse events was about 45% for both groups but the adverse events were sertraline and endocrine adverse events with amisulpride (Amore & Jori, 2001).

4.6.B Amitriptyline

4.6.B.1 Depression

a) SUMMARY: Five clinical studies have reported similar efficacy between amitriptyline and sertraline in the Doogan & Caillard, 1988b; Reimherr et al, 1988a). Sertraline has had a higher incidence of gastrointestinal si with anticholinergic effects, sedation, dizziness, and hypotension (Cohen et al, 1990)(Reimherr et al, 1990).
b) In an 8-week, double-blind, parallel-group study (n=385), sertraline and amitriptyline were comparable for (Lydiard et al, 1997). Patients were randomly assigned to receive placebo, sertraline 50 milligrams (mg), or a in the protocol. Selected sections of Profile of Mood States (POMS) showed greater improvement in patients similar between treatments. Significantly more patients reported adverse effects (71.8%) and dropped out of adverse effects, blinding may have been inadequate in this study. Long-term studies are needed to compare
c) In an 8-week, double-blind placebo-controlled parallel study of 379 patients with major depression, sertral amitriptyline 50 to 150 mg/day. However, both drugs produced significant improvement over placebo. Patient Global Impressions (CGI) measurement (Doogan & Caillard, 1988b). Similar results were reported in 77 patie controlled trial, the investigators found that sertraline caused fewer adverse reactions than did amitriptyline.
d) However, in another study, patients receiving sertraline had a significantly higher incidence of gastrointest treated group. The amitriptyline-treated group had a high incidence of anticholinergic effects, sedation and di (mean dose 145 milligrams), amitriptyline (mean dose 104 milligrams), or placebo. As measured by both the groups showed significantly greater improvement than placebo (Reimherr et al, 1990).
e) In 241 elderly depressed patients, amitriptyline 50 to 150 milligrams daily or sertraline 50 to 200 milligrams effects varied greatly. A higher proportion of amitriptyline-treated patients (38%) withdrew from the study due compared with a 28% incidence of treatment-withdrawal with sertraline. Sertraline-treated patients had a high

4.6.C Bupropion

4.6.C.1 Depression

a) In a randomized, double-blind comparison trial between sustained- release bupropion (bupropion SR) and treated patients (Segraves et al, 2000). In the study, 248 patients diagnosed with moderate to severe major d dose of bupropion SR was 100 milligrams/day (mg/day). If indicated, the dose was increased to 200 mg/day was increased to 100 mg/day on day 8, 150 mg/day on day 15, and 200 mg/day on day 22, if clinically indicat dysfunction compared with bupropion SR (men: 63% and 15%, respectively, p less than 0.001; women: 41% disorder, sexual arousal disorder, orgasm dysfunction, decreased satisfaction with sexual functioning, and wo treated patients reported instances of premature ejaculation; however, this difference was not statistically sign determine the extent of influence of the natural course of depression. This data does suggest, however, that whom sexual dysfunction is of concern.
b) In an 8-week, double-blind trial, sertraline and bupropion produced similar antidepressant effects while bu received bupropion sustained release 150 to 400 milligrams (mg)/day (n=120), sertraline 50 to 200 mg/day (r were bupropion SR 293 mg/day and sertraline 121 mg/day. Both active treatment groups responded better th bupropion SR 66%, sertraline 68%, placebo 47%, p=0.002). At baseline, sexual desire disorder was reported patients. At the end of 8 weeks this problem decreased to only 19% of bupropion patients versus 31% receivi the disorder (not significant as compared to placebo). More sertraline patients also experienced orgasmic dys 0.001). Somnolence, insomnia, nausea, and diarrhea also occurred more often in the sertraline group than in
c) In a randomized, double-blind trial, bupropion sustained release (SR) and sertraline were similarly effectiv received either bupropion SR 100 to 300 milligrams (mg) daily in 2 doses (n=119) or sertraline 50 to 200 mg and sertraline 114 mg/day. Patients improved similarly on several scales including the Hamilton Rating Scale Scale for Severity of Illness and for Improvement. Nausea, diarrhea, somnolence and sweating were experie Orgasm delay and/or failure was also experienced more often in the sertraline group (p less than 0.001).

4.6.D Desipramine

Depression - Obsessive-compulsive disorder

Premenstrual dysphoric disorder

4.6.D.1 Depression - Obsessive-compulsive disorder

a) Sertraline was more effective than desipramine for reducing symptoms of major depressive disorder (MDD assigned to receive desipramine 50 milligrams (mg) per day or sertraline 50 mg per day for 12 weeks. The do desipramine was 300 mg/day. At study end-point, the mean dosage of sertraline and desipramine was 160.1 Rating Scale for Depression (HAM-D) and Yale-Brown Obsessive Compulsive Scale (Y-BOCS), sertraline wa treated with sertraline than desipramine had a 40% or greater reduction in the Y-BOCS (p=0.01); remission o patients in the sertraline than desipramine groups (p=0.04). Discontinuation due to adverse effects occurred i p=0.009). For patients with OCD and MDD, sertraline is an effective treatment (Hoehn-Saric et al, 2000).

4.6.D.2 Premenstrual dysphoric disorder

a) Sertraline more effectively reduced symptoms and improved functioning in women with premenstrual dysp al, 1999). After a 3-month screening period, patients (n=189) were randomly assigned to sertraline 50 milligra intervals to a maximum of 150 mg/day were allowed. Significantly more patients assigned to desipramine dis resulted in a significantly greater decrease from baseline to endpoint in the Premenstrual Daily Symptom Rep 17-item Hamilton Depression Rating Scale (p less than 0.001). Direct comparison of a sertraline and desipra

b) In an open-label trial of 32 women with a history of severe premenstrual symptoms, sertraline and desipra months treatment, 78% of sertraline-treated patients and 75% of desipramine-treated patients experienced a more sertraline-treated patients (68%) reported a 50% or more reduction in premenstrual symptoms than des the study, but this difference may not apply to long-term therapy. Long-term, placebo-controlled trials are nee syndrome.

4.6.E Fluoxetine

Depression

Obsessive-compulsive disorder

Weight gain

4.6.E.1 Depression

a) Paroxetine, fluoxetine, and sertraline were equally effective for the treatment of depression and for improv label trial (the ARTIST trial), depressed patients, whose symptoms warranted antidepressant treatment, acco (n=184) or sertraline (n=182). Starting doses were paroxetine 20 milligrams (mg), fluoxetine hydrochloride 20 response and could switch the treatment to one of the other study drugs. Final average doses were 23.5 mg substantial improvement in depressive symptoms and quality of life. Overall, the percentage of patients categ and 26% at 9 months. No significant differences were evident among the 3 groups. When data from subgrou assigned) were analyzed separately, still no differences among the drug treatments was evident. Patient satis to show improvement for all drug treatments. The drugs were associated with similar incidences of adverse e

b) An eight-week, double-blind, randomized study evaluated the efficacy and safety of fluoxetine vs sertralin with major depression entered into the study, but only 88 (48 sertraline and 40 fluoxetine) were evaluable. Th treatment groups showed a statistically significant improvement from baseline at one week, and this was mai between the two treatment groups on the primary efficacy variables measured by Hamilton Rating Scale for D Asberg Depression Rating Scale (MADRS), Leeds Sleep Score scale and Zung Anxiety Rating Scale. The in common were gastrointestinal (nausea and abdominal pain) and central nervous system (irritability, headach tolerated than fluoxetine overall; 9.6% of sertraline-treated patients discontinued treatment, compared with 19 population is warranted to definitively establish the comparative efficacy and safety of the two drugs (Aguagli

4.6.E.2 Obsessive-compulsive disorder

a) Both fluoxetine and sertraline were effective and well tolerated in the treatment of patients with obsessive- per day (mean 139.5 +/- 58.5 mg; N=76), or fluoxetine, 20 to 80 mg/day (mean 56.7 +/- 23.0 mg; N=72), in a matched patient populations. Safety and efficacy measures were taken at the end of study weeks 1, 2, 4, 6, 8 the study. Primary efficacy measures included the Yale-Brown Obsessive- Compulsive Scale (Y-BOCS), the the Clinical Global Impression Severity and Improvement scales (CGI-S and CGI-I). Secondary measures inc Anxiety Scale (CAS). By the end of the 24 week study, both medications were effective and there were no sig measures showed similar amounts of improvement. The time-course of improvement was also similar for bot measures (Y-BOCS change score and global severity of illness score) during some of the early assessments differences between the drug treatments during this time period. Adverse drug effects were described as mild sertraline or fluoxetine (Bergeron et al, 2002).

4.6.E.3 Weight gain

a) Weight gain is a common complaint during antidepressant therapy, and weight gain was significantly grea meeting DSM-IV criteria for major depressive disorder were randomized to double-blind treatment with sertra daily (n=96) for 4 weeks. Patients responding to this dose continued for an additional 6 weeks, and those not 60 mg fluoxetine, and 60 mg paroxetine, and then maintained at their optimal doses for 6 weeks. After this tre consecutive weeks) continued for 16 additional weeks. The number of responders participating in the 16 addi paroxetine. However, among these responders, the mean increase in weight in the paroxetine group (3.6%) v

with fluoxetine (-0.2%). A gain of 7% or greater in weight occurred in 25.5% of paroxetine patients, 4.2% of se
2000a).

4.6.F Fluvoxamine

4.6.F.1 Depression

a) In a small study (n=64), the incidence of recurrent depression was similar between patients treated prophy
received either sertraline 100 milligrams(mg)/day or fluvoxamine 200 mg/day for 2 years; increases in dose w
fluvoxamine-treated patients had a new episode of depression (p=0.88). Adverse effects were minor and tran
were effective for preventing recurrent depression episodes, but are limited by the absence of a placebo cont
b) The pharmacology, pharmacokinetics, adverse effects, drug interactions, efficacy, and dosage of fluvoxar
review (Grimsley & Jann, 1992b). All three agents have large volumes of distribution and are highly protein-b
lives (approximately 24 hours) and are metabolized to clinically-inactive compounds. These agents, therefore

b) In patients with major depressive disorder, almost twice as many experienced a remission with venlafaxin
depressive disorder randomly received venlafaxine 37.5 mg twice daily (n=75) or sertraline 50 mg daily (n=72
or the sertraline increased to 50 mg twice daily on day 15. After 8 weeks, patients in both groups showed sig
Montgomery- Asberg Depression Rating Scale (p less than 0.05). In the venlafaxine group 83% were respon
the venlafaxine group and in 45% of the sertraline group (p=0.008). The most common adverse events were
with sertraline (Mehtonen et al, 2000).

4.6.N.3 Depression, Elderly

a) Treatment with venlafaxine had a lower tolerability, but was equally effective to sertraline therapy in elderl study, fifty-two elderly patients (mean age, 82.5 years) with depression received either sertraline (initial, 25 m mg/day, titrated to 150 mg/day) for 10 weeks. No significant differences were found in Hamilton Rating Scale groups. However, early termination and withdrawal rates due to serious adverse events were higher in venlaf tract infection, cerebrovascular accident, hypertension, decreased renal function, rapid atrial fibrillation, anem were observed in both treatment groups. From baseline to endpoint, heart rate increased in the venlafaxine g bpm to 70.9 bpm, respectively). The authors suggest that the lowered tolerability of venlafaxine may be relate
